# Example: Demand for Ice Cream

#### Verbeek's time series dataset "icecream"

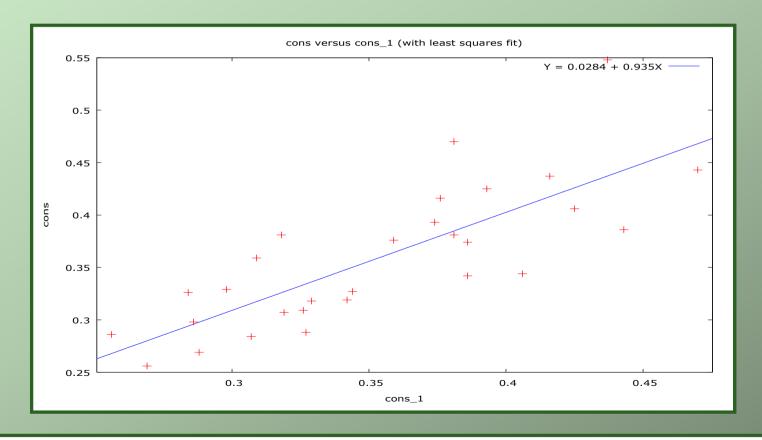

- 30 four weekly observations (1951-1953)
- Variables
  - cons: consumption of ice cream per head (in pints)
  - income: average family income per week (in USD, red line)
  - price: price of ice cream (in USD per pint, blue line)
  - temp: average temperature (in Fahrenheit); tempc: (green, in °C)

Consumption (cons) of ice cream per head (in pints): scatter diagram of actual values cons over lagged values cons<sub>-1</sub>

## Autocorrelation

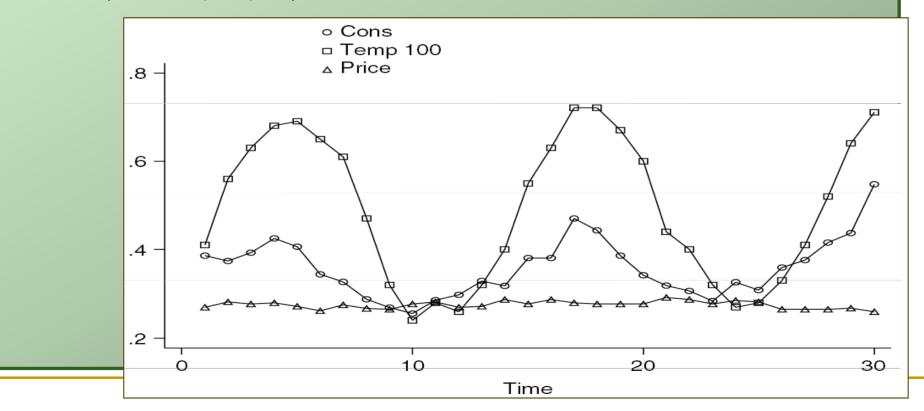

- Typical for time series data such as consumption, production, investments, etc.
- Autocorrelation of error terms is typically observed if
  - a relevant regressor with trend or seasonal pattern is not included in the model: miss-specified model
  - the functional form of a regressor is incorrectly specified
  - the dependent variable is correlated in a way that is not appropriately represented in the systematic part of the model
- Autocorrelation of the error terms indicates deficiencies of the model specification such as omitted regressors, incorrect functional form, incorrect dynamic
- Tests for autocorrelation are the most frequently used tool for diagnostic checking the model specification

### Time series plot of

Cons: consumption of ice cream per head (in pints); mean: 0.36

Temp/100: average temperature (in Fahrenheit)

Price (in USD per pint); mean: 0.275 USD

Demand for ice cream, measured by *cons*, explained by *price*, *income*, and *temp* 

	Table 4.9	OLS results

Time series diagramme of demand for ice cream, actual values (o) and predictions (polygon), based on the model with income and

price

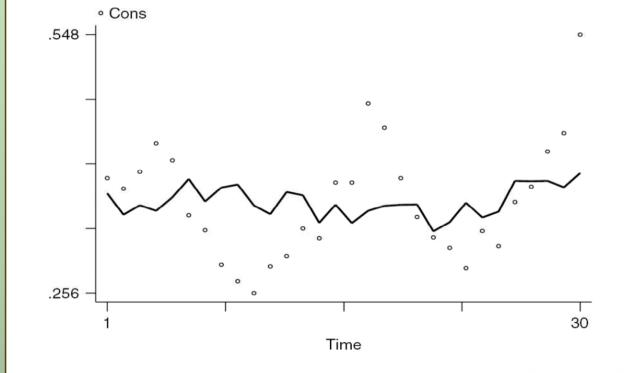

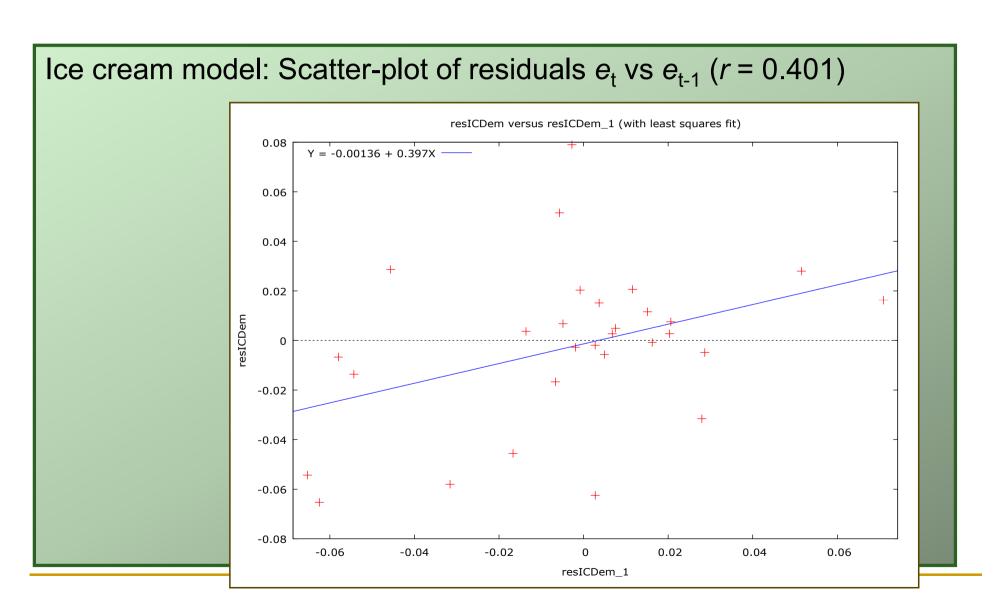

Figure 4.1 Actual and fitted consumption of ice cream, March 1951–July 1953

# A Model with AR(1) Errors

Linear regression

$$y_t = x_t' \beta + \varepsilon_t^{-1}$$

with

$$\varepsilon_t = \rho \varepsilon_{t-1} + v_t$$
 with  $-1 < \rho < 1$  or  $|\rho| < 1$ 

where  $v_t$  are uncorrelated random variables with mean zero and constant variance  $\sigma_v^2$ 

- For ρ ≠ 0, the error terms  $ε_t$  are correlated; the Gauss-Markov assumption  $V{ε} = σ_ε^2 I_N$  is violated
- The other Gauss-Markov assumptions are assumed to be fulfilled

The sequence  $\varepsilon_t$ , t = 0, 1, 2, ... which follows  $\varepsilon_t = \rho \varepsilon_{t-1} + v_t$  is called an autoregressive process of order 1 or AR(1) process

<sup>1)</sup> In the context of time series models, variables are indexed by "t"

# Properties of AR(1) Processes

Repeated substitution of  $\varepsilon_{t-1}$ ,  $\varepsilon_{t-2}$ , etc. results in

$$\varepsilon_{t} = \rho \varepsilon_{t-1} + v_{t} = v_{t} + \rho v_{t-1} + \rho^{2} v_{t-2} + \dots$$

with  $v_t$  being uncorrelated and having mean zero and variance  $\sigma_v^2$ :

- $\blacksquare \quad \mathsf{E}\{\varepsilon_{\mathsf{t}}\} = 0$
- $V\{\varepsilon_t\} = \sigma_{\varepsilon}^2 = \sigma_{v}^2 (1-\rho^2)^{-1}$

This results from V{ $\epsilon_t$ } =  $\sigma_v^2 + \rho^2 \sigma_v^2 + \rho^4 \sigma_v^2 + ... = <math>\sigma_v^2 (1-\rho^2)^{-1}$  for  $|\rho| < 1$ ; the geometric series  $1 + \rho^2 + \rho^4 + ...$  has the sum  $(1 - \rho^2)^{-1}$  given that  $|\rho| < 1$ 

- □ for  $|\rho| > 1$ ,  $V\{\varepsilon_t\}$  is undefined
- Cov $\{\varepsilon_t, \varepsilon_{t-s}\} = \rho^s \sigma_v^2 (1-\rho^2)^{-1}$  for s > 0 all error terms are correlated; covariances and correlations Corr $\{\varepsilon_t, \varepsilon_{t-s}\} = \rho^s (1-\rho^2)^{-1}$  decrease with growing distance s in time

# AR(1) Process, cont'd

The covariance matrix  $V\{\varepsilon\}$ :

$$V\{\varepsilon\} = \sigma_{v}^{2} \Psi = \frac{\sigma_{v}^{2}}{1 - \rho^{2}} \begin{pmatrix} 1 & \rho & \cdots & \rho^{N-1} \\ \rho & 1 & \cdots & \rho^{N-2} \\ \vdots & \vdots & \ddots & \vdots \\ \rho^{N-1} & \rho^{N-2} & \cdots & 1 \end{pmatrix}$$

- V(ε) has a band structure
- Depends only of two parameters:  $\rho$  and  $\sigma_v^2$

# Consequences of $V(\epsilon) \neq \sigma^2 I_T$

### OLS estimators b for $\beta$

- are unbiased
- are consistent
- have the covariance-matrix

$$V{b} = \sigma^2 (X'X)^{-1} X'\Psi X (X'X)^{-1}$$

- are not efficient estimators, not BLUE
- follow under general conditions asymptotically the normal distribution

The estimator  $s^2 = e'e/(T-K)$  for  $\sigma^2$  is biased

For an AR(1)-process  $\varepsilon_t$  with  $\rho > 0$ , s.e. from  $\sigma^2$  (X'X)<sup>-1</sup> underestimates the true s.e.

# Inference in Case of Autocorrelation

Covariance matrix of *b*:

$$V{b} = \sigma^2 (X'X)^{-1} X'\Psi X (X'X)^{-1}$$

Use of  $\sigma^2$  (X'X)<sup>-1</sup> (the standard output of econometric software) instead of V{*b*} for inference on  $\beta$  may be misleading

#### Identification of autocorrelation:

Statistical tests, e.g., Durbin-Watson test

#### Remedies

- Use of correct variances and standard errors
- Transformation of the model so that the error terms are uncorrelated

# Estimation of ρ

Autocorrelation coefficient ρ: parameter of the AR(1) process

$$\varepsilon_{t} = \rho \varepsilon_{t-1} + V_{t}$$

Estimation of p

• by regressing the OLS residual  $e_{\rm t}$  on the lagged residual  $e_{\rm t-1}$ 

$$r = \frac{\sum_{t=2}^{T} e_t e_{t-1}}{(T - K)s^2}$$

- estimator is
  - biased
  - but consistent (under weak conditions)

## Autocorrelation Function

Autocorrelation of order s:

$$r_{s} = \frac{\sum_{t=s+1}^{T} e_{t} e_{t-s}}{(T-k)s^{2}}$$

- Autocorrelation function (ACF) assigns  $r_s$  to s = 0, 1, ...
- Correlogram: graphical representation of the autocorrelation function

**GRETL**: <u>Variable => Correlogram</u>

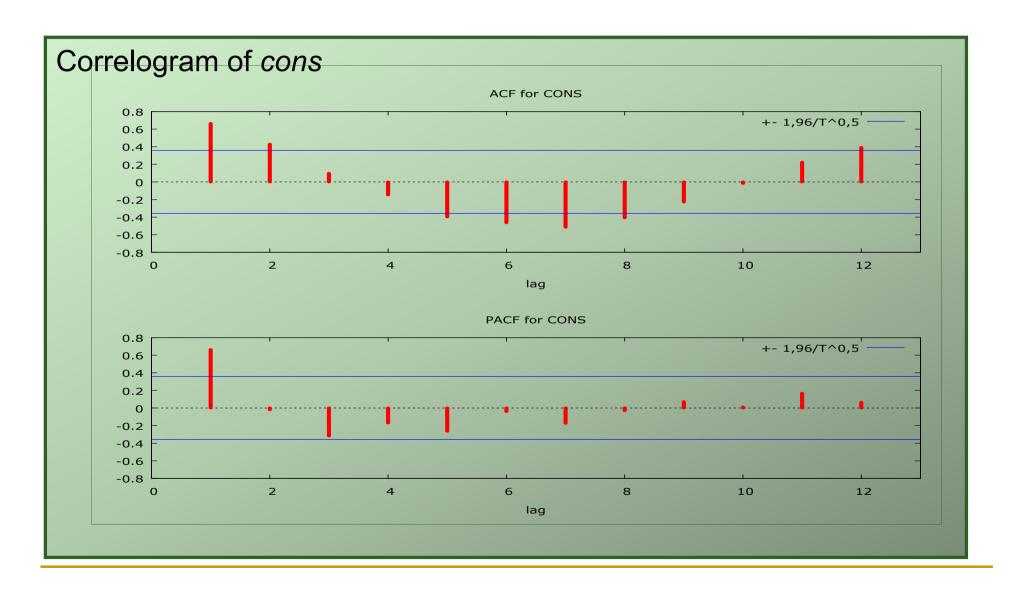

Produces (a) the autocorrelation function (ACF) and (b) the graphical representation of the ACF (and the partial autocorrelation function, PACF)

# Example: Ice Cream Demand

### Autocorrelation function (ACF) of cons

# Tests for Autocorrelation of Error Terms

Due to unbiasedness of *b*, residuals are expected to indicate autocorrelation

Graphical displays, e.g., the correlogram of residuals may give useful hints

Residual-based tests:

- Durbin-Watson test
- Box-Pierce test
- Breusch-Godfrey test

## **Durbin-Watson Test**

Test of  $H_0$ :  $\rho = 0$  against  $H_1$ :  $\rho \neq 0$ 

Test statistic

$$dw = \frac{\sum_{t=2}^{T} (e_t - e_{t-1})^2}{\sum_{t=1}^{T} e_t^2} \approx 2(1-r)$$

- For  $\rho > 0$ , dw is expected to have a value in (0,2)
- For  $\rho$  < 0, dw is expected to have a value in (2,4)
- dw close to the value 2 indicates no autocorrelation of error terms
- Critical limits of dw
  - $\Box$  depend upon  $x_t$ 's
  - exact critical value is unknown, but upper and lower bounds can be derived, which depend upon x<sub>t</sub>'s only via the number of regression coefficients
- Test can be inconclusive
- $H_1$ :  $\rho > 0$  may be more appropriate than  $H_1$ :  $\rho \neq 0$

# Durbin-Watson Test: Bounds for Critical Limits

Derived by Durbin and Watson

Upper  $(d_{II})$  and lower  $(d_{I})$  bounds for the critical limits and  $\alpha = 0.05$ 

Ψ.	K=2		K=3		<i>K</i> =10	
	$d_{L}$	$d_{U}$	$d_{L}$	$d_{U}$	$d_{L}$	$d_{U}$
15	1.08	1.36	0.95	1.54	0.17	3.22
20	1.20	1.41	1.10	1.54	0.42	2.70
100	1.65	1.69	1.63	1.71	1.48	1.87

- $dw < d_L$ : reject H<sub>0</sub> in favour of H<sub>1</sub>:  $\rho > 0$
- $dw > d_U$ : do not reject  $H_0$
- $d_L < dw < d_U$ : no decision (inconclusive region)

## Durbin-Watson Test: Remarks

- Durbin-Watson test gives no indication of causes for the rejection of the null hypothesis and how the model to modify
- Various types of misspecification may cause the rejection of the null hypothesis
- Durbin-Watson test is a test against first-order autocorrelation; a test against autocorrelation of other orders may be more suitable, e.g., order four if the model is for quarterly data
- Use of tables unwieldy
  - $\Box$  Limited number of critical bounds (K, T,  $\alpha$ ) in tables
  - Inconclusive region
- GRETL: Standard output of the OLS estimation reports the Durbin-Watson statistic; to see the p-value:
  - OLS output => Tests => Durbin-Watson p-value

# Asymptotic Tests

AR(1) process for error terms

$$\varepsilon_t = \rho \varepsilon_{t-1} + V_t$$

Auxiliary regression of  $e_t$  on (an intercept,)  $x_t$  and  $e_{t-1}$ : produces

 $R_e^2$ 

Test of  $H_0$ :  $\rho = 0$  against  $H_1$ :  $\rho > 0$  or  $H_1$ :  $\rho \neq 0$ 

- 1. Breusch-Godfrey test
  - Arr R<sub>e</sub><sup>2</sup> of the auxiliary regression: close to zero if ho = 0
  - Under H<sub>0</sub>: ρ = 0, (*T*-1) R<sub>e</sub><sup>2</sup> follows approximately the Chi-squared distribution with 1 d.f.
  - Lagrange multiplier F (LMF) statistic: F-test for explanatory power of  $e_{t-1}$ ; follows approximately the F(1, T-K-1) distribution if  $\rho = 0$
  - General case of the Breusch-Godfrey test: Auxiliary regression based on higher order autoregressive process

## Asymptotic Tests, cont'd

#### Box-Pierce test

- The Box-Pierce test uses the test statistic  $Q_{\rm m} = T \sum_{\rm s=1}^{\rm m} r_{\rm s}^2$  with correlations  $r_{\rm s}$  between  $e_{\rm t}$  and  $e_{\rm t-s}$ ;  $Q_{\rm m}$  follows approximately the Chi-squared distribution with m d.f. if  $\rho = 0$ ,  $\varepsilon_{\rm t}$  are white noise
- The *t*-statistic  $t = \sqrt{(T)r}$ , based on the OLS estimate r of  $\rho$  from  $\varepsilon_t = \rho \varepsilon_{t-1} + v_t$ , is the special case of the Box-Pierce test with m = 1; if  $\rho = 0$ , t follows approximately the t-distribution,  $t^2 = T r^2$  the Chi-squared distribution with 1 d.f.
- 3. Similar the Ljung-Box test, based on

$$Q^{LB} = T (T+2) \sum_{s=1}^{m} r_s^2 / (T-s)$$

with correlations  $r_s$  between  $e_t$  and  $e_{t-s}$ ;  $Q^{LB}$  follows the Chisquared distribution with m d.f. if  $\rho = 0$ 

## Asymptotic Tests, cont'd

#### **GRETL**:

- OLS output => Tests => Autocorrelation (shows the Breusch-Godfrey LMF statistic, the Box-Pierce statistic with m=1, and the Ljung-Box statistic as well as p-values)
- OLS output => Graphs => Residual correlogram (shows besides the correlogram of the residuals Ljung-Box statistic Q and p-value)

#### Remarks

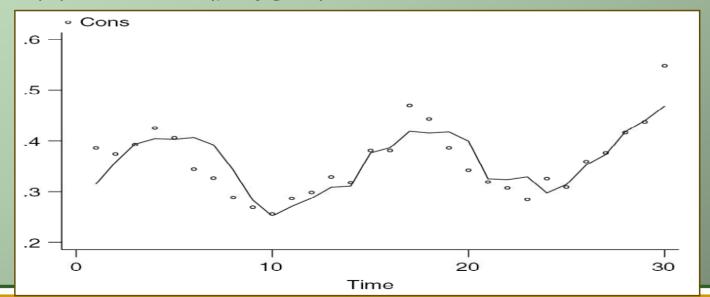

- If the model of interest contains lagged values of y the auxiliary regression should also include all explanatory variables (just to make sure the distribution of the test is correct)
- If heteroskedasticity is suspected, White standard errors may be used in the auxiliary regression

#### Test for autocorrelation of error terms

- $H_0$ :  $\rho = 0$ ,  $H_1$ :  $\rho \neq 0$
- $dw = 1.02 < 1.21 = d_L$  for T = 30, K = 4; p = 0.0003 (in GRETL: 0.0003025); reject H<sub>0</sub>
- GRETL also shows the autocorrelation coefficient: r = 0.401
   Plot of actual (o) and fitted (polygon) values

Auxiliary regression  $\varepsilon_t = x_t'\beta + \rho\varepsilon_{t-1} + v_t$ : OLS estimation gives r = 0.401,  $R^2 = 0.141$ 

Test of  $H_0$ :  $\rho = 0$  against  $H_1$ :  $\rho > 0$ 

- 1. Breusch-Godfrey test: LMF = 4.11, *p*-value: 0.053
- 2. Box-Pierce test:  $t^2 = 4.237$ , p-value: 0.040
- 3. Ljung-Box test:  $Q^{LB} = 3.6$ , *p*-value: 0.058

All three tests reject the null hypothesis

# Inference under Autocorrelation

Covariance matrix of *b*:

$$V{b} = \sigma^2 (X'X)^{-1} X'\Psi X (X'X)^{-1}$$

Use of  $\sigma^2$  (X'X)<sup>-1</sup> (the standard output of econometric software) instead of V{*b*} for inference on  $\beta$  may be misleading

#### Remedies

- Use of correct variances and standard errors
  - HAC-estimator for V{b}
- Transformation of the model so that the error terms are uncorrelated
  - Cochrane-Orcutt estimator

# HAC-estimator for V{b}

Substitution of Ψ in

$$V{b} = \sigma^2 (X'X)^{-1} X'\Psi X (X'X)^{-1}$$

by a suitable estimator

Newey-West: substitution of  $S_x = \sigma^2(X'\Psi X)/T = (\Sigma_t \Sigma_s \sigma_{ts} x_t x_s')/T$  by

$$\hat{S}_{x} = \frac{1}{T} \sum_{t} e_{t}^{2} x_{t} x_{t}' + \frac{1}{T} \sum_{j=1}^{p} \sum_{t} (1 - w_{j}) e_{t} e_{t-j} (x_{t} x_{t-j}' + x_{t-j} x_{t}')$$

with  $w_i = j/(p+1)$ ; p, the truncation lag, is to be chosen suitably

The estimator

$$T(X'X)^{-1} \hat{S}_{X}(X'X)^{-1}$$

for V{b} is called *heteroskedasticity and autocorrelation consistent* (HAC) or Newey-West estimator, the corresponding standard errors are the HAC s.e.

Demand for ice cream, measured by *cons*, explained by *price*, income, and temp, OLS and HAC standard errors

	coeff	s.e.	
		OLS	HAC
constant	0.197	0.270	0.288
price	-1.044	0.834	0.876

temp*10 <sup>-3</sup>	3.458	0.446	0.411

## Cochrane-Orcutt Estimator

#### **GLS** estimator

• With transformed variables  $y_t^* = y_t - \rho y_{t-1}$  and  $x_t^* = x_t - \rho x_{t-1}$ , also called "quasi-differences", the model  $y_t = x_t \cdot \beta + \varepsilon_t$  with  $\varepsilon_t = \rho \varepsilon_{t-1} + v_t$  can be written as

$$y_{t} - \rho y_{t-1} = y_{t}^{*} = (x_{t} - \rho x_{t-1})^{*}\beta + v_{t} = x_{t}^{*}\beta + v_{t}$$
 (A)

- The model in quasi-differences has error terms which fulfill the Gauss-Markov assumptions
- Given observations for t = 1, ..., T, model (A) is defined for t = 2, ..., T
- Estimation of ρ using, e.g., the auxiliary regression  $\varepsilon_t = \rho \varepsilon_{t-1} + v_t$  gives the estimate r; substitution of r in (A) for ρ results in FGLS estimators for  $\beta$
- The FGLS estimator is called Cochrane-Orcutt estimator

## Cochrane-Orcutt Estimation

### In following steps

- 1. OLS estimation of b for  $\beta$  from  $y_t = x_t'\beta + \varepsilon_t$ , t = 1, ..., T
- 2. Estimation of r for  $\rho$  from the auxiliary regression  $\varepsilon_t = \rho \varepsilon_{t-1} + v_t$
- 3. Calculation of quasi-differences  $y_t^* = y_t ry_{t-1}$  and  $x_t^* = x_t rx_{t-1}$
- 4. OLS estimation of  $\beta$  from

$$y_t^* = x_t^{*'}\beta + v_t, t = 2, ..., T$$

resulting in the Cochrane-Orcutt estimators

Steps 2. to 4. can be repeated in order to improve the estimate *r*: iterated Cochrane-Orcutt estimator

**GRETL** provides the iterated Cochrane-Orcutt estimator:

Model => Time series => AR errors (GLS) => AR(1)

#### **Iterated Cochrane-Orcutt estimator**

**Table 4.10** EGLS (iterative Cochrane–Orcutt) results

Variable	Estimate	Standard error	t-ratio
constant	0.157	0.300	0.524
price	-0.892	0.830	-1.076

temp <sub>-1</sub>					-2.204	0.731

Adding temp<sub>-1</sub> improves the adj R<sup>2</sup> from 0.687 to 0.800

# General Autocorrelation Structures

Generalization of model

$$y_t = x_t'\beta + \varepsilon_t$$
  
with  $\varepsilon_t = \rho \varepsilon_{t-1} + v_t$ 

Alternative dependence structures of error terms

- Autocorrelation of higher order than 1
- Moving average pattern

## Higher Order Autocorrelation

For quarterly data, error terms may develop according to

$$\varepsilon_{t} = \gamma \varepsilon_{t-4} + V_{t}$$

or - more generally - to

$$\varepsilon_t = \gamma_1 \varepsilon_{t-1} + \dots + \gamma_4 \varepsilon_{t-4} + V_t$$

- $\varepsilon_t$  follows an AR(4) process, an autoregressive process of order 4
- More complex structures of correlations between variables with autocorrelation of order 4 are possible than with that of order 1

## Moving Average Processes

Moving average process of order 1, MA(1) process

$$\varepsilon_{t} = V_{t} + \alpha V_{t-1}$$

- $\epsilon_{t}$  is correlated with  $\epsilon_{t-1}$ , but not with  $\epsilon_{t-2}$ ,  $\epsilon_{t-3}$ , ...
- Generalizations to higher orders

# Remedies against Autocorrelation

- Change functional form, e.g., use log(y) instead of y
- Extend the model by including additional explanatory variables, e.g., seasonal dummies, or additional lags
- Use HAC standard errors for the OLS estimators
- Reformulate the model in quasi-differences (FGLS) or in differences

#### **OLS Estimator**

Linear model for  $y_t$ 

$$y_i = x_i'\beta + \varepsilon_i$$
,  $i = 1, ..., N$  (or  $y = X\beta + \varepsilon$ )

given observations  $x_{ik}$ , k = 1, ..., K, of the regressor variables, error term  $\varepsilon_i$ 

**OLS** estimator

$$b = (\Sigma_i x_i x_i')^{-1} \Sigma_i x_i y_i = (X'X)^{-1} X' y$$

From

$$b = (\sum_{i} x_{i} x_{i}')^{-1} \sum_{i} x_{i} y_{i} = (\sum_{i} x_{i} x_{i}')^{-1} \sum_{i} x_{i} x_{i}' \beta + (\sum_{i} x_{i} x_{i}')^{-1} \sum_{i} x_{i} \varepsilon_{i}$$
$$= \beta + (\sum_{i} x_{i} x_{i}')^{-1} \sum_{i} x_{i} \varepsilon_{i} = \beta + (X'X)^{-1} X' \varepsilon$$

follows

$$E\{b\} = (\Sigma_{i}x_{i} x_{i}')^{-1}\Sigma_{i}x_{i}y_{i} = (\Sigma_{i}x_{i} x_{i}')^{-1}\Sigma_{i}x_{i} x_{i}' \beta + (\Sigma_{i}x_{i} x_{i}')^{-1}\Sigma_{i}x_{i} \varepsilon_{i}$$

$$= \beta + (\Sigma_{i}x_{i} x_{i}')^{-1} E\{\Sigma_{i}x_{i} \varepsilon_{i}\} = \beta + (X'X)^{-1} E\{X'\varepsilon\}$$

## OLS Estimator: Properties

- 1. OLS estimator b is unbiased if
  - (A1)  $E\{\varepsilon\} = 0$
  - E{Σ<sub>i</sub> $x_i$  ε<sub>i</sub>} = E{X'ε} = 0; is fulfilled if (A7) or a stronger assumption is true
    - $\triangle$  (A2)  $\{x_i, i=1, ..., N\}$  and  $\{\varepsilon_i, i=1, ..., N\}$  are independent; is the strongest assumption
    - (A10)  $E{\{\varepsilon|X\}} = 0$ , i.e., X uninformative about  $E{\{\varepsilon_i\}}$  for all i (ε is conditional mean independent of X); is implied by (A2)
    - $(A8) x_i$  and  $ε_i$  are independent for all i (no contemporaneous dependence); is less strong than (A2) and (A10)
    - (A7)  $E\{x_i \varepsilon_i\} = 0$  for all i (no contemporaneous correlation); is even less strong than (A8)

## OLS Estimator: Properties, cont'd

- 2. OLS estimator b is consistent for  $\beta$  if
  - (A8)  $x_i$  and  $\varepsilon_i$  are independent for all *i*
  - (A6) (1/N)Σ<sub>i</sub> x<sub>i</sub> x<sub>i</sub> has as limit (N→∞) a non-singular matrix Σ<sub>xx</sub>
     (A8) can be substituted by (A7) [E{x<sub>i</sub> ε<sub>i</sub>} = 0 for all i, no contemporaneous correlation]
- 3. OLS estimator b is asymptotically normally distributed if (A6), (A8) and
  - (A11)  $\varepsilon_i \sim \text{IID}(0, \sigma^2)$  are true;
  - for large N, b follows approximately the normal distribution  $b \sim_a N\{\beta, \sigma^2(\Sigma_i x_i x_i')^{-1}\}$
  - Use White and Newey-West estimators for V{b} in case of heteroskedasticity and autocorrelation of error terms, respectively

# Assumption (A7): $E\{x_i \varepsilon_i\} = 0$ for all i

Implication of (A7): for all *i*, each of the regressors is uncorrelated with the current error term, no contemporaneous correlation

- (A7) guaranties unbiasedness and consistency of the OLS estimator
- Stronger assumptions (A2), (A10), (A8) have same consequences

In reality, (A7) is not always true: alternative estimation procedures are required for ascertaining consistency and unbiasedness

Examples of situations with  $E\{x_i \ \varepsilon_i\} \neq 0$  (see the following slides):

- Regressors with measurement errors
- Regression on the lagged dependent variable with autocorrelated error terms (dynamic regression)
- Unobserved heterogeneity
- Endogeneity of regressors, simultaneity

#### Contents

- Autocorrelation
- Tests against Autocorrelation

- IV Estimator: The Method
- An Example
- Some Tests

# Omission of Relevant Regressors

Two models:

$$y_i = x_i'\beta + z_i'\gamma + \varepsilon_i$$
 (A)

$$y_i = x_i'\beta + v_i \tag{B}$$

- True model (A), fitted model (B)
- OLS estimates  $b_{\rm B}$  of  $\beta$  from (B)

$$b_B = \beta + \left(\sum_i x_i x_i'\right)^{-1} \sum_i x_i z_i' \gamma + \left(\sum_i x_i x_i'\right)^{-1} \sum_i x_i \varepsilon_i$$

- Omitted variable bias:  $E\{(\Sigma_i x_i x_i')^{-1} \Sigma_i x_i z_i'\} \gamma = E\{(X'X)^{-1} X'Z\} \gamma$
- No bias if (a)  $\gamma = 0$ , i.e., model (A) is correct, or if (b) variables in  $x_i$  and  $z_i$  are uncorrelated (orthogonal)

OLS estimators are biased, if relevant regressors are omitted that are not uncorrelated with regressors in  $x_i$ 

# Unobserved Heterogeneity

Example: Wage equation with  $y_i$ : log wage,  $x_{1i}$ : personal characteristics,  $x_{2i}$ : years of schooling,  $u_i$ : abilities (unobservable)

$$y_i = x_{1i}'\beta_1 + x_{2i}\beta_2 + u_i\gamma + v_i$$

Model for analysis (unobserved u<sub>i</sub> covered in error term)

$$y_i = x_i'\beta + \varepsilon_i$$
with  $x_i = (x_{1i}', x_{2i})'$ ,  $\beta = (\beta_1', \beta_2)'$ ,  $\varepsilon_i = u_i \gamma + v_i$ 

- Given  $E\{x_i \ v_i\} = 0$ plim  $b = \beta + \sum_{xx}^{-1} E\{x_i \ u_i\} \ \gamma$
- OLS estimators b are not consistent if  $x_i$  and  $u_i$  are correlated ( $\gamma \neq 0$ ), e.g., if higher abilities induce more years at school: estimator for  $\beta_2$  might be overestimated, hence effects of years at school etc. are overestimated: "ability bias"

Unobserved heterogeneity: observational units differ in other aspects than ones that are observable

## **Dynamic Regression**

Allows modelling dynamic effects of changes of x on y:

$$y_{t} = \beta_{1} + \beta_{2}x_{t} + \beta_{3}y_{t-1} + \varepsilon_{t}$$

with  $\varepsilon_t$  following the AR(1) model

$$\varepsilon_{t} = \rho \varepsilon_{t-1} + V_{t}$$

 $v_{\rm t}$  white noise with  $\sigma_{\rm v}^2$ 

From 
$$y_t = \beta_1 + \beta_2 x_t + \beta_3 y_{t-1} + \rho \varepsilon_{t-1} + v_t$$
 follows

$$E\{y_{t-1}\varepsilon_t\} = \beta_3 E\{y_{t-2}\varepsilon_t\} + \rho^2\sigma_v^2(1 - \rho^2)^{-1}$$

i.e.,  $y_{t-1}$  is correlated with  $\varepsilon_t$ 

Remember:  $E\{\varepsilon_t, \varepsilon_{t-s}\} = \rho^s \sigma_v^2 (1-\rho^2)^{-1}$  for s > 0

OLS estimators not consistent if  $\rho \neq 0$ 

The model does not correspond to the conditional expectation of  $y_t$  given the regressors  $x_t$  and  $y_{t-1}$ :

$$\mathsf{E}\{y_{t}|x_{t},\,y_{t-1}\} = \beta_{1} + \beta_{2}x_{t} + \beta_{3}y_{t-1} + \mathsf{E}\{\varepsilon_{t}\,|x_{t},\,y_{t-1}\}$$

# Regressor with Measurement Error

$$y_i = \beta_1 + \beta_2 w_i + v_i \tag{A}$$

with white noise  $v_i$ ,  $V\{v_i\} = \sigma_v^2$ , and  $E\{v_i|w_i\} = 0$ ; conditional expectation of  $y_i$  given  $w_i$ :  $E\{y_i|w_i\} = \beta_1 + \beta_2 w_i$ 

Example:  $y_i$ : household savings,  $w_i$ : household income

Measurement process: reported household income  $x_i$  may deviate from actual household income  $w_i$ 

$$x_i = w_i + u_i$$

where  $u_i$  is (i) white noise with  $V\{u_i\} = \sigma_u^2$ , (ii) independent of  $v_i$ , and (iii) independent of  $w_i$ 

The model to be analyzed is

$$y_i = \beta_1 + \beta_2 x_i + \varepsilon_i$$
 with  $\varepsilon_i = v_i - \beta_2 u_i$  (B)

- E{ $x_i$   $ε_i$ } =  $β_2$   $σ_u^2 ≠ 0$ : requirement for consistency and unbiasedness of OLS estimates is violated
- $x_i$  and  $\varepsilon_i$  are negatively (positively) correlated if  $\beta_2 > 0$  ( $\beta_2 < 0$ )

# Consequences of Measurement Errors

Inconsistency of  $b_2 = s_{xy}/s_x^2$ plim  $b_2 = \beta_2 + (\text{plim } s_{x\epsilon})/(\text{plim } s_x^2) = \beta_2 + \text{E}\{x_i \epsilon_i\} / \text{V}\{x_i\}$  $= \beta_2 \left(1 - \frac{\sigma_u^2}{\sigma_w^2 + \sigma_u^2}\right)$ 

β<sub>2</sub> is underestimated

- Inconsistency of  $b_1 = \overline{y} b_2 \overline{x}$ plim  $(b_1 - \beta_1) = -$  plim  $(b_2 - \beta_2) \to \{x_i\}$ given  $\to \{x_i\} > 0$  for the reported income:  $\beta_1$  is overestimated; inconsistency of  $b_2$  "carries over"
- The model does not correspond to the conditional expectation of y<sub>i</sub> given x<sub>i</sub>:

$$E\{y_i|x_i\} = \beta_1 + \beta_2 x_i - \beta_2 E\{u_i|x_i\} \neq \beta_1 + \beta_2 x_i$$
  
as  $E\{u_i|x_i\} \neq 0$ 

### Endogenous Regressors

Regressors in X which are correlated with error term,  $E\{X^t \varepsilon\} \neq 0$ , are called endogenous

- OLS estimators  $b = \beta + (X^t X)^{-1} X^t \varepsilon$ 
  - □  $E\{b\} \neq \beta$ , b is biased; bias  $E\{(X^tX)^{-1}X^t\epsilon\}$  difficult to assess
  - - For q = 0 (regressors and error term asymptotically uncorrelated),
       OLS estimators b are consistent also in case of endogenous regressors
    - For  $q \neq 0$  (error term and at least one regressor asymptotically correlated): plim  $b \neq \beta$ , the OLS estimators b are not consistent
- Endogeneity bias
- Relevant for many economic applications

Exogenous regressors: with error term uncorrelated, all regressors that are not endogenous

## Income and Consumption

#### AWM data base, 1970:1-2003:4

- C: private consumption (PCR), growth rate p.y.
- Y: disposable income of households (PYR), growth rate p.y.

$$C_{t} = \beta_{1} + \beta_{2} Y_{t} + \varepsilon_{t} \tag{A}$$

 $\beta_2$ : marginal propensity to consume,  $0 < \beta_2 < 1$ 

OLS estimates:

$$\hat{C}_t = 0.011 + 0.718 \ Y_t$$
  
with  $t = 15.55$ ,  $R^2 = 0.65$ ,  $DW = 0.50$ 

It: per capita investment (exogenous,  $E\{I_t \varepsilon_t\} = 0$ )

$$Y_{t} = C_{t} + I_{t} \tag{B}$$

- Both  $Y_t$  and  $C_t$  are endogenous:  $E\{C_t \varepsilon_i\} = E\{Y_t \varepsilon_i\} = \sigma_{\varepsilon}^2 (1 \beta_2)^{-1}$
- The regressor Y<sub>t</sub> has an impact on C<sub>t</sub>; at the same time C<sub>t</sub> has an impact on Y<sub>t</sub>

# Simultaneous Equation Models

Illustrated by the preceding consumption function:

$$C_{t} = \beta_{1} + \beta_{2}Y_{t} + \varepsilon_{t}$$
 (A)

$$Y_{t} = C_{t} + I_{t} \tag{B}$$

Variables  $Y_t$  and  $C_t$  are simultaneously determined by equations (A) and (B)

- Equations (A) and (B) are the structural equations or the structural form of the simultaneous equation model that describes both Y<sub>t</sub> and C<sub>t</sub>
- The coefficients  $β_1$  and  $β_2$  are behavioural parameters
- Reduced form of the model: one equation for each of the endogenous variables C<sub>t</sub> and Y<sub>t</sub>, with only the exogenous variable I<sub>t</sub> as regressor

The OLS estimators are biased and not consistent

## Income and Consumption, cont'd

Reduced form of the model:

$$C_{t} = \frac{\beta_{1}}{1 - \beta_{2}} + \frac{\beta_{2}}{1 - \beta_{2}} I_{t} + \frac{1}{1 - \beta_{2}} \varepsilon_{t}$$

$$Y_{t} = \frac{\beta_{1}}{1 - \beta_{2}} + \frac{1}{1 - \beta_{2}} I_{t} + \frac{1}{1 - \beta_{2}} \varepsilon_{t}$$

- OLS estimator b<sub>2</sub> from (A) is inconsistent; E{Y<sub>t</sub> ε<sub>t</sub>} ≠ 0 plim b<sub>2</sub> = β<sub>2</sub> + Cov{Y<sub>t</sub> ε<sub>t</sub>} / V{Y<sub>t</sub>} = β<sub>2</sub> + (1 β<sub>2</sub>) σ<sub>ε</sub><sup>2</sup>(V{I<sub>t</sub>} + σ<sub>ε</sub><sup>2</sup>)<sup>-1</sup> for 0 < β<sub>2</sub> < 1, b<sub>2</sub> overestimates β<sub>2</sub>
- The OLS estimator  $b_1$  is also inconsistent

#### Contents

- Autocorrelation
- Tests against Autocorrelation
- Inference under Autocorrelation
- OLS Estimation: Assumptions
- Cases of Endogenous Regressors
- Instrumental Variables (IV) Estimator: The Concept
- IV Estimator: The Method
- An Example
- Some Tests

#### A New Estimator

#### Model

$$y_i = \beta_1 + \beta_2 x_i + \varepsilon_i$$

with E{  $\varepsilon_i x_i$  }  $\neq$  0, i.e., endogenous regressor  $x_i$ : OLS estimators are biased and inconsistent

Instrumental variable z<sub>i</sub> satisfying

- 1. Exogeneity:  $E\{\varepsilon_i z_i\} = 0$ :  $z_i$  is uncorrelated with error term
- 2. Relevance:  $Cov\{x_i, z_i\} \neq 0$ : is correlated with endogenous regressor

Transformation of model equation

$$Cov\{y_i, z_i\} = \beta_2 Cov\{x_i, z_i\} + Cov\{\varepsilon_i, z_i\}$$

gives

$$\beta_2 = \frac{Cov\{y_i, z_i\}}{Cov\{x_i, z_i\}}$$

# IV Estimator for $\beta_2$

Substitution of sample moments for covariances gives the instrumental variables (IV) estimator

$$\hat{\beta}_{2,IV} = \frac{\sum_{i} (z_i - \overline{z})(y_i - \overline{y})}{\sum_{i} (z_i - \overline{z})(x_i - \overline{x})}$$

- Consistent estimator for  $\beta_2$  given that the instrumental variable  $z_i$  is valid, i.e., it is
  - $\Box$  Exogenous, i.e.  $E\{\varepsilon_i z_i\} = 0$
  - □ Relevant, i.e.  $Cov\{x_i, z_i\} \neq 0$
- Typically, nothing can be said about the bias of an IV estimator; small sample properties are unknown
- Coincides with OLS estimator for  $z_i = x_i$

## Income and Consumption, cont'd

#### Alternative model: $C_t = \beta_1 + \beta_2 Y_{t-1} + \varepsilon_t$

- $Y_{t-1}$  and  $\varepsilon_t$  are certainly uncorrelated; avoids risk of inconsistency due to correlated  $Y_t$  and  $\varepsilon_t$
- $Y_{t-1}$  is certainly highly correlated with  $Y_t$ , is almost as good as regressor as  $Y_t$

#### Fitted model:

$$\hat{C} = 0.012 + 0.660 \ Y_{-1}$$
  
with  $t = 12.86$ ,  $R^2 = 0.56$ ,  $DW = 0.79$  (instead of  $\hat{C} = 0.011 + 0.718 \ Y$   
with  $t = 15.55$ ,  $R^2 = 0.65$ ,  $DW = 0.50$ )

Deterioration of *t*-statistic and R<sup>2</sup> are price for improvement of the estimator

### IV Estimator: The Concept

#### Alternative to OLS estimator

Avoids inconsistency in case of endogenous regressors Idea of the IV estimator:

Replace regressors which are correlated with error terms by regressors which are

- uncorrelated with the error terms
- (highly) correlated with the regressors that are to be replaced

and use OLS estimation

The hope is that the IV estimator is consistent (and less biased than the OLS estimator)

Price: IV estimator is less efficient; deteriorated model fit as measured by, e.g., *t*-statistic, R<sup>2</sup>

#### Contents

- Autocorrelation
- Tests against Autocorrelation
- Inference under Autocorrelation
- OLS Estimation: Assumptions
- Cases of Endogenous Regressors
- Instrumental Variables (IV) Estimator: The Concept
- IV Estimator: The Method
- An Example
- Some Tests

#### IV Estimator: General Case

The model is

$$y_i = x_i'\beta + \varepsilon_i$$
  
with  $V\{\varepsilon_i\} = \sigma_{\varepsilon}^2$  and  $E\{\varepsilon_i x_i\} \neq 0$ 

at least one component of  $x_i$  is correlated with the error term. The vector of instruments  $z_i$  (with the same dimension as  $x_i$ ) fulfils

$$E\{\varepsilon_i z_i\} = 0$$

$$Cov\{x_i, z_i\} \neq 0$$

IV estimator based on the instruments  $z_i$ 

$$\hat{\beta}_{IV} = \left(\sum_{i} z_{i} x_{i}'\right)^{-1} \left(\sum_{i} z_{i} y_{i}\right)$$

#### IV Estimator: Distribution

The (asymptotic) covariance matrix of the IV estimator is given by

$$V\left\{\hat{\boldsymbol{\beta}}_{IV}\right\} = \boldsymbol{\sigma}^{2} \left[ \left(\sum_{i} x_{i} z_{i}^{\prime}\right) \left(\sum_{i} z_{i} z_{i}^{\prime}\right)^{-1} \left(\sum_{i} z_{i} x_{i}^{\prime}\right) \right]^{-1}$$

In the estimated covariance matrix  $\hat{V}\{\hat{\beta}_{IV}\}$ ,  $\sigma^2$  is substituted by

$$\hat{\sigma}^2 = \frac{1}{N} \sum_{i} \left( y_i - x_i' \hat{\beta}_{IV} \right)^2$$

which is based on the IV residuals  $y_i - x_i' \hat{\beta}_{IV}$ 

The asymptotic distribution of IV estimators, given IID(0,  $\sigma_{\epsilon}^{2}$ ) error terms, leads to the approximate distribution

$$N(oldsymbol{eta}, \hat{V}\{\hat{oldsymbol{eta}}_{IV}\})$$

with the estimated covariance matrix  $\hat{V}\{\hat{oldsymbol{eta}}_{IV}\}$ 

#### Calculation of IV Estimators

The model in matrix notation

$$y = X\beta + \varepsilon$$

The IV estimator

$$\hat{\beta}_{IV} = \left(\sum_{i} z_{i} x_{i}'\right)^{-1} \sum_{i} z_{i} y_{i} = (Z'X)^{-1} Z'y$$

with  $z_i$  obtained from  $x_i$  by substituting instrumental variable(s) for all endogenous regressors

Calculation in two steps:

1. Reduced form: Regression of the explanatory variables  $x_1, ..., x_K$  – including the endogenous ones – on the columns of Z: fitted values

$$\hat{X} = Z(Z'Z)^{-1}Z'X$$

2. Regression of *y* on the fitted explanatory variables:

$$\hat{\boldsymbol{\beta}}_{IV} = (\hat{X}'\hat{X})^{-1}\hat{X}'y$$

## Calculation of IV Estimators: Remarks

- The KxK matrix  $Z'X = \sum_i z_i x_i$  is required to be finite and invertible
- From

$$\hat{X}'\hat{X}\hat{X})^{-1}\hat{X}'y = (X'Z(Z'Z)^{-1}Z'X)^{-1}X'Z(Z'Z)^{-1}Z'y$$

$$= (Z'X)^{-1}Z'Z(X'Z)^{-1}X'Z(Z'Z)^{-1}Z'y = (Z'X)^{-1}Z'y = \hat{\beta}_{IV}$$

it is obvious that the estimator obtained in the second step is the IV estimator

- However, the estimator obtained in the second step is more general; see below
- In GRETL: The sequence "Model > Instrumental variables >
   Two-Stage Least Squares" leads to the specification window with
   boxes (i) for the regressors and (ii) for the instruments

# Choice of Instrumental Variables

Instrumental variable are required to be

- exogenous, i.e., uncorrelated with the error terms
- relevant, i.e., correlated with the endogenous regressors

#### Instruments

- must be based on subject matter arguments, e.g., arguments from economic theory
- should be explained and motivated
- must show a significant effect in explaining an endogenous regressor
- choice of instruments often not easy

Regression of endogenous variables on instruments

- Best linear approximation of endogenous variables
- Economic interpretation not of importance and interest

#### Contents

# Returns to Schooling: Causality?

Human capital earnings (wage) function:

$$w_i = \beta_1 + \beta_2 S_i + \beta_3 E_i + \beta_4 E_i^2 + \varepsilon_i$$

with  $w_i$ : log of individual earnings,  $S_i$ : years of schooling,  $E_i$ : years of experience ( $E_i = age_i - S_i - 6$ )

Empirically, more education implies higher income

Question: Is this effect causal?

- If yes, one year more at school increases wage by  $\beta_2$  (Theory A)
- Alternatively, personal abilities of an individual causes higher income and also more years at school; more years at school do not necessarily increase wage (Theory B)

Issue of substantial attention in literature

# Returns to Schooling: Endogenous Regressors

Wage equation: besides  $S_i$  and  $E_i$ , additional explanatory variables like gender, regional, racial dummies, family background

Model for analysis:

$$W_{i} = \beta_{1} + z_{i}' y + \beta_{2} S_{i} + \beta_{3} E_{i} + \beta_{4} E_{i}^{2} + \varepsilon_{i}$$

 $z_i$ : observable variables besides  $E_i$ ,  $S_i$ 

- $z_i$  is assumed to be exogenous, i.e.,  $E\{z_i \epsilon_i\} = 0$
- $S_i$  may be endogenous, i.e.,  $E{S_i ε_i} \neq 0$ 
  - Unobservable factors like intelligence, family background, etc. enable to more schooling and higher earnings
  - Measurement error in measuring schooling
  - Etc.
- With  $S_i$ , also  $E_i = age_i S_i 6$  and  $E_i^2$  are endogenous
- OLS estimators may be inconsistent

# Returns to Schooling: Data

- Verbeek's data set "schooling"
- National Longitudinal Survey of Young Men (Card, 1995)
- Data from 3010 males, survey 1976
- Individual characteristics, incl. experience, race, region, family background, etc.
- Human capital earnings or wage function

$$\log(wage_i) = \beta_1 + \beta_2 ed_i + \beta_3 exp_i + \beta_3 exp_i^2 + \varepsilon_i$$

with  $ed_i$ : years of schooling  $(S_i)$ ,  $exp_i$ : years of experience  $(E_i)$ 

- Variables: wage76 (wage in 1976, raw, cents p.h.), ed76 (years at school in 1976), exp76 (experience in 1976), exp762 (exp76 squared)
- Further explanatory variables: black: dummy for afro-american, smsa: dummy for living in metropolitan area, south: dummy for living in the south

### Some Comments

### Instrumental variables (age, age<sup>2</sup>, nearc4a)

- are relevant, i.e., have explanatory power for ed76, exp76, exp76<sup>2</sup>
- Whether they are exogenous, i.e., uncorrelated with the error terms, is not answered
- Test for exogeneity of regressors: Wu-Hausman test (see below) Estimates of ed76-coefficient:
- IV estimate: 0.16 (0.13), i.e., 16% higher wage for one additional year of schooling; more than the double of the OLS estimate (0.07); not in line with "ability bias" argument!
- s.e. of IV estimate (0.04) much higher than s.e. of OLS estimate (0.004)
- Loss of efficiency especially in case of weak instruments: R<sup>2</sup> of model for ed76: 0.12; Corr{ed76, ed76 h} = 0.35

### GRETL's TSLS Estimation

#### Wage equation, estimated by **GRETL**'s TSLS

Model 8: TSLS, using observations 1-3010

<sup>1)</sup> The model differs from that used by Verbeek

### Some Comments

#### Verbeek's IV estimates

- Deviate from GRETL results
- Do not report R<sup>2</sup>; definition of R<sup>2</sup> does not apply to IV estimated models

#### IV estimates of coefficients

- are smaller than the OLS estimates; exception is ed76
- have higher s.e. than OLS estimates, smaller t-statistics

#### Questions

- Robustness of IV estimates to changes in the specification
- Exogeneity of instruments
- Weak instruments

### Contents

- Autocorrelation
- Tests against Autocorrelation
- Inference under Autocorrelation
- OLS Estimation: Assumptions
- Cases of Endogenous Regressors
- Instrumental Variables (IV) Estimator: The Concept
- IV Estimator: The Method
- An Example
- Some Tests

### Some Tests

#### Questions of interest

- Is it necessary to use IV estimation, must violation of exogeneity be expected? To be tested: the null hypothesis of exogeneity of suspected variables
- 2. If IV estimation is used: Are the chosen instruments valid (relevant)?

### For testing

- exogeneity of regressors: Wu-Hausman test, also called Durbin-Wu-Hausman test, in GRETL: Hausman test
- relevance of potential instrumental variables: Sargan test or over-identifying restrictions test
- weak instruments, i.e., only weak correlation between endogenous regressor and instrument: Cragg-Donald test

### Wu-Hausman Test

For testing whether one or more regressors  $x_i$  are endogenous (correlated with the error term);  $H_0$ :  $E\{\varepsilon_i x_i\} = 0$ 

- If the null hypothesis
  - is true, OLS estimates are more efficient than IV estimates
  - is not true, OLS estimates are inefficient, the less efficient but consistent IV estimates to be used

Based on the assumption that the instrumental variables are valid, i.e., given that  $E\{\varepsilon_i z_i\} = 0$ , the null hypothesis  $E\{\varepsilon_i x_i\} = 0$  can be tested against the alternative  $E\{\varepsilon_i x_i\} \neq 0$ 

#### The idea of the test:

- Under the null hypothesis, both the OLS and IV estimator are consistent; they should differ by sampling errors only
- Rejection of the null hypothesis indicates inconsistency of the OLS estimator

## Wu-Hausman Test, cont'd

Based on the differences between OLS- and IV-estimators; various versions of the Wu-Hausman test

Added variable interpretation of the Wu-Hausman test: checks whether the residuals  $v_i$  from the reduced form equation of potentially endogenous regressors contribute to explaining

$$y_i = x_{1i}'\beta_1 + x_{2i}'\beta_2 + v_i'\gamma + \varepsilon_i$$

- $x_2$ : potentially endogenous regressors, J components
- $v_i$ : residuals from reduced form equation for  $x_2$  (predicted values for  $x_2$ :  $x_2 + v$ )
- $H_0$ : γ = 0; corresponds to:  $x_2$  is exogenous

For testing H<sub>0</sub>: use of

- t-test, if γ has one component,  $x_2$  is just one regressor
- F-test, if more than one regressor are tested for exogeneity

### Hausman Test Statistic

Based on the quadratic form of differences between OLS- estimators  $b_{\rm LS}$  and IV-estimators  $b_{\rm IV}$ 

- $H_0$ : both  $b_{LS}$  and  $b_{IV}$  are consistent,  $b_{LS}$  is efficient relative to  $b_{IV}$
- $\blacksquare$   $H_1$ :  $b_{IV}$  is consistent,  $b_{IS}$  is inconsistent

Hausman test statistic

$$H = (b_{IV} - b_{LS})' V (b_{IV} - b_{LS})$$

with estimated covariance matrix V of  $b_{IV} - b_{LS}$  follows the approximate Chi-square distribution with J d.f.

### Wu-Hausman Test: Remarks

#### Remarks

- Test requires valid instruments
- Test has little power if instruments are weak or invalid
- Various versions of the test, all based on differences between OLSand IV-estimators

In **GRETL**: Whenever the TSLS estimation is used, GRETL produces automatically the Hausman test statistic

# Sargan Test

For testing whether the instruments are valid

The validity of the instruments  $z_i$  requires that all moment conditions are fulfilled; for the R-vector  $z_i$ , the R sums

$$\frac{1}{N}\sum_{i}e_{i}z_{i}=0$$

must be close to zero

Test statistic

$$\xi = NQ_N(\hat{\beta}_{IV}) = \left(\sum_i e_i z_i\right)' \left(\hat{\sigma}^2 \sum_i z_i z_i'\right)^{-1} \left(\sum_i e_i z_i\right)$$

has, under the null hypothesis, an asymptotic Chi-squared distribution with *R-K* df

Calculation of  $\xi$ :  $\xi = NR_e^2$  using  $R_e^2$  from the auxiliary regression of IV residuals  $e_i = y_i - x_i' \hat{\beta}_{IV}$  on the instruments  $z_i$ 

# Sargan Test: Remarks

#### Remarks

- In case of an identified model (R = K), all R moment conditions are fulfilled, ξ = 0
- Over-identified model: R > K; the Sargan test is also called overidentifying restrictions test
- Rejection implies: the joint validity of all moment conditions and hence of all instruments is not acceptable
- The Sargan test gives no indication of invalid instruments
- In **GRETL**: Whenever the TSLS estimation is used and R > K, GRETL produces automatically the Sargan test statistic

# Cragg-Donald Test

Weak (only marginally valid) instruments, i.e., only weak correlation between endogenous regressor and instrument:

- Biased IV estimates
- Inconsistent IV estimates
- Inappropriate large-sample approximations to the finite-sample distributions even for large N

Definition of weak instruments: estimates are biased to an extent that is unacceptably large

Null hypothesis: instruments are weak, i.e., can lead to an asymptotic relative bias greater than some value *b* 

# Cragg-Donald Test, cont'd

#### Test procedure

- Regression of the endogenous regressor on all instruments, both external, i.e., ones not included among the regressors, and internal
- F-test of the null hypothesis that the coefficients of all external instruments are zero
- If F-statistic is less a not too large value, e.g., 10: consider the instruments as weak

### Your Homework

- 1. Use the data set "icecream" of Verbeek for the following analyses:
  - a) Estimate the model where *cons* is explained by *price* and *temp*; show a diagramme of the residuals which may indicate autocorrelation of the error terms.
  - b) Use the Durbin-Watson and the Breusch-Godfrey test against autocorrelation; state suitably H<sub>0</sub> and H<sub>1</sub>.
  - c) Compare (i) the OLS and (ii) the HAC standard errors of the estimated coefficients.
  - d) Repeat a), using (i) the iterative Cochrane-Orcutt estimation and (ii) OLS estimation of the model in differences; compare and interpret the results.
- 2. For the Durbin-Watson test: (a) show that  $dw \approx 2 2r$ ; (b) can you agree with the statement "The Durbin-Watson test is a misspecification test".

# Your Homework, cont'd

 Use the data set "schooling" of Verbeek for the following analyses based on the wage equation

$$\log(wage76) = \beta_1 + \beta_2 \ ed76 + \beta_3 \ exp76 + \beta_4 \ exp762$$
$$+ \beta_5 \ black + \beta_6 \ momed + \beta_7 \ smsa76 + \epsilon$$

- a) Assuming that *ed76* is endogenous, (i) estimate the reduced form for *ed76*, including external instruments *south66*, and *mar76*; (ii) assess the validity of the potential instruments; what indicate the correlation coefficients?
- b) Estimate, by means of the GRETL Instrumental variables (Two-Stage Least Squares ...) procedure, the wage equation, using the external instruments *black*, *momed*, *sinmom14*, *smsa66*, *south76*, *mar76*, and *age76*. Interpret the results including the Hausman and the Sargan test.
- c) Compare the estimates for  $\beta_2$  (i) from the model in b), (ii) from the model with instruments *black*, *momed*, *smsa66*, *south76*, *mar76*, and *age76*, and (iii) with the OLS estimates.

# Your Homework, cont'd

4. The model for consumption and income consists of two equations:

$$C_{t} = \beta_{1} + \beta_{2}Y_{t} + \varepsilon_{t}$$

$$Y_{t} = C_{t} + I_{t}$$

a. Show that both  $C_t$  and  $Y_t$  are endogenous:

$$E\{C_i \varepsilon_i\} = E\{Y_i \varepsilon_i\} = \sigma_{\varepsilon}^2 (1 - \beta_2)^{-1}$$

b. Derive the reduced form of the model
