Chapter 26

Monopoly Behavior

How Should a Monopoly Price?

- ◆ **So far a monopoly has been thought of as a firm which has to sell its product at the same price to every customer. This is uniform pricing.**
- ◆ **Can price-discrimination earn a monopoly higher profits?**

Types of Price Discrimination

- ◆ **1st-degree: Each output unit is sold at a different price. Prices may differ across buyers.**
- ◆ **2nd-degree: The price paid by a buyer can vary with the quantity demanded by the buyer. But all customers face the same price schedule. *E.g.*, bulk-buying discounts.**

Types of Price Discrimination

- ◆ **3rd-degree: Price paid by buyers in a given group is the same for all units purchased. But price may differ across buyer groups.
*E.g., senior citizen and student discounts vs. no discounts for middle-aged persons.***

First-degree Price Discrimination

- ◆ **Each output unit is sold at a different price. Price may differ across buyers.**
- ◆ **It requires that the monopolist can discover the buyer with the highest valuation of its product, the buyer with the next highest valuation, and so on.**

First-degree Price Discrimination

\$/output unit

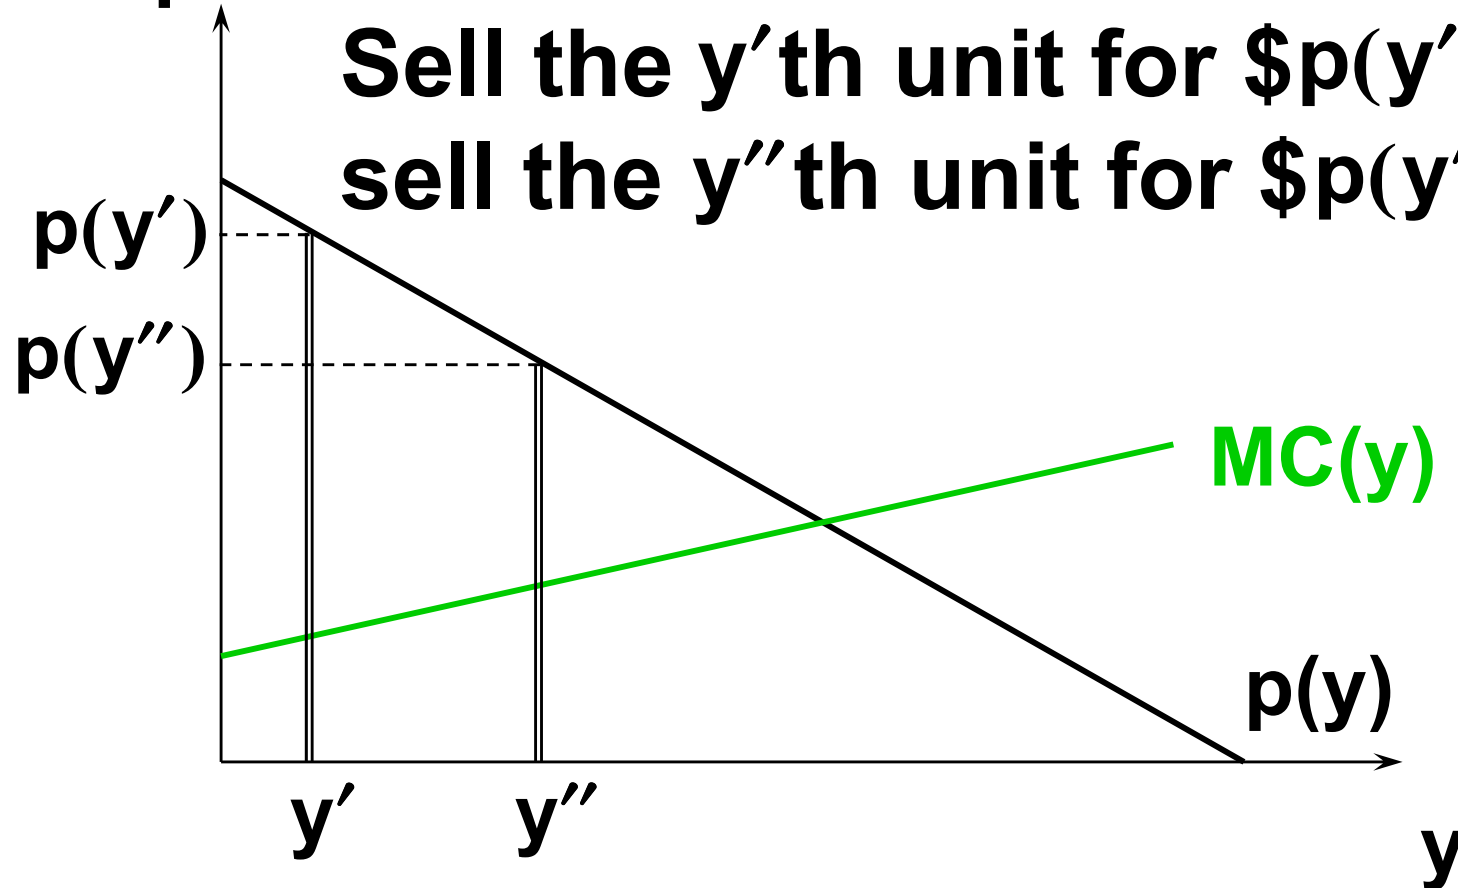

Sell the y' th unit for $\$p(y')$.

First-degree Price Discrimination

\$/output unit

**Sell the y' th unit for $\$p(y')$. Later on
sell the y'' th unit for $\$p(y'')$.**

First-degree Price Discrimination

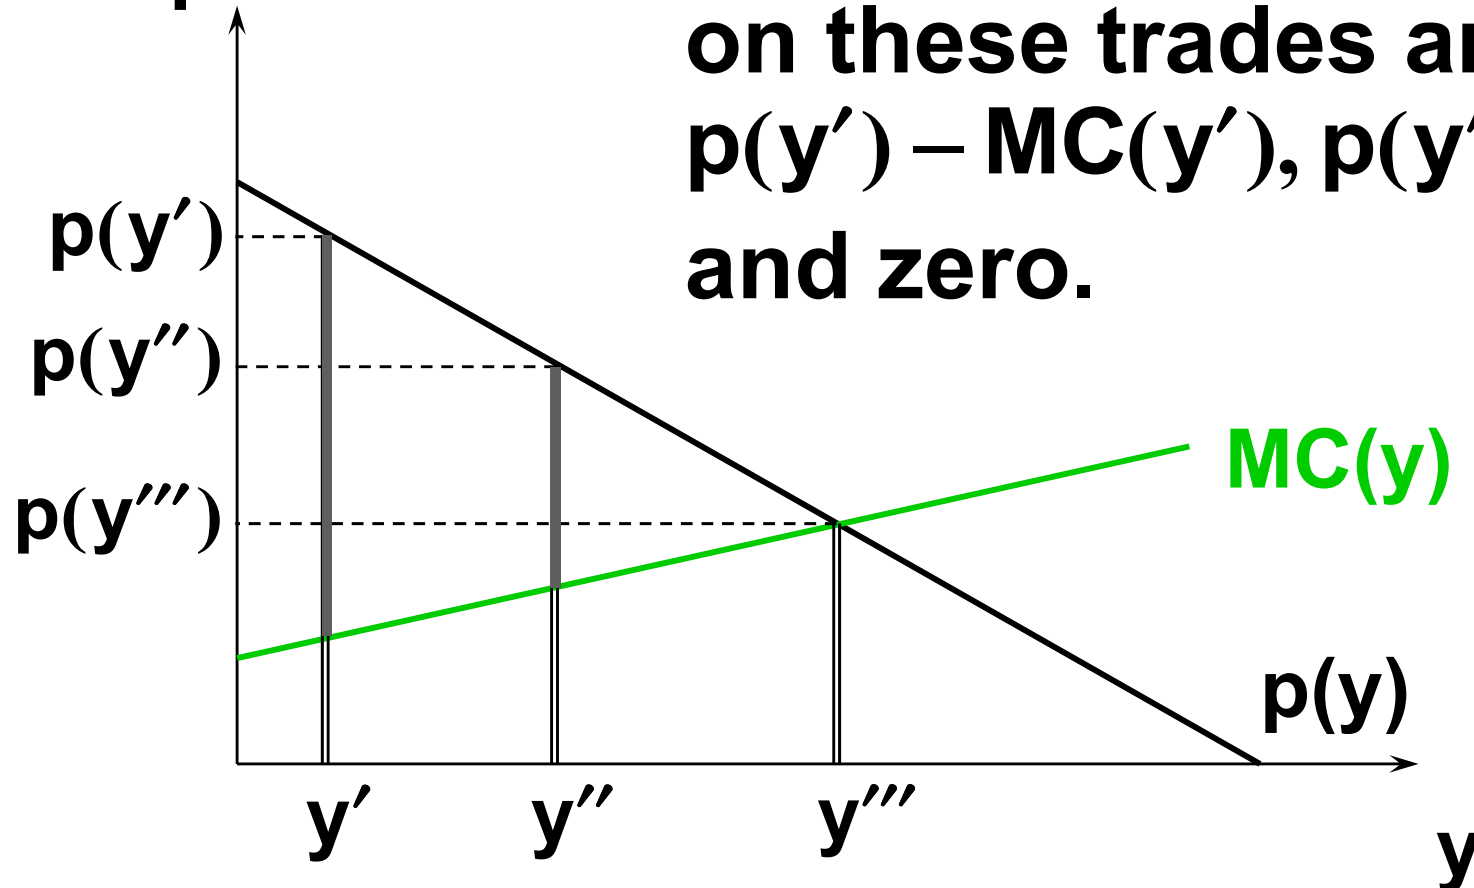

\$/output unit

Sell the y' th unit for $\$p(y')$. Later on sell the y'' th unit for $\$p(y'')$. Finally sell the y''' th unit for marginal cost, $\$p(y''')$.

First-degree Price Discrimination

\$/output unit

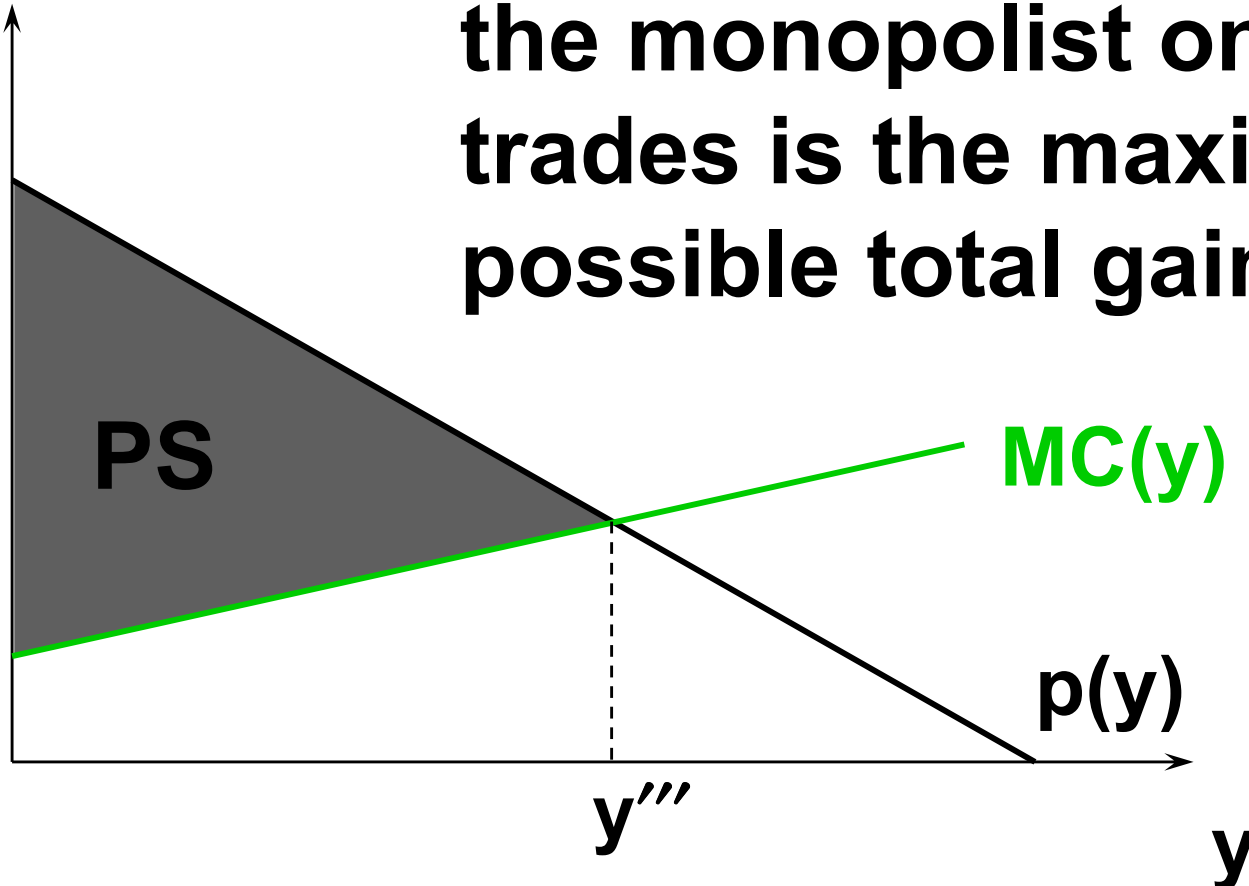

The gains to the monopolist on these trades are:
 $p(y') - MC(y')$, $p(y'') - MC(y'')$
and zero.

The consumers' gains are zero.

First-degree Price Discrimination

So the sum of the gains to the monopolist on all trades is the maximum possible total gains-to-trade.

\$/output unit

First-degree Price Discrimination

The monopolist gets the maximum possible gains from trade.

\$/output unit

First-degree price discrimination is Pareto-efficient.

First-degree Price Discrimination

- ◆ **First-degree price discrimination gives a monopolist all of the possible gains-to-trade, leaves the buyers with zero surplus, and supplies the efficient amount of output.**

Third-degree Price Discrimination

- ◆ **Price paid by buyers in a given group is the same for all units purchased. But price may differ across buyer groups.**

Third-degree Price Discrimination

- ◆ **A monopolist manipulates market price by altering the quantity of product supplied to that market.**
- ◆ **So the question “What discriminatory prices will the monopolist set, one for each group?” is really the question “How many units of product will the monopolist supply to each group?”**

Third-degree Price Discrimination

- ◆ **Two markets, 1 and 2.**
- ◆ **y_1 is the quantity supplied to market 1.
Market 1's inverse demand function is $p_1(y_1)$.**
- ◆ **y_2 is the quantity supplied to market 2.
Market 2's inverse demand function is $p_2(y_2)$.**

Third-degree Price Discrimination

- ◆ For given supply levels y_1 and y_2 the firm's profit is

$$\Pi(y_1, y_2) = p_1(y_1)y_1 + p_2(y_2)y_2 - c(y_1 + y_2).$$

- ◆ What values of y_1 and y_2 maximize profit?

Third-degree Price

Discrimination

$$\Pi(y_1, y_2) = p_1(y_1)y_1 + p_2(y_2)y_2 - c(y_1 + y_2).$$

The profit-maximization conditions are

$$\begin{aligned} \frac{\partial \Pi}{\partial y_1} &= \frac{\partial}{\partial y_1} (p_1(y_1)y_1) - \frac{\partial c(y_1 + y_2)}{\partial (y_1 + y_2)} \times \frac{\partial (y_1 + y_2)}{\partial y_1} \\ &= 0 \end{aligned}$$

Third-degree Price

Discrimination

$$\Pi(y_1, y_2) = p_1(y_1)y_1 + p_2(y_2)y_2 - c(y_1 + y_2).$$

The profit-maximization conditions are

$$\begin{aligned} \frac{\partial \Pi}{\partial y_1} &= \frac{\partial}{\partial y_1} (p_1(y_1)y_1) - \frac{\partial c(y_1 + y_2)}{\partial (y_1 + y_2)} \times \frac{\partial (y_1 + y_2)}{\partial y_1} \\ &= 0 \end{aligned}$$

$$\begin{aligned} \frac{\partial \Pi}{\partial y_2} &= \frac{\partial}{\partial y_2} (p_2(y_2)y_2) - \frac{\partial c(y_1 + y_2)}{\partial (y_1 + y_2)} \times \frac{\partial (y_1 + y_2)}{\partial y_2} \\ &= 0 \end{aligned}$$

Third-degree Price

$$\frac{\partial (y_1 + y_2)}{\partial y_1} = 1 \quad \text{and} \quad \frac{\partial (y_1 + y_2)}{\partial y_2} = 1 \quad \text{so}$$

the profit-maximization conditions are

$$\frac{\partial}{\partial y_1} (p_1(y_1)y_1) = \frac{\partial c(y_1 + y_2)}{\partial (y_1 + y_2)}$$

$$\text{and} \quad \frac{\partial}{\partial y_2} (p_2(y_2)y_2) = \frac{\partial c(y_1 + y_2)}{\partial (y_1 + y_2)}.$$

Third-degree Price

$$\frac{\partial}{\partial \mathbf{y}_1} (\mathbf{p}_1(\mathbf{y}_1)\mathbf{y}_1) = \frac{\partial}{\partial \mathbf{y}_2} (\mathbf{p}_2(\mathbf{y}_2)\mathbf{y}_2) = \frac{\partial \mathbf{c}(\mathbf{y}_1 + \mathbf{y}_2)}{\partial (\mathbf{y}_1 + \mathbf{y}_2)}$$

Third-degree Price

$$\underbrace{\frac{\partial}{\partial y_1} (\mathbf{p}_1(\mathbf{y}_1)\mathbf{y}_1) = \frac{\partial}{\partial y_2} (\mathbf{p}_2(\mathbf{y}_2)\mathbf{y}_2) = \frac{\partial \mathbf{c}(\mathbf{y}_1 + \mathbf{y}_2)}{\partial (\mathbf{y}_1 + \mathbf{y}_2)}}_{\text{Discrimination}}$$

$\text{MR}_1(\mathbf{y}_1) = \text{MR}_2(\mathbf{y}_2)$ says that the allocation $\mathbf{y}_1, \mathbf{y}_2$ maximizes the revenue from selling $\mathbf{y}_1 + \mathbf{y}_2$ output units.

***E.g.*, if $\text{MR}_1(\mathbf{y}_1) > \text{MR}_2(\mathbf{y}_2)$ then an output unit should be moved from market 2 to market 1 to increase total revenue.**

Third-degree Price

$$\frac{\partial}{\partial y_1} (\mathbf{p}_1(\mathbf{y}_1)\mathbf{y}_1) = \frac{\partial}{\partial y_2} (\mathbf{p}_2(\mathbf{y}_2)\mathbf{y}_2) = \frac{\partial \mathbf{c}(\mathbf{y}_1 + \mathbf{y}_2)}{\partial (\mathbf{y}_1 + \mathbf{y}_2)}$$

Disgrimination

The marginal revenue common to both markets equals the marginal production cost if profit is to be maximized.

Third-degree Price Discrimination

$$MR_1(y_1^*) = MR_2(y_2^*) = MC$$

Third-degree Price

Discrimination

$$MR_1(y_1^*) = MR_2(y_2^*) = MC \text{ and } p_1(y_1^*) \neq p_2(y_2^*).$$

Third-degree Price Discrimination

- ◆ **In which market will the monopolist cause the higher price?**

Third-degree Price Discrimination

◆ In which market will the monopolist cause the higher price?

◆ Recall that

$$\mathbf{MR}_1(\mathbf{y}_1) = \mathbf{p}_1(\mathbf{y}_1) \left[1 + \frac{1}{\varepsilon_1} \right]$$

and

$$\mathbf{MR}_2(\mathbf{y}_2) = \mathbf{p}_2(\mathbf{y}_2) \left[1 + \frac{1}{\varepsilon_2} \right].$$

Third-degree Price Discrimination

◆ In which market will the monopolist cause the higher price?

◆ Recall that $MR_1(y_1) = p_1(y_1) \left[1 + \frac{1}{\varepsilon_1} \right]$

and

$$MR_2(y_2) = p_2(y_2) \left[1 + \frac{1}{\varepsilon_2} \right].$$

◆ But, $MR_1(y_1^*) = MR_2(y_2^*) = MC(y_1^* + y_2^*)$

Third-degree Price

So
$$p_1(y_1^*) \left[1 + \frac{1}{\varepsilon_1} \right] = p_2(y_2) \left[1 + \frac{1}{\varepsilon_2} \right].$$

Third-degree Price Discrimination

So $p_1(y_1^*) \left[1 + \frac{1}{\varepsilon_1} \right] = p_2(y_2^*) \left[1 + \frac{1}{\varepsilon_2} \right].$

Therefore, $p_1(y_1^*) > p_2(y_2^*)$ if and only if

$$1 + \frac{1}{\varepsilon_1} < 1 + \frac{1}{\varepsilon_2}$$

Third-degree Price Discrimination

So $p_1(y_1^*) \left[1 + \frac{1}{\varepsilon_1} \right] = p_2(y_2^*) \left[1 + \frac{1}{\varepsilon_2} \right].$

Therefore, $p_1(y_1^*) > p_2(y_2^*)$ if and only if

$$1 + \frac{1}{\varepsilon_1} < 1 + \frac{1}{\varepsilon_2} \quad \Rightarrow \quad \varepsilon_1 > \varepsilon_2.$$

Third-degree Price Discrimination

So $p_1(y_1^*) \left[1 + \frac{1}{\varepsilon_1} \right] = p_2(y_2^*) \left[1 + \frac{1}{\varepsilon_2} \right]$.

Therefore, $p_1(y_1^*) > p_2(y_2^*)$ if and only if

$$1 + \frac{1}{\varepsilon_1} < 1 + \frac{1}{\varepsilon_2} \Rightarrow \varepsilon_1 > \varepsilon_2.$$

The monopolist sets the higher price in the market where demand is least own-price elastic.

Two-Part Tariffs

- ◆ **A two-part tariff is a lump-sum fee, p_1 , plus a price p_2 for each unit of product purchased.**
- ◆ **Thus the cost of buying x units of product is**

$$p_1 + p_2x.$$

Two-Part Tariffs

- ◆ **Should a monopolist prefer a two-part tariff to uniform pricing, or to any of the price-discrimination schemes discussed so far?**
- ◆ **If so, how should the monopolist design its two-part tariff?**

Two-Part Tariffs

- ◆ $p_1 + p_2x$
- ◆ Q: What is the largest that p_1 can be?

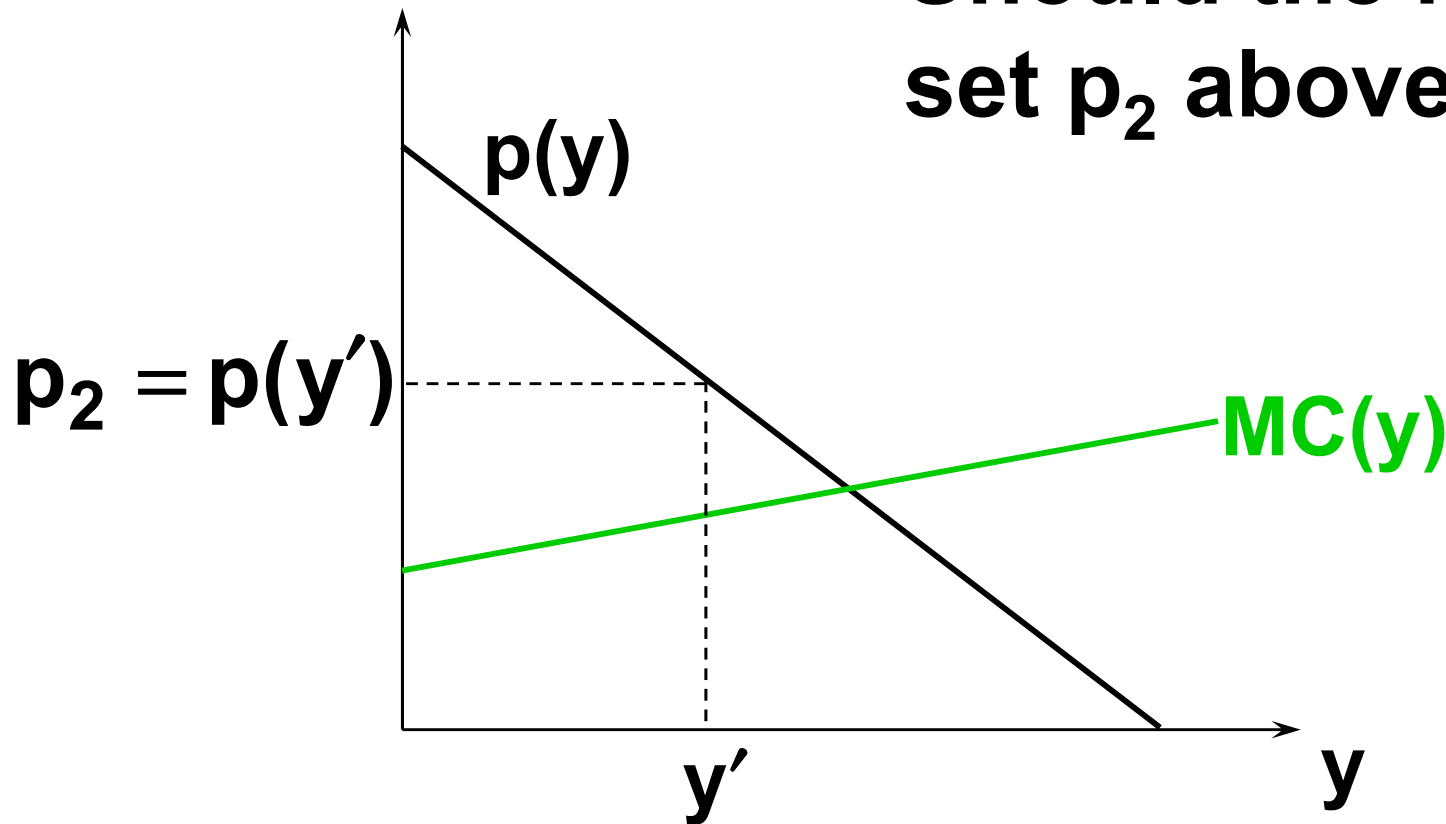

Two-Part Tariffs

- ◆ $p_1 + p_2x$
- ◆ **Q: What is the largest that p_1 can be?**
- ◆ **A: p_1 is the “market entrance fee” so the largest it can be is the surplus the buyer gains from entering the market.**
- ◆ **Set $p_1 = CS$ and now ask what should be p_2 ?**

Two-Part Tariffs

\$/output unit

Should the monopolist set p_2 above MC?

Two-Part Tariffs

**Should the monopolist
set p_2 above MC?
 $p_1 = CS$.**

Two-Part Tariffs

**Should the monopolist
set p_2 above MC?**

$p_1 = CS.$

PS is profit from sales.

Two-Part Tariffs

Should the monopolist set p_2 above MC?

$p_1 = CS.$

PS is profit from sales.

Two-Part Tariffs

\$/output unit

**Should the monopolist
set $p_2 = MC$?**

Two-Part Tariffs

\$/output unit

Should the monopolist
set $p_2 = MC$?
 $p_1 = CS$.

Two-Part Tariffs

\$/output unit

Should the monopolist
set $p_2 = MC$?
 $p_1 = CS$.
PS is profit from sales.

Two-Part Tariffs

Should the monopolist
set $p_2 = MC$?
 $p_1 = CS$.
PS is profit from sales.

Two-Part Tariffs

Should the monopolist
set $p_2 = MC$?
 $p_1 = CS$.
PS is profit from sales.

Two-Part Tariffs

\$/output unit

Should the monopolist
set $p_2 = MC$?
 $p_1 = CS$.
PS is profit from sales.

Additional profit from setting $p_2 = MC$.

Two-Part Tariffs

- ◆ **The monopolist maximizes its profit when using a two-part tariff by setting its per unit price p_2 at marginal cost and setting its lump-sum fee p_1 equal to Consumers' Surplus.**

Two-Part Tariffs

- ◆ **A profit-maximizing two-part tariff gives an efficient market outcome in which the monopolist obtains as profit the total of all gains-to-trade.**

Differentiating Products

- ◆ **In many markets the commodities traded are very close, but not perfect, substitutes.**
- ◆ ***E.g.*, the markets for T-shirts, watches, cars, and cookies.**
- ◆ **Each individual supplier thus has some slight “monopoly power.”**
- ◆ **What does an equilibrium look like for such a market?**

Differentiating Products

- ◆ **Free entry \Rightarrow zero profits for each seller.**

Differentiating Products

- ◆ **Free entry \Rightarrow zero profits for each seller.**
- ◆ **Profit-maximization \Rightarrow $MR = MC$ for each seller.**

Differentiating Products

- ◆ **Free entry \Rightarrow zero profits for each seller.**
- ◆ **Profit-maximization \Rightarrow $MR = MC$ for each seller.**
- ◆ **Less than perfect substitution between commodities \Rightarrow slight downward slope for the demand curve for each commodity.**

Differentiating Products

Price

Slight downward slope

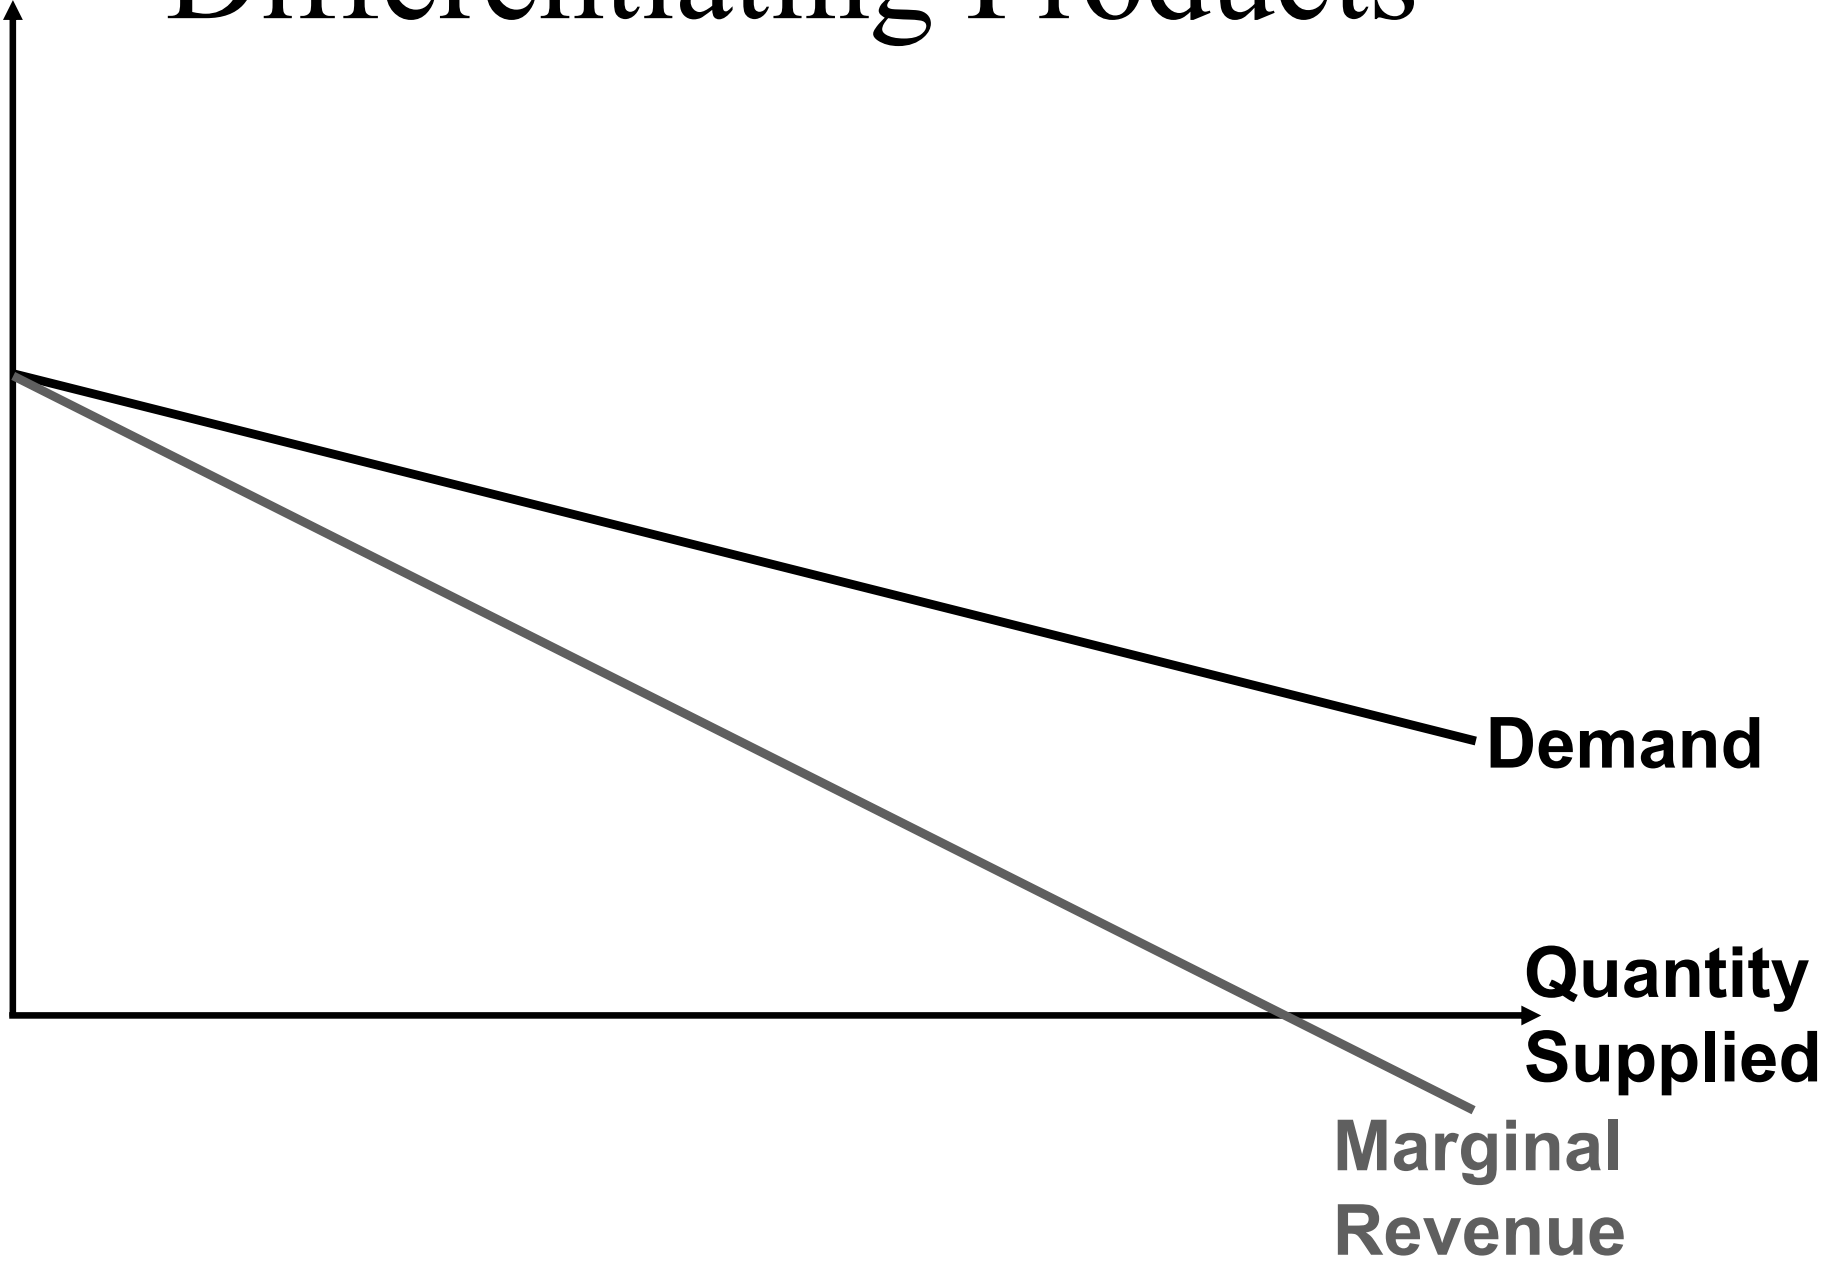

Demand

**Quantity
Supplied**

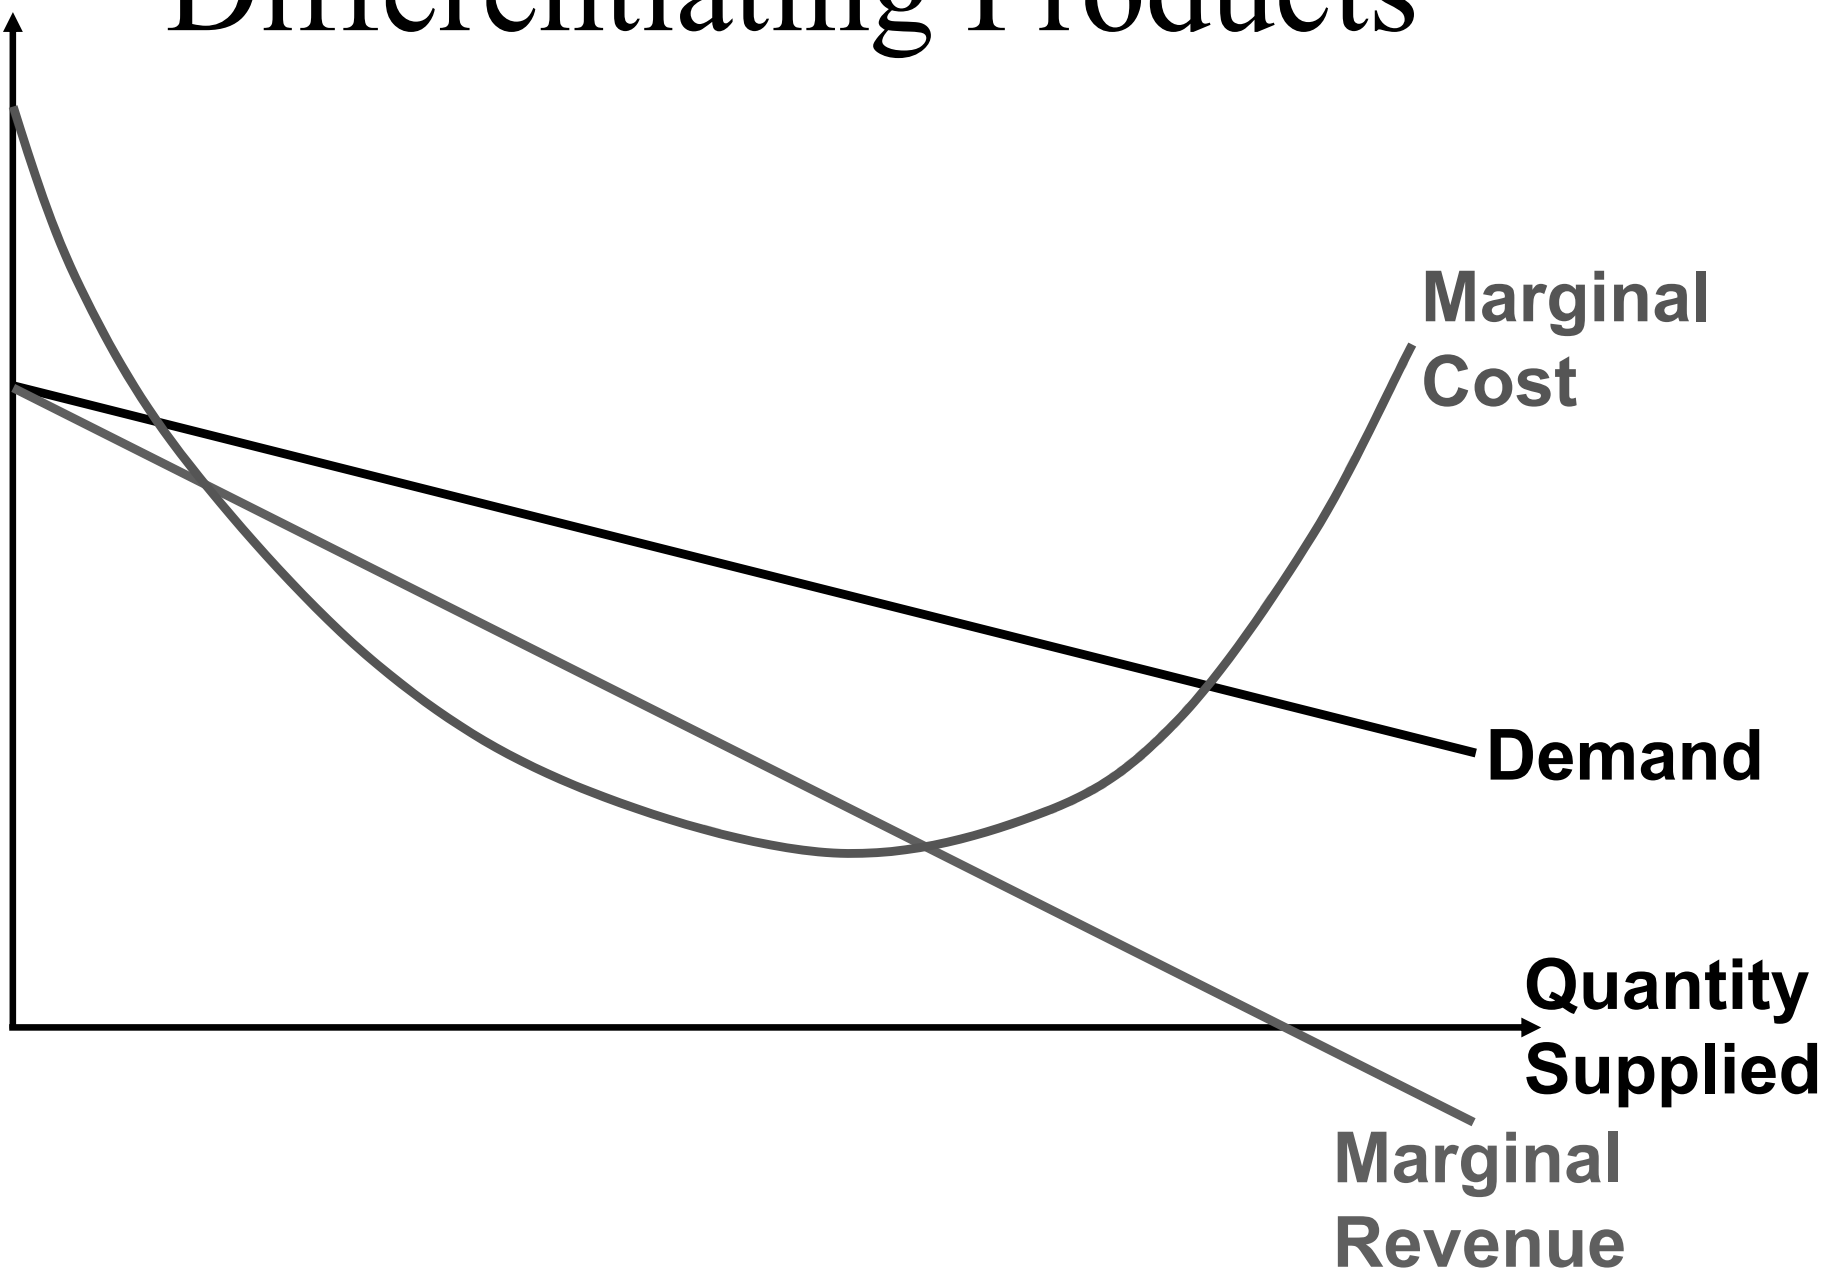

Differentiating Products

Price

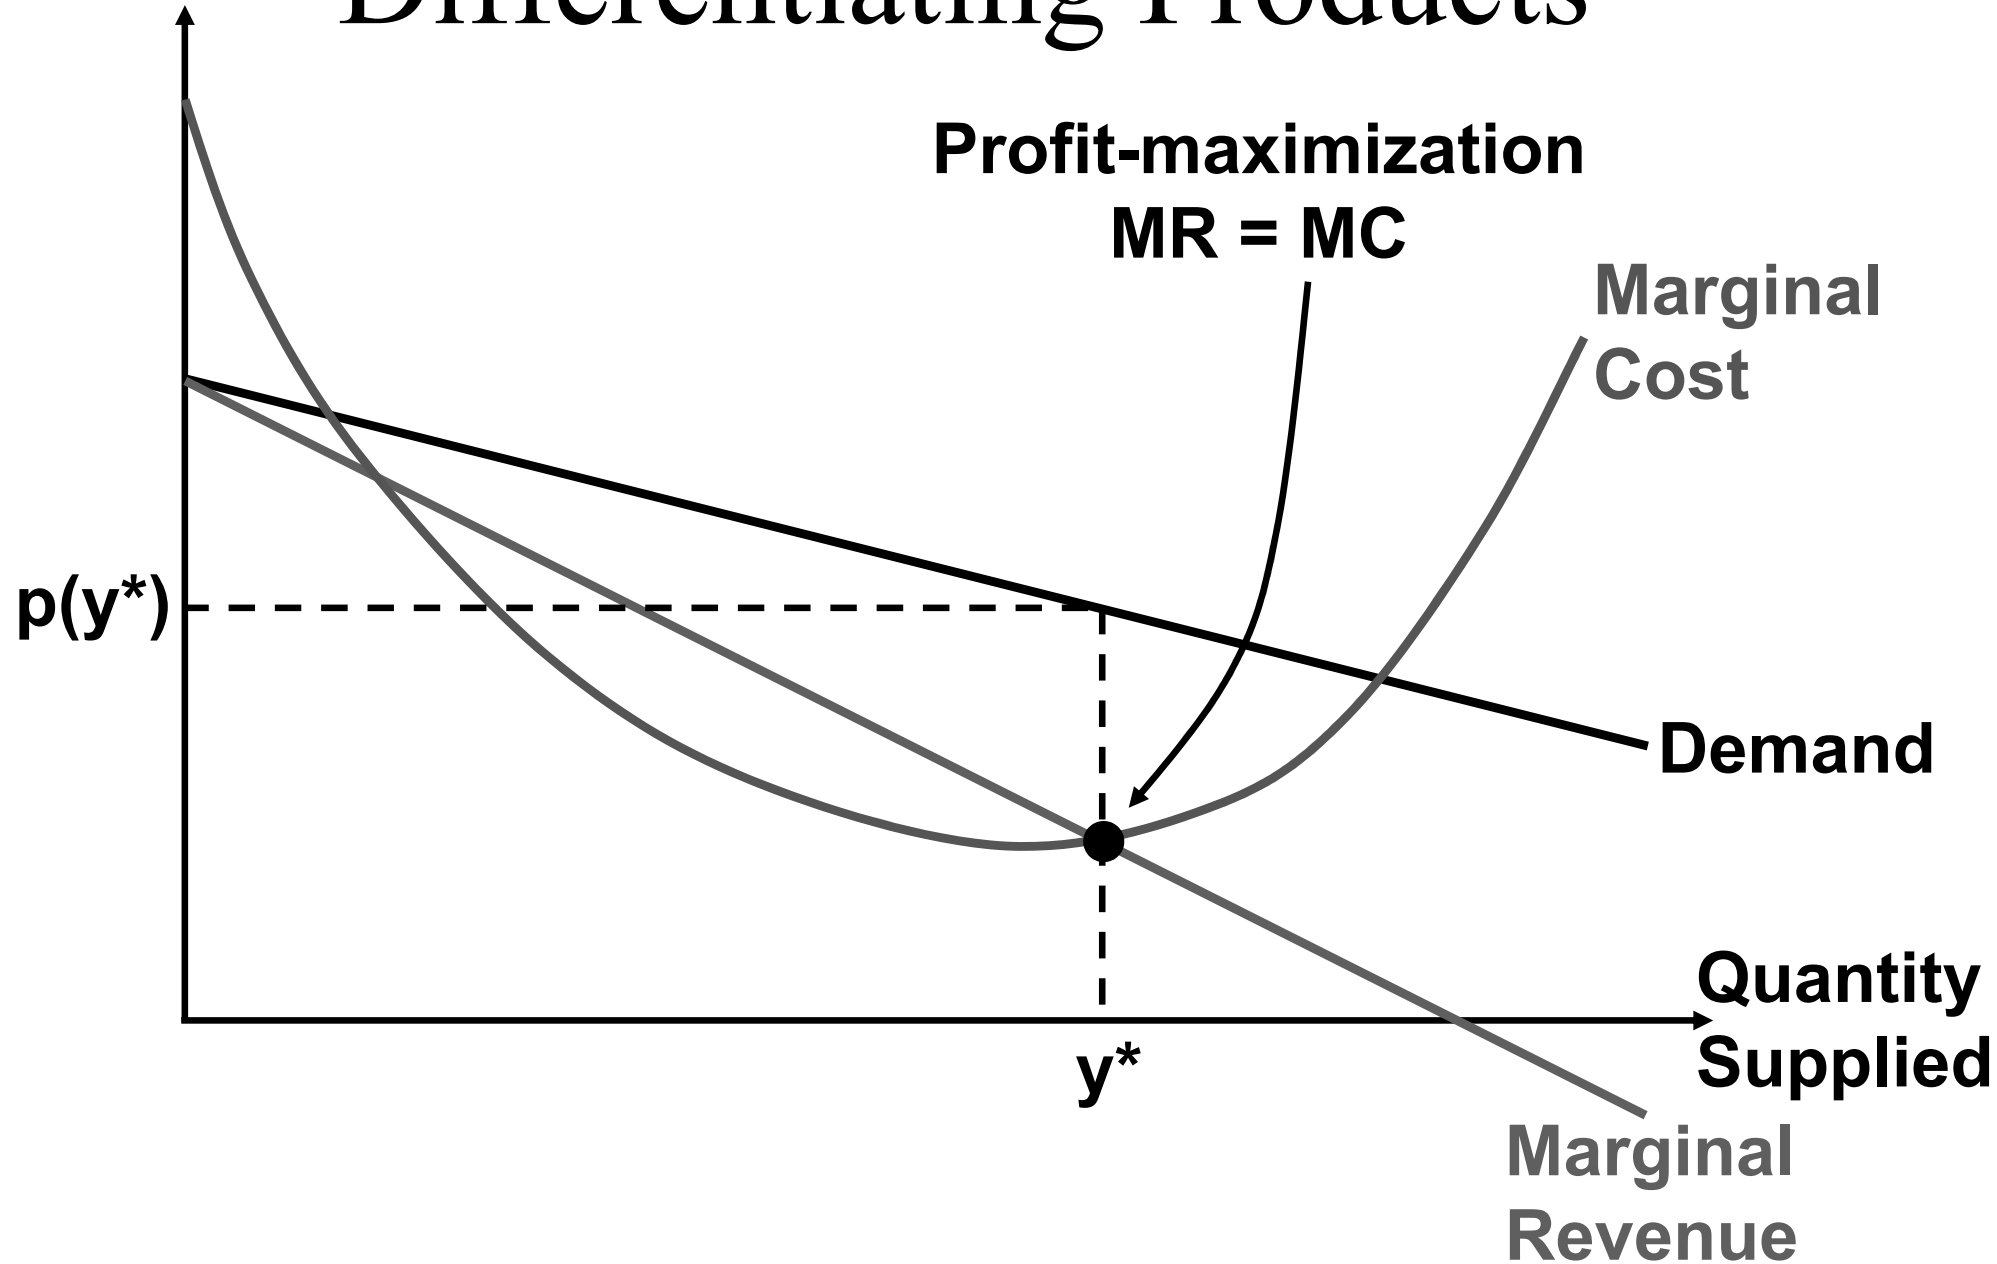

Differentiating Products

Price

Differentiating Products

Differentiating Products

Zero profit

Price = Av. Cost

Profit-maximization

MR = MC

Differentiating Products

- ◆ **Such markets are monopolistically competitive.**
- ◆ **Are these markets efficient?**
- ◆ **No, because for each commodity the equilibrium price $p(y^*) > MC(y^*)$.**

Differentiating Products

Differentiating Products

Differentiating Products

- ◆ **Each seller supplies less than the efficient quantity of its product.**
- ◆ **Also, each seller supplies less than the quantity that minimizes its average cost and so, in this sense, each supplier has “excess capacity.”**

Differentiating Products

Differentiating Products by Location

- ◆ **Think a region in which consumers are uniformly located along a line.**
- ◆ **Each consumer prefers to travel a shorter distance to a seller.**
- ◆ **There are $n \geq 1$ sellers.**
- ◆ **Where would we expect these sellers to choose their locations?**

Differentiating Products by Location

- ◆ If $n = 1$ (monopoly) then the seller maximizes its profit at $x = ??$

Differentiating Products by Location

- ◆ If $n = 1$ (monopoly) then the seller maximizes its profit at $x = \frac{1}{2}$ and minimizes the consumers' travel cost.

Differentiating Products by Location

- ◆ If $n = 2$ (duopoly) then the equilibrium locations of the sellers, A and B, are $x_A = ??$ and $x_B = ??$

Differentiating Products by Location

- ◆ If $n = 2$ (duopoly) then the equilibrium locations of the sellers, A and B, are $x_A = ??$ and $x_B = ??$
- ◆ How about $x_A = 0$ and $x_B = 1$; *i.e.* the sellers separate themselves as much as is possible?

Differentiating Products by Location

- ◆ If $x_A = 0$ and $x_B = 1$ then A sells to all consumers in $[0, \frac{1}{2})$ and B sells to all consumers in $(\frac{1}{2}, 1]$.
- ◆ Given B's location at $x_B = 1$, can A increase its profit?

Differentiating Products by

Location

- ◆ If $x_A = 0$ and $x_B = 1$ then A sells to all consumers in $[0, 1/2)$ and B sells to all consumers in $(1/2, 1]$.
- ◆ Given B's location at $x_B = 1$, can A increase its profit? What if A moves to x' ?

Differentiating Products by

- ◆ If $x_A = 0$ and $x_B = 1$ then A sells to all consumers in $[0, 1/2)$ and B sells to all consumers in $(1/2, 1]$.
- ◆ Given B's location at $x_B = 1$, can A increase its profit? What if A moves to x' ? Then A sells to all customers in $[0, 1/2 + 1/2 x')$ and increases its profit.

Differentiating Products by Location

- ◆ Given $x_A = x'$, can B improve its profit by moving from $x_B = 1$?

Differentiating Products by

- ◆ Given $x_A = x'$, can B improve its profit by moving from $x_B = 1$? What if B moves to $x_B = x''$?

Differentiating Products by

- ◆ Given $x_A = x'$, can B improve its profit by moving from $x_B = 1$? What if B moves to $x_B = x''$? Then B sells to all customers in $(\frac{x'+x''}{2}, 1]$ and increases its profit.
- ◆ So what is the NE?

Differentiating Products by Location

- ◆ Given $x_A = x'$, can B improve its profit by moving from $x_B = 1$? What if B moves to $x_B = x''$? Then B sells to all customers in $((x' + x'')/2, 1]$ and increases its profit.
- ◆ So what is the NE? $x_A = x_B = 1/2$.

Differentiating Products by Location

- ◆ The only NE is $x_A = x_B = \frac{1}{2}$.
- ◆ Is the NE efficient?

Differentiating Products by Location

- ◆ The only NE is $x_A = x_B = \frac{1}{2}$.
- ◆ Is the NE efficient? No.
- ◆ What is the efficient location of A and B?

Differentiating Products by

- ◆ The only NE is $x_A = x_B = 1/2$.
- ◆ Is the NE efficient? No.
- ◆ What is the efficient location of A and B? $x_A = 1/4$ and $x_B = 3/4$ since this minimizes the consumers' travel costs.

Differentiating Products by Location

◆ What if $n = 3$; sellers A, B and C?

Differentiating Products by Location

- ◆ What if $n = 3$; sellers A, B and C?
- ◆ Then there is no NE at all! Why?

Differentiating Products by Location

- ◆ **What if $n = 3$; sellers A, B and C?**
- ◆ **Then there is no NE at all! Why?**
- ◆ **The possibilities are:**
 - (i) **All 3 sellers locate at the same point.**
 - (ii) **2 sellers locate at the same point.**
 - (iii) **Every seller locates at a different point.**

Differentiating Products by

- ◆ (iii) Every seller locates at a different point.
- ◆ Cannot be a NE since, as for $n = 2$, the two outside sellers get higher profits by moving closer to the middle seller.

Differentiating Products by

Location^{1/3}

- ◆ (i) All 3 sellers locate at the same point.
- ◆ Cannot be an NE since it pays one of the sellers to move just a little bit left or right of the other two to get all of the market on that side, instead of having to share those customers.

Differentiating Products by

- ◆ (i) All 3 sellers locate at the same point.
- ◆ Cannot be an NE since it pays one of the sellers to move just a little bit left or right of the other two to get all of the market on that side, instead of having to share those customers.

Differentiating Products by

Location^{1/2}

- ◆ 2 sellers locate at the same point.
- ◆ Cannot be an NE since it pays one of the two sellers to move just a little away from the other.

Differentiating Products by

Location

A gets almost $1/2$ of the market

- ◆ 2 sellers locate at the same point.
- ◆ Cannot be an NE since it pays one of the two sellers to move just a little away from the other.

Differentiating Products by

Location

A gets almost $1/2$ of the market

- ◆ 2 sellers locate at the same point.
- ◆ Cannot be an NE since it pays one of the two sellers to move just a little away from the other.

Differentiating Products by Location

- ◆ If $n = 3$ the possibilities are:
 - (i) ~~All 3 sellers locate at the same point.~~
 - (ii) ~~2 sellers locate at the same point.~~
 - (iii) ~~Every seller locates at a different point.~~
- ◆ There is no NE for $n = 3$.

Differentiating Products by Location

- ◆ If $n = 3$ the possibilities are:
 - (i) ~~All 3 sellers locate at the same point.~~
 - (ii) ~~2 sellers locate at the same point.~~
 - (iii) ~~Every seller locates at a different point.~~
- ◆ There is no NE for $n = 3$.
- ◆ However, this is a NE for every $n \geq 4$.
