Masaryk University

April 9, 2009

- Create a service which provides one method: string GetTranslation(string)
- The service will be hosted in a console
- After startup, pairs of strings are read from a file and stored in the memory
- When GetTranslation is called, the parameter is looked up and the second string from the pair is returned

- Implement a console client

If You Want Something a Bit Harder

- Add a `SaveTranslation(string, string)` method.
- Change the application logic so that one word may have several translations.
- (For the above, you will need to employ synchronization techniques from the last lecture.)
