
Naïve Bayes Learning

Based on Raymond J. Mooney's slides

University of Texas at Austin

Axioms of Probability Theory

- All probabilities between 0 and 1

$$0 \leq P(A) \leq 1$$

- True proposition has probability 1, false has probability 0.

$$P(\text{true}) = 1 \quad P(\text{false}) = 0.$$

- The probability of disjunction is:

$$P(A \vee B) = P(A) + P(B) - P(A \wedge B)$$

Conditional Probability

- $P(A | B)$ is the probability of A given B
- Assumes that B is all and only information known.
- Defined by:

$$P(A | B) = \frac{P(A \wedge B)}{P(B)}$$

Independence

- A and B are *independent* iff:

$$P(A | B) = P(A)$$

These two constraints are logically equivalent

$$P(B | A) = P(B)$$

- Therefore, if A and B are independent:

$$P(A | B) = \frac{P(A \wedge B)}{P(B)} = P(A)$$

$$P(A \wedge B) = P(A)P(B)$$

Joint Distribution

- The joint probability distribution for a set of random variables, X_1, \dots, X_n gives the probability of every combination of values (an n -dimensional array with v^n values if all variables are discrete with v values, all v^n values must sum to 1): $P(X_1, \dots, X_n)$

positive

| | circle | square |
|------|--------|--------|
| red | 0.20 | 0.02 |
| blue | 0.02 | 0.01 |

negative

| | circle | square |
|------|--------|--------|
| red | 0.05 | 0.30 |
| blue | 0.20 | 0.20 |

- The probability of all possible conjunctions (assignments of values to some subset of variables) can be calculated by summing the appropriate subset of values from the joint distribution.

$$P(\text{red} \wedge \text{circle}) = 0.20 + 0.05 = 0.25$$

$$P(\text{red}) = 0.20 + 0.02 + 0.05 + 0.3 = 0.57$$

- Therefore, all conditional probabilities can also be calculated.

$$P(\text{positive} \mid \text{red} \wedge \text{circle}) = \frac{P(\text{positive} \wedge \text{red} \wedge \text{circle})}{P(\text{red} \wedge \text{circle})} = \frac{0.20}{0.25} = 0.80$$

Probabilistic Classification

- Let Y be the random variable for the class which takes values $\{y_1, y_2, \dots, y_m\}$.
- Let X be the random variable describing an instance consisting of a vector of values for n features $\langle X_1, X_2, \dots, X_n \rangle$, let x_k be a possible value for X and x_{ij} a possible value for X_i .
- For classification, we need to compute $P(Y=y_i | X=x_k)$ for $i=1 \dots m$
- However, given no other assumptions, this requires a table giving the probability of each category for each possible instance in the instance space, which is impossible to accurately estimate from a reasonably-sized training set.
 - Assuming Y and all X_i are binary, we need 2^n entries to specify $P(Y=\text{pos} | X=x_k)$ for each of the 2^n possible x_k 's since $P(Y=\text{neg} | X=x_k) = 1 - P(Y=\text{pos} | X=x_k)$
 - Compared to $2^{n+1} - 1$ entries for the joint distribution $P(Y, X_1, X_2, \dots, X_n)$

Bayes Theorem

$$P(H | E) = \frac{P(E | H)P(H)}{P(E)}$$

Simple proof from definition of conditional probability:

$$P(H | E) = \frac{P(H \wedge E)}{P(E)} \quad (\text{Def. cond. prob.})$$

$$P(E | H) = \frac{P(H \wedge E)}{P(H)} \quad (\text{Def. cond. prob.})$$

$$P(H \wedge E) = P(E | H)P(H)$$

$$\text{QED: } P(H | E) = \frac{P(E | H)P(H)}{P(E)}$$

Bayesian Categorization

- Determine category of x_k by determining for each y_i

$$P(Y = y_i | X = x_k) = \frac{P(Y = y_i)P(X = x_k | Y = y_i)}{P(X = x_k)}$$

- $P(X=x_k)$ can be determined since categories are complete and disjoint.

$$\sum_{i=1}^m P(Y = y_i | X = x_k) = \sum_{i=1}^m \frac{P(Y = y_i)P(X = x_k | Y = y_i)}{P(X = x_k)} = 1$$

$$P(X = x_k) = \sum_{i=1}^m P(Y = y_i)P(X = x_k | Y = y_i)$$

Bayesian Categorization (cont.)

- Need to know:
 - Priors: $P(Y=y_i)$
 - Conditionals: $P(X=x_k | Y=y_i)$
- $P(Y=y_i)$ are easily estimated from data.
 - If n_i of the examples in D are in y_i then $P(Y=y_i) = n_i / |D|$
- Too many possible instances (e.g. 2^n for binary features) to estimate all $P(X=x_k | Y=y_i)$.
- Still need to make some sort of independence assumptions about the features to make learning tractable.

Generative Probabilistic Models

- Assume a simple (usually unrealistic) probabilistic method by which the data was generated.
- For categorization, each category has a different parameterized generative model that characterizes that category.
- **Training:** Use the data for each category to estimate the parameters of the generative model for that category.
 - **Maximum Likelihood Estimation (MLE):** Set parameters to maximize the probability that the model produced the given training data.
 - If M_λ denotes a model with parameter values λ and D_k is the training data for the k th class, find model parameters for class k (λ_k) that maximize the likelihood of D_k :

$$\lambda_k = \operatorname{argmax}_\lambda P(D_k | M_\lambda)$$

- **Testing:** Use Bayesian analysis to determine the category model that most likely generated a specific test instance.

Naïve Bayes Inference Problem

Naïve Bayesian Categorization

- If we assume features of an instance are independent **given the category** (*conditionally independent*).

$$P(X | Y) = P(X_1, X_2, \dots, X_n | Y) = \prod_{i=1}^n P(X_i | Y)$$

- Therefore, we then only need to know $P(X_i | Y)$ for each possible pair of a feature-value and a category.
- If Y and all X_i are binary, this requires specifying only $2n$ parameters:
 - $P(X_i=\text{true} | Y=\text{true})$ and $P(X_i=\text{true} | Y=\text{false})$ for each X_i
 - $P(X_i=\text{false} | Y) = 1 - P(X_i=\text{true} | Y)$
- Compared to specifying 2^n parameters without any independence assumptions.

Naïve Bayes Example

| Probability | positive | negative |
|--------------------------|----------|----------|
| $P(Y)$ | 0.5 | 0.5 |
| $P(\text{small} Y)$ | 0.4 | 0.4 |
| $P(\text{medium} Y)$ | 0.1 | 0.2 |
| $P(\text{large} Y)$ | 0.5 | 0.4 |
| $P(\text{red} Y)$ | 0.9 | 0.3 |
| $P(\text{blue} Y)$ | 0.05 | 0.3 |
| $P(\text{green} Y)$ | 0.05 | 0.4 |
| $P(\text{square} Y)$ | 0.05 | 0.4 |
| $P(\text{triangle} Y)$ | 0.05 | 0.3 |
| $P(\text{circle} Y)$ | 0.9 | 0.3 |

Test Instance:
<medium ,red, circle>

Naïve Bayes Example

| Probability | positive | negative |
|---------------|----------|----------|
| P(Y) | 0.5 | 0.5 |
| P(medium Y) | 0.1 | 0.2 |
| P(red Y) | 0.9 | 0.3 |
| P(circle Y) | 0.9 | 0.3 |

Test Instance:
<medium ,red, circle>

$$\begin{aligned} P(\text{positive} | X) &= P(\text{positive}) * P(\text{medium} | \text{positive}) * P(\text{red} | \text{positive}) * P(\text{circle} | \text{positive}) / P(X) \\ &= 0.5 * 0.1 * 0.9 * 0.9 / P(X) \\ &= 0.0405 / P(X) = 0.0405 / 0.0495 = 0.8181 \end{aligned}$$

$$\begin{aligned} P(\text{negative} | X) &= P(\text{negative}) * P(\text{medium} | \text{negative}) * P(\text{red} | \text{negative}) * P(\text{circle} | \text{negative}) / P(X) \\ &= 0.5 * 0.2 * 0.3 * 0.3 / P(X) \\ &= 0.009 / P(X) = 0.009 / 0.0495 = 0.1818 \end{aligned}$$

$$P(\text{positive} | X) + P(\text{negative} | X) = 0.0405 / P(X) + 0.009 / P(X) = 1$$

$$P(X) = (0.0405 + 0.009) = 0.0495$$

Estimating Probabilities

- Normally, probabilities are estimated based on observed frequencies in the training data.
- If D contains n_k examples in category y_k , and n_{ijk} of these n_k examples have the j th value for feature X_i , x_{ij} , then:

$$P(X_i = x_{ij} | Y = y_k) = \frac{n_{ijk}}{n_k}$$

- However, estimating such probabilities from small training sets is error-prone.
- If due only to chance, a rare feature, X_i , is always false in the training data, $\forall y_k : P(X_i = \text{true} | Y = y_k) = 0$.
- If $X_i = \text{true}$ then occurs in a test example, X , the result is that $\forall y_k : P(X | Y = y_k) = 0$ and $\forall y_k : P(Y = y_k | X) = 0$

Probability Estimation Example

| Ex | Size | Color | Shape | Category |
|----|-------|-------|----------|----------|
| 1 | small | red | circle | positive |
| 2 | large | red | circle | positive |
| 3 | small | red | triangle | negative |
| 4 | large | blue | circle | negative |

Test Instance X :
<medium, red, circle>

| Probability | positive | negative |
|--------------------------|----------|----------|
| $P(Y)$ | 0.5 | 0.5 |
| $P(\text{small} Y)$ | 0.5 | 0.5 |
| $P(\text{medium} Y)$ | 0.0 | 0.0 |
| $P(\text{large} Y)$ | 0.5 | 0.5 |
| $P(\text{red} Y)$ | 1.0 | 0.5 |
| $P(\text{blue} Y)$ | 0.0 | 0.5 |
| $P(\text{green} Y)$ | 0.0 | 0.0 |
| $P(\text{square} Y)$ | 0.0 | 0.0 |
| $P(\text{triangle} Y)$ | 0.0 | 0.5 |
| $P(\text{circle} Y)$ | 1.0 | 0.5 |

$$P(\text{positive} | X) = 0.5 * 0.0 * 1.0 * 1.0 / P(X) = 0$$

$$P(\text{negative} | X) = 0.5 * 0.0 * 0.5 * 0.5 / P(X) = 0$$

Smoothing

- To account for estimation from small samples, probability estimates are adjusted or *smoothed*.
- Laplace smoothing using an m -estimate assumes that each feature is given a prior probability, p , that is assumed to have been previously observed in a “virtual” sample of size m .

$$P(X_i = x_{ij} | Y = y_k) = \frac{n_{ijk} + mp}{n_k + m}$$

- For binary features, p is simply assumed to be 0.5.

Laplace Smoothing Example

- Assume training set contains 10 positive examples:
 - 4: small
 - 0: medium
 - 6: large
- Estimate parameters as follows (if $m=1, p=1/3$)
 - $P(\text{small} \mid \text{positive}) = (4 + 1/3) / (10 + 1) = 0.394$
 - $P(\text{medium} \mid \text{positive}) = (0 + 1/3) / (10 + 1) = 0.03$
 - $P(\text{large} \mid \text{positive}) = (6 + 1/3) / (10 + 1) = \underline{0.576}$
 - $P(\text{small or medium or large} \mid \text{positive}) = \underline{1.0}$

Continuous Attributes

- If X_i is a continuous feature rather than a discrete one, need another way to calculate $P(X_i | Y)$.
- Assume that X_i has a Gaussian distribution whose mean and variance depends on Y .
- During training, for each combination of a continuous feature X_i and a class value for Y , y_k , estimate a mean, μ_{ik} , and standard deviation σ_{ik} based on the values of feature X_i in class y_k in the training data.
- During testing, estimate $P(X_i | Y=y_k)$ for a given example, using the Gaussian distribution defined by μ_{ik} and σ_{ik} .

$$P(X_i | Y = y_k) = \frac{1}{\sigma_{ik} \sqrt{2\pi}} \exp\left(\frac{-(X_i - \mu_{ik})^2}{2\sigma_{ik}^2}\right)$$

Comments on Naïve Bayes

- Tends to work well despite strong assumption of conditional independence.
- Experiments show it to be quite competitive with other classification methods on standard UCI datasets.
- Although it does not produce accurate probability estimates when its independence assumptions are violated, it may still pick the correct maximum-probability class in many cases.
 - Able to learn conjunctive concepts in any case
- Does not perform any search of the hypothesis space. Directly constructs a hypothesis from parameter estimates that are easily calculated from the training data.
 - Strong bias
- Not guarantee consistency with training data.
- Typically handles noise well since it does not even focus on completely fitting the training data.
