Big Data

A general approach to process multimedia datasets

 Batch data approach
 Stream data approach

3 System development

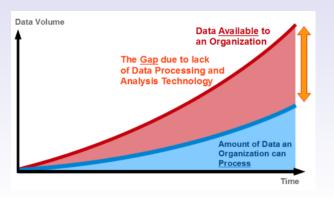

Highest system overview

Sac

- Main goals
- System overview
- Lambda architecture
- System architecture
- Main challenges
- System prototype
- Ongoing work

Introduction Big Data

- Organizations have potential access to huge datasets of heterogeneous data.
- Stored data are usually not structured.
- Data should be processed to uncover useful information.

Batch data

- Static snapshot of a dataset
- Batch computation has a 'start' and an 'end'
- Fast datasets processing

Stream data

- Stream of events that flows into the system at a given data rate over which we have no control
- Stream computation 'never' ends
- The processing system must keep up with the event rate or degrade gracefully
- Near-real time answers

Table of Contents

Introduction Big Data Terminology

Big data processing systems
Batch data approach
Stream data approach

3 System development

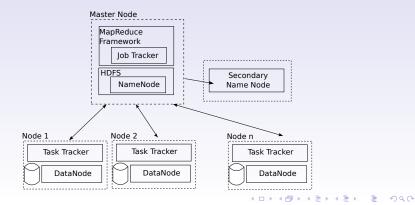

Highest system overview

Sac

- Main goals
- System overview
- Lambda architecture
- System architecture
- Main challenges
- System prototype
- Ongoing work

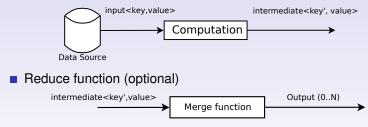

MapReduce

- MapReduce is a framework for paralleling the processing of massive datasets.
- The Hadoop implementation is highly optimized for batch processing
- Hadoop attempts to run Map and Reduce tasks at the machines were data being processed are located

MapReduce Job

Map function (mandatory)

Storm Distributed and fault-tolerant realtime computation

Storm cluster

- Master node
 - The Nimbus daemon is responsible for distributing code around the cluster, assigning tasks to machines, and monitoring for failures
- Worker nodes
 - The Supervisor daemon listens for work assigned to its machine and starts and stops worker processes as necessary based on what Nimbus has assigned to it.

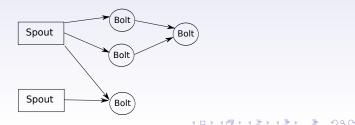

Communication - Zookeeper

Storm Components

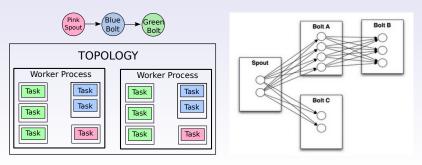

Storm runs topologies

- Graph of computation
- Each node in a topology contains processing logic
- Stream
 - Unbounded sequence of tuples
- Spout
 - It reads input data from an external source and emits them as a stream
 - It is capable of replaying a tuple
- Bolt
 - Input streams -> some processing -> new streams.

Storm Parallelism of a Storm topology

- Topologies execute across worker processes (JVM)
- Tasks are spread evenly across all the workers
- The parallelism for each node is defined by the user
- User can also specify tasks for each node
- Stream grouping How a stream should be partitioned
 - i.e.Shuffle grouping
- Scalability in processing time

"Attempting to build a general-purpose platform for both batch and stream computing would result in a highly complex system that may end up not being optimal for either task"

System development Goals

- Efficient processing of huge datasets
- External and internal data access
- Heterogeneous data management

- Processing of arbitrary functions
- Data relations management
- Infrastructure flexibility

System development System overview

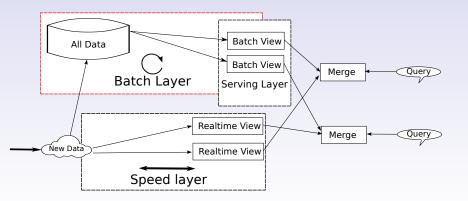

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = 釣�(♡

System development Lambda architecture

Batch layer

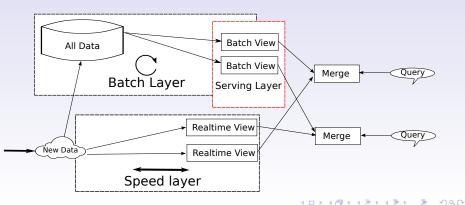

- Storage of the master dataset
- Batch views computation

System development Lambda architecture

Serving layer

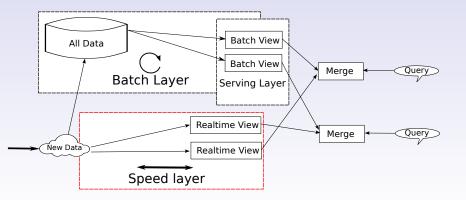

- Batch views storage
- Efficient query system
- The views are updated whenever the batch layer finishes precomputing a batch view

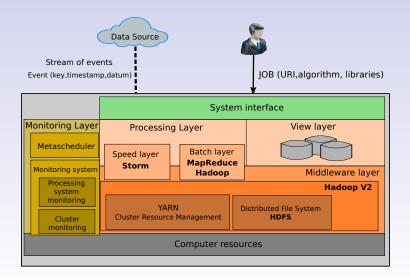

System development Lambda architecture

Speed layer

- Realtime processing of arbitrary functions on arbitrary data
- Real time views computation via incremental updates

System development General overview of the architecture

System development Processing layer - Main challenges

Data source access

- URIs (Uniform Resource Identifier)
- External data: Speed Layer (virtual streams)

(日) (日) (日) (日) (日) (日) (日)

- Internal data: Batch Layer
- Data management
 - Heterogeneous data
 - Data storage
- Data relations
 - Timestamp
 - Specialized Storm topologies
- Processing arbitrary functions
 - Meta-language
 - Scheduler

Infraestructure flexibility

- Dedicated hardware infrastructure: it is expensive and very often it is wasted
- Shared infraestructure: processing systems are not usually adapted.

Main Challenges

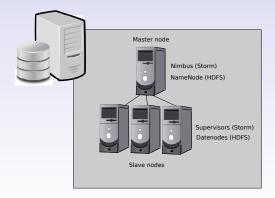

Monitoring system to analyze the status of the cluster and jobs

(日) (日) (日) (日) (日) (日) (日)

 Metascheduler to automatically modify the use of the infraestructure according to the monitoring system

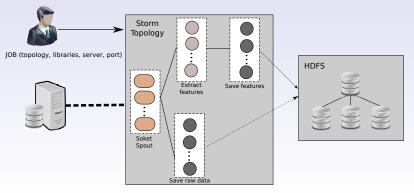

System development Prototype

- A virtual cluster via Virtual Box was deployed
- Hadoop and HDFS were installed (batch layer)
- Storm was installed (speed layer)

System development Prototype

- A Spout to get external data was deployed
- Data containers were developed
- A generic bolt was designed to store data
 - Specific implementation to deal with HDFS
 - Bolt takes into account the block size

Ongoing work

- Deployment of the prototype in a real cluster
- Comparative study between the prototype and other processing approaches

- Sequential computing
- Grid computing
- MapReduce
- Infrastructure flexibility
 - Storm flexibility
 - Monitoring system development
 - Cluster status
 - Job status
 - Metascheduler development

Big Data
