Seminar 4

Definition 1 (Term weight) Weight of a term t in a document d is counted as

$$w_{t,d} = \begin{cases} 1 + \log(tf_{t,d}) & \text{if } n > 0\\ 0 & \text{otherwise} \end{cases}$$

where $tf_{t,d}$ is the number of terms t in a document d.

Definition 2 (Inverse document frequency) Inverse document frequency of a term t is defined as

$$idf_t = \log\left(\frac{N}{df_t}\right)$$

where N is the number of all documents and df_t (document frequency) is the number of documents that contain t.

Definition 3 (tf-idf weighting scheme) In the tf-idf weighting scheme, a term t in a document d has weight

$$tf - idf_{t,d} = tf_{t,d} \cdot idf_t$$

Definition 4 (Cosine (Euclidean) normalization) A vector v is cosine-normalized by

$$v_j = \frac{v_j}{||v||} = \frac{v_j}{\sqrt{\sum_{k=1}^{|v|} v_k^2}}$$

where v_j be the number on the *j*-th position in v.

Exercise 1

Consider the frequency table of the words of three documents doc_1 , doc_2 , doc_3 below. Calculate the *tf-idf* weight of the terms *car*, *auto*, *insurance*, *best* for each document. *idf* values of terms are in the table.

	doc_1	doc_2	doc_3	idf
car	27	4	24	1.65
auto	3	33	0	2.08
insurance	0	33	29	1.62
best	14	0	17	1.5

Table 1: Exercise.

After counting tf-idf weights by Definition 3 individually for each term we get the following table

	tf-idf				
	doc_1	doc_2	doc_3		
car	44.55	6.6	39.6		
auto	6.24	68.64	0		
insurance	0	53.46	46.98		
best	21	0	25.5		

Table 2: Solution.

Exercise 2

Count document representations as normalized Euclidean weight vectors for each document from the previous exercise. Each vector has four components, one for each term.

Normalized Euclidean weight vectors are counted by Definition 4. Denominators m_{doc_n} for the individual documents are

$$m_{doc_1} = \sqrt{44.55^2 + 6.24^2 + 21^2} = 49.6451$$
$$m_{doc_2} = \sqrt{6.6^2 + 68.64^2 + 53.46^2} = 87.2524$$
$$m_{doc_3} = \sqrt{39.6^2 + 46.98^2 + 25.5^2} = 66.5247$$

and the document representations are

$$d_{1} = \left(\frac{44.55}{49.6451}; \frac{6.24}{49.6451}; \frac{0}{49.6451}; \frac{21}{49.6451}\right) = (0.8974; 0.1257; 0; 0.423)$$

$$d_{2} = \left(\frac{6.6}{87.2524}; \frac{68.64}{87.2524}; \frac{53.46}{87.2524}; \frac{0}{87.2524}\right) = (0.0756; 0.7876; 0.6127; 0)$$

$$d_{3} = \left(\frac{39.6}{66.5247}; \frac{0}{66.5247}; \frac{46.98}{66.5247}; \frac{25.5}{66.5247}\right) = (0.5953; 0; 0.7062; 0.3833)$$

Exercise 3

Based on the weights from the last exercise, compute the relevance scores of the three documents for the query *car insurance*. Use each of the two weighting schemes:

- a) Term weight is 1 if the query contains the word and 0 otherwise.
- b) Euclidean normalized tf-idf.

Please note that a document and a representation of this document are different things. Document is always fixed but the representations may vary under different settings and conditions. In this exercise we fix document representations from the last exercises and will count relevance scores for query and documents under two different representations of the query. It might be helpful to view on a query as on another document, as it is a sequence of words. We count the relevance scores for **a**) as the scalar products of the representation of the query q = (1, 0, 1, 0) with representations of the documents d_n from the last exercise:

$$q \cdot d_1 = 1 \cdot 0.8974 + 0 \cdot 0.1257 + 1 \cdot 0 + 0 \cdot 0.423 = 0.8974$$
$$q \cdot d_2 = 1 \cdot 0.0756 + 0 \cdot 0.7876 + 1 \cdot 0.6127 + 0 \cdot 0 = 0.6883$$
$$q \cdot d_3 = 1 \cdot 0.5953 + 0 \cdot 0 + 1 \cdot 0.7062 + 0 \cdot 0.3833 = 1.3015$$

For **b**) we first need the normalized *tf-idf* vector q, which is obtained by dividing each component of the query by the length of *idf* vector $\sqrt{1.65^2 + 0^2 + 1.62^2 + 0^2} = 2.3123$

	tf	idf	tf-idf	q
car	1	1.65	1.65	0.7136
auto	0	2.08	0	0
insurance	1	1.62	1.62	0.7006
best	0	1.5	0	0

Table 3: Process of finding the Euclidean normalized *tf-idf*.

Now we multiply q with the document vectors and we obtain the relevance scores:

$$\begin{aligned} q \cdot d_1 &= 0.7136 \cdot 0.8974 + 0 \cdot 0.1257 + 0.7006 \cdot 0 + 0 \cdot 0.423 = 0.6404 \\ q \cdot d_2 &= 0.7136 \cdot 0.0756 + 0 \cdot 0.7876 + 0.7006 \cdot 0.6127 + 0 \cdot 0 = 0.4832 \\ q \cdot d_3 &= 0.7136 \cdot 0.5953 + 0 \cdot 0 + 0.7006 \cdot 0.7062 + 0 \cdot 0.3833 = 0.9196 \end{aligned}$$

Exercise 4

Calculate the vector-space similarity between the query digital cameras and a document containing digital cameras and video cameras by filling in the blank columns in the table below. Assume N = 10000000, logarithmic term weighting (columns w) for both query and documents, *idf* weighting only for the query and cosine normalization only for the document. and is a STOP word.

		Query			Do	cume	ent	relevance	
	df	tf	w	idf	q	tf	w	d	$q \cdot d$
digital	10 000								
video	100 000								
cameras	$50\ 000$								

Table 4: Exercise.

The *tf* value is filled according to the occurrences of the terms in both query and document.

Logarithmic weighting uses the Definition 1. For the query the values are

$$\begin{array}{ll} w_{digital} &= 1 + \log{(1)} &= 1 + 0 &= 1 \\ w_{video} &= 0 \\ w_{cameras} &= 1 + \log{(1)} &= 1 + 0 &= 1 \end{array}$$

and for the document

$$\begin{array}{ll} w_{digital} &= 1 + \log\left(1\right) &= 1 + 0 &= 1 \\ w_{video} &= 1 + \log\left(1\right) &= 1 + 0 &= 1 \\ w_{cameras} &= 1 + \log\left(2\right) &= 1 + 0.301 &= 1.301 \end{array}$$

Now we need to count the idf weights for the query. These are counted by Definition 2.

$$idf_{digital} = \log\left(\frac{10^7}{10^4}\right) = \log\left(10^3\right) = 3$$
$$idf_{video} = \log\left(\frac{10^7}{10^5}\right) = \log\left(10^2\right) = 2$$
$$idf_{cameras} = \log\left(\frac{10^7}{5\times10^4}\right) = \log\left(200\right) = 2.301$$

and $q = w \cdot idf$. Cosine normalization for the document is counted similarly as in the last exercises by Definition 4 using w.

$$d_{digital} = \frac{1}{\sqrt{1^2 + 1^2 + 1.301^2}} = 0.5204$$
$$d_{video} = \frac{1}{\sqrt{1^2 + 1^2 + 1.301^2}} = 0.5204$$
$$d_{cameras} = \frac{1.301}{\sqrt{1^2 + 1^2 + 1.301^2}} = 0.677$$

The score is the scalar multiple of q and d. The final table is

		Query			Document			relevance	
	df	tf	w	idf	q	tf	w	d	$q \cdot d$
digital	10 000	1	1	3	3	1	1	0.5204	1.5612
video	100 000	0	0	2	0	1	1	0.5204	0
cameras	50000	1	1	2.301	2.301	2	1.301	0.677	1.5578

Table 5: Solution.

and the similarity score is

$$score(d,q) = \sum_{i=1}^{3} (d_i \cdot q_i) = 3.119.$$

Exercise 5

Show that for the query $q_1 = affection$ the documents in the table below are sorted by relevance in the opposite order as for the query $q_2 = jealous \ gossip$. Query is tf weight normalized.

	SaS	PaP	WH
affection	0.996	0.993	0.847
jealous	0.087	0.120	0.466
gossip	0.017	0	0.254

Table 6: Exercise.

We add queries to the original table:

	SaS	PaP	WH	q_1	q_2
affection	0.996	0.993	0.847	1	0
jealous	0.087	0.120	0.466	0	1
gossip	0.017	0	0.254	0	1

Table 7: Exercise with queries.

Now we normalize the vectors q_i by Definition 4 and get

	SaS	PaP	WH	q_1	q_2	q_{1n}	q_{2n}
affection	0.996	0.993	0.847	1	0	1	0
jealous	0.087	0.120	0.466	0	1	0	0.7071
gossip	0.017	0	0.254	0	1	0	0.7071

Table 8: Exercise with queries after normalization.

In the last step we count the similarity score between the queries and documents by $score(d,q) = \sum_{i=1}^{|d|} (d_i \cdot q_i)$

=	$0.9961 \cdot 1 + 0.087 \cdot 0 + 0.017 \cdot 0$	= 0.9961
=	$0.993 \cdot 1 + 0.120 \cdot 0 + 0 \cdot 0$	= 0.993
=	$0.847 \cdot 1 + 0.466 \cdot 0 + 0.254 \cdot 0$	= 0.847
=	$0.9961 \cdot 0 + 0.087 \cdot 0.7071 + 0.017 \cdot 0.7071$	= 0.0735
=	$0.993 \cdot 0 + 0.120 \cdot 0.7071 + 0 \cdot 0.7071$	= 0.0849
=	$0.847 \cdot 0 + 0.466 \cdot 0.7071 + 0.254 \cdot 0.7071$	= 0.5091
	 	$= 0.9961 \cdot 1 + 0.087 \cdot 0 + 0.017 \cdot 0$ = 0.993 \cdot 1 + 0.120 \cdot 0 + 0 \cdot 0 = 0.847 \cdot 1 + 0.466 \cdot 0 + 0.254 \cdot 0 = 0.9961 \cdot 0 + 0.087 \cdot 0.7071 + 0.017 \cdot 0.7071 = 0.993 \cdot 0 + 0.120 \cdot 0.7071 + 0 \cdot 0.7071 = 0.847 \cdot 0 + 0.466 \cdot 0.7071 + 0.254 \cdot 0.7071

The ordering for q_1 is SaS > PaP > WH and for q_2 is WH > PaP > SaS, and we see that they are opposite.
