

# IA169 System Verification and Assurance

## Course Intro & Fundamentals of Testing

Jiří Barnat

## Course Organization

## Topics to be covered ...

- Introduction to Testing
- Symbolic Execution
- Model Checking (4 lectures)
- Deductive Verification
- Bounded Model Checking
- Verification of Real-Time and Hybrid Systems
- Verification of Probabilistic Systems
- CEGAR and Abstract Interpretation
- Assurance, Threat Models, Relevant Security Standards

## Prerequisites

- Formally none, but we expect ...
- ... capability of basic math reasoning and abstractions.
- ... some experience with coding.
- ... you can handle Unix as a user.

## Mutual Exclusion with

- IV113 and IV101

## Possible Follow-Up

- IA159 Formal Verification Methods

## Structure

- 2/2/2 + 2 ECTS credits
- Lecture/Tutorials/Homework

## Marking

- Final exam 70% (written test)
- Assignments 30% (five evaluated tasks)
- 50% for E or Colloquy or Credit
- 60% for D
- 70% for C
- 80% for B
- 90% for A

## Seminar schedule

- [https://is.muni.cz/auth/el/1433/jaro2019/IA169/op/IA169\\_semester\\_schedule\\_2019.pdf](https://is.muni.cz/auth/el/1433/jaro2019/IA169/op/IA169_semester_schedule_2019.pdf)

## **Fundamentals of Testing**

`http://www.testingeducation.org/BBST/`

**Testing is an empirical technical investigation conducted to provide stakeholders with information about the quality of the product or service under test.**

## **Empirical Technical**

- Conduct experimental measurements.
- Logic and math.
- Modelling.
- Employs SW tools.

## **Investigation**

- Organised and thorough.
- Self-reflecting.
- Challenging.

## **Product or Service**

- Software.
- Hardware.
- Data.
- Documentation and specification.
- ... other parts that are delivered.

## **Information**

- Not know before.
- Has some value.

## **Stakeholders**

- Who has interest in the success of testing effort.
- Who has interest in the success of the product.

# Fundamental Questions of Testing

## Mission

- Why do we test? What we want to achieve?

## Strategy

- How to proceed to fulfil the mission efficiently?

## Oracle

- How to recognise success of the test.

## Incompleteness

- Do we realise that testing cannot prove absence of error?

## Measure

- How much of of our testing plan has been completed?
- How far we are to complete the mission?

## Most Typical Mission

- Bug hunting.
- Identification of factors that reduce quality.

## Other Missions

- Collect data to support manager decisions, such as: Is the product good enough to be released?
- How much different is the product from product available on market?
- Is the product complete with respect to specification?
- Are individual components logically and ergonomically connected.
- ...

## Other Missions – continued

- Support manager decision with empirical results.
- Evaluate the cost of support after release.
- To check compatibility with other products.
- Confirm accordance with the specification.
- Find safe scenarios of product usage.
- To acquire certification.
- Minimise consequences of low quality.
- Evaluate the product for third party.
- ...

## Strategy

**Strategy is a plan, how to fulfil the mission in the given context.**

**Example:** Consider spreadsheet computation in four different contexts.

- a) Computer game.
- b) Early stage of development of database product.
- c) Late stage of development of database product.
- d) Driver for medical X-ray scanning device.

**Question:**

- Will you proceed with the same strategy?

## What factors influence strategy selection

- What is the mission?
- How aggressively we need to detect bugs.
- What bugs are less important than others?
- How thoroughly testing will be documented?

## Discussion

- Assume that a program has an enter field that is expecting numerical values. Is it meaningful to test the product for situation when we enter non-numeric value? (Not mentioned in specification at all.)

Oracle

**Oracle (in the context of testing) is a detection mechanism or principle to learn that the product passed or failed a test.**

## Facts

- If tester claims that the program passed a test, it does not mean the program is correct with respect to the tested property. It depends on the oracle used.
- Basically, any test may fail or pass with a suitable oracle.

## Example

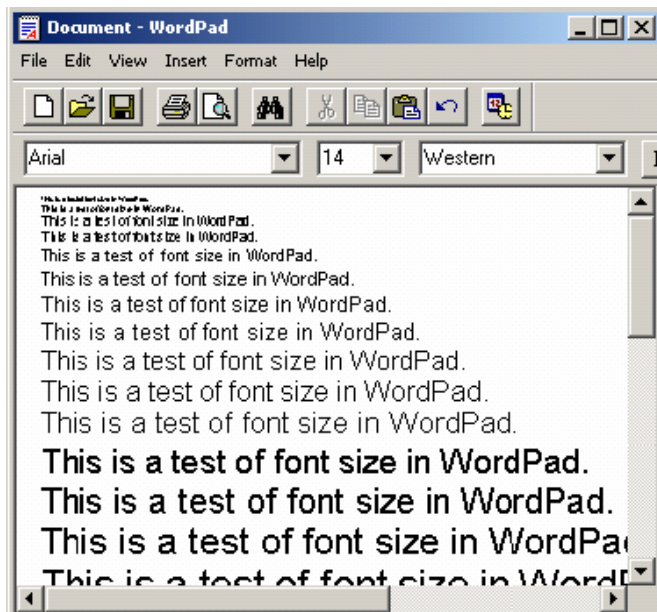

- Does font sizes work properly in OpenOffice, WordPad, and MS Word text editors?

# Example – OpenOffice 1.0

# Example – WordPad

# Example – WordPad versus MS Word

## Questions

- Is the observed difference in font sizes a bug in WordPad?
- Is the observed difference in font sizes a bug in MS Word?
- Is the observed difference in font sizes a bug at all?

## Possible Conclusions

- We do not know if sizes are correct, but we have tendency to believe MS Word rather than to WordPad.
- For WordPad it is not necessary to stick precisely to typographic standards.
- For WordPad it is possibly a bug, but definitely it is not a problem.

## Possible (Pragmatic) Position

- It is/isn't a bug?  $\implies$  It is/isn't a problem?
- It is necessary to know the context, to guess the metrics that the final consumer will use to judge the issue.
- With some risk we can achieve simplification of the decision.

## Simplification in Testing Process

- Avoid tests that obviously does not reveal any problems.
- Avoid tests that obviously reveal only uninteresting problems.

## How much do we actually know about typography?

- Point definition is unclear.  
(<http://www.oberonplace.com/dtp/fonts/point.htm>)
- Absolute sizes are difficult to measure.  
(<http://www.oberonplace.com/dtp/fonts/fontsize.htm>)

## From Uncertainty to Heuristics

- How precisely must the sizes agree in order to declare that the sizes are correct?
- Obtaining complete information and evaluation of all the facts is too complicated and costly.
- **Heuristics** are used instead.

## Decision Heuristics

- Allows for simplification of decision problem.
- Advice, recommendation, or procedure to be used within the given context.
- Should not build on any hidden knowledge.
- Does not guarantee a good decision.
- Various heuristics may lead to contradictory decisions.

## Disadvantages

- Heuristics might be subjective.
- If misused, may cause more harm than good.

## Consistency

- Good heuristics for decision making.

## Consistency with ...

- other functions of the product, similar products, history, producer image, specifications, standards, user expectations, the purpose of the product, etc.

## Advantages

- Consistency is objective enough.
- Easily described in bug report.

## Unintentional Blindness

- Human tester does not consider any test outputs that he/she does not pay attention to.
- Similarly, mechanical tester does not consider test outputs that it is not told to include into decision.

## Uncertainty Principle

- The presence of observer may affect what is observed.

## Consequence

- It is impossible to observe all possible outputs from a single test.

## Motivation

- Automation process eliminates human errors.
- Automation leads to repeatable procedures.
- Automation allows faster test evaluation.

## Problems of Automation

- It is necessary to automate the decision making (oracle) principle.
- Can we do it? Only partially.

## Standard Way of Oracle Automation

- A file of expected outputs, which is required to match precisely with the outputs of a test being executed.
- Example: MS Word could be used to define a the file of expected outputs for testing WordPad.

## Amount of Agreement

- Assume MS Word to serve as the file of expected outputs for testing WordPad.
- How exactly is the expected output stored?
- Is 99% agreement still agreement?
- How is the percentage of agreement defined?

## False Alarms

- Using outdated expected output.
- Consequence of simplification of decision making.

## Undiscovered Errors

- Expected file exhibits the same error as test output.
- Unintentional Blindness.

## Measure Methods in Testing

## Coverage

- A set of source code entities that has been checked with at least one test.
- Source-code entities: lines of code, conditions, function calls, branches, etc.
- Used to identify parts that have not been tested yet.

## Coverage as a Measure

- Possible test plan is to achieve a given percentage of coverage.
- The percentage that expresses how much of the final product has been tested.
- Numeric expression for managers to see how much of the product remains to be tested.

## Problems

- Could avoid testing of interesting input data.
- Does not properly test parts of the product that rely on external services.

## Using Coverage as a Measure

- The mission is to test all entities of the product, is that OK?
- Complete coverage does not guarantee quality of the product.
- Stimulates to prefer quantity rather than quality.
- Misleading satisfaction (shouldn't feel safe).

## Example

```
Input A      // program accepts any
Input B      // integer into A and B
Print A/B
```

## Observation

- Complete coverage is easy achievable.
- For example:  
    input: 2,1  
    output: 2
- There is of course a hidden bug in the program!

# Coverage Criteria for Control-Flow Graphs

There are various criteria for control-flow graph coverage.

# Coverage Criteria for Control-Flow Graphs

## Statement coverage

- Every statement (assignment, input, output, condition) is executed in at least one test.
- Set of tests to achieve full coverage:  
( $x = 2, y = 1, z = 4, w = 3$ )

## Edge coverage

- Every edge of CFG is executed in at least one test.
- Set of tests to achieve full coverage:  
( $x = 2, y = 1, z = 4, w = 3$ ), ( $x = 3, y = 3, z = 5, w = 7$ )

## Condition coverage

- Every condition is a Boolean combination of **elementary conditions**, for example  $x < y$  or  $\text{even}(x)$ .
- If it is possible, every elementary condition is evaluated in at least one test to TRUE and in at least one test to FALSE.

# Coverage Criteria for Control-Flow Graphs

## Condition coverage

- Set of tests to achieve full coverage:  
( $x = 3, y = 2, z = 5, w = 7$ ), ( $x = 3, y = 3, z = 7, w = 5$ )
- In both cases, only the FALSE branch of IF statement is taken.

## Edge/Condition coverage

- Edge and Condition coverage at the same time.
- Set of tests to achieve full coverage:  
( $x = 2, y = 1, z = 4, w = 3$ ), ( $x = 3, y = 2, z = 5, w = 7$ ),  
( $x = 3, y = 3, z = 7, w = 5$ )
- Is the set the smallest possible one?

## Multiple condition coverage

- Every Boolean combination of TRUE/FALSE values that may appear in some decision condition must occur in at least one test.

# Coverage Criteria for Control-Flow Graphs

## Multiple condition coverage

- Set of tests to achieve full coverage:  
( $x = 2, y = 1, z = 4, w = 3$ ), ( $x = 3, y = 2, z = 5, w = 7$ ),  
( $x = 3, y = 3, z = 7, w = 5$ ), ( $x = 3, y = 3, z = 5, w = 6$ )
- Exponential growth in the number of tests.

# Coverage Criteria for Control-Flow Graphs

## Path coverage

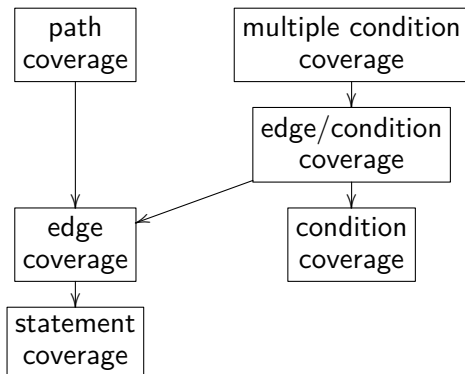

- Every executable path is executed in at least one test.
- The number of paths is big, even infinite in case there is an unbounded cycle in the control-flow graph.

# Hierarchy of Coverage Criteria

- Criterion A **includes** criterion B, denoted with  $A \rightarrow B$ , if after full coverage of type A we guarantee full coverage of type B.

# Hierarchy of Coverage Criteria

- Criterion A **includes** criterion B, denoted with  $A \rightarrow B$ , if after full coverage of type A we guarantee full coverage of type B.

## Coverage and Number of Cycle Iterations

- All criteria except the path criterion does not reflect the number of iterations over a cycle body.
- In case of nested cycles, systematic testing of all possible executable paths become complicated.

## Ad hoc Strategy for Testing Cycles

- Check the case when the cycle is completely skipped.
- Check the case when the cycle is executed exactly once.
- Check the case when the cycle is executed the expected number of times.
- If a boundary  $n$  is known for the number of cycle executions, try to design tests where the cycle is executed  $n - 1$ ,  $n$ , and  $n + 1$  times.

## Motivation

- Detect usage of undefined variables.
- On some paths, a variable may be set for a specific purpose and later on its value misused for other purpose.
- Control Flow criteria do not guarantee inclusion of tests for above mentioned or likewise situations.

## Data Flow Coverage

- Cover paths through control flow graph that go through a location where a variable is used but it is not defined along all incoming paths through control-flow graph.

## C/C++, Linux

- Tools `gcov` and `lcov`.

### Example: `lcov`

- `gcc -fprofile-arcs -ftest-coverage foo.c -o foo`  
`lcov -d . -z`  
`lcov -c -i -d . -o base.info`  
`./foo`  
`lcov -c -d . -o collect.info`  
`lcov -d . -a base.info -a collect.info -o result.info`  
`genhtml result.info`

## Week statistics

- The number of newly discovered errors.
- The number of fixed errors.
- The ratio of found versus fixed errors.

## Visualisation

## Observation

- The number of discovered errors per time unit exhibits Weibull Distribution.
- Can be used as a measure for the remaining amount of testing.
- Software Engineering Method to set the release date.

## Using Weibull Distribution

- At the moment the curve reaches the peak, the remaining part of the curve may be predicted, hence, a moment in time may be set, when expected number of errors discovered per week drops below a given threshold.
- Parameters of Weibull distribution influence the “width” and “height/slope” of the peak.
- $F(x) = 1 - e^{-ax^{-b}}$  for  $x > 0$

## Vague Precision

- Testing does not follow the typical usage of the product.
- The probability of error discovery is different for different errors.
- Fix may cause other new errors.
- Bugs are dependent.
- The number of errors in the product changes over time.
- Error insertion exhibits Weibull distribution itself.
- Testing epochs (various testing procedures) are independent.
- ...

## Conclusions

- Weibull Distribution is not very reliable.
- Can be used only with large projects for very rough estimation.

## Assumption

- Software developers are aware of being measured.

## Phase one

- Reach the peak as quickly as possible.
- Double reporting of errors.
- Avoid fixing known errors.
- ...

## Phase two

- Stick to expected shape of the curve.
- Delay reporting of errors.
- Reporting outside bug-tracking system.
- ...

## Incompleteness of Testing

## Observation

- The amount of tests to be run is extremely large.
- Resources for testing are always limited.

## What Is Not Complete Testing

- Complete Coverage
  - Every line of code.
  - Every branching point.
  - ...
- When testers do not find more errors.
- Testing plan is finished.

## What Is Complete Testing

- There are no hidden or unknown errors in the product.
- If new issue is reported, testing could not be complete.

**The number of tests is too large (infinitely many).**

**To perform all tests means:**

- To test all possible input values of every input variable.
- To test all combinations of input variables.
- To test every possible run of a system.
- To test every combination of HW and SW, including future technology.
- To test every way a user may use the product.

## Data Bus-Width

- The number of tests grows exponentially with respect to bit used for data representation.
- $n$ -bits requires  $2^n$  tests.

## Other Reasons

- Timing of actions.
- Invalid or unexpected inputs (buffer overflow).
- Edited inputs
- Easter egg [<http://j-walk.com/ss/excel/eastereg.htm>]

## Common Argumentation

- “This is not what the customer would do with our product.”

# Incapability to Test All Runs

Assume the following system

## Questions

- How many different ways it is possible to reach `EXIT` ?
- How many different ways it is possible to reach `EXIT` , if `A` can be visited at most  $n$ -times?

## Example

- In [F] is a memory leak, in [B] garbage collector.
- System will reach an invalid state, if [B] is avoided long enough.

## Observation

- Simplified testing of paths may not discover the error.
- The error manifests in circumstances that cannot be achieved with a simple test.

## Incompleteness

- Testing cannot prove absence of error.
- It is impossible to test all valid inputs.
- Existence of testing plan inhibits testing creativity.

## Measure

- There are methods to measure progress in testing phase.
- These are unreliable.
- Focusing strongly on a selected measure may influence the effectiveness of testing.

## Homework

- Reading on MC/DC:  
[http://www.faa.gov/aircraft/air\\_cert/design\\_approvals/air\\_software/cast/cast\\_papers/media/cast-10.pdf](http://www.faa.gov/aircraft/air_cert/design_approvals/air_software/cast/cast_papers/media/cast-10.pdf)
- List, and briefly describe as many black-box testing approaches as you can find or are aware of.  
<http://www.testingeducation.org/BBST/>
- Optional: Learn about CMAKE and CTEST systems.

# IA169 System Verification and Assurance

## Symbolic Execution and Concolic Testing

Jiří Barnat

## Testing Strategies

## Black-box

- A product under test is viewed as a **black box**.
- It is analysed through the input-output behaviour.
- Inner details (such as source code) are hidden or not taken into account.

## White-box Testing (Glass-box)

- Inner details are taken into account.
- Tests are selected and executed with respect to the inner details of the product, e.g. code coverage.
- Error insertion, modification of the product for the purpose of testing.
- **Basically only extends any Black-box approach.**

## Gray-box Testing

- In between of Black-box and White-box.
- Sometimes the same as White-box, inconsistent terminology.

## Primary Black-box Strategies

- Domain Testing
- Combinatory Testing
- Scenario Testing
- Risk-based Testing
- Functional Testing
- Fuzz Testing (Mutation Testing)

## Primary White-box Extensions

- Model-based Testing
- Unit Testing

## Support for Developers

- Regression Testing

## Symbolic Execution

## **Problem**

- To detect errors that systematically exhibit only for specific input values is difficult.
- Relates to incompleteness of testing.

## **Still we would like to ...**

- test the program on inputs that make program execute differently from what has already been tested.
- test the program for all inputs.

## Idea

- Execute a program so that values of input variables are referred to as symbols instead of concrete values.

## Demo

Program	Selected concrete values	Symbolic representation
read(A)	A = 3	$A = \alpha$
A = A * 2	A = 6	$A = \alpha * 2$
A = A + 1	A = 7	$A = (\alpha * 2) + 1$
output(A)		

## Observation

- Branching in the code put some restrictions on the data depending on the condition of a branching point.

## Example

1	if (A == 2)	$A = (\alpha * 2) + 1$	
2	then ...		$(\alpha * 2) + 1 = 2$
3	else ...		$(\alpha * 2) + 1 \neq 2$

## Path Condition

- Formula over symbols referring to input values.
- Encodes history of computation, i.e. cumulative restrictions implied from all the branching points walked-through up to the current point of execution.
- Initially set to **true**.

## Observation

- The path condition may become unsatisfiable.
- If so, there are no input values that would make the program execute that way.

## Example 1

```
1 if (A == B)       $A = \alpha, B = \beta$ 
2   then
3     if (A == B)
4       then ...    $\alpha = \beta$ 
5     else ...      $\alpha = \beta \wedge \alpha \neq \beta$  is UNSAT
6   else ...        $\alpha \neq \beta$ 
```

## Example 2

% – operation modulo

```
1 A=A%2            $A = \alpha\%2$ 
2 if (A == 3) then ...    $\alpha\%2 = 3$  is UNSAT
3   else ...        $\alpha\%2 \neq 3$ 
```

## Observation

- All possible executions of program may be represented by a tree structure – **Symbolic Execution Tree**.
- The tree is obtained by unfolding/unwinding the control flow graph of the program.

## Symbolic Execution Tree

- Node of the tree encodes program location, symbolic representation of variables, and a concrete path condition.

location	symbolic valuation	path condition
#12	$A = \alpha + 2, B = \alpha + \beta - 2$	$\alpha = 2 * \beta - 1$

- An edge in the tree corresponds to a symbolic execution of a program instruction on a given location.
- Branching point is reflected as branching in the tree and causes updates of path conditions in individual branches.

## Program

```
1 input A,B
2 if (B<0) then
3   return 0
4 else
5   while (B > 0)
6     { B=B-1
7       A=A+B
8     }
9 return A
```

Draw Yourself.

## Properties of Symbolic Tree Execution

- No nodes are merged, even if they are the same (the structure is a tree).
- A single program location may be contained in (infinitely) many nodes of the tree.
- Tree may contain infinite paths.

## Path Explosion Problem

- The number of branches in the symbolic execution tree may be large for non-trivial programs.
- The number of paths may grow exponentially with the number of branching points visited.

## Analysis of the Tree

- Breadth-first strategy, the tree may be infinite.

## Deduced Program Properties

- Identification of feasible and unfeasible paths.
- Proof of reachability of a given program location.
- Error detection (division by zero, out-of-array access, assertion violation, etc.).

## Synthesis of Test Input Data

- If the formula encoded as a path condition is satisfiable for a symbolic run, the model of the formula gives concrete input values that make the program to follow the symbolic run.
- Excellent for synthesis of tests that increase code coverage.

## Principle

- 1 Generate random input values (encode some random path).
- 2 Perform a walk through the Symbolic Execution Tree with the random input values and record the path condition.
- 3 Generate a new path condition from the recorded one by negating one of the restrictions related to a single branching point.
- 4 Find input values satisfying the new path condition.
- 5 Repeat from number 2 until desired coverage is reached.

## Practical Notes

- Heuristics for selection of branching point to be negated.
- Augmentation of the code to enable path condition recording.

## Undecidability

- Using complex arithmetic operations on unbounded domains implies general undecidability of the formula satisfaction problem.
- Symbolic Execution Tree is infinite (due to unwinding of cycles with unbound number of iterations).

## Computational Complexity

- Path explosion problem.
- Efficiency of algorithms for formula satisfiability on finite domains.

## Known Limits

- Symbolic operations on non-numerical variables.
- Not clear how to deal with dynamic data structures.
- Symbolic evaluation of calls to external functions.

## Tools for SAT Solving

## **Satisfiability Problem – SAT**

- Is to decide if there exists a valuation of Boolean variables of propositional logic formula that makes the formula hold true (be valid).

## **SAT Problem Properties**

- Famous NP-complete problem.
- Polynomial algorithm is unlikely to exist.
- Still there are existing SAT solvers that are very efficient and due to a plethora of heuristics can solve surprisingly large instances of the problem.

## **ZZZ** aka **Z3**

- Developed by Microsoft Research.
- SAT and SMT Solver.
- WWW interface — <http://www.rise4fun.com/Z3>
- Standardised binary API for use within other verification tools.

## **Decide using Z3**

- Is formula  $(a \vee \neg b) \wedge (\neg a \vee b)$  satisfiable?

## Reformulate into language of Z3

$$(a \vee \neg b) \wedge (\neg a \vee b)$$

- ```
(declare-const a Bool)
(declare-const b Bool)
(assert (and (or a (not b)) (or (not a) b)))
(check-sat)
(get-model)
```

## Answer of Z3

- ```
sat
(model
  (define-fun b () Bool
    false)
  (define-fun a () Bool
    false)
)
```

## Satisfiability Modulo Theory – SMT

- Is to decide satisfiability of first order logic with predicates and function symbols that encode one or more selected theories.
- Typically used theories
  - Arithmetic of integer and floating point numbers.
  - Theories of data structures (lists, arrays, bit-vectors, ...).

### Other view (Wikipedia)

- SMT can be thought of as a form of the constraint satisfaction problem and thus a certain formalised approach to constraint programming.

## Solve using Z3

<http://rise4fun.com/Z3/tutorial/guide>

- Are there two integer non-zero numbers  $x$  and  $y$  such that  $y=x*(x-y)$ ?

```
(declare-const y Int)
(declare-const x Int)
(assert (= y (* x (- x y))))
(assert (not (= y 0)))
(check-sat)
(get-model)
```

- Are there two integer non-zero numbers  $x$  and  $y$  such that  $y=x*(x-(y*y))$ ?

```
(declare-const y Int)
(declare-const x Int)
(assert (= y (* x (- x (* y y)))))
(assert (not (= x 0)))
(check-sat)
```

## Observation

- A formula is valid if and only if its negation is not satisfiable.

## Consequence

- SAT and SMT solvers can be used as theorem provers to show validity of some theorems.

## Model Synthesis

- SAT solvers not only decide satisfiability of formulae but in positive case also give concrete valuation of variables for which the formula is valid.
- Unlike general theorem provers they provide a counterexample in case the theorem to be proved is invalid (negation is satisfiable).

## Concolic Testing

## Problem

- Efficient undecidability of path feasibility.
- In practice, unknown result often means unsatisfiability (no witness found).
- However, skipping paths that we only think are unfeasible, may result in undetected errors.
- On the other hand, executing unfeasible path may report unreal errors.

## Partial Solution

- Let us use concrete and symbolic values at the same time in order to support decisions that are practically undecidable by a SAT or SMT solver.
- Heuristics.
- An interesting case (correct): UNKNOWN  $\implies$  SAT
- **Concrete and Symbolic Testing = Concolic Testing**

# Hypothetical demo of concolic testing

## Program

```
1 input A,B
2 if (A==(B*B)%30) then
3   ERROR
4 else
5   return A
```

## Concolic Testing

- 1 A=22, B=7 (random values), test executed, no errors found.
- 2  $(22==(7*7)\%30)$  is *False*, path condition:  $\alpha \neq (\beta * \beta)\%30$
- 3 Synthesis of input data from negation of path condition:  
 $\alpha = (\beta * \beta)\%30 - \text{UNKNOWN}$
- 4 Employ concrete values:  $\alpha = (7 * 7)\%30 - \text{SAT}$ ,  $\alpha = 19$
- 5 A=19, B=7
- 6 Test detected error location on program line 3.

## SAGE Tool

## Systematic Testing for Security: Whitebox Fuzzing

Patrice Godefroid  
Michael Y. Levin and David Molnar

<http://research.microsoft.com/projects/atg/>

Microsoft Research

## Whitebox Fuzzing (SAGE tool)

- Start with a well-formed input (not random)
- Combine with a **generational** search (not DFS)
  - Negate 1-by-1 **each** constraint in a path constraint
  - Generate **many** children for each parent run
  - Challenge **all** the layers of the application sooner
  - Leverage expensive symbolic execution
- Search spaces are **huge**, the search is **partial**... yet **effective** at finding bugs !

## Example: Dynamic Test Generation

```
void top(char input[4])
{
    int cnt = 0;
    if (input[0] == 'b') cnt++;
    if (input[1] == 'a') cnt++;
    if (input[2] == 'd') cnt++;
    if (input[3] == '!') cnt++;
    if (cnt > 3) crash();
}

input = "good"
```

## Dynamic Test Generation

```
void top(char input[4])  
{  
    int cnt = 0;                               input = "good"  
    if (input[0] == 'b') cnt++;  
    if (input[1] == 'a') cnt++;  
    if (input[2] == 'd') cnt++;  
    if (input[3] == '!') cnt++;  
    if (cnt > 3) crash();  
}
```

Path constraint:

```
I0 != 'b'  
I1 != 'a'  
I2 != 'd'  
I3 != '!'
```

Negate a condition in path constraint  
Solve new constraint → new input

## Depth-First Search

```
input = "good"
```

```
void top(char input[4])
{
    int cnt = 0;
    if (input[0] == 'b') cnt++;  $I_0 \neq \text{'b'}$ 
    if (input[1] == 'a') cnt++;  $I_1 \neq \text{'a'}$ 
    if (input[2] == 'd') cnt++;  $I_2 \neq \text{'d'}$ 
    if (input[3] == '!') cnt++;  $I_3 \neq \text{'!'}$ 
    if (cnt > 3) crash();
}
```

## Depth-First Search

```

void top(char input[4])
{
    int cnt = 0;
    if (input[0] == 'b') cnt++; I0 != 'b'
    if (input[1] == 'a') cnt++; I1 != 'a'
    if (input[2] == 'd') cnt++; I2 != 'd'
    if (input[3] == '!') cnt++; I3 == '!'
    if (cnt > 3) crash();
}
    
```

## Generational Search

Four "Generation 1"  
test cases !

```
void top(char input[4])
```

```
{
```

```
int cnt = 0;
```

```
if (input[0] == 'b') cnt++;  $I_0 == 'b'$ 
```

```
if (input[1] == 'a') cnt++;  $I_1 == 'a'$ 
```

```
if (input[2] == 'd') cnt++;  $I_2 == 'd'$ 
```

```
if (input[3] == '!') cnt++;  $I_3 == '!''$ 
```

```
if (cnt > 3) crash();
```

```
}
```

## The Search Space

```
void top(char input[4])
{
  int cnt = 0;
  if (input[0] == 'b') cnt++;
  if (input[1] == 'a') cnt++;
  if (input[2] == 'd') cnt++;
  if (input[3] == '!') cnt++;
  if (cnt >= 3) crash();
}
```

## Zero to Crash in 10 Generations

Generation 10 – crash bucket 1212954973!

## Initial Experiences with SAGE

- Since 1<sup>st</sup> internal release in April'07: tens of new security bugs found
- Apps: image processors, media players, file decoders,... Confidential !
- Bugs: Write A/Vs, Read A/Vs, Crashes,... Confidential !
- Many bugs found triaged as “security critical, severity 1, priority 1”

## Homework

- Follow Klee tutorials 1 and 2  
(<http://klee.github.io/klee/Tutorials.html>)
- Solve The Wolf, Goat and Cabbage problem with Klee

# IA169 System Verification and Assurance

## LTL Model Checking

Jiří Barnat

## Checking Quality

- Testing is incomplete, gives no guarantees of correctness.
- Deductive verification is expensive.

## Typical reasons for system failure after deployment

- Interaction with environment (unexpected input values).
- Interaction with other system components.
- Parallelism (difficult to test).

## Model Checking

- Automated verification process for ...
- ... reactive systems.
- ... parallel/distributed systems.

## Verification of Reactive and Parallel Programs

## Parallel Composition

- Components concurrently contribute to the transformation of a computation state.
- The meaning comes from interleaving of actions (transformation steps) of individual components.

## Meaning Functions Do Not Compose

- Meaning function of a composition cannot be obtain as composition of meaning functions of participating components.
- The result depends on particular interleaving.

## Parallel System

- System:  $(y=x; y++; x=y) \parallel (y=x; y++; x=y)$
- Input-output variable  $x$
- Meaning function of both processes is  $\lambda x \rightarrow x+1$ .
- The composition is:  $(\lambda x \rightarrow x+1) \cdot (\lambda x \rightarrow x+1)$ .
- $(\lambda x \rightarrow x+1) \cdot (\lambda x \rightarrow x+1) 0 = 2$

## Two Different System Runs

- State =  $(x, y_1, y_2)$
- $(0, -, -) \xrightarrow{y_1=x} (0, 0, -) \xrightarrow{y_2=x} (0, 0, 0) \xrightarrow{y_1++} \xrightarrow{x=y_1} (1, 1, 0) \xrightarrow{y_2++} \xrightarrow{x=y_2} (\mathbf{1}, 1, 1)$
- $(0, -, -) \xrightarrow{y_1=x} (0, 0, -) \xrightarrow{y_1++} \xrightarrow{x=y_1} (1, 1, -) \xrightarrow{y_2=x} (1, 1, 1) \xrightarrow{y_2++} \xrightarrow{x=y_2} (\mathbf{2}, 1, 2)$

## Consequence 1

- In general, we cannot deduce correctness of the system from the correctness of its components.

## Consequence 2

- In general, we cannot decompose the problem of checking correctness of the system into subproblems, i.e. to reduce it to the verification of correctness of all the participating system components.

## Problem of Specification

- The number of inputs and the input values are unknown before a particular execution of a reactive system.
- **How to specify the system properties?**

## Examples of Specification

- Events A and B happens before event C.
- User is not allowed to enter a new value until the system processes the previous one.
- Procedure X cannot be executed simultaneously by processes P and Q (mutual exclusion).
- Every action A is immediately followed by a sequence of actions B,C and D.

## Model checking

- Approach to formal verification of systems.
- Based on the system's state-space exploration.
- Requires specification to be given with formulae of temporal logics.

## Assumption

- System properties are described formally using formulae of some temporal logic.

## Turning into Formal Language

- Use of Modal and Temporal Logics.
- Amir Pnueli, 1977

## Model Checking

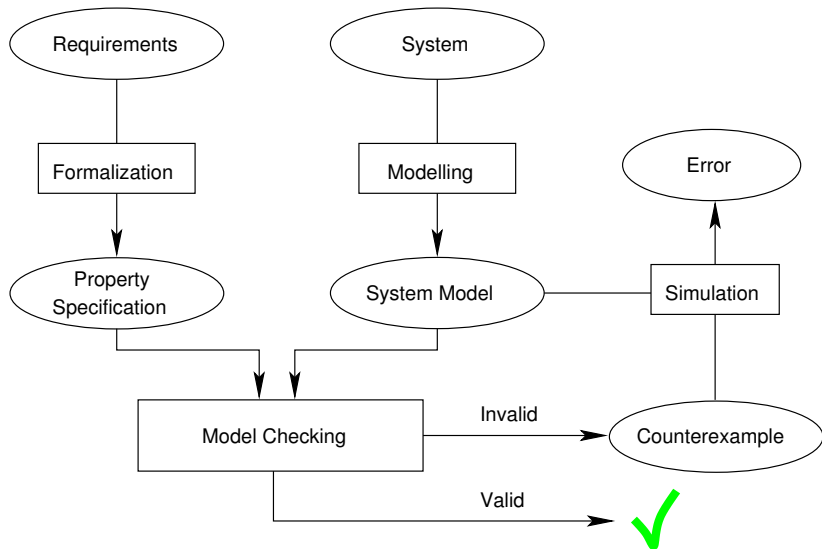

## Model Checking – Overview

- Build a formal model  $\mathcal{M}$  of the system under verification.
- Express specification as a formula  $\varphi$  of selected temporal logic.
- Decide, if  $\mathcal{M} \models \varphi$ . That is, if  $\mathcal{M}$  is a model of formula  $\varphi$ . (Hence the name.)

## Optionally

- As a side effect of the decision a **counterexample** may be produced.
- The counterexample is a sequence of states witnessing violation (in the case the system is erroneous) of the formula.
- **Model checking (the decision process) can be fully automated for all finite (and some infinite) models of systems.**

# Model Checking – Schema

## Model Checkers

- Software tools that can decide validity of a formula over a model of system under verification.
- SPIN, UppAal, SMV, Prism, DIVINE . . .

## Modelling Languages

- Processes described as extended finite state machines.
- Extension allows to use shared or local variables and guard execution of a transition with a Boolean expression.
- Optionally, some transitions may be synchronised with transitions of other finite state machines/processes.

## Modelling and Formalization of Verified Systems

## Reminder

- System can be viewed as a set of states that are walked along by executing instructions of the program.
- State = valuation of modelled variables.

## Atomic Propositions

- Basic statements describing qualities of individual states, for example:  $\max(x, y) \geq 3$ .
- Validity of atomic proposition for a given state must be decidable with information merely encoded by the state.
- Amount of observable events and facts depends on amount of abstraction used during the system modelling.

## Kripke Structure

- Let  $AP$  be a set of atomic propositions.
- Kripke structure is a quadruple  $(S, T, I, s_0)$ , where
  - $S$  is a (finite) set of states,
  - $T \subseteq S \times S$  is a transition relation,
  - $I: S \rightarrow 2^{AP}$  is an interpretation of AP.
  - $s_0 \in S$  is an initial state.

## Kripke Transition System

- Let  $Act$  be a set of instructions executable by the program.
- Kripke structure can be extended with transition labelling to form a Kripke Transitions System.
- Kripke Transition System is a five-tuple  $(S, T, I, s_0, \mathcal{L})$ , where
  - $(S, T, I, s_0)$  is Kripke Structure,
  - $\mathcal{L}: T \rightarrow Act$  is labelling function.

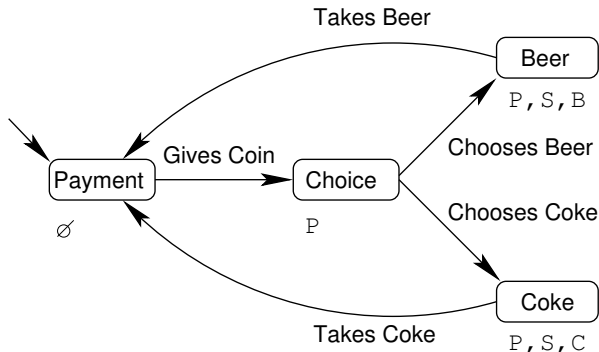

## Kripke Structure

$AP = \{P - \text{Paid}, S - \text{Served}, C - \text{Coke}, B - \text{Beer}\}$

# Kripke Structure – Example

## Kripke Transition System

$AP = \{P - \text{Paid}, S - \text{Served}, C - \text{Coke}, B - \text{Beer}\}$

## Run

- Maximal path (such that it cannot be extended) in the graph induced by Kripke Structure starting at the initial state.
- Let  $M = (S, T, I, s_0)$  be a Kripke structure. Run is a sequence of states  $\pi = s_0, s_1, s_2, \dots$  such that  $\forall i \in \mathbb{N}_0. (s_i, s_{i+1}) \in T$ .

## Finite Paths and Runs

- Some finite path  $\pi = s_0, s_1, s_2, \dots, s_k$  cannot be extended if  $\nexists s_{k+1} \in S. (s_k, s_{k+1}) \in T$ .
- Technically, we will turn maximal finite path into infinite by repeating the very last state.
- Maximal path  $s_0, \dots, s_k$  will be understood as infinite run  $s_0, \dots, s_k, s_k, s_k, \dots$

## Observation

- Usually, Kripke structure that captures system behaviour is not given by full enumeration of states and transitions (explicitly), but it is given by the program source code (implicitly).
- Implicit description tends to be exponentially more succinct.

## State-Space Generation

- Computation of explicit representation from the implicit one.
- Interpretation of implicit representation must be formally precise.

## Practise

- Programming languages do not have precise formal semantics.
- Model checkers often build on top of modelling languages.

# An Example of Modelling Language – DVE

- Finite Automaton
  - States (Locations)
  - Initial state
  - Transitions
  - (Accepting states)
- Transitions Extended with
  - Guards
  - Synchronisation and Value Passing
  - Effect (Assignment)
- Local Variables
  - integer, byte
  - channel

# Example of System Described in DVE Language

```
channel {byte} c[0];
```

```
process A {  
  byte a;  
  state q1,q2,q3;  
  init q1;  
  trans  
  q1→q2 { effect a=a+1; },  
  q2→q3 { effect a=a+1; },  
  q3→q1 { sync c!a; effect a=0; };  
}
```

```
process B {  
  byte b,x;  
  state p1,p2,p3,p4;  
  init p1;  
  trans  
  p1→p2 { effect b=b+1; },  
  p2→p3 { effect b=b+1; },  
  p3→p4 { sync c?x; },  
  p4→p1 { guard x==b; effect b=0, x=0; };  
}
```

```
system async;
```

# Semantics Shown By Interpretation

State:  $[]$ ; A:[q1, a:0]; B:[p1, b:0, x:0]  
0 (0.0): q1  $\rightarrow$  q2 { effect a = a+1; }  
1 (1.0): p1  $\rightarrow$  p2 { effect b = b+1; }

## Formalizing System Properties

## Problem

- How to formally describe properties of a single run?
- How to mechanically check for their satisfaction?

## Solution

- Employ finite automaton as a mechanical observer of run.
- Runs are infinite.
- Finite automata for infinite words ( $\omega$ -regular languages).
- Büchi acceptance condition – automaton accepts a word if it passes through an accepting state infinitely many often.

## Büchi automata

- Büchi automaton is a tuple  $A = (\Sigma, S, s, \delta, F)$ , where
  - $\Sigma$  is a finite set of symbols,
  - $S$  is a finite set of states,
  - $s \in S$  is an initial state,
  - $\delta : S \times \Sigma \rightarrow 2^S$  is transition relation, and
  - $F \subseteq S$  is a set of accepting states.

## Language accepted by a Büchi automaton

- Run  $\rho$  of automaton  $A$  over infinite word  $w = a_1 a_2 \dots$  is a sequence of states  $\rho = s_0, s_1, \dots$  such that  $s_0 \equiv s$  and  $\forall i : s_i \in \delta(s_{i-1}, a_i)$ .
- $\text{inf}(\rho)$  – Set of states that appear infinitely many times in  $\rho$ .
- Run  $\rho$  is accepting if and only if  $\text{inf}(\rho) \cap F \neq \emptyset$ .
- Language accepted with an automaton  $A$  is a set of all words for which an accepting run exists. Denoted as  $L(A)$ .

## Observation

- Let  $AP = \{X, Y, Z\}$ .
- Transition labelled with  $\{X\}$  denotes that  $X$  must hold true upon execution of the transition, while  $Y$  and  $Z$  are false.
- If we want to express that  $X$  is true,  $Z$  is false, and for  $Y$  we do not care, we have to create two transitions labelled with  $\{X\}$  and  $\{X, Y\}$ .

## APs as Boolean Formulae

- Transitions between the two same states may be combined and labelled with a Boolean formula over atomic propositions.

## Example

- Transitions  $\{X\}$ ,  $\{Y\}$ ,  $\{X, Y\}$ ,  $\{X, Z\}$ ,  $\{Y, Z\}$  a  $\{X, Y, Z\}$  can be combined into a single one labelled with  $X \vee Y$ .
- If there are no restrictions upon execution of the transition, it may be labelled with  $true \equiv X \vee \neg X$ .

## System

- Vending machine as seen before.
- $\Sigma = 2^{\{P,S,C,B\}}$ ,
- $Paid = \{A \in \Sigma \mid P \in A\}$ ,  $Served = \{A \in \Sigma \mid S \in A\}$ , ...

## Express the following properties

- Vending machine serves at least one drink.
- Vending machine serves at least one coke.
- Vending machine serves infinitely many drinks.
- Vending machine serves infinitely many beers.
- Vending machine does not serve a drink without being paid.
- After being paid, vending machine always serve a drink.

## Linear Temporal Logic

## Formula $\varphi$

- Is evaluated on top of a single run of Kripke structure.
- Express validity of APs in the states along the given run.

## Temporal Operators of LTL

- $F\varphi$  —  $\varphi$  holds true eventually (Future).
- $G\varphi$  —  $\varphi$  holds true all the time (Globally).
- $\varphi U\psi$  —  $\varphi$  holds true until eventually  $\psi$  holds true (Until).
- $X\varphi$  —  $\varphi$  is valid after execution of one transition (Next).
- $\varphi R\psi$  —  $\psi$  holds true until  $\varphi \wedge \psi$  holds true (Release).
- $\varphi W\psi$  — until, but  $\psi$  may never become true (Weak Until).

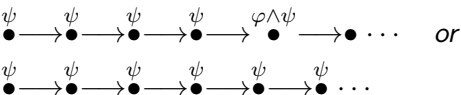

# Graphical Representation of LTL Temporal Operators

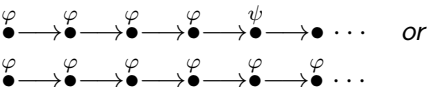

$X\varphi$  : 

$\varphi U \psi$  : 

$F\varphi$  : 

$G\varphi$  : 

$\varphi R \psi$  :  or

$\varphi W \psi$  :  or

Let  $AP$  be a set of atomic propositions.

- If  $p \in AP$ , then  $p$  is an LTL formula.
- If  $\varphi$  is an LTL formula, then  $\neg\varphi$  is an LTL formula.
- If  $\varphi$  and  $\psi$  are LTL formulae, then  $\varphi \vee \psi$  is an LTL formula.
- If  $\varphi$  is an LTL formula, then  $X\varphi$  is an LTL formula.
- If  $\varphi$  and  $\psi$  are LTL formulae, then  $\varphi U\psi$  is an LTL formula.

Alternatively

$$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid X\varphi \mid \varphi U\varphi$$

## Propositional Logic

- $\varphi \wedge \psi \equiv \neg(\neg\varphi \vee \neg\psi)$
- $\varphi \Rightarrow \psi \equiv \neg\varphi \vee \psi$
- $\varphi \Leftrightarrow \psi \equiv (\varphi \Rightarrow \psi) \wedge (\psi \Rightarrow \varphi)$

## Temporal operators

- $F\varphi \equiv \text{true } U \varphi$
- $G\varphi \equiv \neg F \neg\varphi$
- $\varphi R \psi \equiv \neg(\neg\varphi U \neg\psi)$
- $\varphi W \psi \equiv \varphi U \psi \vee G\varphi$

## Alternative syntax

- $F\varphi \equiv \diamond\varphi$
- $G\varphi \equiv \square\varphi$
- $X\varphi \equiv \circ\varphi$

## Model of an LTL formula

- Let  $AP$  be a set of atomic propositions.
- Model of an LTL formula is a run  $\pi$  of Kripke structure.

## Notation

- Let  $\pi = s_0, s_1, s_2, \dots$
- Suffix of run  $\pi$  starting at  $s_k$  is denoted as  $\pi^k = s_k, s_{k+1}, s_{k+2}, \dots$
- $k$ -th state of the run, is referred to as  $\pi(k) = s_k$ .

## Assumptions

- Let  $AP$  be a set of atomic propositions.
- Let  $\pi$  be a run of Kripke structure  $M = (S, T, I, s_0)$ .
- Let  $\varphi, \psi$  be syntactically correct LTL formulae.
- Let  $p \in AP$  denote atomic proposition.

## Semantics

$$\begin{aligned}\pi \models p & \text{ iff } p \in I(\pi(0)) \\ \pi \models \neg\varphi & \text{ iff } \pi \not\models \varphi \\ \pi \models \varphi \vee \psi & \text{ iff } \pi \models \varphi \text{ or } \pi \models \psi \\ \pi \models X\varphi & \text{ iff } \pi^1 \models \varphi \\ \pi \models \varphi U\psi & \text{ iff } \exists k. 0 \leq k, \pi^k \models \psi \text{ and} \\ & \forall i. 0 \leq i < k, \pi^i \models \varphi\end{aligned}$$

# Semantics of Other Temporal Operators

$$\pi \models F \varphi \quad \text{iff} \quad \exists k. k \geq 0, \pi^k \models \varphi$$

$$\pi \models G \varphi \quad \text{iff} \quad \forall k. k \geq 0, \pi^k \models \varphi$$

$$\begin{aligned} \pi \models \varphi R \psi \quad \text{iff} \quad & (\exists k. 0 \leq k, \pi^k \models \varphi \wedge \psi \text{ and} \\ & \forall i. 0 \leq i < k, \pi^i \models \psi) \\ & \text{or } (\forall k. k \geq 0, \pi^k \models \psi) \end{aligned}$$

$$\begin{aligned} \pi \models \varphi W \psi \quad \text{iff} \quad & (\exists k. 0 \leq k, \pi^k \models \psi \text{ and} \\ & \forall i. 0 \leq i < k, \pi^i \models \varphi) \\ & \text{or } (\forall k. k \geq 0, \pi^k \models \varphi) \end{aligned}$$

## Verification Employing LTL

- System is viewed as a set of runs.
- System satisfies LTL formula if and only if all system runs satisfy the formula.
- In other words, any run violating the formula is a witness that the system does not satisfy the formula.

## Lemma

- If a finite state system does not satisfy an LTL formula then this may be witnessed with a **lasso-shaped** run.
- Run  $\pi$  is lasso-shaped if  $\pi = \pi_1 \cdot (\pi_2)^\omega$ , where
$$\pi_1 = s_0, s_1, \dots, s_k$$
$$\pi_2 = s_{k+1}, s_{k+2}, \dots, s_{k+n}, \text{ where } s_k \equiv s_{k+n}.$$
- Note that  $\pi^\omega$  denotes infinite repetition of  $\pi$ .

## Homework

- Model Peterson's mutual exclusion protocol in ProMeLa.
- State expected LTL properties of Peterson's protocol.
- Verify them using SPIN model checker.

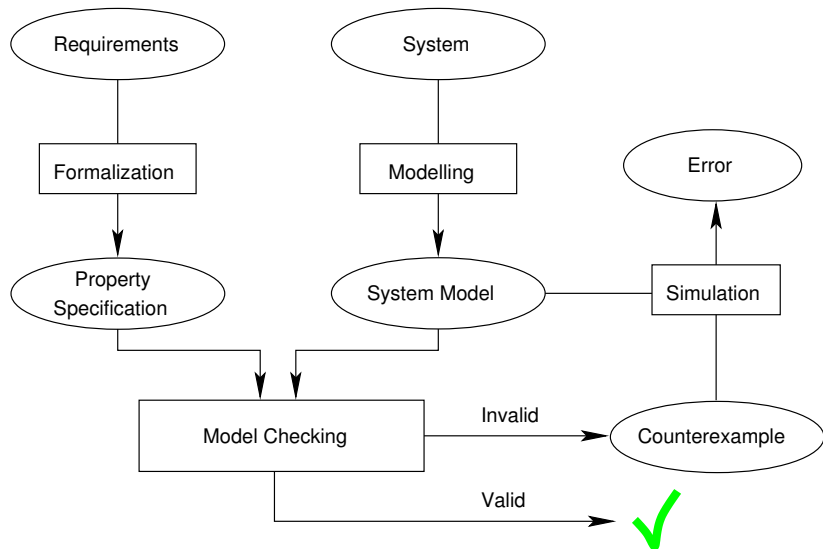

# IA169 System Verification and Assurance

## LTL Model Checking (continued)

Jiří Barnat

# Model Checking – Schema

## Property Specification

- English text.
- Formulae of Linear Temporal Logic.

## System Description

- Source code in programming language.
- Source code in modelling language.
- Kripke structure representing the state space.

## Problem

- Kripke structure  $M$
- LTL formula  $\varphi$
- $M \models \varphi$  ?

## Automata-Based Approach to LTL Model Checking

## Observation One

- System is a set of (infinite) runs.
- Also referred to as formal language of infinite words.

## Observation Two

- Two different runs are equal with respect to an LTL formula if they agree in the interpretation of atomic propositions (need not agree in the states).
- Let  $\pi = s_0, s_1, \dots$ , then  $I(\pi) \stackrel{def}{\iff} I(s_0), I(s_1), I(s_2), \dots$

## Observation Three

- Every run either satisfies an LTL formula, or not.
- Every LTL formula defines a set of satisfying runs.

## Reformulation as Language Problem

- Let  $\Sigma = 2^{AP}$  be an alphabet.
- Language  $L_{sys}$  of all runs of system  $M$  is defined as follows.

$$L_{sys} = \{I(\pi) \mid \pi \text{ is a run in } M\}.$$

- Language  $L_\varphi$  of runs satisfying  $\varphi$  is defined as follows.

$$L_\varphi = \{I(\pi) \mid \pi \models \varphi\}.$$

## Observation

$$M \models \varphi \iff L_{sys} \subseteq L_\varphi$$

## Theorem

- For every LTL formula  $\varphi$  we can construct Büchi automaton  $A_\varphi$  such that  $L_\varphi = L(A_\varphi)$ .

[Vardi and Wolper, 1986]

## Theorem

- For every Kripke structure  $M = (S, T, I, s_0)$  we can construct Büchi automaton  $A_{sys}$  such that  $L_{sys} = L(A_{sys})$ .

## Construction of $A_{sys}$

- Let  $AP$  be a set of atomic propositions.
- Then  $A_{sys} = (S, 2^{AP}, s_0, \delta, S)$ , where  $q \in \delta(p, a)$  if and only if  $(p, q) \in T \wedge I(p) = a$ .

## Property Specification

- English text.
- Formulae  $\varphi$  of Linear Temporal Logic.
- Buchi automaton accepting  $L_\varphi$ .

## System Description

- Source code in programming language.
- Source code in modelling language.
- Kripke structure  $M$  representing the state space.
- Buchi automaton accepting  $L_{sys}$ .

## Problem Reformulation

- $M \models \varphi \iff L_{sys} \subseteq L_\varphi$

## Notation

- $co-L$  denotes complement of  $L$  with respect to  $\Sigma^{AP}$ .

## Lemma

- $co-L(A_\varphi) = L(A_{\neg\varphi})$  for every LTL formula  $\varphi$ .

## Reduction of $M \models \varphi$ to the emptiness of $L(A_{sys} \times A_{\neg\varphi})$

- $M \models \varphi \iff L_{sys} \subseteq L_\varphi$
- $M \models \varphi \iff L(A_{sys}) \subseteq L(A_\varphi)$
- $M \models \varphi \iff L(A_{sys}) \cap co-L(A_\varphi) = \emptyset$
- $M \models \varphi \iff L(A_{sys}) \cap L(A_{\neg\varphi}) = \emptyset$
- $M \models \varphi \iff L(A_{sys} \times A_{\neg\varphi}) = \emptyset$

## Theorem

- Let  $A = (S_A, \Sigma, s_A, \delta_A, F_A)$  and  $B = (S_B, \Sigma, s_B, \delta_B, F_B)$  be Büchi automata over the same alphabet  $\Sigma$ . Then we can construct Büchi automaton  $A \times B$  such that  $L(A \times B) = L(A) \cap L(B)$ .

## Construction of $A \times B$

- $A \times B = (S_A \times S_B \times \{0, 1\}, \Sigma, (s_A, s_B, 0), \delta_{A \times B}, F_A \times S_B \times \{0\})$
- $(p', q', j) \in \delta_{A \times B}((p, q, i), a)$  for all
  - $p' \in \delta_A(p, a)$
  - $q' \in \delta_B(q, a)$
  - $j = (i + 1) \bmod 2$  if  $(i = 0 \wedge p \in F_A) \vee (i = 1 \wedge q \in F_B)$
  - $j = i$  otherwise

## Observation

- For the purpose of LTL model checking, we do not need general synchronous product of Büchi automata, since Büchi automaton  $A_{sys}$  is constructed in such a way that  $F_A = S_A$ , i.e. it has all states accepting.
- For such a special case the construction of product automata can be significantly simplified.

## Construction of $A \times B$ when $F_A = S_A$

- $A \times B = (S_A \times S_B, \Sigma, (s_A, s_B), \delta_{A \times B}, S_A \times F_B)$
- $(p', q') \in \delta_{A \times B}((p, q), a)$  for all
  - $p' \in \delta_A(p, a)$
  - $q' \in \delta_B(q, a)$

## Observation

- Any finite automaton may visit accepting state infinitely many times only if it contains a cycle through that accepting state.

## Decision Procedure for $M \models \varphi$ ?

- Build a product automaton  $(A_{sys} \times A_{\neg\varphi})$ .
- Check the automaton for presence of an accepting cycle.
- If there is a reachable accepting cycle then  $M \not\models \varphi$ .
- Otherwise  $M \models \varphi$ .

## Detection of Accepting Cycles

## Reachability in Directed Graph

- Depth-first or breadth-first search algorithm.
- $\mathcal{O}(|V| + |E|)$ .

## Algorithmic Solution to Accepting Cycle Detection

- Compute the set of accepting states in time  $\mathcal{O}(|V| + |E|)$ .
- Detect self-reachability for every accepting state in  $\mathcal{O}(|F|(|V| + |E|))$ .
- Overall time  $\mathcal{O}(|V| + |E| + |F|(|V| + |E|))$ .

## Can we do better?

- Yes, with **Nested DFS** algorithm in  $\mathcal{O}(|V| + |E|)$ .

# Depth-First Search Procedure

```
proc Reachable( $V, E, v_0$ )
  Visited =  $\emptyset$ 
  DFS( $v_0$ )
  return (Visited)
end

proc DFS(vertex)
  if vertex  $\notin$  Visited
    then /* Visits vertex */
      Visited := Visited  $\cup$  {vertex}
      foreach {  $v \mid (vertex, v) \in E$  } do
        DFS( $v$ )
      od
      /* Backtracks from vertex */
    fi
  fi
```

## Observation

- When running DFS on a graph all vertices can be classified into one of the three following categories (denoted with colours).

## Colour Notation for Vertices

- White vertex – Has not been visited yet.
- Gray vertex - Visited, but yet not backtracked.
- Black vertex - Visited and backtracked.

## Recursion Stack

- Gray vertices form a path from the initial vertex to the vertex that is currently processed by the outer procedure.

## Observation

- If two distinct vertices  $v_1, v_2$  satisfy that
  - $(v_0, v_1) \in E^*$ ,
  - $(v_1, v_1) \notin E^+$ ,
  - $(v_1, v_2) \in E^+$ .
- Then procedure  $DFS(v_0)$  backtracks from vertex  $v_2$  before it backtracks from vertex  $v_1$ .

## DFS post-order

- If  $(v, v) \notin E^+$  and  $(v_0, v) \in E^*$ , then upon the termination of sub-procedure  $DFS(v)$ , called within procedure  $DFS(v_0)$ , all vertices  $u$  such that  $(v, u) \in E^+$  are visited and backtracked.

## Observation

- If a sub-graph reachable from a given accepting vertex does not contain accepting cycle, then no accepting cycle starting in an accepting state outside the sub-graph can reach the sub-graph.

## The Key Idea

- Execute the inner procedures in a bottom-up manner.
- The inner procedures are called in the same order in which the outer procedure backtracks from accepting states, i.e. the ordering of calls follows a DFS post-order.

# Detection of Accepting Cycles in $\mathcal{O}(|V| + |E|)$

```
proc Detection_of_accepting_cycles
  Visited :=  $\emptyset$ 
  DFS( $v_0$ )
end
```

```
proc DFS(vertex)
  if (vertex)  $\notin$  Visited
  then Visited := Visited  $\cup$  {vertex}
  foreach {s | (vertex,s)  $\in$  E} do
    DFS(s)
  od
  if IsAccepting(vertex)
  then DetectCycle(vertex)
  fi
fi
end
```

## Assumption On Early Termination

- The inner procedure reports the accepting cycle and terminates the whole algorithm if called for an accepting vertex that lies on an accepting cycle.

## Consequences

- If the inner procedure called for an accepting vertex  $v$  reports no accepting cycle, then there is no accepting cycle in the graph reachable from vertex  $v$ .

## Linear Complexity of Nested DFS Algorithm

- Employing DFS post-order it follows that vertices that have been visited by previous invocation of inner procedure may be safely skipped in any later invocation of the inner procedure.

## $\mathcal{O}(|V| + |E|)$ Algorithm

- 1) Nested procedures are called in DFS post-order as given by the outer procedure, and are limited to vertices not yet visited by inner procedure.
- 2) All vertices are visited at most twice.

## Theorem

- If the immediate successor to be processed by an inner procedure is grey (on the stack of the outer procedure), then the presence of an accepting cycle is guaranteed.

## Application

- It is enough to reach a vertex on the stack of the outer procedure in the inner procedure in order to report the presence of an accepting cycle.

# $O(|V| + |E|)$ Algorithm

```
proc Detection_of_accepting_cycles
  Visited := Nested := in_stack :=  $\emptyset$ 
  DFS( $v_0$ )
  Exit("Not Present")
end
```

```
proc DFS(vertex)
  if (vertex)  $\notin$  Visited
    then Visited := Visited  $\cup$  {vertex}
    in_stack := in_stack  $\cup$  {vertex}
    foreach {s | (vertex,s)  $\in$  E} do
      DFS(s)
    od
    if IsAccepting(vertex)
      then DetectCycle(vertex)
    fi
    in_stack := in_stack  $\setminus$  {vertex}
  fi
end
```

```
proc DetectCycle (vertex)
  if vertex  $\notin$  Nested
    then Nested := Nested  $\cup$  {vertex}
    foreach {s | (vertex,s)  $\in$  E} do
      if s  $\in$  in_stack
        then WriteOut(in_stack)
        Exit("Present")
      else DetectCycle(s)
    fi
  od
fi
end
```

## Outer Procedure

- Time:  $\mathcal{O}(|V| + |E|)$
- Space:  $\mathcal{O}(|V|)$

## Inner Procedures

- Time (overall):  $\mathcal{O}(|V| + |E|)$
- Space:  $\mathcal{O}(|V|)$

## Complexity

- Time:  $\mathcal{O}(|V| + |E| + |V| + |E|) = \mathcal{O}(|V| + |E|)$
- Space:  $\mathcal{O}(|V| + |V|) = \mathcal{O}(|V|)$

# Nested DFS – Example

- 1st DFS: A,B,D,B,G,F,H,H,F,G  
1st DFS stack: A,B,D,G  
visited: A,B,D,F,G,H / –
- 2nd DFS: G,F,H,H,F,G  
visited: A,B,D,F,G,H / F,G,H
- 1st DFS: G,D,B,C,E,C,G,E,F,C  
1st DFS stack: A,C  
visited: all / F,G,H
- 2nd DFS: C,E,C  
counterexample: A,C,E,C

visited state    backtrack non-accepting state    backtrack accepting state

## Classification of Büchi Automata

## Terminal Büchi Automata

- All accepting cycles are self-loops on accepting states labelled with `true`.

## Weak Büchi Automata

- Every strongly connected component of the automaton is composed either of accepting states, or of non-accepting states.

## Automaton $A_{\neg\varphi}$

- For a number of LTL formulae  $\varphi$ ,  $A_{\neg\varphi}$  is terminal or weak.
- $A_{\neg\varphi}$  is typically quite small.
- Type of  $A_{\neg\varphi}$  can be pre-computed prior verification.
- Types of components of  $A_{\neg\varphi}$ 
  - **Non-accepting** – Contains no accepting cycles.
  - **Strongly accepting** – Every cycle is accepting.
  - **Partially accepting** – Some cycles are accepting and some are not.

## Product Automaton

- The graph to be analysed is a graph of product automaton  $A_S \times A_{\neg\varphi}$ .
- Types of components of  $A_S \times A_{\neg\varphi}$  are given by the corresponding components of  $A_{\neg\varphi}$ .

## $A_{\neg\varphi}$ is terminal Büchi automaton

- For the proof of existence of accepting cycle it is enough to proof reachability of any state that is accepting in  $A_{\neg\varphi}$  part.
- Verification process is reduced to the reachability problem.

## „Safety” Properties

- Those properties  $\varphi$  for which  $A_{\neg\varphi}$  is a terminal BA.
- Typical phrasing: „Something bad never happens.”
- Reachability is enough to proof the property.

## $A_{\neg\varphi}$ is weak Büchi automaton

- Contains no partially accepting components.
- For the proof of existence of accepting cycle it is enough to proof existence of reachable cycle in a strongly accepting component.
- Can be detected with a single DFS procedure.
- Time-optimal algorithm exists that does not rely on DFS.

## „Weak” LTL Properties

- Those properties  $\varphi$  for which  $A_{\neg\varphi}$  is a weak BA.
- Typically, responsiveness:  $G(a \implies F(b))$ .

## Classification

- Every LTL formula belongs to one of the following classes:  
Reactivity, Recurrence, Persistence, Obligation, Safety, Guarantee

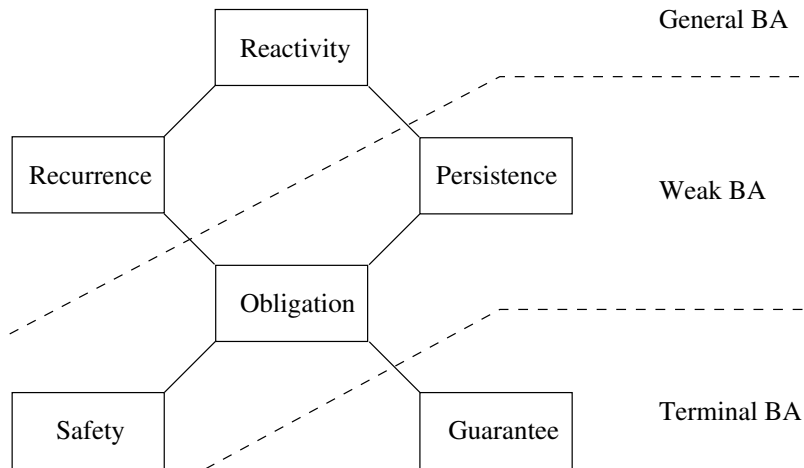

## Interesting Relations

- **Guarantee** class properties can be described with a terminal Büchi automaton.
- **Persistence**, **Obligation**, and **Safety** class properties can be described with a weak Büchi automaton.

## Negation in Verification Process ( $\varphi \mapsto A_{\neg\varphi}$ )

- $\varphi \in \text{Safety} \iff \neg\varphi \in \text{Guarantee}.$
- $\varphi \in \text{Recurrence} \iff \neg\varphi \in \text{Persistence}.$

# Classification of LTL Properties

## Fighting State Space Explosion

## What is State Space Explosion

- System is usually given as a **composition of parallel processes**.
- Depending on the order of execution of actions of parallel processes various intermediate states emerge.
- The number of reachable states may be up to exponentially larger than the number of lines of code.

## Consequence

- Main memory cannot store all states of the product automaton as they are too many.
- Algorithms for accepting cycle detection suffer for lack of memory.

## State Compression

- Lossless compression.
- Lossy compression – Heuristics.

## On-The-Fly Verification

## Symbolic Representation of State Space

## Reduced Number of States of the Product Automaton

- Introduction of atomic blocks.
- Partial order on execution of process actions.
- Avoid exploration of symmetric parts.

## Parallel and Distributed Verification

## Observation

- Product automaton graph is defined implicitly with:
  - $|F|_{init}()$  — Returns initial state of automaton.
  - $|F|_{succs}(s)$  — Gives immediate successors of a given state.
  - $|Accepting|(s)$  — Gives whether a state is accepting or not.

## On-The-Fly Verification

- Some algorithms may detect the presence of accepting cycle without the need of complete exploration of the graph.
- Hence,  $\mathcal{M} \models \varphi$  can be decided without the full construction of  $A_{sys} \times A_{\neg\varphi}$ .
- This is referred to as **on-the-fly** verification.

## Example

- Consider a system made of processes  $A$  and  $B$ .
- $A$  can do a single action  $\alpha$ , while  $B$  is a sequence of actions  $\beta$ , e.g.  $\beta_1, \dots, \beta_m$ .

## Unreduced State Space:

**Property to be verified: Reachability of state  $r$ .**

## Observation

- Runs  $(\alpha\beta_1\beta_2 \dots \beta_m)$ ,  $(\beta_1\alpha\beta_2 \dots \beta_m)$ ,  $\dots$ ,  $(\beta_1\beta_2 \dots \beta_m\alpha)$  are equivalent with respect to the property.
- It is enough to consider only a representative from the equivalence class, say, e.g.  $(\beta_1\beta_2 \dots \beta_m\alpha)$ .

- The representative is obtained by postponing of action  $\alpha$ .

## Reduction Principle

- Do not consider all immediate successor during state space exploration, but pick carefully only some of them.
- Some states are never generated, which results in a smaller state space graph.

## Technical Realisation

- To pick correct but optimal subset of successors is as difficult as to generate the whole state space. Hence, heuristics are used.
- The reduced state space must contain an accepting cycle if and only if the unreduced state space does so.
- LTL formula must not use  $X$  operator (subclass of *LTL*).

## Principle

- Employ aggregate power of multiple CPUs.
- Increased memory and computing power.

## Problem of Nested DFS

- Typical implementation relies on hashing mechanism, hence, the main memory is accessed extremely randomly. Should memory demands exceeds the amount of available memory, **thrashing** occurs.
- Mimicking serial Nested DFS algorithm in a distributed-memory setting is extremely slow. (Token-based approach).
- It is unknown whether the DFS post-order can be computed by a time-optimal scale-able parallel algorithm (Still an open problem.)

## Observation

- Instead of DFS other graph procedures are used.
- Tasks such as breadth-first search, or value propagation can be efficiently computed in parallel.
- Parallel algorithms do not exhibit optimal complexity.

	Complexity	Optimal	On-The-Fly
<b>Nested DFS</b>	$O(V+E)$	Yes	Yes
<b>OWCTY</b>			
general Büchi automata	$O(V.(V+E))$	No	No
weak Büchi automata	$O(V+E)$	Yes	No
<b>MAP</b>	$O(V.V.(V+E))$	No	Partially
<b>OWCTY+MAP</b>

weak Büchi automata	$O(V+E)$	Yes	Partially

## Model Checking – Summary

## Properties Validity

- Property to be verified may be violated by a single particular (even extremely unlikely) run of the system under inspection.
- The decision procedure relies on exploration of state space graph of the system.

## State Space Explosion

- Unless there are other reasons, all system runs have to be considered.
- The **number of states**, that system can reach is up to **exponentially larger** than the size of the system description.
- Reasons: Data explosion, asynchronous parallelism.

## General Technique

- Applicable to Hardware, Software, Embedded Systems, Model-Based Development, ...

## Mathematically Rigorous Precision

- The decision procedure results with  $\mathcal{M} \models \varphi$ , if and only if, it is the case.

## Tool for Model Checking – Model Checkers

- The so called "Push-Button" Verification.
- No human participation in the decision process.
- Provides users with witnesses and counterexamples.

## Not Suitable for Everything

- Not suitable to show that a program for computing factorial really computes  $n!$  for a given  $n$ .
- Though it is perfectly fine to check that for a value of 5 it always returns the value of 120.

## Often Relies on Modelling

- Need for model construction.
- Validity of a formula is guaranteed for the model, not the modelled system.

## Size of the State Space

- Applicable mostly to system with finite state space.
- Due to state space explosion, practical applicability is limited.

## Verifies Only What Has Been Specified

- Issues not covered with formulae need not be discovered.

## Homework

- Analysis with DIVINE model checker on a more complex example (some homework from previous course on secure coding).

# IA169 System Verification and Assurance

## CTL Model Checking

Jiří Barnat

## **Pnueli, 1977**

- System is viewed as a set of state sequences — **Runs**.
- System properties are given as properties of runs,
- ... and can be described with a linear-time logic.

## **Clarke & Emerson, 1980**

- System is viewed as a branching structure of possible executions from individual system states — **Computation Tree**.
- System properties are given as properties of the tree,
- ... and can be described with a branching-time logic.

# System and Computation Tree

## Computation Tree Logic (CTL)

## Possible Future Computations

- For a given node of a computation tree, the sub-tree rooted in the given node describes all possible runs the system can still take.
- Every such a run is possible future computation.

## CTL Formulae Allow For

- Specification of state qualities with atomic propositions.
- Quantify over possible future computations.
- Restrict the set of possible future computations with (quantified) LTL operators.

## Example

- $\varphi \equiv EF(a)$
- It is possible to take a future computation such that  $a$  will hold true in the computation eventually.

Let  $AP$  be a set of atomic propositions.

- If  $p \in AP$ , then  $p$  is a CTL formula.
- If  $\varphi$  is a CTL formula, then  $\neg\varphi$  is a CTL formula.
- If  $\varphi$  and  $\psi$  are CTL formulae, then  $\varphi \vee \psi$  is a CTL formula.
- If  $\varphi$  is a CTL formula, then  $EX \varphi$  is a CTL formula.
- If  $\varphi$  and  $\psi$  are CTL formulae, then  $E[\varphi U \psi]$  is a CTL formula.
- If  $\varphi$  and  $\psi$  are CTL formulae, then  $A[\varphi U \psi]$  is a CTL formula.

Alternatively (Backus-Naur Form)

$$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid EX \varphi \mid E[\varphi U \varphi] \mid A[\varphi U \varphi]$$

## Already Known

- The standard shortcuts from the propositional logic.
- Syntactic shortcuts from LTL
  - $F \varphi \equiv true U \varphi$
  - $G \varphi \equiv \neg F \neg \varphi$

## Deduced CTL Operators

- $EF \varphi \equiv E[true U \varphi]$
- $AF \varphi \equiv A[true U \varphi]$
- $EG \varphi \equiv \neg AF \neg \varphi$
- $AG \varphi \equiv \neg EF \neg \varphi$
- $AX \varphi \equiv \neg EX \neg \varphi$

## Model of a CTL formula

- Let  $AP$  be a set of atomic propositions.
- Model of a CTL formula is a state  $s \in S$  of Kripke structure  $M = (S, T, I, s_0)$ .

## Reminder

- Run of a Kripke structure is maximal path starting at the initial state of the structure.
- Finite maximal paths are viewed as infinite runs due to infinite repetition of the last state on the path.

## Notation

- Let  $s \in S$  be a state of Kripke structure  $M = (S, T, I, s_0)$ .
- $P_M(s) = \{\pi \mid \pi \text{ is a run initiated at state } s\}$

## Assumptions

- Let  $AP$  be a set of atomic propositions.
- Let  $p \in AP$  be an atomic proposition.
- Let  $s \in S$  be a state of Kripke structure  $M = (S, T, I, s_0)$ .
- Let  $\varphi, \psi$  denote syntactically correct CTL formulae.

## Semantics

$$s \models p \quad \text{iff} \quad p \in I(s)$$

$$s \models \neg\varphi \quad \text{iff} \quad \neg(s \models \varphi)$$

$$s \models \varphi \vee \psi \quad \text{iff} \quad s \models \varphi \text{ or } s \models \psi$$

$$s \models EX \varphi \quad \text{iff} \quad \exists \pi \in P_M(s). \pi(1) \models \varphi$$

$$s \models E[\varphi U \psi] \quad \text{iff} \quad \exists \pi \in P_M(s). (\exists k \geq 0. (\pi(k) \models \psi \text{ and} \\ \forall 0 \leq i < k. \pi(i) \models \varphi))$$

$$s \models A[\varphi U \psi] \quad \text{iff} \quad \forall \pi \in P_M(s). (\exists k \geq 0. (\pi(k) \models \psi \text{ and} \\ \forall 0 \leq i < k. \pi(i) \models \varphi))$$

## Atomic Propositions

- $AP = \{a, b, Req, Ack, Restart\}$

## Express with CTL Formulae

- A state where  $a$  is true, but  $b$  is not, is reachable.
- Whenever system receives a request  $Req$ , it generates acknowledgement  $Ack$  eventually.
- In every run there are infinitely many  $b$ 's.
- There is always an option to reset the system (reach state  $Restart$ ).

## Model Checking CTL

## Model Checking CTL

- Let  $M = (S, T, I, s_0)$  be a Kripke structure.
- Let  $\varphi$  be a CTL formula.
- Does initial state of  $M$  satisfies  $\varphi$ ?

## Alternatively

- Let  $M = (S, T, I, s_0)$  be a Kripke structure.
- Let  $\varphi$  be a CTL formula.
- Compute a set of states of  $M$  satisfying  $\varphi$ .

## Above mentioned approaches are also referred to as to

- Local model checking problem —  $M, s_0 \models \varphi$ .
- Global model checking problem —  $\{s \mid M, s \models \varphi\}$ .

## Observation

- If the validity of formulae  $\varphi$  and  $\psi$  is known for all states, it is easy to deduce validity of formulae  $\neg\varphi$ ,  $\varphi \vee \psi$ ,  $EX \varphi$ ,  $\dots$

## CTL Model Checking – Sketch

- Let  $M = (S, T, I)$  be a Kripke structure and  $\varphi$  a CTL Formula.
- A labelling function  $label : S \rightarrow 2^{2^\varphi}$  is computed such that it gives validity of all sub-formulae of  $\varphi$  for all states of Kripke structure  $M$ .
- Obviously,  $s_0 \models \varphi \iff \varphi \in label(s_0)$ .
- Function  $label$  is computed gradually for individual sub-formulae of  $\varphi$ , starting with the simplest sub-formula and proceeding towards more complex sub-formulae, ending with  $\varphi$  itself.

## Sub-formulae of formula $\varphi$

- Let  $\varphi$  be a CTL formula.
- The set of all sub-formulae of formula  $\varphi$  is denoted by  $2^\varphi$ .
- $2^\varphi$  is defined inductively according to the structure of  $\varphi$ .

## Inductive Definition of $2^\varphi$

- 1)  $\varphi \in 2^\varphi$  ( $\varphi$  is a sub-formula of  $\varphi$ )
- 2) If  $\eta \in 2^\varphi$  and
  - $\eta \equiv \neg\psi$ , then  $\psi \in 2^\varphi$
  - $\eta \equiv \psi_1 \vee \psi_2$ , then  $\psi_1, \psi_2 \in 2^\varphi$
  - $\eta \equiv EX \psi$ , then  $\psi \in 2^\varphi$
  - $\eta \equiv E[\psi_1 U \psi_2]$ , then  $\psi_1, \psi_2 \in 2^\varphi$
  - $\eta \equiv A[\psi_1 U \psi_2]$ , then  $\psi_1, \psi_2 \in 2^\varphi$
- 3) Nothing else.

## Observation

- It is easier to prove validity of existential quantified modal operators than validity of universally quantified ones.
- For the purpose of verification of CTL-specified properties, it is possible to express the CTL formula in an equivalently expressive existential form of CTL.

## Equivalent CTL Syntax

- $\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid EX\varphi \mid E[\varphi U \varphi] \mid EG\varphi$

## Task

- Express formula  $EG\varphi$  in the original syntax of CTL.
- Give accordingly modified definition of the set of sub-formulae of  $\varphi$  for the above mentioned equivalent syntax.

# Algorithm for CTL Model-Checking

INPUT: Kripke structure  $M = (S, T, I, s_0)$ , CTL formula  $\varphi$ .

OUTPUT: *True*, if  $s_0 \models \varphi$ ; *False* otherwise.

```
proc CTLMC( $\varphi, M$ )
  label := I
  Solved := AP  $\cap$   $2^\varphi$ 
  while  $\varphi \notin$  Solved do
    foreach (  $\eta \in \{\neg\psi_1, \psi_1 \vee \psi_2, EX \psi_1, E[\psi_1 U \psi_2], EG \psi_1 \mid \psi_1, \psi_2 \in$  Solved $\}$ ) do
      if ( $\eta \in 2^\varphi$  and  $\eta \notin$  Solved)
        then label := updateLabel( $\eta, label, M$ )
           Solved := Solved  $\cup$   $\{\eta\}$ 
        fi
      od
    od
  return ( $\varphi \in label(s_0)$ )
end
```

```
proc updateLabel( $\eta$ , label, M)
  if ( $\eta \equiv E[\psi_1 U \psi_2]$ )
    then return checkEU( $\psi_1, \psi_2$ , label, M)
  fi
  if ( $\eta \equiv EG \psi$ )
    then return checkEG( $\psi$ , label, M)
  fi
  foreach ( s  $\in$  S)do
    if ( $\eta \equiv \neg\psi$  and  $\psi \notin \text{label}(s)$ ) or
      ( $\eta \equiv \psi_1 \vee \psi_2$  and ( $\psi_1 \in \text{label}(s) \vee \psi_2 \in \text{label}(s)$ )) or
      ( $\eta \equiv EX \psi$  and ( $\exists t \in \{t \mid (s, t) \in T\}$  such that  $\psi \in \text{label}(t)$ ))
      then label(s) := label(s)  $\cup$  { $\eta$ }
    fi
  od
  return label
end
```

INPUT: Kripke structure  $M = (S, T, I)$ ,  
 Labelling function  $label : S \rightarrow 2^\varphi$ , correct w.r.t validity of  $\psi_1$  and  $\psi_2$   
 OUTPUT: Labelling function  $label : S \rightarrow 2^\varphi$ , correct w.r.t  $E[\psi_1 U \psi_2]$

```

proc checkEU( $\psi_1, \psi_2, label, M$ )
  Q := {s |  $\psi_2 \in label(s)$ }
  foreach ( s  $\in$  Q)do
     $label(s) := label(s) \cup \{E[\psi_1 U \psi_2]\}$ 
  od
  while (Q  $\neq \emptyset$ ) do
    choose s  $\in$  Q
    Q := Q  $\setminus$  {s}
    foreach ( t  $\in$  {t | T(t, s)} ) do          /* all immediate predecessors */
      if ( $E[\psi_1 U \psi_2] \notin label(t) \wedge \psi_1 \in label(t)$ )
        then  $label(t) := label(t) \cup \{E[\psi_1 U \psi_2]\}$ 
           Q := Q  $\cup$  {t}
        fi
      od
    od
  return label
end

```

## Sub-graph

- Let  $G = (V, E)$  be a graph, ie.  $E \subseteq V \times V$ .
- Graph  $G' = (V', E')$  is called sub-graph of  $G$  if it holds that  $V' \subseteq V$  and  $E' = E \cap V' \times V'$ .

## Sub-graph $C = (V', E')$ of $G = (V, E)$ is called

- **Strongly Connected Component**, if  $\forall u, v \in V'$  it holds that  $(u, v) \in E'^*$  and  $(v, u) \in E'^*$ .
- **Maximal Strongly Connected Component (SCC)**, if  $C$  is strongly connected component and for every  $v \in (V \setminus V')$  it is the case that  $(V' \cup \{v\}, E \cap (V' \cup \{v\} \times V' \cup \{v\}))$  is not.
- **Non-trivial SCC**, if  $C$  is Strongly Connected Component and  $E' \neq \emptyset$ .

INPUT: Kripke structure  $M = (S, T, I, s_0)$ ,  
 Labelling function  $label : S \rightarrow 2^\varphi$ , correct w.r.t.  $\psi$   
 OUTPUT: Labelling function  $label : S \rightarrow 2^\varphi$ , correct w.r.t.  $EG \psi$

```

proc checkEG( $\psi$ , label, M)
  S' := {s |  $\psi \in label(s)$ }
  SCC := {C | C is non-trivial SCC  $G' = (S', T \cap S' \times S')$ }
  Q :=  $\bigcup_{C \in SCC} \{s \mid s \in C\}$ 
  foreach ( s  $\in$  Q)do
    label(s) := label(s)  $\cup$  {EG  $\psi$ }
  od
  while Q  $\neq$   $\emptyset$  do
    choose s  $\in$  Q
    Q := Q  $\setminus$  {s}
    foreach ( t  $\in$  ( $S' \cap \{t \mid T(t, s)\}$ ))do /* all immediate predecessors in S' */
      if EG  $\psi \notin label(t)$ 
        then label(t) := label(t)  $\cup$  {EG  $\psi$ }
           Q := Q  $\cup$  {t}
        fi
      od
    od
  od
end

```

## Observation

- Every CTL formula  $\varphi$  is made of at most  $|\varphi|$  sub-formulae.
- Decomposition of every sub-graph of  $G = (S, T)$  into SCCs can be done in time  $\mathcal{O}(|S| + |T|)$ .
- Every call to *updateLabel* terminates in time  $\mathcal{O}(|S| + |T|)$ .

## Overall complexity

- Algorithm *CTLMC* exhibits  $\mathcal{O}(|\varphi| |S|)$  space and  $\mathcal{O}(|\varphi| (|S| + |T|))$  time complexity.

Transformation of formula  $\varphi \equiv AG(Start \implies AF(Heat))$

- $AG(Start \implies AF(Heat))$
- $AG(\neg(Start \wedge \neg AF(Heat)))$
- $AG(\neg(Start \wedge EG(\neg Heat)))$
- $\neg EF(Start \wedge EG(\neg Heat))$
- $\neg E[true U (Start \wedge EG(\neg Heat))]$

Validity of sub-formulae [ $S(\varphi) = \{s \mid s \models \varphi\}$ ]

- $S(Start) = \{2, 5, 6, 7\}$
- $S(Heat) = \{4, 7\}$
- $S(\neg Heat) = \{1, 2, 3, 5, 6\}$
- $S(EG(\neg Heat)) = \{1, 2, 3, 5\}$
- $S(Start \wedge EG(\neg Heat)) = \{2, 5\}$
- $S(E[true U (Start \wedge EG(\neg Heat))]) = \{1, 2, 3, 4, 5, 6, 7\}$
- $S(\neg E[true U (Start \wedge EG(\neg Heat))]) = \emptyset$

CTL\*

## Observation

- Every use of temporal operator in a formula of CTL must be immediately preceded with a quantifier, i.e. use of a modal operator without quantification is not possible.

## Logic CTL\*

- Branching time logic.
- Similar to CTL.
- Unlike CTL, allows for standalone use of modal operators.

## Example

- $A[p \wedge X(\neg p)]$  is CTL\*, but is not CTL formula.

## Types of CTL\* formulae

- Quantifiers  $E$  and  $A$  are standalone operators in syntax construction rules. As a result there are two types of formulae in  $CTL$ : **path** and **state** formulae.
- Application of  $E$  and  $A$  operators on a path formula (formula of which model is a run of Kripke structure) results in a state formula (formula of which model is a state of Kripke structure)

## Syntax of CTL\*

state formula

$$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid E\psi$$

path formula

$$\psi ::= \varphi \mid \neg\psi \mid \psi \vee \psi \mid X\psi \mid \psi U\psi$$

## Assumption

- Let  $AP$  be a set of atomic propositions, and  $p \in AP$ .
- Let  $M = (S, T, I)$  be a Kripke structure.
- Let  $\varphi_i$  denote CTL\* state formulae, and  $\psi_i$  denote CTL\* state formulae.

## Semantics

$M, s \models p$	iff	$p \in I(s)$
$M, s \models \neg\varphi_1$	iff	$\neg(M, s \models \varphi_1)$
$M, s \models \varphi_1 \vee \varphi_2$	iff	$M, s \models \varphi_1$ or $M, s \models \varphi_2$
$M, s \models E\psi_1$	iff	$\exists \pi \in P_M(s). \pi \models \psi_1$
$M, \pi \models \varphi_1$	iff	$M, \pi(0) \models \varphi_1$
$M, \pi \models \neg\psi_1$	iff	$\neg(M, \pi \models \psi_1)$
$M, \pi \models \psi_1 \vee \psi_2$	iff	$M, \pi \models \psi_1$ or $M, \pi \models \psi_2$
$M, \pi \models X\psi_1$	iff	$M, \pi^1 \models \psi_1$
$M, \pi \models \psi_1 U \psi_2$	iff	$\exists k \geq 0. (M, \pi^k \models \psi_2$ and $\forall 0 \leq i < k. M, \pi^i \models \psi_1)$

## Comparison of Expressive Power of LTL, CTL and CTL\*

## Observation

- Every LTL formula is a CTL\* path formula.
- Every CTL formula is a CTL\* state formula.
- Model of a path formula is a run of Kripke structure.
- Model of a state formula is a state of Kripke structure.
- Not very suitable for comparison.

## Model Unification

- For the purpose of comparison we define how a CTL\* path formula is evaluated in a state of Kripke structure.
- Let  $\psi$  be CTL\* path formula, then

$$M, s \models \psi \quad \text{iff} \quad M, s \models A\psi$$

## Goals

- We intend to find out whether there are properties (formulae) that can be expressed in one of the logic, but cannot be expressed in another one.
- We intend to find out in which logic more properties can be expressed.
- We intend to identify concrete properties, that cannot be expressed in some other logic, i.e. to find out a formula of logic  $\mathcal{L}_1$ , for which an equivalent formula of logic  $\mathcal{L}_2$  does not exist.

## Formula Equivalence

- Formulae  $\varphi$  and  $\psi$  are equivalent if and only if for any possible Kripke structure  $M = (S, T, I, s_0)$  and any state  $s \in S$  it is true that

$$M, s \models \varphi \quad \text{iff} \quad M, s \models \psi.$$

## Equivalently Expressive

- Temporal logic  $\mathcal{L}_1$  and  $\mathcal{L}_2$  have the same expressive power, if for all Kripke structures  $M = (S, T, I, s_0)$  and states  $s \in S$  it holds that

$$\forall \varphi \in \mathcal{L}_1. (\exists \psi \in \mathcal{L}_2. (M, s \models \varphi \iff M, s \models \psi)) \quad (1)$$

$$\wedge \forall \psi \in \mathcal{L}_2. (\exists \varphi \in \mathcal{L}_1. (M, s \models \varphi \iff M, s \models \psi)). \quad (2)$$

## Less Expressiveness

- If only statement (1) is valid, then logic  $\mathcal{L}_1$  is less expressive than logic  $\mathcal{L}_2$ , and vice versa.

## Theorem

- LTL and CTL are incomparable in expressive power.
  - 1)  $AG(EF(q))$  is a CTL formula that cannot be expressed in LTL.
  - 2)  $FG(q)$  is an LTL formula that cannot be expressed in CTL.

## Example – Proof Sketch for 1)

- Find two different Kripke structures and identify two states that can be differentiated with CTL formula  $AG(EF(q))$ , but cannot be differentiated with any LTL formula (they generate the same set of runs).

## Example – Intuition behind 2) [proof is too complex]

- Show that CTL formula  $AF(AG(q))$  is not equivalent to LTL formula  $FG(q)$ .

## Consequence

- CTL\* is strictly more expressive than LTL.
  - Every LTL formula is a CTL\* formula.
  - CTL\* formula  $AG(EFq)$  is not expressible in LTL.

## Consequence 2

- CTL\* is strictly more expressive than CTL.
  - Every CTL formula is a CTL\* formula.
  - CTL\* formula  $FG(q)$  is not expressible in CTL.

## Observation

- There are properties expressible on both LTL and CTL.
  - CTL formula  $A[p U q]$  is equivalent to LTL formula  $p U q$ .

## Homework

- Solve The wolf, goat and cabbage problem with NuSMV
- Moshe Vardi: *Branching vs. Linear Time: Final Showdown*

# IA169 System Verification and Assurance

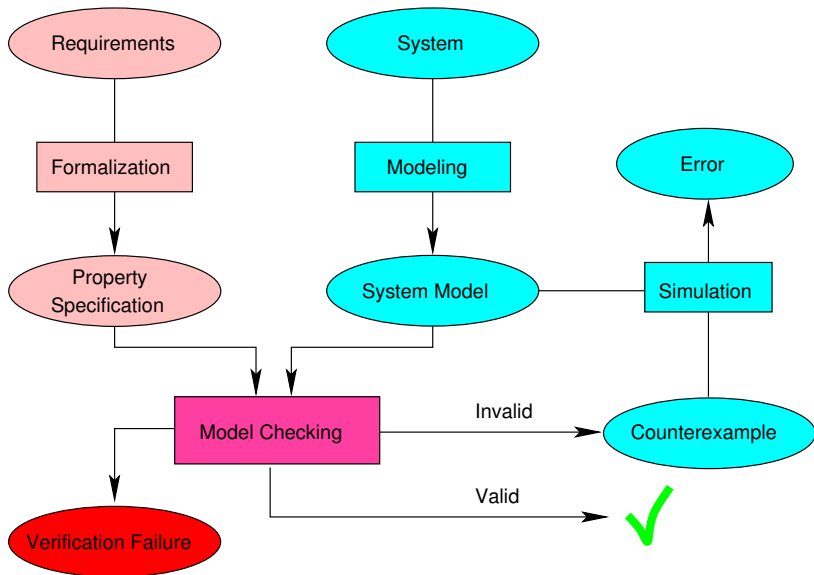

## Symbolic Representations in CTL Model Checking

Jiří Barnat

# State Space Explosion Problem and Model Checking

# State Space Explosion Problem and Model Checking

## Observation

- Computation state is given by valuation of state variables.
- Every variable has a finite domain, its value may be stored using a fixed number of bits.
- Computation state represented as a bit vector  $(a_1, \dots, a_n)$  of fixed length  $n$ .

## Set of States

- Algorithms for verification store set of states.
- Set of state can be viewed as a set of binary vectors.
- Set of binary vectors may be described with a **Boolean function**.

## Boolean Functions

- These are formulae in propositional logic over a given set of Boolean variables.

## Task

- Let system state be given by valuation of four bit variables  $(a1, b1, a2, b2)$ .
- A state is erroneous if the values of  $a1$  and  $b1$  and values of  $a2$  and  $b2$  agree.
- Describe a set of erroneous states with Boolean function.

## Some Possible Solutions

## Boolean Functions

- These are formulae in propositional logic over a given set of Boolean variables.

## Task

- Let system state be given by valuation of four bit variables  $(a1, b1, a2, b2)$ .
- A state is erroneous if the values of  $a1$  and  $b1$  and values of  $a2$  and  $b2$  agree.
- Describe a set of erroneous states with Boolean function.

## Some Possible Solutions

- $(a1 \wedge b1 \wedge a2 \wedge b2) \vee (a1 \wedge b1 \wedge \neg a2 \wedge \neg b2) \vee (\neg a1 \wedge \neg b1 \wedge \neg a2 \wedge \neg b2) \vee (\neg a1 \wedge \neg b1 \wedge a2 \wedge b2)$
- $a1 \Leftrightarrow b1 \wedge a2 \Leftrightarrow b2$

## Binary Decision Trees (BDTs)

- Directed tree with a single root state.
- Every inner node is denoted with a Boolean variable ( $v$ ) and lead to exactly two successors referred to as to ( $low(v)$ ,  $high(v)$ ).
- Every leaf is assigned a binary value, i.e. 0 or 1.

## Coding of Boolean Functions with BDTs

- Every combination of values of input variables corresponds to exactly one path from the root of BDT to a leaf.
- Values stored at leaves give the the value of the function for the corresponding input values.

# Binary Decision Tree $\psi = (a_1 \Leftrightarrow b_1) \wedge (a_2 \Leftrightarrow b_2)$

## Disadvantage of BDTs

- BDTs are uselessly space demanding (contain redundant information).

## Task

- Identify isomorphic sub-trees of the BDT from the previous slide.

## Binary Decision Diagrams (BDD)

- Acyclic directed graph, of which vertices have output degree either zero (leaf) or two (inner vertex).
- Vertices of BDD have otherwise the same properties as BDT nodes.

## Initialisation

- For a given Boolean function take arbitrary BDD or BDT.
- Eliminate unreachable vertices
- Eliminate duplicate
  - 1) Remove all but one leaves with the same value.
  - 2) All edges incident with eliminated leaves reconnect to the the remaining leaf with the same value.

## Repeat Until Fixpoint

- Eliminate duplicate inner vertices.
  - If there are two inner vertices  $u, v$  with the same label such that  $low(v) = low(u)$  a  $high(v) = high(u)$ , then remove  $u$  and reconnect edges originally leading to  $u$  to  $v$ .
- Eliminate useless tests
  - Eliminate inner vertex  $v$  if  $low(v) = high(v)$ . Reconnect edges originally leading to  $v$  to  $low(v)$ .

# BDD pro $\psi = (a_1 \Leftrightarrow b_1) \wedge (a_2 \Leftrightarrow b_2)$

## Observation

- Every vertex  $v$  of BDD encodes some Boolean function  $F_v(x_1, \dots, x_n)$ .

## Computing $F_v(x_1, \dots, x_n)$ for values $h_1, \dots, h_n$ .

- If  $v$  is a leaf then
  - $F_v(h_1, \dots, h_n) = 1$ , if  $v$  is labelled with value 1.
  - $F_v(h_1, \dots, h_n) = 0$ , if  $v$  is labelled with value 0.
- If  $v$  is an inner vertex then
  - $F_v(h_1, \dots, h_n) = F_{low(v)}(h_1, \dots, h_n)$ , if  $h_i == 0$ .
  - $F_v(h_1, \dots, h_n) = F_{high(v)}(h_1, \dots, h_n)$ , if  $h_i == 1$ .

## Observation

- Some intermediate representation computed during minimisation of a BDD are also valid BDDs.
- A given Boolean function may be represented with multiple different BDDs.

## Canonical Form for BDD

- Minimal BDD computed from a BDD, or BDT with a fixed ordering on variables in inner vertices **is unique**.
- BDD with a fixed variable ordering is referred to as to Ordered BDD (**OBDD**).

## Computing Canonical Form

- Apply algorithm for minimal BDD.
- If performed in a bottom-up manner, obtained in linear time w.r.t. the size of initial BDT or BDD.

# OBDDs for Different Variable Ordering

## Observation

- Every OBDD represents some Boolean function.
- Boolean functions can be combined/composed using unary and binary logic operators such as  $\neg, \wedge, \vee, \implies, XOR, \dots$
- OBDDs can be composed similarly.

## Application of Logic Operators on OBDD

- Let  $O$  and  $O'$  be OBDDs corresponding to functions  $f$  and  $f'$ , respectively.
- We will refer to function  $Apply(O, O', \star)$ , as to function that computes OBDD that represents result of application of logic operator  $\star$  to functions  $f$  and  $f'$ .

## Operation of Restriction

- $F_{x_i \leftarrow b}(x_1, \dots, x_n) = F(x_1, \dots, x_{i-1}, b, x_{i+1}, \dots, x_n)$
- Produces Boolean function with all but one free variables.

## Realisation for OBDD

- If root  $r$  is denoted with the restricted variable  $x_i$ , the resulting OBDD will have new root
  - $low(r)$  if  $b = 0$
  - $high(r)$  if  $b = 1$
- Any edge leading to a inner vertex  $t$  that is denoted with the restricted variable  $x_i$  is reconnected to
  - $low(t)$  if  $b = 0$
  - $high(t)$  if  $b = 1$
- OBDD is minimised (contains unreachable nodes).

## Shannon expansion

- Any binary logic operator can be applied on OBDDs using **Shannon expansion**:

$$F = (\neg x \wedge F_{x \leftarrow 0}) \vee (x \wedge F_{x \leftarrow 1})$$

- If  $F = f \star f'$ , for any binary logic operation  $\star$ , then

$$f \star f' = (\neg x \wedge (f_{x \leftarrow 0} \star f'_{x \leftarrow 0})) \vee (x \wedge (f_{x \leftarrow 1} \star f'_{x \leftarrow 1}))$$

$Apply(O, O', \star)$

- Let  $v, v'$  be root nodes of  $O, O'$ , denoted with  $x, x'$ , respectively.
- If  $v$  and  $v'$  are leaves denoted with values  $h$  and  $h'$ , respectively, then return a leaf denoted with  $h \star h'$ .
- Otherwise, if

$x = x'$  then return a new node  $w$  denoted with variable  $x$ , where

- $low(w) = Apply(low(v), low(v'), \star)$
- $high(w) = Apply(high(v), high(v'), \star)$

$x < x'$  then return a new node  $w$  denoted with variable  $x$ , where

- $low(w) = Apply(low(v), O', \star)$
- $high(w) = Apply(high(v), O', \star)$

$x' < x$  then return a new node  $w$  denoted with variable  $x$ , where

- $low(w) = Apply(O, low(v), \star)$
- $high(w) = Apply(O, high(v), \star)$

## Observation

- Let *OBDD*  $X$  encodes function  $F_X$ , then *OBDD*  $Y$  encoding negation function  $\neg F_X$  is created as a copy of *OBDD*  $X$  in which values of leaves are switched.

## Emptiness Check

- OBDDs have canonical form.
- Canonical OBDD representing an empty set is made of a single leaf denoted with 0.

## Test for a Presence of Set Member (complicated way)

- Create an OBDD describing the tested member.
- Apply operation  $\wedge$  on tested and newly created OBDDs.
- Employ emptiness check on the resulting OBDD.

## Symbolic Representation of Kripke Structure

## Observation

- A state of Kripke structure  $M = (S, T, I)$  is given by  $n$  binary variables  $a_1, \dots, a_n$ .
- Every set of states of Kripke structure can be encoded by an OBDD with  $n$  variables.
- Similarly, transition relation  $T \subseteq S \times S$  can be encoded by Boolean function with  $2n$  variables.

## Simplification of OBDD

- Edges leading to zero leaf can be omitted.
- Non-existence of an edge indicates an edge to zero leaf.

- $M = (\{00, 01, 11\}, \{(11, 00), (11, 01), (01, 00)\}, I)$

- $T$  can be encoded as  $F(a, b, a', b')$
- $F(a, b, a', b') =$   
 $(a \wedge b \wedge \neg a' \wedge b') \vee (a \wedge b \wedge \neg a' \wedge \neg b') \vee (\neg a \wedge b \wedge \neg a' \wedge \neg b')$
- Assume variable ordering  $a < b < a' < b'$  and draw OBDD for  $F$ .

## Observation

- Assume  $M = (S, T, I)$  and  $OBDD_T(a, b, a', b')$ .
- Let  $X$  be a set of states given with  $OBDD_X(a, b)$ .
- Using  $OBDD_T$  and  $OBDD_X$ ,  $OBDD_{X'}(a', b')$  representing **set of successors of states in  $X$**  can be computed, i.e.

$$X' = \{v \in S \mid u \in X \wedge (u, v) \in T\}.$$

## Computing $OBDD_{X'}$ (intuitively)

- $OBDD_{X'} = Apply(OBDD_T, OBDD_X, \wedge)$
- Modify  $OBDD'_X$  so that every path of it contains vertex labelled with  $a'$ .
- In  $OBDD_{X'}$  erase all vertices labelled with  $a$  and  $b$ .
- Iterate over all  $a'$  vertices, consider them as root and compute respective minimal OBDDs.
- The computed set of OBDDs combine with operation  $\vee$ .
- Minimise the resulting OBDD.
- Rename primed variables to unprimed.

## Task

- Compute OBDD representing successors of states  $\{00, 11\}$ .

## Computing Predecessors (intuitively).

- Modify all vertices of  $OBDD_X$  to be labelled with primed variables.
- $OBDD_{X'} = Apply(OBDD_T, OBDD_X, \wedge)$
- Modify  $OBDD'_{X'}$  so that every path contains vertex labelled with  $a'$ .
- Those  $a'$  that cannot reach leaf labelled with 1 replace with a new zero leaf.
- Other  $a'$  vertices replace with the other leaf.
- Remove all primed nodes and old leaves, and minimise OBDD.

## Task

- Compute OBDD representing predecessor of state  $\{00\}$ .

## Symbolic Approach to Model Checking CTL

## Observation

- If validity of formulae  $\varphi$  and  $\psi$  is known for all states of Kripke structure, validity of formulae  $\neg\varphi$ ,  $\varphi \vee \psi$ ,  $EX \varphi$ , etc., can be easily deduced.

## Algorithm Idea for Model Checking CTL

- Let  $M = (S, T, I)$  be a Kripke structure and  $\varphi$  a CTL formula.
- Labelling function  $label : S \rightarrow 2^\varphi$  is computed, stating which sub-formulae of  $\varphi$  are valid in which states of  $M$ .
- Obviously,  $s_0 \models \varphi \iff \varphi \in label(s_0)$ .
- Function  $label$  is computed gradually for every sub-formula of  $\varphi$  starting with the simplest sub-formulae (atomic propositions) and terminating after computing the validity of  $\varphi$ .

## Idea

- Set of states in which particular sub-formulae hold can be efficiently represented with OBDDs.
- Computation of *label* function for more complex sub-formulae employs manipulation with respective OBDDs.

## Realisation

- Set of states represented with OBDDs.
- Boolean functions to evaluate atomic proposition form initial OBDDs.
- According to the structure of the verified formula OBDDs for more complex sub-formulae are computed.
- Test membership of initial state of Kripke structure in the set of states satisfying verified formula.

## Recall Syntax of CTL

- $\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid EX \varphi \mid E[\varphi U \varphi] \mid EG \varphi$

## Computing Set of States Satisfying CTL Formula

- Notation
  - $F(\psi)$  denotes (a function describing) set of states satisfying  $\psi$ .
  - $Succ(X)$  denotes immediate successors of states in the set  $X$ .
  - $Pred(X)$  denotes immediate predecessors of states in the set  $X$ .
- Boolean Functions for Atomic Proposition
  - Atomic propositions describe properties of state variables.
  - Atomic Propositions can be encoded as Boolean functions.
- Computing Boolean Operators  $\neg$  and  $\vee$ 
  - $F(\neg\psi_1) = \neg(F\psi_1)$
  - $F(\varphi \vee \psi) = F(\varphi) \vee F(\psi)$

## Operator $EX(\varphi)$

- $F(EX(\varphi)) = Pred(F(\varphi))$

## Operator $E(\varphi U \psi)$

- $F(E(\varphi U \psi)) = X$ ,  
where  $X$  is the least fix-point of recursive rule

$$X = F(\psi) \cup (F(\varphi) \cap EX(X))$$

## Operator $EG(\varphi)$

- $F(EG \varphi) = X$ ,  
where  $X$  is the greatest fix-point of recursive rule

$$X = F(\varphi) \cap EX(X)$$

## The Least Fix-Point

```
proc LFP( $f$ )  
   $X = \emptyset$   
   $Xold = \emptyset$   
  do  
     $Xold = X$   
     $X := f(X)$   
  while ( $X \neq Xold$ )  
end
```

## The Greatest Fix-Point

```
proc GFP( $f$ )  
   $X = S$   
   $Xold = S$   
  do  
     $Xold = X$   
     $X := f(X)$   
  while ( $X \neq Xold$ )  
end
```

## Model Checking – Summary

## **Enumerative** × **Symbolic Approach**

- Enumerative – focused on "control-flow"
- Symbolic – focused on "data-flow"

## **Pros w.r.t. Testing**

- No source-code necessary (can be applied on models).
- Suitable for testing of parallel programs.

## **Pros w.r.t. Static Analysis**

- Complete for systems with a finite state space.
- Verification of temporal properties.

## **Cons**

- State space explosion problem.

## Homework

- Explore Z3 tutorial ([rise4fun.com](http://rise4fun.com)).

# IA169 System Verification and Assurance

## Deductive Verification

Jiří Barnat

## Validation and Verification

- A general goal of V&V is to prove correct behaviour of algorithms.

## Reminder

- Testing is incomplete.
- Testing can detect errors but cannot prove correctness.
- Model checking is limited.
- Requires finite state space description, suffers from state space explosion, verifies specific program properties only.

## Conclusion

- Need for yet another way of verification.

## Goal of formal verification

- The goal is to show that system behaves correctly with the same level of confidence as it is given with a mathematical proof.

## Requirements

- Formally precise semantics of system behaviour.
- Formally precise definition of system properties to be shown.

## Methods of formal verification

- Model checking
- Deductive verification
- Abstract interpretation

## Deductive verification

## Program is correct if ...

- ... it **terminates** for a valid input and returns **correct** output.
- There is a need to show two parts – partial correctness and termination.

## **Partial correctness** (Correctness, Soundness)

- If the computation terminates for valid input values (i.e. values for which the program is defined) the resulting values are correct.

## **Termination** (Completeness, Convergence)

- If executed on valid input values, the computation always terminates.

## Serial programs (sequential)

- Input-output-closed programs.
  - All input values are known prior program execution.
  - All output values are stored in output variables.
- Examples: Quick sort, Greatest Common Divider, ...

## General Principle

- Program instructions are viewed as state transformers.
- The goal is to show that the mutual relation of input and output values is as expected or given by the specification.
- To verify the correctness of procedure of transformation of input values to output values.

## State of Computation

- State of computation of a program is given by the value of program counter and values of all variables.

## Atomic predicates

- Basic statements about individual states of the computation.
- The validity is deduced purely from the values of variables given by the state of computation.
- Examples of atomic propositions:  $(x == 0)$ ,  $(x1 \geq y3)$ .
- Beware of the scope of variables.

## Set of States

- Can be described with a Boolean combination of atomic predicates.
- Example:  $(x == m) \wedge (y > 0)$

## Assertion

- For a given program location defines a Boolean expression that should be satisfied with the current values of program variables in the given location during program execution.
- Invariant of a program location.

## Assertions – Proving Correctness

- Assigning properties to individual locations of Control Flow Graph.
- Robert Floyd: Assigning Meanings to Programs (1967)

## Testing

- Assertion violation serves as a test oracle.

## Run-Time Checking

- Checking location invariants during run-time.
- Improved error localisation as the assertion violated relates to a particular program line.

## Undetected Errors

- If an error does not manifest itself for the given input data.
- If the program behaves non-deterministically (parallelism).

## Hoare Proof System

## Principle

- Programs = State Transformers.
- Specification = Relation between input and output state of computation.

## Hoare logic

- Designed for showing partial correctness of programs.
- Let  $P$  and  $Q$  be predicates and  $S$  be a program, then

$$\{P\} S \{Q\}$$

is the so called *Hoare triple*.

## Intended meaning of $\{P\} S \{Q\}$

- $S$  is a program that transforms any state satisfying *pre-condition*  $P$  to a state satisfying *post-condition*  $Q$ .

## Example

- $\{z = 5\} x = z * 2 \{x > 0\}$
- Valid triple, though post-condition could be more precise (stronger).
- Example of a stronger post-condition:  $\{x > 5 \wedge x < 20\}$ .
- Obviously,  $\{x > 5 \wedge x < 20\} \implies \{x > 0\}$ .

## The Weakest Pre-Condition

- $P$  is **the weakest pre-condition**, if and only if
- $\{P\}S\{Q\}$  is a valid triple and
- $\forall P'$  such that  $\{P'\}S\{Q\}$  is valid,  $P' \implies P$ .
- Edsger W. Dijkstra (1975)

## How to prove $\{P\} S \{Q\}$

- Pick suitable conditions  $P'$  a  $Q'$

- Decomposition into three sub-problems:

$$\{P'\} S \{Q'\} \quad P \implies P' \quad Q' \implies Q$$

- Use axioms and rules of Hoare system to prove  $\{P'\} S \{Q'\}$ .
- $P \implies P'$  and  $Q' \implies Q$  are called proof obligations.
- Proof obligations are **proven in the standard way.**

## Axiom

- Assignment axiom:  $\{\phi[x \text{ replaced with } k]\} x := k \{\phi\}$

## Meaning

- Triple  $\{P\}x := y\{Q\}$  is an axiom in Hoare system, if it holds that  $P$  is equal to  $Q$  in which all occurrences of  $x$  has been replaced with  $y$ .

## Examples

- $\{y+7>42\} x:=y+7 \{x>42\}$  is an axiom
- $\{r=2\} r:=r+1 \{r=3\}$  is not an axiom
- $\{r+1=3\} r:=r+1 \{r=3\}$  is an axiom

## Example

- Prove that the following program returns value greater than zero if executed for value of 5.
- Program:  $out := in * 2$

## Proof

1) We built a Hoare triple:

$$\{in = 5\} out := in * 2 \{out > 0\}$$

2) We deduce/guess a suitable pre-condition:

$$\{in * 2 > 0\}$$

3) We prove Hoare triple:

$$\{in * 2 > 0\} out := in * 2 \{out > 0\} \quad (\text{axiom})$$

4) We prove auxiliary statement:

$$(in = 5) \implies (in * 2 > 0)$$

## Rule

- Sequential composition: 
$$\frac{\{\phi\}S_1\{\chi\} \wedge \{\chi\}S_2\{\psi\}}{\{\phi\}S_1;S_2\{\psi\}}$$

## Meaning

- If  $S_1$  transforms a state satisfying  $\phi$  to a state satisfying  $\chi$  and  $S_2$  transforms a state satisfying  $\chi$  to a state satisfying  $\psi$  then the sequence  $S_1; S_2$  transforms a state satisfying  $\phi$  to a state satisfying  $\psi$ .

## In the proof

- Should  $\{\phi\}S_1; S_2\{\psi\}$  be used in the proof, an intermediate condition  $\chi$  has to be found, and  $\{\phi\}S_1\{\chi\}$  and  $\{\chi\}S_2\{\psi\}$  have to be proven.

# Hoare System – Partial Correctness

Axiom for **skip**:  $\{\phi\} \text{ skip } \{\phi\}$

Axiom for **:=**:  $\{\phi[x := k]\} x := k \{\phi\}$

Composition rule: 
$$\frac{\{\phi\} S_1 \{\chi\} \wedge \{\chi\} S_2 \{\psi\}}{\{\phi\} S_1; S_2 \{\psi\}}$$

Conditional rule: 
$$\frac{\{\phi \wedge B\} S_1 \{\psi\} \wedge \{\phi \wedge \neg B\} S_2 \{\psi\}}{\{\phi\} \text{if } B \text{ then } S_1 \text{ else } S_2 \text{ fi} \{\psi\}}$$

While rule: 
$$\frac{\{\phi \wedge B\} S \{\phi\}}{\{\phi\} \text{while } B \text{ do } S \text{ od } \{\phi \wedge \neg B\}}$$

Consequence rule: 
$$\frac{\phi \implies \phi', \{\phi'\} S \{\psi'\}, \psi' \implies \psi}{\{\phi\} S \{\psi\}}$$

**Prove that for  $n \geq 0$  the following code computes  $n!$ .**

```
r = 1;
```

```
while (n  $\neq$  0) {  
    r = r * n;
```

```
    n = n - 1;
```

```
}
```

**Notes:**

Prove that for  $n \geq 0$  the following code computes  $n!$ .

- $\{ n \geq 0 \wedge t=n \}$  {P}  
   $r = 1;$   
  
  while ( $n \neq 0$ ) {  
     $r = r * n;$   
  
     $n = n - 1;$   
  }  
   $\{ r=t! \}$  {Q}

## Notes:

- Reformulation in terms of Hoare logic.
- Note the use of auxiliary variable  $t$ .

Prove that for  $n \geq 0$  the following code computes  $n!$ .

- $\{ n \geq 0 \wedge t=n \}$   $\{P\}$   
   $r = 1;$   
   $\{ n \geq 0 \wedge t=n \wedge r = 1 \}$   $\{I_1\}$   
  while ( $n \neq 0$ ) {  
     $r = r * n;$   
  
     $n = n - 1;$   
  }  
   $\{ r=t! \}$   $\{Q\}$

**Notes:**

- $\{ n \geq 0 \wedge t=n \wedge 1=1 \} r=1 \{ n \geq 0 \wedge t=n \wedge r=1 \}$
- $(n \geq 0 \wedge t=n) \implies (n \geq 0 \wedge t=n \wedge 1=1)$

Prove that for  $n \geq 0$  the following code computes  $n!$ .

- $\{ n \geq 0 \wedge t=n \}$   $\{P\}$   
   $r = 1;$   
   $\{ n \geq 0 \wedge t=n \wedge r = 1 \}$   $\{I_1\}$   
  while ( $n \neq 0$ )  $\{ r=t!/n! \wedge t \geq n \geq 0 \}$   $\{I_2\}$   
     $r = r * n;$   
  
     $n = n - 1;$   
  }  
   $\{ r=t! \}$   $\{Q\}$

## Notes:

- Invariant of a cycle:  $\{I_2\} \equiv \{ r=t!/n! \wedge t \geq n \geq 0 \}$
- $I_1 \implies I_2$       $( I_2 \wedge \neg(n \neq 0) ) \implies Q$

Prove that for  $n \geq 0$  the following code computes  $n!$ .

- $\{ n \geq 0 \wedge t=n \}$  {P}  
   $r = 1;$   
   $\{ n \geq 0 \wedge t=n \wedge r = 1 \}$  {I<sub>1</sub>}  
  while ( $n \neq 0$ )  $\{ r=t!/n! \wedge t \geq n \geq 0 \}$  {I<sub>2</sub>}  
     $r = r * n;$   
     $\{ r=t!/(n-1)! \wedge t \geq n > 0 \}$  {I<sub>3</sub>}  
     $n = n - 1;$   
  }  
   $\{ r=t! \}$  {Q}

**Notes:**

- $\{ r*n = t!/(n-1)! \wedge t \geq n > 0 \} r=r*n \{I_3\}$
- $I_2 \wedge (n \neq 0) \implies ( r*n = t!/(n-1)! \wedge t \geq n > 0 )$

Prove that for  $n \geq 0$  the following code computes  $n!$ .

- $\{ n \geq 0 \wedge t=n \}$  {P}  
   $r = 1;$   
   $\{ n \geq 0 \wedge t=n \wedge r = 1 \}$  {I<sub>1</sub>}  
  while ( $n \neq 0$ )  $\{ r=t!/n! \wedge t \geq n \geq 0 \}$  {I<sub>2</sub>}  
     $r = r * n;$   
     $\{ r=t!/(n-1)! \wedge t \geq n > 0 \}$  {I<sub>3</sub>}  
     $n = n - 1;$   
  }  
   $\{ r=t! \}$  {Q}

**Notes:**

- $\{ r = t!/(n-1)! \wedge t \geq (n-1) \geq 0 \} n=n-1$  {I<sub>2</sub>}
- $I_3 \implies ( r = t!/(n-1)! \wedge t \geq (n-1) \geq 0 )$

## Observation

- Hoare logic allowed us to reduce the problem of proving program correctness to a problem of proving a set of mathematical statements with arithmetic operations.

## Notice about correctness's and (in)completeness

- Hoare logic is correct, i.e. if it is possible to deduce  $\{P\}S\{Q\}$  then executing program  $S$  from a state satisfying  $P$  may terminate only in a state satisfying  $Q$ .
- If a proof system is strong enough to express integral arithmetics, it is necessarily incomplete, i.e. there exists claims that cannot be proven or dis-proven using the system.
- Hoare system for proving correctness of programs is incomplete due to the proof obligations generated with the consequence rule.

## Troubles with Proof Construction

- Often pre- and post- condition must be suitable reformulated for the purpose of the proof.
- It is very difficult to identify loop invariants.

## Partial Correctness in Practice

- Often reduced to formulation of all the loop invariants, and demonstration that they actually are the loop invariants.
- The proof of being an invariant is often achieved with math induction.

## Well-Founded Domain

- Partially ordered set that does not contain infinitely decreasing sequence of members.
- Examples:  $(\mathbf{N}, <)$ ,  $(PowerSet(\mathbf{N}), \subseteq)$

## Proving Termination

- For every loop in the program a suitable well-founded domain and an expression over the domain is chosen.
- It is shown that the value associated with a location cannot grow along any instruction that is part of the loop.
- It is shown that there exists at least one instruction in the loop that decreases the value of the expression.

## Automating Deductive Verification

## **Pre-processing**

- Transformation of program to a suitable intermediate language.
- Examples of IL: Boogie (Microsoft Research), Why3 (INRIA)

## **Structural Analysis and Construction of the Proof Skeleton**

- Identification of Hoare triples, loop invariants and suitable pre- and post-conditions (some of that might be given with the program to be verified).
- Generation of auxiliary proof obligations.

## **Solving proof obligations**

- Using tools for automated proving.
- May be human-assisted.

## **Tools for Automated Proving**

- User guides a tool to construct a proof.
- HOL, ACL2, Isabelle, PVS, Coq, ...

## **Reduced to the satisfiability problem**

- Employ SAT and SMT solvers.
- Z3, ...

## Proof

- A finite sequence of steps that using axioms and rules of a given proof system that transforms assumptions  $\psi$  into the conclusion  $\varphi$ .

## Observation

- For systems with finitely many axioms and rules, proofs may be systematically generated. Hence, for all provable claims the proof can be found in finite time.
- All reasonable proving systems has infinitely many axioms. Consider, e.g. an axiom  $x = x$ . This is virtually a shortcut (template) for axioms  $1 = 1$ ,  $2 = 2$ ,  $3 = 3$ , etc.
- Semi-decidable with dove-tailing approach.

## Searching for a Proof of Valid Statement

- The number of possible finite sequences of steps of rules and axiom applications is too many (infinitely many).
- In general there is no algorithm to find a proof in a given proof system even for a valid statement.
- Without some clever strategy, it cannot be expected that a tool for automated proof generation will succeed in a reasonable short time.
- The strategy is typically given by an experienced user of the automated proving tool. The user typically has to have appropriate mathematical feeling and education.
- At the end, the tool is used as a mechanical checker for a human constructed proof.

## Theorem Provers

- The goal is find the proof within a given proof system.
- the proof is searched for in two modes:
  - Algorithmic mode – Application of rules and axioms
    - Guided by the user of the tool.
    - Application of the general proving techniques, such as deduction, resolution, unification, . . . .
  - Search mode – Looking for new valid statements
    - Employs brute-force approach and various heuristics.

## Existing Tools

- The description of system (axioms, rules) as well as the claim to be proven is given in the language of the tool.

## Possible Outputs

- a) Proof has been found and checked.
- b) Proof has not been found.
  - The statement is valid, can be proven, but the proof has not yet been found.
  - The statement is valid, but it cannot be proven in the system.
  - The statement is invalid.

## Observation

- In the case that no proof has been found, there is no indication of why it is so.

`http://rise4fun.com/dafny`

## Homework

- Prove correctness of the following program using Dafny

```
method Count(N: nat, M: int, P: int) returns (R: int) {  
  var a := M;  
  var b := P;  
  var i := 1;  
  while (i <= N) {  
    a := a+3;  
    b := 2*a+b+1;  
    i := i+1;  
  }  
  R := b;  
}
```

- Read and repeat:

**Jaco van de Pol:** *Automated verification of Nested DFS*

[http://dx.doi.org/10.1007/978-3-319-19458-5\\_12](http://dx.doi.org/10.1007/978-3-319-19458-5_12)

# IA169 System Verification and Assurance

## Bounded Model Checking

Jiří Barnat

## **Satisfiability – SAT**

- Finding a valuation of Boolean variables that makes a given formula of propositional logic true.

## **Satisfiability Modulo Theory – SMT**

- Deciding satisfiability of a first-order formula with equality, predicates and function symbols that encode one or more theories.

## **Typical SMT Theories**

- Unbounded integer and real arithmetic.
- Bounded integer arithmetic (bit-vectors).
- Theory of data structures (lists, arrays, ...).

## **ZZZ** aka **Z3**

- Tool developed by Microsoft Research.
- WWW interface — <http://www.rise4fun.com/Z3>
- Binary API for use in other tools and applications.

## **SMT-LIB**

- Standardised language for SMT queries.
- Freely available library with a SMT implementation.

## Observation

- Formula is valid if and only if its negation is not satisfiable.

## Consequence

- SAT and SMT solvers can be used as tools for proving validity of formulated statements.

## Model Synthesis

- SAT solvers not only decide satisfiability of formulas, but for satisfiable formulas also give the valuation which makes the formula true.
- Unlike theorem provers, they give a "counterexample" in case the statement to be proven is false.

## Checking Safety Properties via SAT Reduction

## Hypothesis

- If the system contains an error, it can be reproduced with only a small number of controlled steps.

## Method Idea

- If we use model checking for error detection, it is sensible to check whether an error (a violation of specification) appears within first  $k$  steps of execution.

## Literature

- Armin Biere, Alessandro Cimatti, Edmund M. Clarke, Yunshan Zhu: Symbolic Model Checking without BDDs. TACAS 1999: 193-207, LNCS 1579.
- Henry A. Kautz, Bart Selman: Planning as Satisfiability. Proceedings of the 10th European conference on Artificial intelligence (ECAI'92): 359-363, 1992, Kluwer.

## Prerequisites

- The set of prefixes of length  $k$  of all runs of a Kripke structure  $M$  can be encoded by a Boolean formula  $[M]^k$ .
- Violation of a *safety* property which can be observed within  $k$  steps of the system can be encoded as  $[\neg\varphi]^k$ .

## Reduction to SAT

- We check the satisfiability of  $[M]^k \wedge [\neg\varphi]^k$ .
- Satisfiability indicates the existence of a counterexample of length  $k$ .
- Unsatisfiability shows non-existence of a counterexample of length  $k$ .

## Prerequisites

- Let  $M = (S, T, I)$  be a Kripke structure with initial state  $s_0 \in S$ .
- Arbitrary state  $s \in S$  can be represented by a bit vector of size  $n$ , that is state  $s = \langle a_0, a_1, \dots, a_{n-1} \rangle$ .

## Encoding M with Boolean Formulae

- $Init(s)$  – formula which is satisfiable for the valuation of variables  $a_1, a_2, \dots, a_n$  that describe the state  $s_0$ .
- $Trans(s, s')$  – a formula which is satisfiable for a pair of state vectors  $s, s'$ , iff the valuations  $a_1, a_2, \dots, a_n, a'_1, a'_2, \dots, a'_n$  describe states between which a transition  $(s, s') \in T$  exists.

## Description of System Runs of Length $k$

- Run of length  $k$  consists of  $k + 1$  states  $s_0, s_1, \dots, s_k$ .
- The set of all runs of size  $k$  of the structure  $M$  is designated  $[M]^k$  and described by the following formula:

$$[M]^k \equiv \text{Init}(s_0) \wedge \bigwedge_{i=1}^k \text{Trans}(s_{i-1}, s_i)$$

## Example $[M]^3 \wedge [\neg\varphi]^3$

- $\text{Init}(s_0) \wedge \text{Trans}(s_0, s_1) \wedge \text{Trans}(s_1, s_2) \wedge \text{Trans}(s_2, s_3) \wedge \neg\varphi(s_3)$

## Completeness of BMC

## Problem – Undetected Violation of a Safety Property

- The violation is not reachable using a path of length  $k$ .
- Paths shorter than  $k$  are not encoded in  $[M]^k$ .

## Upper Bound on $k$

- If  $k \geq d$  where  $d$  is the graph diameter, all possible error locations are covered.
- The diameter of the graph is bounded by  $2^n$ , where  $n$  is the number of bits of the state vector.

## Solution

- Executing BMC iteratively for each  $k \in [0, d]$ .

## Facts

- Asking the user is unrealistic.
- Safe upper bounds are extremely overstated.
- We would like the verification procedure itself to detect whether  $k$  should be increased further.

## Skeleton of an Algorithm for Complete BMC

$k = 0$

**while** (true) **do**

**if** (counterexample of length  $k$  exists)

**then return** "Invalid"

**if** (all states are reachable within  $k$  steps)

**then return** "Valid"

$k = k + 1$

**od**

## Prerequisites

- Kripke structure  $M = (S, T, I)$ .
- States are described by bit vectors of fixed length.
- $Trans$  is a SAT representation of a binary relation  $T$ .

## Path of Length $n$

$$path(s_{[0..n]}) \equiv \bigwedge_{0 \leq i < n} Trans(s_i, s_{i+1})$$

## Validity of Statement $Q$ Along the Entire Path

$$all.Q(s_{[0..n]})$$

## A Loop-Free Path

$$\text{loopFree}(s_{[0..n]}) \equiv \text{path}(s_{[0..n]}) \wedge \bigwedge_{0 \leq i < j \leq n} s_i \neq s_j$$

## Existence of a Path of Length $n$ From $s_0$ to $s_n$

$$\text{path}_n(s_0, s_n) \equiv \exists s_1 \dots s_{n-1}. \text{path}(s_{[0..n]})$$

## Shortest Path

$$\text{shortest}(s_{[0..n]}) \equiv \text{path}(s_{[0..n]}) \wedge \neg \left( \bigvee_{0 \leq i < n} \text{path}_i(s_0, s_n) \right)$$

## Verification

- We would like to show that no state that would violate the specification  $\varphi$  is reachable from the initial configuration, i.e. we want to show that

$$\forall i. \forall s_0 \dots s_i. (Init(s_0) \wedge path(s_{[0..i]}) \implies \varphi(s_i))$$

## Alternatively

- We want to show that from an error state, the initial state is not reachable when going backwards

$$\forall i. \forall s_0 \dots s_i. (Init(s_0) \iff path(s_{[0..i]}) \wedge \neg\varphi(s_i))$$

## Equivalently

$$\forall i. \forall s_0 \dots s_i. \neg (Init(s_0) \wedge path(s_{[0..i]}) \wedge \neg\varphi(s_i))$$

## Termination Condition in the BMC Algorithm Skeleton

- No longer acyclic path from the initial state exists, that is, the following formula is unsatisfiable:

$$Init(s_0) \wedge loopFree(s_{[0..i+1]})$$

- **Holds symmetrically for backwards reachability from error states.**

## Solution 1

- not SAT  $\left( loopFree(s_{[0..i+1]}) \wedge Init(s_0) \right)$   
   $\vee$   
  not SAT  $\left( loopFree(s_{[0..i+1]}) \wedge \neg\varphi(s_{i+1}) \right)$

## Higher Efficiency Termination Criterion

- When using backward reachability from  $\neg\varphi$  states, paths that visit other  $\neg\varphi$  states do not need to be considered.
- Symmetrically holds also for forward reachability with multiple initial states: for completeness detection, paths that visit other initial states do not need to be considered.

## Solution 2

- $$\text{not SAT} \left( \text{loopFree}(s_{[0..i+1]}) \wedge \text{Init}(s_0) \wedge \text{all}.\neg\text{Init}(s_{[1..i+1]}) \right)$$
$$\vee$$
$$\text{not SAT} \left( \text{loopFree}(s_{[0..i+1]}) \wedge \neg\varphi(s_{i+1}) \wedge \text{all}.\varphi(s_{[0..i]}) \right)$$

## Observation

- For small values of  $k$ , SAT queries give neither a counterexample nor enable termination.
- We want to start BMC with  $k > 0$ .

## Reformulating the Counterexample Test

- The original test for counterexample existence for a given  $k$

$$\text{SAT}\left(\text{Init}(s_0) \wedge \text{path}(s_{[0..k]}) \wedge \neg\varphi(s_k)\right)$$

needs to be changed so that we do not miss counterexamples shorter than the initial value of  $k$ .

- New test for the existence of a counterexample:

$$\text{SAT}\left(\text{Init}(s_0) \wedge \text{path}(s_{[0..k]}) \wedge \neg \text{all}.\varphi(s_{[0..k]})\right)$$

## Observation

- The tests can be re-formulated so that they resemble the structure of mathematical induction.
- TAUT is a tautology test (unsatisfiability of negation).

## Base Case

- Test for counterexample existence.

$$\text{SAT} \left( \neg \left( \text{Init}(s_0) \wedge \text{path}(s_{[0..i]}) \implies \text{all}.\varphi(s_{[0..i]}) \right) \right)$$

## Inductive Step

- Test for completeness.

$$\begin{aligned} & \text{TAUT} \left( \neg \text{Init}(s_0) \iff \text{all}.\neg \text{Init}(s_{[1..(i+1)]}) \wedge \text{loopFree}(s_{[0..i+1]}) \right) \\ & \vee \\ & \text{TAUT} \left( \text{loopFree}(s_{[0..i+1]}) \wedge \text{all}.\varphi(s_{[0..i]}) \implies \varphi(s_{i+1}) \right) \end{aligned}$$

## Observation

- Graph diameter ( $d$ ) is the length of the longest of the shortest paths between each pair of vertices in the graph.
- An acyclic path can be substantially longer than the graph diameter.

## BMC with Shortest Paths

- BMC is correct if *loopFree* is replaced with *shortest*.
- The *shortest* predicate, however, needs quantifiers and is as such not a purely SAT application.

## For more details, see ...

- Mary Sheeran, Satnam Singh, and Gunnar Stålmarck: Checking Safety Properties Using Induction and a SAT-Solver, FMCAD 2000, 108-125, LNCS 1954, Springer.

## LTL and BMC

## Observation 1

- LTL is only well-defined for infinite runs.
- For evaluating LTL on finite paths, we use three-value logic (true, false, cannot say).
- Validity of some LTL formulas cannot be decided on any finite path (eg.  $GF a$ ).

## Observation 2

- Cycles that consist of only a few states are unrolled by BMC to acyclic paths of length  $k$ .
- We allow encoding lasso-shaped paths.
- That is,  $(k, l)$ -cyclic paths.

## $(k,l)$ -cyclic runs

- A run  $\pi = s_0 s_1 s_2 \dots$  of a Kripke structure  $M = (S, T, I, s_0)$  is  $(k, l)$ -cyclic if

$$\pi = (s_0 s_1 s_2 \dots s_{l-1})(s_l \dots s_k)^\omega,$$

where  $0 < l \leq k$  and  $s_{l-1} = s_k$ .

## Observation

- If  $\pi$  is  $(k, l)$ -cyclic,  $\pi$  is also  $(k + 1, l + 1)$ -cyclic.
- Treating finite paths as  $(k, k)$ -cyclic is incorrect (could create a non-existent run in  $M$ ).
- Every path of length  $k$  is either acyclic or  $(k, l)$ -cyclic.

## Semantics of LTL for Finite Prefixes

- Let  $\pi$  be a run of a Kripke structure  $M$ .
- $k$  is given.
- $\pi = \pi^0$

$$\begin{aligned}\pi^i \models_{nl} X\varphi & \text{ iff } i < k \wedge \pi^{i+1} \models_{nl} \varphi \\ \pi^i \models_{nl} \varphi U \psi & \text{ iff } \exists j. i \leq j \leq k, \pi^j \models_{nl} \psi \text{ and} \\ & \forall m. i \leq m < j, \pi^m \models_{nl} \varphi\end{aligned}$$

## Semantics of $\models_k$ for LTL in BMC

- For  $(k, l)$ -cyclic paths,  $\pi \models_k \varphi \iff \pi \models \varphi$  holds.
- For acyclic paths,  $\pi \models_k \varphi \iff \pi^0 \models_{nl} \varphi$  holds.
- $\models_k \implies \models_{k+1}$ ,  $\models_k$  approximates  $\models$

## Goal

- We construct a Boolean formula  $[M, \varphi, k]$  which is satisfiable iff Kripke structure  $M$  has a run  $\pi$  such that  $\pi \models_k \varphi$ .
- $[M, \varphi, k] \equiv [M]^k \wedge [\varphi, k]$

## Encoding

- $[M]^k$  encodes all paths of length  $k$
- $[\varphi, k] \equiv \neg[\varphi, k]_0 \vee \bigvee_{l=1}^k l[\varphi, k]_0$
- $\neg[\varphi, k]_0$  encodes that the path is acyclic and  $\models_{nl} \varphi$
- $l[\varphi, k]_0$  encodes that the path is  $(k, l)$ -cyclic and  $\models \varphi$

## Fragment LTL-X

- Reduces the number of transitions (smaller SAT instance).
- Similar to partial order reduction.

## Conclusions on BMC

## General

- Reduces to a standard SAT problem, advances in SAT solving help with BMC.
- Often finds counterexamples of minimal length (not always).
- Boolean formulas can be more compact than OBDD representation.

## Verification of HW

- Thanks to k-induction, a very successful method.

## Verification of SW

- Currently, according to Software Verification Competition (TACAS 2014), BMC in connection with SMT is currently among the best software verification methods (actually falsification).

## General

- Not complete in general.
- Large SAT instances are still unsolvable.

## Verification of SW

- Encoding an entire CFG as a SAT instance is currently unrealistic.
- K-induction cannot be used (the graph is incomplete, no back edges).
- Problems with dynamic data structure analysis.
- Loop analysis is hard.
- Inefficient for full arithmetic (partially solved by SMT).

## Tools

- CBMC – BMC for ANSI-C.
- ESBMC – uses SMT, built on top of CBMC.
- LLBMC – BMC for LLVM bitcode.

## Food for Thought...

- What differentiates modern SMT-BMC from symbolic execution?
- Boundaries are not clear.

## Homework

- Study structure and results of Software Verification Competition (TACAS).

# IA169 System Verification and Assurance

## Verification of Real-Time and Hybrid systems

Jiří Barnat

## Software Engineering Experience

- Employing V&V techniques too late in the development process significantly increases the cost of poor quality.
- The sooner a bug is detected the cheaper is the fix.
- Model-Based Development
- Model-Based Verification

## Model-Based Development

- Consider models of the target system in order to ,e.g., simulate its behaviour in the design phase prior implementation.
- Behavioural models can be used for verification.

## Hybrid Systems

- Systems that combine multiple kinds of dynamics.
- Continuous systems driven by discrete events.

## Areas of existence

- Mechanical systems
  - Continuous movement and contact with physical obstacle.
- Electrical systems
  - Continuous nature of electric charge in circuit driven by discrete switches.
- **Embedded systems**
  - Computer-driven systems in analogue environment.

## System Description

- A ball released at height  $h$  bounces on a hard surface. The ball is under continuous influence of the gravity ( $9.8\text{m/s}^2$ ). When bounces some energy is consumed by friction and elasticity and turns into heat.

## Physics

- Acceleration = First derivative of speed with respect to time.
- Speed = First derivative of height with respect to time.

## Abstraction and simplification

- Modelled with a mass point.
- Instant (time-less) bounce.

## Automaton Description

- $x_1$  — height
- $x_2$  — vertical speed (+ means up, - means down)
- $c \in [0, 1]$  — loss of energy (elasticity and heat)

## Schema

## Questions

- What time elapses between the fourth and fifth bounce?
- If given horizontal speed, will the ball jump over an obstacle?
- ...

## Searching for Answers

- Need for precise formal description of hybrid system.
- Algorithmic analysis of properties of hybrid systems and controller synthesis.

## Hybrid Automata

**Hybrid Automaton** is a tuple

- $Q = \{q_1, q_2, \dots\}$  — Set of discrete states.
- $X = \mathbf{R}^n$  — Set of continuous states.
- $f : Q \times X \rightarrow \mathbf{R}^n$  — System dynamics.
- $Init \subseteq Q \times X$  — Set of initial states.
- $Dom : Q \rightarrow PowerSet(X)$  — State invariants.
- $E \subseteq Q \times Q$  — Set of discrete transitions
- $G : E \rightarrow PowerSet(X)$  — Map of transition guards.
- $R : E \times X \rightarrow PowerSet(X)$  — Map of transition resets.

## State of Hybrid Automaton

- Given by the discrete state and the current value of continuous variables:  $(q, \vec{x}) \in Q \times X$ .

## Initial State

- Set of initial states in both the discrete and continuous part.
- $(q_0, \vec{x}_0) \in I$

## Transition by Time Passing

- Let  $(q, \vec{x})$  be origin state.
- Continuous part for every variable  $x$  follows the system dynamics

$$\frac{dx(t)}{dt} = f(q, x), \text{ where } x(0) = x$$

- Discrete part does not change:

$$q(t) = q$$

- Time may pass only if the state invariant is valid:

$$x(t) \in Dom(q)$$

## Discrete Transition

- Let  $(q, \vec{x})$  be origin state.
- It is possible (but not necessary) to perform a transition

$$(q, q') \in E,$$

- if transition guard is valid, i.e.

$$\vec{x} \in G(q, q').$$

- If the transition is taken, the continuous part of the state is updated accordingly:

$$\vec{x}' := R((q, q'), \vec{x})$$

- The target state after a discrete transition is  $(q', \vec{x}')$ .

## Restrictions in Continuous Part

- $f(q, \vec{x})$  is Lipschitz continuous for  $\forall q \in Q$ ,  
(solution of differential equations is well defined)
- $\forall e \in E$  we assume non-empty  $G(e)$
- $\forall e \in E$  and  $\forall x \in Q$  we assume non-empty  $R(e, x)$

## Restrictions in Discrete Part

- The set of discrete state is finite.

## Example 2 – Water Tank

### System Description

- Two water tanks, volume of water denoted with  $x_1$  and  $x_2$ .
- There is a constant speed leak from both tanks,  $v_1$  and  $v_2$ .
- A hose can fill one of the tanks with speed  $w$ .
- The hose is always in exactly one of the tanks.

## Example 2 – Water Tank

### Goal

- Keep water level above the necessary minimum  $r_1$  and  $r_2$ .
- Initially, there is enough water in both tanks.
- The hose is switched to a tank at the moment the water level in the tank drops to the required minimum.

# Water Tanks — Formal Definition of the System

- $Q = \{q_1, q_2\}$

- $X = \mathbf{R} \times \mathbf{R}$

- $f(q_1, x) = \begin{bmatrix} w - v_1 \\ -v_2 \end{bmatrix} \quad f(q_2, x) = \begin{bmatrix} -v_1 \\ w - v_2 \end{bmatrix}$

# Water Tanks — Formal Definition of the System

- $Init = \{q_1, q_2\} \times \{x \in \mathbf{R} \times \mathbf{R} \mid x_1 \geq r_1 \wedge x_2 \geq r_2\}$
- $Dom(q_1) = \{x \in \mathbf{R} \times \mathbf{R} \mid x_2 \geq r_2\}$   
 $Dom(q_2) = \{x \in \mathbf{R} \times \mathbf{R} \mid x_1 \geq r_1\}$

# Water Tanks — Formal Definition of the System

- $E = \{(q_1, q_2), (q_2, q_1)\}$
- $G(q_1, q_2) = \{x \in \mathbf{R} \times \mathbf{R} \mid x_2 \leq r_2\}$   
 $G(q_2, q_1) = \{x \in \mathbf{R} \times \mathbf{R} \mid x_1 \leq r_1\}$
- $R(q_1, q_2, x) = R(q_2, q_1, x) = \{x\}$

# Hybrid Time Sequence (HTS)

## Informally

- A run of hybrid automaton proceeds in a sequence of continuous time intervals. Discrete transitions happen on the boundaries of the intervals in instant time.
- The time characteristic of a run of hybrid automaton is formalised with the usage of the so called **Hybrid Time Sequence**.

## Definitions

- Hybrid Time Sequence is a (finite or infinite) sequence of intervals  $\tau = \{I_0, I_1, \dots, I_N\} = \{I_i\}_{i=0}^N$  such that:
  - $I_i = [\tau_i, \tau'_i]$  for all  $i < N$
  - If  $N < \infty$  then either  $I_N = [\tau_N, \tau'_N)$  or  $I_N = [\tau_N, \tau'_N]$
  - $\tau_i \leq \tau'_i = \tau_{i+1}$  for all  $0 \leq i < N$ .

# Graphical Representation of Hybrid Time Sequence

## Observation

- If every time moment is related with an interval of HTS ...
- ... then time moments can be linearly ordered.

## Ordering $\prec$

- $t_1 \in I_i, t_2 \in I_j$
- $t_1 \prec t_2 \stackrel{def}{=} (t_1 < t_2) \vee (t_1 = t_2 \wedge i < j)$

## Generalisation

- Every hybrid time sequence is linearly ordered with  $\prec$  relation.

## Prefix Of Hybrid Time Sequence

- $\tau = \{I_i\}_{i=0}^N$
- $\hat{\tau} = \{\hat{I}_i\}_{i=0}^M$
- We say that  $\tau$  is a prefix of  $\hat{\tau}$  (denoted with  $\tau \sqsubseteq \hat{\tau}$ ), if  
 $\tau = \hat{\tau}$ , or  
 $N$  is finite  $\wedge I_N \subseteq \hat{I}_N \wedge \forall i \in [0, N) : I_i = \hat{I}_i$

## Proper Prefix

- $\tau \sqsubset \hat{\tau} \equiv \tau \sqsubseteq \hat{\tau} \wedge \tau \neq \hat{\tau}$

## Relation $\sqsubseteq$ is a Partial Ordering

- There exist  $\tau$  and  $\hat{\tau}$  such that  $\tau \not\sqsubseteq \hat{\tau}$  and  $\hat{\tau} \not\sqsubseteq \tau$ .

**Task** – Find  $\tau$ ,  $\tilde{\tau}$  and  $\hat{\tau}$  such that

- $\tau \sqsubseteq \tilde{\tau}$
- $\tau \sqsubseteq \hat{\tau}$
- $\tilde{\tau} \not\sqsubseteq \hat{\tau} \wedge \hat{\tau} \not\sqsubseteq \tilde{\tau}$

**Solution**

## Definition

- Hybrid trajectory is a triple  $(\tau, q, x)$ , where  $\tau$  is hybrid time sequence  $\tau = \{I\}_0^N$  and  $q, x$  are two sequences of functions  $q = \{q_i\}_0^N$  and  $x = \{x_i\}_0^N$  such that  $q_i : I_i \rightarrow Q$  and  $x_i : I_i \rightarrow \mathbf{R}^n$ , respectively.

## Intuition

- Continuous part flows within individual time intervals of hybrid time sequence.
- Discrete state within a single interval does not change.
- Discrete transitions realise transitions from the end of one interval to the beginning of the succeeding interval.

## Run of Hybrid Automaton

- Let  $\mathcal{H} = (Q, X, f, Init, Dom, E, G, R)$  be hybrid automaton.
- Let  $(\tau, q, x)$  be hybrid trajectory.
- Trajectory  $(\tau, q, x)$  is a run of automaton  $\mathcal{H}$ , if it is compliant with  $\mathcal{H}$  in: initial condition, discrete behaviour and continuous behaviour.

## Initial Condition

- $(q_0(0), x_0(0)) \in Init$

**Discrete Behaviour** – For all  $i < N$  it holds that

- $(q_i(\tau'_i), q_{i+1}(\tau_{i+1})) \in E$
- $x_i(\tau') \in G(q_i(\tau'_i), q_{i+1}(\tau_{i+1}))$
- $x_{i+1}(\tau_{i+1}) \in R(q_i(\tau'_i), q_{i+1}(\tau_{i+1}), x_i(\tau'_i))$

## Run of Hybrid Automaton

- Let  $\mathcal{H} = (Q, X, f, Init, Dom, E, G, R)$  be hybrid automaton.
- Let  $(\tau, q, x)$  be hybrid trajectory.
- Trajectory  $(\tau, q, x)$  is a run of automaton  $\mathcal{H}$ , if it is compliant with  $\mathcal{H}$  in: initial condition, discrete behaviour and continuous behaviour.

**Continuous Behaviour** – For all  $i \leq N$  it holds that

- $q_i : I_i \rightarrow Q$  is constant over  $t \in I_i$ ,
- $x_i : I_i \rightarrow X$  is a solution to differential equation

$$\frac{dx_i(t)}{dt} = f(q_i(t), x_i(t))$$

over  $I_i$  beginning in  $x_i(\tau_i)$ ,

- For all  $t \in [\tau_i, \tau'_i)$  it holds that  $x_i(t) \in Dom(q_i(t))$ .

# Water Tanks – Example

## Specification

- $\tau = \{[0, 2], [2, 3], [3, 3.5]\}$
- Constants  $r_1 = r_2 = 0$ ,  $v_1 = v_2 = 0.5$ ,  $w = 0.75$
- Initial state  $q = q_1$ ,  $x_1 = 0$ ,  $x_2 = 1$ .

# Water Tanks – Trajectories

# Classification of Runs $(\tau, q, x)$

## Finite

- If  $\tau$  is finite and the last interval of  $\tau$  is closed.

## Infinite

- If  $\tau$  is infinite sequence, or the sum of time intervals in  $\tau$  is infinite, i.e.

$$\sum_{i=0}^N (\tau'_i - \tau_i) = \infty.$$

## Zeno

- If  $\tau$  is infinite, but

$$\sum_{i=0}^N (\tau'_i - \tau_i) < \infty.$$

## Maximal

- If  $\tau$  is no proper suffix of any other run  $\tau'$  of  $\mathcal{H}$ .

# Classification of Runs

$\tau_A$  finite;  $\tau_C$  and  $\tau_D$  infinite;  $\tau_E$  and  $\tau_F$  Zeno.  
What class is run  $\tau_B$ ?

# Examples of ZENO Runs

# Examples of ZENO Runs

Let

$$\rho(x) = \begin{cases} \sin\left(\frac{1}{x^2}\right) \exp\left(-\frac{1}{x^2}\right) & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$

Then

- the following hybrid system has infinitely many intersections with  $x$  axis in the interval  $(-\epsilon, 0]$ .

## Observation

- Hybrid automata are meant to describe real hybrid systems.
- Due to abstraction and simplification, it is possible to specify unrealistic situation.

## Risk of Modelling

- Can create system that have no solutions.
- Can create system that have only unrealistic solutions.
- Can create system that have non-deterministic solutions.

## Terminology

- System that has no solution (no run exist) is called *blocking* system.

## Observation

- Non-blocking system does not guarantee that some runs are realistic.
- Non-blocking system does not guarantee that some runs are time divergent.

## Unrealistic Runs

- Runs that perform infinitely many discrete transitions in finite time are called **ZENO** runs.
- Created by abstraction and simplification in modelling.

## Discussion

- Why the ball does not bounce forever?
- It is important to see which simplification lead to ZENO runs.

## Non-determinism

- In general can be described as absence of unique solutions, i.e. that a hybrid automaton accepts multiple different runs emanating from the same initial conditions.
- When limited to Lipschitz continuous functions with unique solution, reason for non-determinism comes from discrete transitions.

## Non-deterministic on Purpose

- Can be used to model uncertainty.
- Modeller should make difference between non-determinism due to simplification, and non-determinism used on purpose.

## Observation

- Non-determinism is a real cause of troubles in both analysis and controller synthesis of hybrid systems.

## Existence of Solution

- How to detect existence of non-blocking run?
- How to detect ZENO behaviour?

## Uniqueness

- How to perform simulation of non-deterministic system?
  - Discrete transition vs. continuous time evolution.
  - Discrete transition vs. discrete transition.
- As-soon-as semantics.

## Discontinuity

- How to detect satisfiability of transition guards?
- What if state invariant ends with open interval  $[a, b)$  and the succeeding transition is allowed to execute at time  $[b]$ ?

## Composition

- How to compose hybrid automata?

## Non-blocking Hybrid Automaton

- Hybrid automaton  $H$  is called non-blocking if for all initial states  $(\hat{q}, \hat{x}) \in \text{Init}$  there exist an infinite run emanating from  $(\hat{q}, \hat{x})$ .

## Deterministic Hybrid Automaton

- Hybrid automaton  $H$  is called deterministic, if for all initial states  $(\hat{q}, \hat{x}) \in \text{Init}$  there exist at most one maximal run emanating from  $(\hat{q}, \hat{x})$ .

## Using Hybrid Automata

## Motivation for Modelling

- The goal of modelling of HS is to deduce properties of, or synthesise controllers for real HS from properties of, or controllers for modelled HS.

## Verification

- Does hybrid system exhibits declared behaviour (does it satisfy specification)?

## Synthesis

- There are number of choices to build a HS, using models it is possible to decide which choices are good and which are bad prior the construction of the real HS.

## Validation

- Check that the design described as a hybrid automaton and the real product produced behave accordingly.
- Some system modelled with hybrid automata may be unrealistic (and cannot be built) due to simplifications and abstractions used during modelling phase.

## Usual Work-flow

- Synthesis (of model)
- Verification (of model)
- Validation (equivalence of model and real product)

## Stability

- Typical property of purely continuous systems.
- To request stability for hybrid systems requires to specify what does the stability means with respect to the discrete part of the system.

## Specification by Set of States

- Specification of safety and forbidden areas.

## Specification by Set of Trajectories

- Properties of hybrid systems that can be expressed as properties of runs.
- Set of allowed runs of a hybrid automaton.
- Formally described using modal and temporal logic, such as (CTL, LTL, CTL\*).

## Deductive Methods

- Using math reasoning, such as math induction, to deduce properties of hybrid systems.

## Model Checking

- Algorithmic procedure for deciding formally specified properties of hybrid systems.
- Decidable only for limited sub-classes of hybrid automata.

## Simulations

- Used to estimate the set of reachable states.
- The precision of estimation is difficult to say.

## Typical Goal

- Typical goal for deductive methods is to set boundaries of the *reach* set using the so called **Invariant Set**.
- Invariant set is a set of states for which it holds that if a run of hybrid system is initiated at the state of the set it only visits states that are in the set (i.e. never leaves invariant set).

## Formal Definition of Invariant Set

- Set of state  $M \subseteq Q \times X$  of hybrid automaton  $H$  is called *invariant* if for all  $(\hat{q}, \hat{x}) \in M$ , all solutions  $(\tau, q, x)$  starting from  $(\hat{q}, \hat{x})$ , all  $I_i \in \tau$  and all  $t \in I_i$  it holds that  $(q_i(t), x_i(t)) \in M$ .

## Observation

- Union and Intersection of Invariant Sets of hybrid automaton  $H$  is also an invariant set for  $H$ .
- If  $M$  is an invariant set and  $Init \subseteq M$ , then  $Reach \subseteq M$ .

## Consequence

- To approximate the  $Reach$  set it is possible to deduce a number of invariant sets that contain initial state and are at the same time below the set of all states of hybrid automaton (here denoted by  $F$ )

$$Init \subseteq M \subseteq F$$

and intersect them.

## **Simplification**

- For hybrid automata we restrict ourselves in the course to algorithmic test of reachability of a given state.

## **Considered Sub-classes of Hybrid Automata**

- Timed Automata (TA).
- Rectangular Hybrid Automata (RHA).
- Linear Hybrid Automata (LHA).

## **Software Tools**

- UPPAAL – Timed Automata
- PHaVer – RHA, partially LHA (HyTech)

## Restriction

- All derivations to drive continuous evolution of the automaton has the form of:

$$\frac{dx_i(t)}{dt} = 1$$

- Resets  $R$  of discrete transitions are allowed either to keep the value of the continuous variable, or to reset it to 0.
- $Dom$  and  $G$  are defined only using relations  $\leq$  and  $\geq$  with respect to integral values.

## Intuition

- Finite automaton with a set of continuous variables to measure elapsed time.
- Measured time values may be reset to 0 using discrete transition.

## Example of Timed Automaton

## Exercise

- In two-dimensional graph with axes  $x_1$  and  $x_2$  show how the values of continuous variables change.

## Key Observation

- With respect to the restriction that comparisons are made only against integral values, two floating point values that have the same integral part cannot be differentiated.

## Equivalence Classes on the Continuous Domain

- If  $c$  is the greatest integral number used in a guard of timed automaton then the continuous domain can be represented with a finite set of intervals as follows:

$$[0], (0, 1), [1], (1, 2), [2], \dots [c - 1], (c - 1, c), [c], (c, \infty)$$

- Abstracted domain is finite for every continuous variable.
- It is possible to construct finite-state automaton that faithfully simulates behaviour of the timed automaton.
- This can be used for verification purposes.

# Region Abstraction

## Restriction

- All derivations to drive continuous evolution of the automaton has the form of:

$$a \leq \frac{dx_i(t)}{dt} \leq b,$$

where  $a$  and  $b$  are rational constants.

- When specifying RHA no derivation equations are given, just the boundary constants  $a$  and  $b$ .

## Exercise

- Consider a RHA with two continuous variables  $x_1$  and  $x_2$ .
- On two-dimensional graph with axes  $x_1$  and  $x_2$  show the evolution of values of the continuous variables.
- Guess the origin of the name of this particular sub-class of hybrid automata.

## Reachability

- Reachability problem for RHA is decidable if there are only finitely many values to which a continuous variable may be reset by a discrete transition.
- The most general sub-class of hybrid automata for which reachability is still decidable.

## Going Beyond Means Undecidability

- Relaxation from restriction of resets is known to result in sub-class of hybrid automata for which the reachability problem is undecidable.

## Definition

- Let  $k_0, \dots, k_m$  be numeric constants and  $x_1, \dots, x_m$  variables. An expression in the form of  $k_0 + k_1x_1 + k_2x_2 + \dots + k_mx_m$  is called a *linear expression*.
- Let  $t_1, t_2$  be linear expressions. An expression of the form  $t_1 \leq t_2$  is called linear inequality.
- Hybrid automaton  $H$  is called **linear hybrid automaton** (LHA), if  $Init, Dom, G$  and  $f$  are defined as Boolean combinations of linear inequalities.

## Undecidability

- The reachability problem for LHA is undecidable.
- Algorithms implemented for the LHA sub-class are incomplete (HyTech).

## Homework

- Will Lake Mead go dry? (SPACEex tool).

# IA169 System Verification and Assurance

## Verification of Systems with Probabilities

Vojtěch Řehák

## Fail-repair system

What are the properties of the model?

- $G(\text{working} \implies F \text{ done})$
- $G(\text{working} \implies F \text{ error})$
- $FG(\text{working} \vee \text{error} \vee \text{repair})$

NO

NO

NO

## Fail-repair system

- What is the probability of reaching “done” from “working” with no visit of “error”?
- What is the probability of reaching “done” from “working” with at most one visit of “error”?
- What is the probability of reaching “done” from “working”?

## Discrete-time Markov Chains (DTMC)

## Discrete-time Markov Chains (DTMC)

- Standard model for probabilistic systems.
- State-based model with probabilities on branching.
- Based on the current state, the succeeding state is given by a discrete probability distribution.
- Markov property (“memorylessness”) — only the current state determines the successors (the past states are irrelevant).
- Probabilities on outgoing edges sums to 1 for each state.
- Hence, each state has at least one outgoing edge (“no deadlock”).

## Model of a queue

Queue for at most 4 items. In every time tick, a new item comes with probability  $1/3$  and an item is consumed with probability  $2/3$ .

What if a new item comes with probability  $p = 1/2$  and an item is consumed with probability  $q = 2/3$ ?

## Model of the new queue

**Discrete-time Markov Chain** is given by

- a set of states  $S$ ,
- an initial state  $s_0$  of  $S$ ,
- a probability matrix  $P : S \times S \rightarrow [0, 1]$ , and
- an interpretation of atomic propositions  $I : S \rightarrow AP$ .

$$P = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0.05 & 0 & 0.95 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

## Fail-Repair System

- What is the probability of reaching “done” from “working” with no visit of “error”?
- What is the probability of reaching “done” from “working” with at most one visit of “error”?
- What is the probability of reaching “done” from “working”?

## Transient analysis

- distribution after  $k$ -steps
- reaching/hitting probability
- hitting time

## Long run analysis

- probability of infinite hitting
- stationary (invariant) distribution
- mean inter visit time
- long run limit distribution

## Property Specification

Recall some non-probabilistic specification languages:

**LTL formulae**

$$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid X\varphi \mid \varphi U \varphi$$

**CTL formulae**

$$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid EX\varphi \mid E[\varphi U \varphi] \mid EG\varphi$$

**Syntax of CTL\***

state formula	$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid E\psi$
path formula	$\psi ::= \varphi \mid \neg\psi \mid \psi \vee \psi \mid X\psi \mid \psi U \psi$

We need to quantify probability that a certain behaviour will occur.

## Probabilistic Computation Tree Logic (PCTL)

Syntax of PCTL

state formula	$\varphi ::= p \mid \neg\varphi \mid \varphi \vee \varphi \mid P_{\bowtie b}\psi$
path formula	$\psi ::= X\varphi \mid \varphi U\varphi \mid \varphi U^{\leq k}\varphi$

where

- $b \in [0, 1]$  is a probability bound,
- $\bowtie \in \{\leq, <, \geq, >\}$ , and
- $k \in \mathbf{N}$  is a bound on the number of steps.

A PCTL formula is always a state formula.

$\alpha U^{\leq k} \beta$  is a bounded until saying that  $\alpha$  holds until  $\beta$  within  $k$  steps. For  $k = 3$  it is equivalent to  $\beta \vee (\alpha \wedge X\beta) \vee (\alpha \wedge X(\beta \vee \alpha \wedge X\beta))$ .

Some tools also supports  $P_{=?}\psi$  asking for the probability that the specified behaviour will occur.

We can also use derived operators like  $G$ ,  $F$ ,  $\wedge$ ,  $\Rightarrow$ , etc.

**Probabilistic reachability**  $P_{\geq 1}(F \text{ done})$

- probability of reaching the state *done* is equal to 1

**Probabilistic bounded reachability**  $P_{>0.99}(F^{\leq 6} \text{ done})$

- probability of reaching the state *done* in at most 6 steps is  $> 0.99$

**Probabilistic until**  $P_{<0.96}((\neg \text{error}) U (\text{done}))$

- probability of reaching *done* with no visit of *error* is less than 0.96

## Qualitative PCTL properties

- $P_{\bowtie b} \psi$  where  $b$  is either 0 or 1

## Quantitative PCTL properties

- $P_{\bowtie b} \psi$  where  $b$  is in  $(0, 1)$

In DTMC where zero probability edges are erased, it holds that

- $P_{>0}(X \varphi)$  is equivalent to  $EX \varphi$ 
  - there is a next state satisfying  $\varphi$
- $P_{\geq 1}(X \varphi)$  is equivalent to  $AX \varphi$ 
  - the next states satisfy  $\varphi$
- $P_{>0}(F \varphi)$  is equivalent to  $EF \varphi$ 
  - there exists a finite path to a state satisfying  $\varphi$

but

- $P_{\geq 1}(F \varphi)$  is **not** equivalent to  $AF \varphi$   
(see, e.g., *AF done* on our running example)

There is no CTL formula equivalent to  $P_{\geq 1}(F \varphi)$ ,  
and no PCTL formula equivalent to  $AF \varphi$ .

# Quantitative - forward reachability

$$P = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0.05 & 0 & 0.95 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Probability distribution after  $k$  steps when starting in 1

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix} \times P = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix} \times P^2 = \begin{bmatrix} 0 & 0 & 0.05 & 0 & 0.95 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix} \times P^3 = \begin{bmatrix} 0 & 0 & 0 & 0.05 & 0.95 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix} \times P^4 = \begin{bmatrix} 0 & 0.05 & 0 & 0 & 0.95 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix} \times P^5 = \begin{bmatrix} 0 & 0 & 0.0025 & 0 & 0.9975 \end{bmatrix}$$

# Quantitative - backward reachability

$$P = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0.05 & 0 & 0.95 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Prob. of being in states 2 or 5 after  $k$  steps, i.e.  $P_{=?} F^{=k}(2 \vee 5)$

$$P \times [0 \ 1 \ 0 \ 0 \ 1]^T = [1 \ 0.95 \ 0 \ 1 \ 1]^T$$

$$P^2 \times [0 \ 1 \ 0 \ 0 \ 1]^T = [0.95 \ 0.95 \ 1 \ 0.95 \ 1]^T$$

$$P^3 \times [0 \ 1 \ 0 \ 0 \ 1]^T = [0.95 \ 1 \ 0.95 \ 0.95 \ 1]^T$$

$$P^4 \times [0 \ 1 \ 0 \ 0 \ 1]^T = [1 \ 0.9975 \ 0.95 \ 1 \ 1]^T$$

$$P^5 \times [0 \ 1 \ 0 \ 0 \ 1]^T = [0.9975 \ 0.9975 \ 1 \ 0.9975 \ 1]^T$$

# "Up to" reachability

Computing  $P_{=?} F^{\leq 6} 3$ .

Is it  $\sum_{i=0}^6 P_{=?} F^{=i} 3$ ?

No, we are summing probabilities of repeated visits.

It is true when the model is changed such that repeated visits are not possible. Alternatively, we can make the target state absorbing.

and it is  $\sum_{i=0}^6 P_{=?} F^{=i} 3$

and it is  $P_{=?} F^{\leq 6} 3$

## Unbounded reachability

Let  $p(s, A)$  be the probability of reaching a state in  $A$  from  $s$ .

It holds that:

- $p(s, A) = 1$  for  $s \in A$
- $p(s, A) = \sum_{s' \in \text{succ}(s)} P(s, s') * p(s', A)$  for  $s \notin A$

where  $\text{succ}(s)$  is a set of successors of  $s$  and  $P(s, s')$  is the probability on the edge from  $s$  to  $s'$ .

## Theorem

- The minimal non-negative solution of the above equations equals to the probability of unbounded reachability.

## Long Run Analysis

# Long run analysis

Recall that we reach the state 5 (*done*) with probability 1.

What are the states visited infinitely often with probability 1?

# States visited infinitely often

Decompose the graph representation onto strongly connected components.

## Theorem <sup>1</sup>

- A state is **not visited** or **visited infinitely often** with probability 1 if and only if it is in a **bottom strongly connected component**.
- All other states are **visited finitely many times** with probability 1.

<sup>1</sup>This holds only in DTMC models with finitely many states.

How often is a state visited among the states visited infinitely many times?

## Theorem

$$\lim_{n \rightarrow \infty} E \left( \frac{\# \text{ visits of state } i \text{ during the first } n \text{ steps}}{n} \right) = \pi_i$$

where  $\pi$  is a so called **stationary** (or **steady-state** or **invariant** or **equilibrium**) **distribution** satisfying  $\pi \times P = \pi$ .

Last remark on some DTMC extensions.

## Modules and synchronisation

# IA169 System Verification and Assurance

## CEGAR and Abstract Interpretation

Jiří Barnat

## Goals of Program Analysis

- Deduce program properties from the program source code and ...
- ... employ them for program optimisation.
- ... employ them for **program verification**.

## Undecidability

- Validity of all interesting program properties written in general programming language is algorithmically undecidable.
- Henry Gordon Rice (1953) – Rice's Theorems.
- Alan Turing (1936) – Halting Problem.

## Abstraction

- To hide details in order to simplify the analysis.
- Aims at correct, even if incomplete solution.

## Using Abstraction

- To build (typically finite state) model of system under verification. (Followed, e.g., by model checking approach to verification.)
- System execution within the context of abstraction – **Abstract Interpretation.**

## Recall Other Approaches

- Fixed input set of values (Testing).
- Limited exploration of the full state space (Bounded MC).
- Practical undecidability (Symbolic Execution).

## Data and Predicate Abstraction

## Motivation

- State space explosion due to large data domains.
- Reduction employing principle of domain testing, i.e. replacing original data domain with a data domain with less number of members.

## Terminology

- Abstraction: mapping concrete states to abstract ones.
- Concretisation: mapping abstract states to set of concrete states.

## Example of Data Abstraction

- $\text{Int} \rightarrow \{ \text{Even}, \text{Odd} \}$
- Concrete state:  $\langle \text{PC}:12, \text{A}:15, \text{B}:0 \rangle$
- Abstract state:  $\langle \text{PC}:12, \text{A}:\text{Odd}, \text{B}:\text{Even} \rangle$

## Transitions in Concrete and Abstract Semantics

- Statement in program code, line 12:  $A := A+A$
- In concrete semantics:  
 $\langle PC:12, A:15, B:0 \rangle \longrightarrow \langle PC:13, A:30, B:0 \rangle$
- in abstract semantics:  
 $\langle PC:12, A:Odd, B:Even \rangle \longrightarrow \langle PC:13, A:Even, B:Even \rangle$

## Non-Determinism in Abstract Transition System

- Abstract state:  $\langle PC:13, A:Even, B:Even \rangle$
- Statement in program code, line 13:  $A := A \text{ div } 2$
- $\langle PC:13, A:Even, B:Even \rangle \longrightarrow$   
 $\langle PC:14, A:Even, B:Even \rangle$   
 $\langle PC:14, A:Odd, B:Even \rangle$

## Over-Approximation

- Every run of concrete system is present in concretisation of some abstract run (run of abstracted transition system).
- There may exist runs that are present in concretisation of some abstract run, but are not allowed in concrete transition system.

## Under-Approximation

- Every run present in concretisation of any abstract run is an existing run of concrete transition system.
- There may exist runs of concrete transition systems that are not present in concretisation of any abstract run.

## Notation

- ATS – Abstract Transition System
- CTS – Concrete Transition System

## Verification of Over-Approximated Systems

- Absence of error in ATS proves absence of error in CTS.
- Error in ATS may, but need not indicate error in CTS.
- Error in ATS that is not an error in CTS, is referred to as false positive (spurious error, false alarm).

## Verification of Under-Approximated Systems

- Error in ATS proves presence of error in CTS.
- Absence of error in ATS does not prove absence of error in CTS.
- Error in CTS that is not present in ATS is referred to as false negative.

## Task

- Is error state reachable in the following program?
- % denotes modulo operation, A in an integral variable

Source-code	Value of A in concrete semantics after execution of program statement	
1 read(A);	[int]	
2 A = A % 2;	[0]	[1]
3 A = A + 1;	[1]	[2]
4 if (A==0)	<false>	<false>
5 <b>error;</b>		
6 else		
7     return;	<ret>	<ret>

## Task

- Is error state reachable in the following program?
- A is abstracted into parity domain {even, odd}.

Source-code	Value of A in abstract semantics after execution of program statement	
1 read(A);	[even]	[odd]
2 A = A % 2;	[even]	[odd]
3 A = A + 1;	[odd]	[even]
4 if (A==0)	<false>	<true/false>
5 <b>error;</b>		< <b>error</b> >
6 else		
7     return;	<ret>	<ret>

## Predicate Abstraction

- Predicates – Boolean expressions about variable values.
- Example of definition of abstract transition system:  
⟨Program Counter, Validity of selected predicates⟩

## Amount of Abstraction

- Amount of predicates influences the precision of abstraction.
- Less predicates  $\rightsquigarrow$  big ambiguity, smaller state space.
- More predicates  $\rightsquigarrow$  increased precision, bigger state space.

## Task

- For the given program code and set of predicates, draw the abstract transition system formed using predicate abstraction.
- Check if there is path in your ATS that is not a spurious run and leads to an error state.

```
1  read(A);  
2  A = A % 2;  
3  A = A + 1;  
4  if (A==0)  
5      error;  
6  else  
7      return;
```

a)  $P1 \equiv A = 0$

b)  $P1 \equiv A = 0,$   
 $P2 \equiv A \geq 0$

## **Analysis of Abstract Runs Leading to Error**

- Decision about validity of the run (Is it a false alarm?)
- Deduction of new predicates to make abstraction more precise.

## **Size of Abstract Transition System**

- The size of the state space grows exponentially with the number of predicates.

## **Possible Solution**

- Predicates are bound to particular program locations.

## CEGAR Approach

## Principle of CEGAR Approach

- Given an initial set of predicates, system is abstracted with predicate abstraction.
- Abstract transition system (over-approximation) is verified with a model checking procedure.
- In the case a reported counterexample is found spurious, it is analysed in order to deduce new predicates and refine predicate abstraction.
- Procedure repeats until real counterexample is found or system is successfully verified.

## Notes

- Deducing new predicates is very difficult.
- Often done within model checking procedure (on-the-fly).
- Berkeley Lazy Abstraction Software Verification Tool (BLAST).

# Schema of CEGAR Approach

## Basics of Abstract Interpretation and Static Analysis of Programs

## Program Representation – Flow Graph

- "Special version" of Control-Flow Graph.
- Every edge is either guarded with a single guard or defines a single assignment.

## Goal

- Compute properties of individual vertices of the flow-graph.

## Goal Examples

- Deduce range of values a particular variable may take in a given program location.
- Compute a set of live variables in a given program location.
- ...

## Property Decomposition

- The property to be verified by general program analysis procedure can be decomposed into local data values assigned to individual vertices of the (control-)flow graph.
- The result of verification is compound or deduced from the values local to the flow-graph vertices.

## Value Improvement

- It is defined how an edge of the (control-)flow graph improves (locally updates) the decomposed value of the property to be verified.
- Application of local update functions gradually (monotonously) improve (approximate) the overall solution.

## Initialisation

- Initially, a suitable value is assigned to every vertex.
- Every edge of the graph is marked as unprocessed.

## Computation

- Pick an unprocessed edge of the graph and perform the local update relevant to the edge and associated vertices. If the update improved the solution, mark the edge as unprocessed again.
- Repeat until there are no unprocessed edges, i.e. until overall fix-point is reached.

## Setup

- Initial value associated with graph vertices is  $\emptyset$ .
- Every edge from vertex  $u$  to vertex  $v$  updates value associated with the vertex  $u$  as follows:

$$V(u) = V(u) \cup \left( V(v) \setminus \text{assigned}(u, v) \cup \text{used}(u, v) \right),$$

where  $V(x)$  denotes value associated with vertex  $x$ ,  $\text{assigned}(u, v)$  and  $\text{used}(u, v)$  denote variables redefined and used along the edge  $(u, v)$ , respectively.

## Observation

- In every moment of computation there is some (approximating) solution to the verified property.
- Reaching a fix-point indicate, no more information can be deduced by program analysis in the current setup.

## Observation

- The procedure presented on previous slides is quite general. Choosing proper setup may result in verification (computation) of many interesting program properties.
- Often this is combined with some data abstraction for variables.
- May be performed on partially unwinded graphs.
- Generally referred to as to **abstract interpretation**.

## Parameters

- What abstract domain is used.
- Direction of update function (forward, backward, both).
- What does update function do.
- How are the values merged over multiple incoming edges.
- Order of processing of unprocessed edges.
- Termination detection.

## **Is there a fix-point?**

- Often the composition of domains of values associated to vertices forms a complete lattice.
- Knaster-Tarski theorem says that every monotonous function over such a domain has a fix point.

## **Does computation terminates?**

- If there is no infinitely ascending sequence of possible solutions in the composition of local domains, then yes.
- Otherwise, need not terminate.

## Widening

- Auxiliary transformation of intermediate results such that it preserves correctness, and at the same times prevents existence of long (possibly infinite) ascending sequence of values in the corresponding domain.

## Example of widening

- Let be given boundaries of precision in which we want to know the range of possible values of some variable.
- Beyond the precision boundaries values will be extended to infinity, i.e.  $+\infty$  or  $-\infty$ .
- Sequence

$$[0,1] \subset [0,2] \subset [0,3] \subset [0,4] \subset [0,5] \subset [0,6] \dots$$

will for precision bound  $[0,3]$  turn into:

$$[0,1] \subset [0,2] \subset [0,3] \subset [0,+\infty]$$

## Narrowing

- Using widening may lead to very imprecise results.
- Widening can be used to accelerate analysis of cycles.
- After widening-based analysis of cycle, the values are made more precised with narrowing (similar but dual technique).

## Example

- Interval  $[0, +\infty]$  will after narrowing shrink to  $[0, n]$ .

## Commentary

- Precise usage of widening and narrowing is beyond the scope of this lecture.

## Other Corners of Program Analysis

- Inter-procedural analysis.
- Analysis of parallel programs.
- Generation of invariants.
- Pointer analysis and analysis of dynamic memory structures.
- ...

## CPA checker

- The Configurable Software-Verification Platform
- <http://cpachecker.sosy-lab.org/>
- Very successful competitor in Software Verification Competition.

## Wanna Challenge?

- Symbolic execution

## Course topics II

- Bounded Model Checking
- CEGAR and Abstract Interpretation
- Verification of Real-Time and Hybrid systems
- Verification of systems with probabilities

## Course structure, credits

- 2/2/2 credits, +2 for the final exam
  - Lecture: 2 hours weekly
  - Seminar: 2 hours weekly
  - Homework: 5+ hours weekly (on average)

# Course marking

- Final exam: 70%
- Assignments: 30%
- Marking scheme:
  - A for 90% or higher, then
  - B for 80% or higher, then
  - C for 70% or higher, then
  - D for 60% or higher, then
  - E for 50% or higher, then
  - F(ail) for less than 50%.

Colloquy or credit – at least 44%.

## Resources used – first lecture

- *Common Criteria for Information Technology Security Evaluation*, v 3.4, rev. 4, Sep 2012
  - <http://www.commoncriteriaportal.org/>
- *Separation Kernel Protection Profile Revisited: Choices and Rationale*, T.E. Levin et al., 4<sup>th</sup> Annual Layered Assurance Workshop, 2010
- *Common Criteria Certification in the UK – UK IT security evaluation & certification scheme*, CESG
- *Understanding the Windows EAL4 evaluation*, J.S. Shapiro, IEEE Computer 03/2003
- *Security Requirements for Cryptographic Modules*, FIPS PUB 140-2
  - <http://csrc.nist.gov/publications/fips/fips140-2/fips1402.pdf>

# Security threat model

- Two views:
  - 1) Description of security threats considered when designing a (security) solution/system.
  - 2) Definition of (all) possible threats to consider.
- Usual security notion:
  - *Assets* to be protected
  - *Vulnerabilities* of assets and relevant systems
  - *Threats* exploiting the vulnerabilities
  - *Countermeasures* (aim to) mitigate the threats

# Threat modelling – approaches

- Attacker centric
  - Popular in the research community (following two slides)
- System centric (a.k.a. design/SW centric)
  - Taking over in the past decade or so, e.g. used in the Microsoft Security Development Lifecycle
- Asset centric
  - Business logic
- Defender/owner view getting more prominent

# Attacker models – Needham & Schroeder

- attacker can eavesdrop and interfere all communication
  - record/modify/replay/inject messages
- node internal processes are safe
  - secret keys, encryption process, ...
- Comms security classics, paper from 1978 – paper Using encryption for authentication in large networks of computers, ACM Communications

## Attacker models – Dolev & Yao

- Network = set of abstract machines exchanging messages.
- Message = formal terms. Terms reveal some of the message internal structure to the adversary, but not all.
- Adversary can overhear, intercept, and synthesize any message, is limited by the constraints of the cryptographic methods used.
  - Sometimes put as “the attacker carries the message.”
- Paper “On the security of public key protocols”, IEEE Trans. on Information Theory, 1983

## Trusted system/product

- Such one that behaves in a way we expect it to behave
- Can be trusted to only such a functionality that adheres to the relevant security policy
- Trust
  - Belief that (a system...) satisfies given (security) requirements and specifications
  - Chance that (a system...) can breach the (security) policy without leaving any trace of evidence 😊

## Common Criteria

- Interests of users, manufacturers, evaluators
- *Target of evaluation* (TOE) – what is (to be) evaluated
- *Protection profile* (PP) (smartcards, biometrics, etc.)
  - Catalogued as a self-standing evaluation document
- *Security target* (ST) – theoretical concept/aim
- *Security Functional Requirements* (SFRs) – individual security functions provided by the TOE
  
- Evaluation of TOE – is the reality corresponding to theory (ST)?

# Common Criteria model

- TOE: Target of Evaluation – the evaluated system
- TSF: TOE Security Functions – HW, SW, FW used by the TOE
- TSC: TSF Scope of Control – interactions under the TOE security policy

## Common Criteria – two catalogues

- Two catalogues of components for specification of assurance and functionality requirements, with a standard terminology.
- Functionality – rules governing access to & use of TOE resources, and thus information and services controlled by the TOE
- Assurance
  - grounds for confidence that an entity meets its security objectives (CC v2.3)
  - grounds for confidence that a TOE meets the SFRs (CC v3.1)

# Assurance is not robustness

- Assurance
  - grounds for confidence that an entity meets its security objectives (CC v2.3)
  - grounds for confidence that a TOE meets the SFRs (CC v3.1)
- Robustness
  - characterization of the strength of a security function, mechanism, service or solution, and the assurance (or confidence) that it is implemented and functioning correctly (US DoD definition)

## CC evaluation in a nutshell

1. Define the product/system for evaluation
2. Specify its functionality
3. Specify the assurance level claimed
4. See details of evaluation with a certification body
5. Prepare evidence

# CC: Functional & Assurance Requirements

## *Security Functional Requirements (SFRs)*

- The core – CC is in a major part a catalogue of security functions
- Same product with different ST => different SFRs
- Correctness of one function can depend on another function

## *Security Assurance Requirements (SARs)*

- Measures taken to assure compliance with the claimed functionality
- Design, development, evaluation/verification
- CC provides a catalogue of SARs

## CC functional classes

- FAU: SECURITY AUDIT
- FCO: COMMUNICATION
- FCS: CRYPTOGRAPHIC SUPPORT
- FDP: USER DATA PROTECTION
- FIA: IDENTIFICATION AND AUTHENTICATION
- FMT: SECURITY MANAGEMENT
- FPR: PRIVACY
- FPT: PROTECTION OF THE TSF
- FRU: RESOURCE UTILISATION
- FTA: TOE ACCESS
- FTP: TRUSTED PATH/CHANNELS

## CC assurance classes

- APE: PROTECTION PROFILE EVALUATION
- ASE: SECURITY TARGET EVALUATION
- ADV: DEVELOPMENT
- AGD: GUIDANCE DOCUMENTS
- ALC: LIFE-CYCLE SUPPORT
- ATE: TESTS
- AVA: VULNERABILITY ASSESSMENT
- ACO: COMPOSITION

## CC assurance paradigms

- *assurance based upon an evaluation* (active investigation)
- measuring the validity of the documentation and of the resulting IT product by expert evaluators with increasing emphasis on scope, depth, and rigour
- CC does not exclude, nor does it comment upon, the relative merits of other means of gaining assurance

# Assurance through evaluation I

- a) analysis and checking of process(es) and procedure(s);
- b) checking that process(es) and procedure(s) are being applied;
- c) analysis of the correspondence between TOE design representations;
- d) analysis of the TOE design representation against the requirements;
- e) verification of proofs;

## Assurance through evaluation II

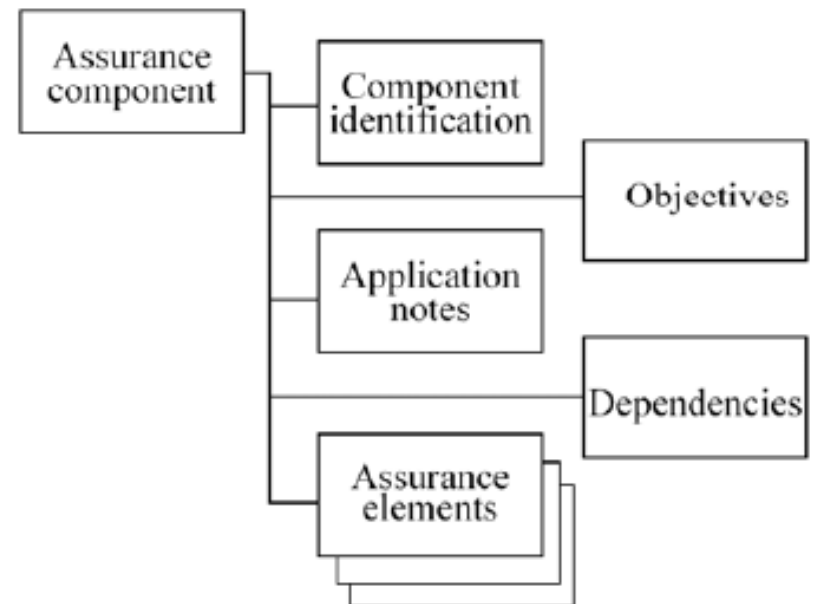

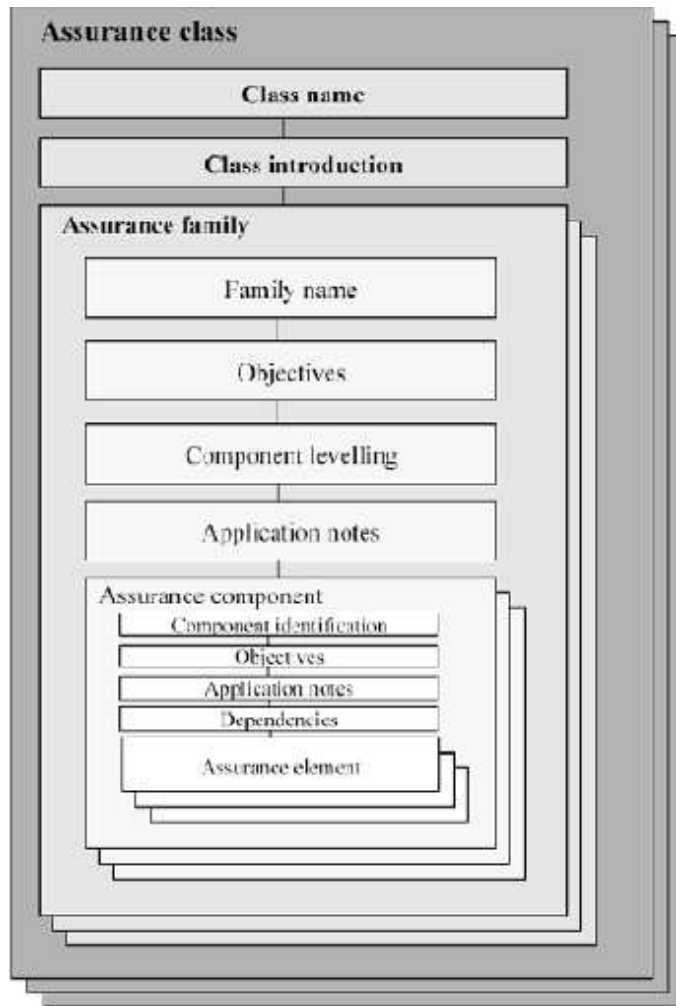

- f) analysis of guidance documents;
- g) analysis of functional tests developed and the results provided;
- h) independent functional testing;
- i) analysis for vulnerabilities (including flaw hypothesis);
- j) penetration testing.

## CC evaluation assurance scale

The increasing level of effort is based upon:

- a) *scope* – the effort is greater because a larger portion of the IT product is included;
- b) *depth* – the effort is greater because it is deployed to a finer level of design and implementation detail;
- c) *rigour* – the effort is greater because it is applied in a more structured, formal manner.

# CC – assurance hierarchy & component structure

## Assurance elements – 3 exclusive classes

1. *Developer action elements*: activities that shall be performed by the developer. Further qualified by evidential material referenced in the following set of elements. Req's marked by "D" at the element No.
2. *Content and presentation of evidence elements*: the evidence required, what the evidence demonstrates, what the evidence shall convey. Marked by "C".
3. *Evaluator action elements*: activities that shall be performed by the evaluator. Marked by "E".

Assurance class	Assurance Family	Assurance Components by Evaluation Assurance Level

## 7 evaluation assurance levels (EALs)

- Hierarchical system – higher or new components  
– bold faced text in the description for the **added components**
- The following slides present first the EALs in the language of the CC and then from a practical perspective.

## EAL1 – functionally tested

- some confidence in correct operation is required, but the threats to security are not viewed as serious
  - sufficient to simply state the SFRs that the TOE must meet, rather than deriving them from threats, etc. through security objectives;
  - analysis is supported by a search for potential vulnerabilities in the public domain and independent testing (functional and penetration) of the TSF;
  - This EAL provides a meaningful increase in assurance over unevaluated IT.

## EAL2 – structurally tested

- assurance by a full security target (with given SFRs);
- analysis of the SFRs, using *functional* and *interface specs*, *guidance documentation* and *basic TOE architecture* description to understand the security behaviour;
- configuration management system and evidence of secure delivery procedures;
- independent confirmation of the developer test results, vulnerability analysis (based upon the *above in italics*) demonstrating resistance to penetration attackers with a basic attack potential.

## EAL3 – methodically tested and checked

- architectural description of the TOE design;
- development environment controls
- improved testing coverage of the security functionality and mechanisms and/or procedures that provide some confidence that the TOE was not tampered with during development.

## EAL4 – methodically designed, tested, and reviewed

- complete interface specification, description of the basic modular design of the TOE, implementation representation for the entire TSF;
- demonstrating resistance to penetration attackers with an Enhanced-Basic attack potential;
- additional TOE configuration mgmt incl. automation;

## EAL5 – semiformally designed and tested

- modular TSF design;
- comprehensive TOE configuration management;
- semiformal design descriptions, a more structured (and hence analysable) architecture.

## EAL6 – semiformally verified design and tested

- formal model of select TOE security policies;
- semiformal presentation of the functional specification and TOE design;
- modular layered and simple TSF design;
- structured development process, development environment controls, and comprehensive TOE configuration mgmt incl. complete automation;
- more comprehensive analysis, more architectural structure (e.g. layering), more comprehensive independent vulnerability analysis.

## EAL7 – formally verified design and tested

- structured presentation of the implementation;
- implementation representation, complete independent confirmation of the developer test results;
- comprehensive analysis using formal representations and formal correspondence, and comprehensive testing.

United States	1	0	17	27	1	1	2	15	0	1	0	0	0	0	0	0	0	43	108
<b>Totals:</b>	<b>34</b>	<b>36</b>	<b>87</b>	<b>208</b>	<b>141</b>	<b>213</b>	<b>76</b>	<b>667</b>	<b>12</b>	<b>333</b>	<b>0</b>	<b>23</b>	<b>5</b>	<b>1</b>	<b>0</b>	<b>0</b>	<b>0</b>	<b>54</b>	<b>1890</b>

## EAL1 – functionally tested

- analysis supported by independent testing of a sample of the security functions;
- applicable where confidence in correct operation is required but the security threat assessment is low.
- This EAL is particularly suitable for legacy systems as it should be achievable without the assistance of the developer.

## EAL2 – structurally tested

- analysis exercises a functional and interface specification and the high-level design of the subsystems of the TOE;
- independent testing of the security functions;
- evidence required of developer 'black box' testing and development search for obvious vulnerabilities.
- EAL2 is applicable where a low to moderate level of independently assured security is required.

## EAL3 – methodically tested and checked

- analysis supported by 'grey box' testing, selective independent confirmation of the developer test results and evidence of a developer search for obvious vulnerabilities;
- development environment controls and TOE configuration management are also required.
- EAL3 for a moderate level of independently assured security, with a thorough investigation of the TOE and its development, without incurring substantial re-engineering costs.

## EAL4 – methodically designed, tested, and reviewed

- analysis supported by the low-level design of TOE modules and a subset of the implementation;
- testing supported by an independent search for obvious vulnerabilities;
- development controls supported by a life-cycle model, identification of tools and automated configuration management.
- EAL4 for a moderate to high level security, where some additional security-specific engineering costs may be incurred.

## EAL5 – semiformally designed and tested

- analysis includes all of the implementation;
- supplemented by a *formal model*, a *semiformal presentation of the functional specification* and high level design and a *semiformal demonstration of correspondence*;
- search for vulnerabilities must ensure resistance to penetration attackers with a moderate attack potential;
- covert channel analysis and modular design required.
- EAL5 for a high level of security in a planned development coupled with a rigorous development approach.

## EAL6 – semiformally verified design and tested

- analysis supported by a *modular approach to design* and a structured presentation of the implementation;
- independent search for vulnerabilities must ensure resistance to penetration attackers with a high attack potential;
- a systematic search for covert channels;
- EAL6 where a specialised security TOE is required for high risk situations.

## EAL7 – formally verified design and tested

- the formal model is supplemented by a *formal presentation of the functional specification and high level design, showing correspondence*;
- evidence of developer 'white box' testing and complete independent confirmation of developer test results.
- EAL7 where a specialised security TOE is required for extremely high risk situations.

## Famous issue – Windows 2000

- Windows 2000 operating system was certified (Common Criteria) at EAL-4 in 2002.
  - with SP3 and one patch;
  - EAL-4, augmented with ALC\_FLR.3 (Systematic Flaw Remediation);
  - Microsoft invested millions of dollars and three years of effort to gain the certification. (S. Bekker, Redmond Magazine).
- Controlled Access Protection Profile (CAPP)

## CAPP assumption A.PEER

“Any other systems with which the TOE communicates are assumed to be under the same management control and operate under the same security policy constraints.

The TOE is applicable to networked or distributed environments only if the entire network operates under the same constraints and resides within a single management domain.

There are no security requirements that address the need to trust external systems or the communications links to such systems.”

## Controlled Access Protection Profile

- Level of protection appropriate for an assumed non-hostile and well-managed user community
  - requiring protection against threats of inadvertent or casual attempts to breach the system security.
- The profile is not intended to be applicable to circumstances in which protection is required against determined attempts by hostile and well funded attackers to breach system security.
- CAPP does not fully address the threats posed by malicious system development or administrative personnel.

## Windows 2000 EAL-4 certification

- EAL4 rating means that you did a lot of paperwork related to the software process, but says absolutely nothing about the quality of the software itself. (J.S. Shapiro)
- System disconnected from networks (at different security level), disabled media drives, etc.
- Don't hook this to the internet, don't run email, don't install software unless you can 100 percent trust the developer, and if anybody who works for you turns out to be out to get you, you are toast. (J.S. Shapiro)

## And Now for Something Completely Different... about Assurance viewed by...

- Customer – what level of guarantee I get that security has been implemented in the product?
- Developer – what (inputs and cooperation) will my team have to provide for the evaluation?
- Evaluator – did I get all required inputs and did all tests run OK to confirm the claim?
- Operator – what assumptions can I build on when preparing for my actions?

# Security Requirements for Cryptographic Modules

- Federal Information Processing Standard (FIPS) Publication 140-2 (FIPS PUB 140-2)
- published May 2001 and last updated Dec 2002
  - FIPS 140-3 (Draft) – proposed revision, hanging in the air since 2009 (!)
- 4 levels, hierarchical levelling
- 11 functions (requirements):
  - Cryptographic module specification; Cryptographic module ports and interfaces; Role, services, and authentication; Physical security; Operational environment; Cryptographic key management; Mitigation of other attacks; ...

## FIPS 140-2 Annexes (drafts)

- Annex A: Approved Security Functions (Draft 2011)
- Annex B: Approved Protection Profiles (Draft 2007)
- Annex C: Approved Random Number Generators (Draft 2010)
- Annex D: Approved Key Establishment Techniques (Draft 2011)

# FIPS 140-2 levels I

## Level 1

- basic security requirements (e.g., certified algorithm);
- no specific physical security mechanisms.

## Level 2

- features that show evidence of tampering – physical access to the plaintext cryptographic keys and critical security parameters (CSPs) within the module
  - including tamper-evident coatings or seals that must be broken to attain,
- or pick-resistant locks on covers or doors to protect against unauthorized physical access.

# FIPS 140-2 levels II

## Level 3

- high probability of detecting and responding to attempts at physical access, use or modification of the cryptographic module;
- may include the use of strong enclosures and tamper detection/response circuitry that zeroes all plain text CSPs when the removable covers/doors of the cryptographic module are opened.

## FIPS 140-2 levels III

### Level 4

- physical security mechanisms provide a complete envelope of protection around the cryptographic module with the intent of detecting and responding to all unauthorized attempts at physical access;
- protects a cryptographic module against a security compromise due to environmental conditions or fluctuations outside of the module's normal operating ranges for voltage and temperature;
- for operation in physically unprotected environments.

## FIPS 140-2

- Level 2 – operating system at EAL2+
- Level 3 – operating system at EAL3+  
– and additional req.: Security Policy Model (ADV\_SPM.1)
- Level 4 – operating system at EAL4+

## Nice standards and theory, but...

- OpenSSL derivative FIPS-certified, found flawed
  - that particular one de-certified, others including the flaw not
- Dual EC DRBG defective by design mandated for FIPS 140-2
- IBM 4758 (with CCA API) – level 4
  - easy/fast logical attacks on CCA API
- Safenet Luna CA<sup>3</sup>
  - disassembling showed no potting material
  - undocumented API functions
  - functionality in breach of security policy

## Study of a particular PP

- PP BSI-PP-0025 – German (BSI) Common Criteria Protection Profile for USB Storage Media
  - [https://www.bsi.bund.de/SharedDocs/Downloads/DE/BSI/Zertifizierung/ReportePP/pp0025b\\_engl\\_pdf.pdf?blob=publicationFile](https://www.bsi.bund.de/SharedDocs/Downloads/DE/BSI/Zertifizierung/ReportePP/pp0025b_engl_pdf.pdf?blob=publicationFile)
- PP organisation:
  - the TOE description,
  - the TOE security environment,
  - the security objectives,
  - the IT security requirements and
  - the rationale.

## PP BSI-PP-0025 – roles in the TOE

- Authorised user (S1)
  - Holds the authentication attribute required to access the TOE's protected memory area, in which the confidential data is stored.
  - Can modify the authentication attribute.

## PP BSI-PP-0025 – roles in the TOE, cont'd

- Non-authorized user (S2)
  - Wishes to access S1's confidential data in the USB storage medium's memory (examples of confidential data are given in Section 2.5).
  - Does not have the authentication attribute to access the protected data.
  - Can obtain a USB storage medium of the same type. Can try out both logical and physical attacks on this USB storage medium.
  - Can gain possession of the TOE relatively easily since the TOE has a compact form.

## PP BSI-PP-0025 – threats (countered)

- T.logZugriff – Assuming that S2 gains possession of the TOE, he/she accesses the confidential data on the TOE. S2 gains logical access by, for example, connecting the TOE to the USB interface of a computer system.
- T.phyZugriff – Assuming that S2 gains possession of the TOE, he/she accesses the TOE's memory by means of a physical attack. Such an attack could take the following form, for example: S2 removes the TOE's memory and places it into another USB storage medium which he/she uses for the purpose of logical access to the memory.

## PP BSI-PP-0025 – threats, cont'd

- T.AuthÄndern – Assuming that S2 gains possession of the TOE, he/she sets a new authentication attribute, with the result that the data becomes unusable for S1.
- T.Störung – A failure (e.g. power failure or operating system error) stops the TOE operating correctly. As a result, confidential data remains unencrypted or the TOE's file system is damaged.

## Study of another PP development

- Security kernel – used to simulate a distributed environment, introduced by J Rushby (1981) as a solution to the difficulties and problems that had arisen in the development and verification of large, complex security kernels that were intended to “provide multilevel secure operation on general-purpose multi-user systems.”
- U.S. Government Protection Profile for Separation Kernels in Environments Requiring High Robustness, v 1.03
