- Experiment, process, test, ...
- Set of possible basic outcomes: sample space Ω (základní prostor obsahující možné výsledky)
	- \triangleright coin toss (Ω = {head, tail}), die (Ω = {1..6})
	- \triangleright yes/no opinion poll, quality test (bad/good) ($\Omega = \{0,1\}$)
	- ► lottery $(|\Omega| \cong 10^7..10^{12})$
	- \triangleright # of traffic accidents somewhere per year $(\Omega = \mathsf{N})$
	- ► spelling errors $(\Omega = \Z^*)$, where Z is an aplhabet, and \Z^* is set of possible strings over such alphabet
	- \triangleright missing word ($|\Omega| \cong$ vocabulary size)

Events

- Event (jev) A is a set of basic outcomes
- Usually A $\subset \Omega$, and all A $\in 2^{\Omega}$ (the event space, jevové pole)
	- \triangleright Ω is the certain event (jistý jev), \emptyset is the impossible event (nemožný jev)
- Example:
	- \triangleright experiment: three times coin toss
		- \triangleright $\Omega = \{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT\}$
	- \triangleright count cases with exactly two tails: then

$$
\blacktriangleright A = \{ \text{HTT, THT, TTH} \}
$$

 \blacktriangleright all heads:

 \triangleright A = {HHH}

- **Repeat experiment many times, record how many times a given event** A occured ("count" c_1).
- \blacksquare Do this whole series many times; remember all c_i s.
- Observation: if repeated really many times, the ratios of $\frac{c_i}{T}$ $\frac{\sigma_i}{T_i}$ (where

 T_i is the number of experiments run in the *i-th* series) are close to some (unknown but) constant value.

Example 1 Call this constant a **probability of A**. Notation: **p(A)**

Estimating Probability

Remember: . . . close to an unknown constant.

- We can only estimate it:
	- \triangleright from a single series (typical case, as mostly the outcome of a series is given to us we cannot repeat the experiment):

$$
p(A) = \frac{c_1}{T_1}
$$

• otherwise, take the weighted average of all $\frac{c_i}{T_i}$ (or, if the data allows, simply look at the set of series as if it is a single long series). **This is the best estimate.**

Example

Recall our example:

- \triangleright experiment: three times coin toss
	- $\Omega = \{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT\}$
- \triangleright count cases with exactly two tails: $A = \{HTT, THT, TTH\}$
- Run an experiment 1000 times (i.e. 3000 tosses)
- Counted: 386 cases with two tails (HTT, THT or TTH)
- **estimate:** $p(A) = 386/100 = .386$
- Run again: 373, 399, 382, 355, 372, 406, 359
	- \triangleright p(A) = .379 (weighted average) or simply 3032/8000
- Uniform distribution assumption: $p(A) = 3/8 = .375$

Basic Properties

- **Basic properties:**
	- \blacktriangleright p: $2^{\Omega} \rightarrow [0, 1]$
	- \blacktriangleright p(Ω) = 1
	- ► Disjoint events: $p(\cup A_i) = \sum_i p(A_i)$
- NB: axiomatic definiton of probability: take the above three conditions as axioms
- **Immediate consequences:**

$$
\blacktriangleright \; \mathsf{P}(\emptyset) = 0
$$

$$
\blacktriangleright \; p(\overline{A}) = 1 - p(a)
$$

$$
\blacktriangleright A \subseteq B \Rightarrow p(A) \leq P(B)
$$

 \blacktriangleright $\sum_{a\in\Omega}$ p $(a)=1$

Joint and Conditional Probability

$$
\mathsf{p}(A, B) = p(A \cap B)
$$
\n
$$
\mathsf{p}(A|B) = \frac{p(A, B)}{p(B)}
$$

 \blacktriangleright Estimating form counts:

$$
\blacktriangleright \ \ \rho(A|B) = \frac{\rho(A,B)}{\rho(B)} = \frac{\frac{c(A \cap B)}{T}}{\frac{c(B)}{T}} = \frac{c(A \cap B)}{c(B)}
$$

Bayes Rule

p(A,B) = p(B,A) since $p(A \cap B) = p(B \cap A)$ In therefore $p(A|B)p(B) = p(B|A)p(A)$, and therefore:

Bayes Rule

$$
p(A|B) = \frac{p(B|A) \times p(A)}{p(B)}
$$

Independence

- Can we compute $p(A,B)$ from $p(A)$ and $p(B)$?
- Recall from previous foil:

$$
p(A|B) = \frac{p(B|A) \times p(A)}{p(B)}
$$

$$
p(A|B) \times p(B) = p(B|A) \times p(A)
$$

$$
p(A, B) = p(B|A) \times p(A)
$$

- ... we're almost there: how $p(B|A)$ relates to $p(B)$?
	- \triangleright p(B|A) = p(B) iff A and B are **independent**
- Example: two coin tosses, weather today and weather on March 4th 1789;
- Any two events for which $p(B|A) = P(B)$!

$$
p(A_1, A_2, A_3, A_4, \ldots, A_n) =
$$

$$
p(A_1|A_2, A_3, A_4, \ldots, A_n) \times p(A_2|A_3, A_4, \ldots, A_n) \times
$$

$$
\times p(A_3|A_4, \ldots, A_n) \times \cdots \times p(A_{n-1}|A_n) \times p(A_n)
$$

this is a direct consequence of the Bayes rule.

Interested in an event A given B (where it is not easy or practical or desirable) to estimate $p(A|B)$:

stake Bayes rule, max over all Bs:

$$
argmax_{AP}(A|B) = argmax_{A} \frac{p(B|A) \times p(A)}{p(B)} = \boxed{argmax_{A}(p(B|A) \times p(A))}
$$

 \blacksquare ... as $p(B)$ is constant when changing As

Random Variables

- is a function $X : \Omega \to Q$
	- in general $Q = R^n$, typically R
	- \triangleright easier to handle real numbers than real-world events
- **Example 1** random variable is *discrete* if Q is countable (i.e. also if finite)
- Example: die: natural "numbering" $[1,6]$, coin: $\{0,1\}$
- **Probability distribution:**
	- \blacktriangleright $p_X(x) = p(X = x) =$ _{df} $p(A_x)$ where $A_x = \{a \in \Omega : X(a) = x\}$
	- \triangleright often just $p(x)$ if it is clear from context what X is

Expectation Joint and Conditional Distributions

■ is a mean of a random variable (weighted average)

$$
\blacktriangleright \ \ E(X) = \sum_{x \in X(\Omega)} x.p_X(x)
$$

- Example: one six-sided die: 3.5, two dice (sum): 7
- **Joint and Conditional distribution rules:**
	- \triangleright analogous to probability of events

Bayes: $p_{X|Y}(x, y) =$ notation $p_{XY}(x|y) =$ even simpler notation

$$
\left(\rho(x|y) = \frac{\rho(y|x).\rho(x)}{\rho(y)}\right)
$$

 \mathbf{a} $^{\prime}$

Chain rule: \sqrt{p} ✝ $p(w, x, y, z) = p(z).p(y|z).p(x|y, z).p(w|x, y, z)$

Standard Distributions

Binomial (discrete)

- \triangleright outcome: 0 or 1 (thus binomial)
- \blacktriangleright make *n* trials
- \triangleright interested in the (probability of) numbers of successes r
- Must be careful: it's not uniform!

$$
\bullet \quad p_b(r|n) = \frac{\binom{n}{r}}{2^n} \text{ (for equally likely outcome)}
$$

 $\binom{n}{r}$ $\binom{n}{r}$ counts how many possibilities there are for choosing r objects out of n;

$$
\blacksquare \binom{n}{r} = \frac{n!}{(n-r)!r!}
$$

Continuous Distributions

■ The normal distribution ("Gaussian")

$$
p_{norm}(x|\mu,\sigma) = \exp\left[\frac{-(x-\mu)^2}{2\sigma^2}\right]
$$

where:

- \triangleright μ is the mean (x-coordinate of the peak) (0)
- \triangleright σ is the standard deviation (1)

other: hyperbolic, t
