

# LAB 9: WiFi security

PA197

Michal Šnajdr  
snajdr@ics.muni.cz

# Warning

All of the advice/information that I'll give is **purely for educational purposes**. MU will not be responsible for any illegal use of this tutorial. Don't hack any wireless network, unless you are the owner of that network.

## Wifi security - vulnerabilities

- ▶ Hidden SSID
- ▶ MAC filtering
- ▶ Weaknesses in WEP encryption
- ▶ Security vs. Comfort (Is WPS secure?)
- ▶ WPA/WPA2 capture handshake
- ▶ Homework: WPA2 attacks

## 1. Hardware

- ▶ laptop with a WiFi module (must support monitor mode)

## 2. Software

- ▶ airmon-ng – a bash script designed to turn wireless cards into monitor mode
- ▶ airodump-ng – a packet capture tool for aircrack-ng
- ▶ aireplay-ng – inject ARP-request packets into a wireless network to generate traffic
- ▶ aircrack-ng – a 802.11 WEP / WPA-PSK key cracker

# Why is WiFi security so important?

- ▶ WiFi connection is very popular (flexible, comfortable, cheap)
- ▶ number of devices is rapidly increasing due to Internet of Things (IoT)
- ▶ we transfer sensitive data

## Vulnerabilities

- ▶ connect to devices in network (capture webcam, access to shared network storage, control intelligent things - heating, light ...)
- ▶ capture and analyze sensitive data → identity theft
- ▶ set up fake AP with stronger signal → MITM attack

# Initial scheme

Topology:

- ▶ SSID: (hidden) - in all labs we will only use the PA197\* SSIDs!
- ▶ Encryption: **None**
- ▶ MAC filtering: **enabled**

1. Start wireless card in monitor mode
  - 1.1 **airmon-ng** - can see available device
  - 1.2 **airmon-ng check kill** - to kill blocking application (in some cases it is not needed)
  - 1.3 **airmon-ng start wlan0** - start monitor mode on specific device (in my case wlan0) → create a new virtual interface
  - 1.4 in next steps we will only use this one (e.g. wlan0mon, mon0...)
2. Start scanning networks **airodump-ng wlan0mon**
  - ▶ lists all of the wireless networks in your area
  - ▶ useful information about them like channel, SSID, encryption...
  - ▶ display hidden SSID of network (when capture new client association)

## LAB 2: MAC filtering

MAC addresses are broadcast unencrypted in header of frame, so it can be captured with a tool such as Wireshark. For this purpose we will use **airodump-ng** with additional options.

```
airodump-ng --bssid AA:AA:AA:AA:AA:AA -c B wlan0mon
```

- ▶ **--bssid AA:AA:AA:AA:AA:AA** (equivalent for **-d**) is the BSSID of the AP
- ▶ **-c B** (equivalent for **--channel**) is the channel the AP is operating on
- ▶ **wlan0mon** is the monitoring wireless adapter

To read SSID from of network we need to capture client associating to AP:

- ▶ wait for client connecting (if no client currently connected on target network)
- ▶ disconnect client, most of implementation will reconnect without user notice

```
aireplay-ng -0 1 -c CLIENT-BSSID -a AP-BSSID wlan0mon
```

-0 1 stands for deauth attack repeat 1 time

# Connecting to wireless network from command line

Above mentioned method we can capture (or use a script to save to file) allowed MAC addresses. If we want to connect to a 'secured' AP we can change the MAC address in OS (Linux *ip link set <DEV> address <MAC>* or tool **macchanger**, interface need to be in down state; in Windows it is in the settings of the adapter)

```
iwconfig <DEV> essid <WIFINAME> key <PASSWORD>
```

- ▶ password is for WEP secured network, skip now, will be next step
  - ▶ input is secret key for network or *key s:<ASCIIPASSWORD>*

Request address on from DHCP server

```
dhclient <DEV>
```

# WEP - Wired Equivalent Privacy

- ▶ the oldest encryption of WiFi (1997)
- ▶ at the time was suppose to provide confidentiality comparable to a traditional wired network.
- ▶ uses a shared key for encrypting packets
- ▶ most common is 64-bit or 128-bit WEP
  - ▶ 64-bit = 40-bit key + 24-bit Initialization Vector(**IV**) → **RC4 keystream** (40 bit key = 5 character password)
  - ▶ 128-bit = 104-bit key + 24-bit Initialization Vector(**IV**) → **RC4 keystream** (104 bit key = 13 character password)
- ▶ WEP encryption is based on RC4 keystream XORed with plain-text
- ▶ exist (very rarely) 152-bit and a 256-bit WEP encryption (vendor specific implementations)

- ▶ administrator realized that MAC filtering is very bad protection and he needs some encryption → enable WEP
- ▶ SSID: **PA197-WEP**
- ▶ MAC filtering: **none**
- ▶ encryption: **WEP**

- ▶ known as PTW attack
  - ▶ created by Andrei **P**ychkine, Erik **T**ews, and Ralf-Philipp **W**einmann (in 2007)
- ▶ cryptanalytic method to discover a 104-bit WEP key
- ▶ needs only 40 000 captured packets to reach 50% probability of success (60 000 is 80% chance and 85 000 packet is about 95% chance to discover the WEP key)
- ▶ use deauth and ARP re-injection → 40 000 packets can be captured in less than minute under ideal conditions
- ▶ Let's it try 😊

## Start capturing data

```
airmon-ng start wlan0 (only if monitor mode is not enabled)
```

```
airodump-ng wlan0mon
```

- ▶ start scanning WiFi networks
- ▶ needs to find target of attack (BSSID, channel)

```
airodump-ng --bssid {BSSID} -c B --write {PATH} wlan0mon
```

- ▶ **--bssid** the BSSID of the AP
- ▶ **-c** the channel of AP
- ▶ **--write** (equivalent for **-w**) name of the file you want to save the captured data to (e.x. /root/Desktop/WEPattack )

## Fake Authentication

- ▶ we need to capture a lot of IV's to recover the password
  - ▶ at least 20 000, ideally 100 000 IV's
- ▶ AP ignores the packet from not associated MAC (send out "DeAuthentication" packet)
- ▶ open new terminal (first one captures data)

```
aireplay-ng -1 0 -e HackMe -a 08:86:30:74:22:76  
-h BB:BB:BB:BB:BB:BB wlan0mon
```

- ▶ attack mode: **-1 0**, ( **--fakeauth={delay}** can be used too) Fake authentication with AP. (0 is delay)
- ▶ **-e HackMe** Set target SSID for Fake Authentication attack
- ▶ **-a 08:86:30:74:22:76** Set Access Point MAC address
- ▶ **-h BB:BB:BB:BB:BB:BB** MAC address client we are forging
- ▶ Next options
  - ▶ **-o {n-packets}** Set the number (in our case only 1) of packets for every authentication and association attempt. Default is multiple and this confuses some APs
  - ▶ **-q 10** - Send keep alive packets every 10 seconds

# LAB 3: How simple is it to hack WEP

## Generate traffic to get new IVs

- ▶ now as we are authenticated so AP will accept ARP request packets
- ▶ each response include unique IV
- ▶ Aireplay-ng listen to the AP for ARP request, and inject them as soon as they find one
- ▶ it causes that data and the beacons should began to grow quickly

```
aireplay-ng -3 -b AA:AA:AA:AA:AA:AA  
-h BB:BB:BB:BB:BB:BB  
-e HackMe wlan0mon
```

- ▶ same tool but different attack mode (In previous command we use -1 fake authentication; now we use -3 arpreplay mode)
- ▶ **-3** (or **-arpreplay**) Standard ARP-request replay
- ▶ **-b** AA:AA:AA:AA:AA:AA MAC address of access point
- ▶ **-h** BB:BB:BB:BB:BB:BB MAC address client we are forging
- ▶ **-e** HackMe Set target SSID
- ▶ **wlan0mon** is the monitoring wireless adapter

## Cracking the password

- ▶ in the first terminal we can see a lot of sent packets
- ▶ we can try to crack the password from captured data
- ▶ open new (third) terminal

```
aircrack-ng -z /root/Desktop/WEPattack-01.cap
```

- ▶ **-z** Uses PTW (Andrei Pyshkin, Erik Tews and Ralf-Philipp Weinmann) attack. (In case we don't specify type, airodump-ng analyze data and choose type based on captured data)
- ▶ `/root/Desktop/WEPattack-01.cap` path to file with captured IV's (\*.cap/\*.ivs file)
- ▶ if there is not enough captured IVs to crack key, aircrack-ng will wait for next capturing and try it crack again
- ▶ we must wait about 1-5 minutes to successful recovering WEP password (based on captured data)

Wifi Protected Setup designed to quickly & easily authenticate a client to an AP mainly aimed for home users

1. AP & the Client exchange a series of EAP messages
2. At the end of this transaction, the Client will have the encryption key & the AP's signature and is ready to connect
3. Client re-associates with the new credentials & signatures
4. The actual passphrase is not exchanged during WPS initiation (an eight digit **PIN** is used for authentication)
5. The client is first authenticated using the PIN and then the actual passphrase is exchanged

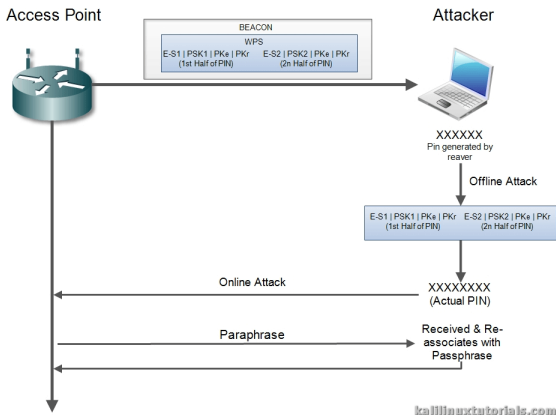

- ▶ WPS PIN consists of 8 digits
- ▶ last digit is a checksum → 7 digits to guess
- ▶ the PIN is validated by dividing it into 2 halves
- ▶ first half leaves  $10^4 = 10\ 000$  guesses
- ▶ second half leaves  $10^3 = 1000$  guesses
- ▶ all together we need only 11 000 guesses instead of  $10^8 = 100\ 000\ 000$
- ▶ can use **brute-force**
  - ▶ *on-line attack reaver tool*
  - ▶ *off-line attack - PixieDust attack reaver with PixieWPS (This attack is only applicable to vulnerable devices)*

- ▶ administrator improve WiFi security → change WEP to WPA2
- ▶ SSID: **PA197** (visible)
- ▶ encryption: **WPA2**
- ▶ WPS: **enabled**

# WPS offline attack

- ▶ lack of randomization in the components of the 2 halves of the PIN
- ▶ capture hashes and can start offline attack

# WPS online attack

- ▶ Simply try PIN and wait for response
- ▶ Speed of founding passphrase is individual
- ▶ Some firmware may be protected against brute-force by **Lock down** time
- ▶ This protection prolongs needed time hence decrease chance of successful attack

```
reaver -i mon0 -b AA:AA:AA:AA:AA:AA -vv
```

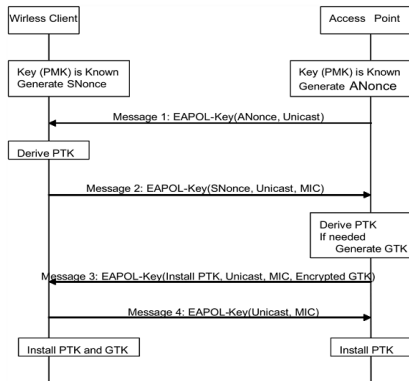

Attempts before lock	Lock down time	Attempts per minute	Maximum attack time	Maximum attack time	Comment
11000	0 minutes	46.15	3.97 hours	0.17 days	no lock down
7 <sup>7</sup>		4.20	43,65 hours	1,82 days	Netgear WGR614v10
3	1 minutes	2.82	65.08 hours	2.71 days	Requirement for WSC 2.0
15	60 minutes	0.25	737.31 hours	30.72 days	Lock down configurations making brute force less practical
10	60 minutes	0.17	1103.97	46.00 days	
5	60 minutes	0.08	2203.97	91.83 days	

Assumed time per attempt: 1.3 seconds

- ▶ currently the safest way to secure a WiFi connection
- ▶ all modern devices support WPA2 with AES (Advanced Encryption Standard)
- ▶ TKIP (Temporal Key Integrity Protocol) vs. AES (in mixed mode TKIP is there as a fallback method)
  - ▶ TKIP is no longer considered secure
- ▶ hackable with dictionary attack or brute-force (expect short password)
- ▶ WPA/WPA2 with strong pass-phrase is not possible to hack in short time (with current technology) -
  - ▶ brute-force lower+upper case characters, password length 8, AMD hd7970 + oclHashcat  $\approx$  12 years 60 days
    - ▶ <http://calc.opensecurityresearch.com/>
- ▶ in next lab we will try to capture data (handshake) required for an offline dictionary and brute-force attack

# WP2 PSK authentication

- ▶ when client associating with AP there is established new temporary key (PTK) for each session calculated from:
  - ▶ PMK - Pair Master key (generated from SSID and password)
  - ▶ ANonce - random 32 bit number generated by AP
  - ▶ SNonce - random 32 bit number generated by client
  - ▶ MAC of AP
  - ▶ MAC of client

## LAB 3: WPA/WPA2 attack

```
airodump-ng --bssid {BSSID} -c B --write {PATH} wlan0mon
```

- ▶ **--bssid** (equivalent for **-d**) is the BSSID of the AP
- ▶ **-c N** (equivalent for **--channel**) is the channel the AP is operating on
- ▶ **--write /root/Desktop/WPAcrack** (equivalent for **-w**) name of file you want to save captured data

We need to capture 4-way handshake from the connected client (in new terminal:)

```
aireplay-ng --deauth 2 -a {AP bssid} -c {client bssid} wlan0mon
```

- ▶ **--deauth** (equivalent for **--0**) is a short cut for the deauth mode and the 2 is the number of deauth packets to send.
- ▶ **-a** indicates the access point/router's BSSID, replace {AP bssid} with the BSSID of the target network
- ▶ **-c** indicates the client's BSSID, the device we're trying to deauth, noted in the previous picture. Replace the {client bssid} with the BSSID of the connected client, this will be listed under "STATION."

# LAB 5: WPA/WPA2 attack

- ▶ after successful deauth we can see in top left corner “WPA handshake: [BSSID]”. That is what we want. The 4-way handshake is captured so we can try to crack it now.
- ▶ the handshake is saved in \*.cap file from airodump-ng
- ▶ based on this handshake we can try to discover the pass-phrase either by brute-force or dictionary attacks (Your Homework)
  - ▶ brute-force = systematically checking **all** possible keys or passwords until the correct one is found (very fast for short passwords)
  - ▶ dictionary attack = based on trying the strings **only** in a pre-arranged list of possible pass-phrases (tries only those possibilities which are deemed most likely to succeed)
- ▶ if we try brute-force we need a lot of luck and time

# WPA2 Brute-force attack

- ▶ need \*.cap file with handshake (using airodump-ng, wifite ...)
- ▶ **wpaclean** cleans captured files to get only the 4-way handshake and a beacon
- ▶ *take care of the right order of output and input file option!*

```
wpaclean <out.cap> <in.cap>
```

Using *hashcat* utility for attack. It requires input file in its own format

- ▶ converting the .cap file to a format cudaHashcat, oclHashcat or Hashcat

```
/root/hashcat-utils-master/src/cap2hccapx.bin input.pcap output.hccapx
```

# Brute-Force Attack with Hashcat

- ▶ Hashcat running on CPU, cudaHashcat or oclHashcat can use power of GPU

```
hashcat -m 2500 -a 3 capture.hccap <MASK>
```

- ▶ **-m 2500** means we are attacking a WPA/WPA2 handshake file
- ▶ **-a 3** Brute Force Attack mode
- ▶ **capture.hccap** source file (generated using wpacli and cap2hccapx)
- ▶ **<MASK>** type of characters to try (all combinations)

## MASK

- ▶ Built-in charsets
  - ▶ ?l = abcdefghijklmnopqrstuvwxyz
  - ▶ ?u = ABCDEFGHIJKLMNOPQRSTUVWXYZ
  - ▶ ?d = 0123456789
  - ▶ ?s = special characters
  - ▶ ?a = ?l?u?d?s
- ▶ own charset using .hcmask file (for specific charset, variable length...)
- ▶ ex. ?u?u?u?u?u?u?u?u try all 8 Letter passwords in CAPS (exactly

# Brute-Force Attack

- ▶ How long it will take?
- ▶ Example:
  - ▶ minimum password length (8 characters)
  - ▶ only lowercase letters
  - ▶  $26^8$  combinations = 208 827 064 576
  - ▶ Thinkpad T400 with Intel P8600 @ 2.40 Ghz 1300 hashes/s => 5 years

# Key Reinstallation Attacks Breaking WPA2 by forcing nonce reuse

- ▶ published in late 2017
- ▶ known as KRACK
- ▶ by replaying message 3 of 4-way handshake allows attacker to weaken encryption and packets can be replayed, decrypted, and/or forged
- ▶ most implementation was vulnerable

<https://www.krackattacks.com/>

# How to protect your Wifi?

1. Never use WEP encryption!
2. Use WPA2 whenever it is possible
3. Disable WPS: Analyze whether your WiFi AP needs to be using WPS at all.
4. Increase timeout period: For advanced routers, we can increase the Receive timeout to slow down the attack
5. WPS Lock: Set the WPS Lock time to a large value
6. MAC Filtering: Of course really old-school, but sometimes can protect against script kiddies.
7. Physically Secure the Router
8. Update or replace old HW to secure against Krack attacks
9. use also application level encryption
