HMM: The Two Tasks

- HMM (the general case):
 - ▶ five-tuple (S, S_0, Y, P_s, P_Y) , where:
 - ▶ $S = \{s_1, s_2, \dots, s_T\}$ is the set of states, S_0 is the initial,
 - ▶ $Y = \{y_1, y_2, \dots, y_v\}$ is the output alphabet,
 - ▶ $P_s(s_j | s_i)$ is the set of prob. distributions of transitions,
 - ▶ $P_Y(y_k | s_i, s_j)$ is the set of output (emission) probability distributions.
- Given an HMM & an output sequence $Y = \{y_1, y_2, \dots, y_k\}$
 - (Task 1) compute the probability of Y ;
 - (Task 2) compute the most likely sequence of states which has generated Y .

Trellis - Deterministic Output

HMM:

Trellis:

$$p(\text{toe}) = \times .6 \times .88 \times 1 + \times .4 \times .1 \times 1 = .568$$

- trellis state: (HMM state, position)
- each state: holds one number (prob): α
- probability of Y: $\sum \alpha$ in the last state

Y: t o e

$$\alpha(\times, 0) = 1 \quad \alpha(A, 1) = .6 \quad \alpha(D, 2) = .568 \quad \alpha(B, 3) = .568$$

$$\alpha(C, 1) = .4$$

Creating the Trellis: The Start

- Start in the start state (\times),
 - ▶ its $\alpha(\times, 0)$ to 1.
- Create the first stage:
 - ▶ get the first “output” symbol y_1
 - ▶ create the first stage (column)
 - ▶ but only those trellis states which generate y_1
 - ▶ set their $\alpha(\text{state}, 1)$ to the $P_s(\text{state}|\times) \underbrace{\alpha(\times, 0)}_1$
- ... and forget about the 0 -th stage

Trellis: The Next Step

- Suppose we are in stage i ,
- Creating the next stage:
 - ▶ create all trellis state in the next stage which generate y_{i+1} , but only those reachable from any of the stage- i states
 - ▶ set their $\alpha(\text{state}, i + 1)$ to:
 $P_S(\text{state} | \text{prev.state}) \times \alpha(\text{prev.state}, i)$
(add up all such numbers on arcs going to a common trellis state)
 - ▶ ... and forget about stage i

Trellis: The Last Step

- Continue until “output” exhausted
 - $|Y| = 3$: until stage 3
- Add together all the $\alpha(\text{state}, |Y|)$
- That's the $\underline{P(Y)}$.
- Observation (pleasant):
 - ▶ memory usage max: $2|S|$
 - ▶ multiplications max: $|S|^2|Y|$

Trellis: The General Case (still, bigrams)

Start as usual:

- ▶ start state (\times), set its $\alpha(\times, 0)$ to 1.

$\times, 0$

$\alpha = 1$

$$\begin{aligned} p(\text{toe}) &= .48 \times .616 \times .6 + \\ &\quad .2 \times 1 \times .176 + \\ &\quad .2 \times 1 \times .12 \cong .237 \end{aligned}$$

General Trellis: The Next Step

■ We are in stage i :

- ▶ Generate the next stage $i+1$ as before (except now arcs generate output, thus use only those arcs marked by the output symbol y_{i+1})
- ▶ For each generated *state* compute

$$\alpha(\text{state}, i + 1) = \sum_{\text{incoming arcs}} P_Y(y_{i+1} | \text{state}, \text{prev.state}) \times \alpha(\text{prev.state}, i)$$

... and forget about stage i as usual

Trellis: The Complete Example

Stage:

The Case of Trigrams

- Like before, but:
 - states correspond to bigrams,
 - output function always emits the second output symbol of the pair (state) to which the arc goes:

$$p(\text{toe}) = .6 \times .88 \times .07 \cong .037$$

Multiple paths not possible \rightarrow trellis not really needed

Trigrams with Classes

More interesting:

- n-gram class LM: $p(w_i | w_{i-2}, w_{i-1}) = p(w_i | c_i) p(c_i | c_{i-2}, c_{i-1})$

→ states are pairs of classes (c_{i-1}, c_i), and emit “words”:
(letters in our example)

$p(t|C) = 1$ usual,
 $p(o|V) = .3$ non-
 $p(e|V) = .6$ overlapping
 $p(y|V) = .1$ classes

$$p(toe) = .6 \times 1 \times .88 \times .3 \times .07 \times .6 \cong .00665$$

$$p(teo) = .6 \times 1 \times .88 \times .6 \times .07 \times .3 \cong .00665$$

$$p(toy) = .6 \times 1 \times .88 \times .3 \times .07 \times .1 \cong .00111$$

$$p(tty) = .6 \times 1 \times .12 \times 1 \times 1 \times .1 \cong .0072$$

Class Trigrams: the Trellis

■ Trellis generation (Y = "toy"):

$$p(t|C) = 1$$

$$p(o|V) = .3$$

$$p(e|V) = .6$$

$$p(y|V) = .1$$

again, trellis useful
 $\alpha = .6 \times 1$
 but not really needed

$$\alpha = .1584$$

$$\cong .00111$$

$$\alpha = .6 \times .88 \times .3$$

Y: t o v

Overlapping Classes

■ Imagine that classes may overlap

- ▶ e.g. 'r' is sometimes vowel sometimes consonant, belongs to V as well as C:

$$p(t|C) = .3$$

$$p(r|C) = .7$$

$$p(o|V) = .1$$

$$p(e|V) = .3$$

$$p(y|V) = .4$$

$$p(r|V) = .2$$

$$p(\text{try}) = ?$$

Overlapping Classes: Trellis Example

$$p(t|C) = .3$$

$$p(r|C) = .7$$

$$p(o|V) = .1$$

$$p(e|V) = .3$$

$$p(y|V) = .4$$

$$p(r|V) = .2$$

$$\alpha = 1$$

$$\alpha = .18 \times .12 = .01512$$

$$\alpha = .031 \cong .0$$

$$\alpha = .6 \times .3 = .18$$

$$\alpha = .01 \cong .0$$

$$\alpha = .18 \times .88 \times .2 = .03168$$

- So far, we went left to right (computing α)
- Same result: going right to left (computing β)
 - ▶ supposed we know where to start (finite data)
- In fact, we might start in the middle going left and right
- Important for parameter estimation
(Forward-Backward Algorithm alias Baum-Welch)
- Implementation issues:
 - ▶ scaling/normalizing probabilities, to avoid too small numbers & addition problems with many transitions

The Viterbi Algorithm

- Solving the task of finding the most likely sequence of states which generated the observed data
- i.e., finding

$$S_{best} = \operatorname{argmax}_S P(S|Y)$$

which is equal to (Y is constant and thus $P(Y)$ is fixed):

$$\begin{aligned} S_{best} &= \operatorname{argmax}_S P(S, Y) = \\ &= \operatorname{argmax}_S P(s_0, s_1, s_2, \dots, s_k, y_1, y_2, \dots, y_k) = \\ &= \operatorname{argmax}_S \prod_{i=1..k} p(y_i | s_i, s_{i-1}) p(s_i | s_{i-1}) \end{aligned}$$

The Crucial Observation

- Imagine the trellis build as before (but do not compute the α s yet; assume they are o.k.); stage i :

this is certainly the “backwards” maximum to (D,2)... but
it cannot change even whenever we go forward (M. Property: Limited History)

Viterbi Example

- 'r' classification (C or V?, sequence?):

$$p(t|C) = .3$$

$$p(r|C) = .7$$

$$p(o|V) = .1$$

$$p(e|V) = .3$$

$$p(y|V) = .4$$

$$p(r|V) = .2$$

$$\operatorname{argmax}_{XYZ} p(rry|XYZ) = ?$$

Possible state seq.:

$(X, V)(V, C)(C, V)[VCV]$, $(X, C)(C, C)(C, V)[CCV]$, $(X, C)(C, V)(V, V)[CVV]$

Viterbi Computation

$$p(t|C) = .3$$

$$p(r|C) = .7$$

$$p(o|V) = .1$$

$$p(e|V) = .3$$

$$p(y|V) = .4$$

$$p(r|V) = .2$$

α in trellis
state:
best prob
from start
to here

$$\alpha = 1$$

Y: r r y

n-best State Sequences

- Keep track of n best “back pointers”:
- Ex.: $n=2$: Two “winners”: VCV (best) CCV (2^{nd} best)

Tracking Back the n-best paths

- Backtracking-style algorithm:
 - ▶ Start at the end, in the best of the n states (s_{best})
 - ▶ Put the other n-1 best nodes/back pointer pairs on stack, except those leading from s_{best} to the same best-back state.
- Follow the back “beam” towards the start of the data, spitting out nodes on the way (backwards of course) using always only the best back pointer.
- At every beam split, push the diverging node/back pointer pairs onto the stack (node/beam width is sufficient!).
- When you reach the start of data, close the path, and pop the topmost node/back pointer(width) pair from the stack.
- Repeat until the stack is empty; expand the result tree if necessary.

Pruning

- Sometimes, too many trellis states in a stage:

- criteria:
- (a) $\alpha < \text{threshold}$
 - (b) $\sum \pi < \text{threshold}$
 - (c) # of states $> \text{threshold}$
(get rid of smallest α)
