Why to lea	rn CUDA	?		

Why CUDA and not OpenCL?

- published results still show higher speed
- better stability of the environment
- biggest number of applications
- biggest number of libraries
- biggest number of publications
- easier to learn
- similarity to OpenCL allows easy transition
- PGI x86 CUDA compiler

New generations bring higher performance and new computing capabilities.

- compute capability describes richness of GPU instruction set and amount of resources such as registers, number of concurrently running threads, etc.
- the performance grows with the ability to put more than one core on a GPU

Cards in on generation also differ in performance substantially

- to produce more affordable cards
- due to changes introduces later in the manufacturing process
- to minimize power consumption of mobile GPUs

イロン イヨン イヨン イヨン

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
00000				
GPUs Av	ailable Tod	av		

Currently available GPUs

- compute capability 1.0 2.1
 - we will learn the differences later
- 1-30 multiprocessors (19.2 1 345.0 GFLOPs)
- frequency of 800 MHz-1.836 GHz
- width and speed of data bus sběrnice (64–512 bit, 6.4–177 GB/s)

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
00000				
Available	products			

GeForce graphics cards

- mainstream solution for gaming
- cheap, wildely used, broad range of performance
- disadvantage limited memory (up to 1.5 GB on GPU)

Professional Quadro graphics cards

- the same as GeForce from CUDA perspective
- up to 4 GB of memory on GPU
- several times more expensive

Tesla

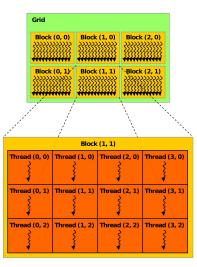

- a solution specially designed for CUDA computing
- one GPU per generation (basic variant), always large memory
- available as a PCIe card or standalone multi-GPU machines
- expensive, interesting for computing centers and personal supercomputers

GPU hardware	Parallelism ●00000	Memory Hierarchy	Synchronization	Matrix Multiplication
GPU Paral	lelism			

Parallel algorithms need to be designed w.r.t. the parallelism available in the $\ensuremath{\mathsf{HW}}$

- GPU: array of SIMT multiprocessors working using shared memory
- Decomposition for GPU
 - coarse-grained decomposition of the problem into the parts that don't need intensive communication
 - fine-grained decomposition similar to vectorization (but SIMT is more flexible)

GPU hardware	Parallelism ○●○○○○	Memory Hierarchy	Synchronization	Matrix Multiplication
Task Hier	archy

GPU hardware	Parallelism ○○●○○○	Memory Hierarchy	Synchronization	Matrix Multiplication
SIMT				

A multiprocessor has one unit executing an instruction

- all 8 SPs have to execute the same instruction
- new instruction is executed every 4 cycles
- 32 threads (so called *warp*) need to execute the same instruction

GPU hardware	Parallelism 00●000	Memory Hierarchy	Synchronization	Matrix Multiplication
SIMT				

A multiprocessor has one unit executing an instruction

- all 8 SPs have to execute the same instruction
- new instruction is executed every 4 cycles
- 32 threads (so called *warp*) need to execute the same instruction
- How about code branching?
 - if different parts of a warp perform different instructions, they are serialized
 - decreases performance-should be avoided

GPU hardware	Parallelism 00●000	Memory Hierarchy	Synchronization	Matrix Multiplication
SIMT				

A multiprocessor has one unit executing an instruction

- all 8 SPs have to execute the same instruction
- new instruction is executed every 4 cycles
- 32 threads (so called *warp*) need to execute the same instruction
- How about code branching?
 - if different parts of a warp perform different instructions, they are serialized
 - decreases performance-should be avoided

The multiprocessor is thus MIMD (Multiple-Instruction Multiple-Thread) from programmer's perspective and SIMT (Single-Instruction Multiple-Thread) from performance perspective.

GPU hardware	Parallelism ○○○○●○	Memory Hierarchy	Synchronization	Matrix Multiplication
Thread P	roperties			

GPU threads are very lightweight compared to CPU threads.

- their run time can be very shorts (even tens of instructions)
- there may be (should be) many of them
- they should not use large amount of resources

Threads are aggregated into blocks

- blocks are run on individual multiprocessors
- having sufficient number of blocks is substantial to achieve good scalability

Number of threads and thread blocks per multiprocesor is limited.

GPU hardware	Parallelism ○○○○○●	Memory Hierarchy	Synchronization	Matrix Multiplication

 Block-Local Memory
 Vemory
 Vemory
 Vemory
 Vemory

Shared memory

- \bullet as fast as registers for c. c. 1.x
 - if memory bank conflicts are avoided
 - instructions can use only one operand in shared memory (otherwise explicit load/store is needed)
- declared using __shared__ in C for CUDA
- a variable in shared memory can have dynamic size (determined at startup), if declared as *extern* withou size specification
- block scoped

< 1[™] >

4 B K 4 B K

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Shared M	emory			

Static shared memory declaration

```
__shared__ float myArray[128];
```

Dynamic allocation

```
extern __shared__ char myArray[];
float *array1 = (float*)myArray;
int *array2 = (int*)&array1[128];
short *array3 = (short*)&array2[256];
```

It creates an array *array1* of *float* type with size 128, *array2* of *int* type sized 256, and *array3* of floating size. Total size has to be specified at kernel startup.

```
myKernel<<<grid, block, n>>>();
```

GPU hardware	Parallelism	Memory Hierarchy ○○○●○○○○○○	Synchronization	Matrix Multiplication
GPU Local	Memory			

Global memory

- an order of magnitude lower bandwidth compared to shared memory
- latency in order of hundreds for GPU cycles
- addressing needs to be aligned to get optimum performance
- application-scoped
- L1 cache (128 bytes/row) and L2 cache (32 bytes/row) in Fermi architecture

May be dynamically allocated using *cudaMalloc* or statically allocated using *__device__* declaration.

GPU hardware	Parallelism	Memory Hierarchy ○○○○●○○○○○	Synchronization	Matrix Multiplication
GPU Local	Memory			

Constant memory

- read-only
- cached
- cache hit is as fast as registry (under certain constraints), cache miss is as fast as global memory
- limited size (64 kB for currently available GPUs)
- application-scoped

Declared using __constant__ keyword; the following function is used for copying data to constant memory:

```
cudaError_t cudaMemcpyToSymbol(const char *symbol,
    const void *src, size_t count, size_t offset,
    enum cudaMemcpyKind kind)
```

Data is copied from system memory (*cudaMemcpyHostToDevice*) or global memory (*cudaMemcpyDeviceToDevice*) from *src* into *symbol*. The copied block has *count* bytes. Copied with *offset* into the *symbol* memory.

・ロト ・同ト ・ヨト ・ヨト

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
GPULLoc	al Memory			

Texture memory

- cached, 2D locality
- read-only for cache coherency reasons
- high latency
- several addressing modes
 - normalization into [0,1] range
 - truncation or overflowing of coordinates
- possible data filtering
 - linear interpolation or nearest value
- this functionality is "for free" (implemented in HW)

More details are available in CUDA Programming Guide.

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
		0000000000		
System_I	ocal Memo	orv		

System RAM

- connected to GPU using PCIe
- CPU (host) and GPU (device) memory transfers are complicated by virtual addressing
- it is possible to allocate so called page-locked memory areas
 - overall system performance may be reduced
 - limited size
 - data is transferred faster over PCIe
 - allows for parallel kernel run and data copying
 - allows for mapping of host address space onto the device
 - allows for write-combining access (data is not cached by CPU)

cudaMallocHost() is used instead of malloc() to allocate the memory; the memory is freed using cudaFreeHost()

- *cudaHostAllocPortable* flag ensures page-locked memory for all CPU threads
- *cudaHostAllocWriteCombined* flag turns off caching for CPU allocated memory
- *cudaHostAllocMapped* flag sets host memory mapping in the device address space

<ロ> <同> <同> <同> < 同> < 同>

GPU hardware	Parallelism	Memory Hierarchy ○○○○○○○○●	Synchronization	Matrix Multiplication
	1 1 8 4			

Page-Locked Memory

Mapped memory

- the same position has a different address for device and host code
- device address may be obtained using cudaHostGetDevicePointer()
- before calling any other CUDA API functions, it is necessary to call *cudaSetDeviceFlags()* with *cudaDeviceMapHost* flag

Asynchronous transfers

- API funkce Async suffix
- both data transfers CPU computation and data transfer GPU computation may be overlapping (more detailed explanation will come with streams)

Non-cached memory

- slow access from host code
- faster access from device memory
- CPU cache doesn't get flushed

 Memory Hierarchy
 Synchronization
 Matrix Multiplication

 Synchronization within the Block
 Synchronization
 Matrix Multiplication

- native barrier synchronization
 - all threads have to enter it (beware of conditions!)
 - one instruction only, very fast if it doesn't degrade parallelism
 - C for CUDA call __syncthreads()
 - Fermi extensions: count, and, or
- shared memory communication
 - threads can exchange data
 - synchronization using atomic variables or a barrier

GPU hardware	Parallelism	Memory Hierarchy	Synchronization o●oooooo	Matrix Multiplication		
Atomic operations						

- performs read-modify-write operations on shared or global memory
- no interference with other threads
- for 32-bit and 64-bit integers (c. c. \geq 1.2) and float (u c. c. \geq 2.0)
- using global memory for c. c. ≥ 1.1 and shared memory for c. c. ≥ 1.2
- arithmetic (Add, Sub, Exch, Min, Max, Inc, Dec, CAS) a bitwise (And, Or, Xor) operations

All threads in one warp evaluate the same condition and perform its comparison. Available in c. c. \geq 1.2.

```
int __all(int predicate);
```

Result is non-zero iff the predicate is non-zero for all the threads in the warp.

```
int __any(int predicate);
```

Result is non-zero iff the predicate is non-zero for at least one thread in the warp.

```
unsigned int __ballot(int predicate);
```

Contains voting bit mask of individual threads.

 Synchronization of Memory Operations
 Synchronization
 Occord
 Occord

Shared memory is usually used for communication among threads or as a cache for data used by threads.

- threads use data stored by other threads
- it is necessary to ensure that we do not read data that is not available yet
- should we wait, we can use ___syncthreads()

.

Compiler can optimize operations on shared/global memory (intermediate results may be kept in registers) and can reorder them

- if we need to ensure that the data is visible for others, we use __threadfence() or __threadfence_block()
- if a variable is declared as *volatile*, all load/store operations are implemented in shared/global memory
 - very important if we assume implicit warp synchronization

イロト イヨト イヨト イヨト

GPU hardware	Parallelism	Memory Hierarchy	Synchronization ○○○○○●○○	Matrix Multiplication
Block Sync	chronizatio	n		

Among blocks

- global memory is visible for all blocks
- poor native support for synchronization
 - no global barrier
 - atomic operations on global memory for newer GPUs
 - global barrier can be implemented using kernel calls (another solution is quite tricky)
 - poor options for global synchronization make programming hard but allow for very good scalability

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Matrix M	ultiplicatio	n		

We want to multiply matrices A a B and store the result into C. For sake of simplicity, we only assume matrices sized  $n \times n$ .

$$C_{i,j} = \sum_{k=1}^{n} A_{i,k} \cdot B_{k,j}$$

#### C language: for (int i = 0; i < n; i++) for (int j = 0; j < n; j++){ C[i*n + j] = 0.0; for (int k = 0; k < n; k++) C[i*n + j] += A[i*n + k] * B[k*n + j]; }

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication ○●○○○○○○○○
Paralleliza	ation			

```
for (int i = 0; i < n; i++)
for (int j = 0; j < n; j++){
 C[i*n + j] = 0.0;
 for (int k = 0; k < n; k++)
 C[i*n + j] += A[i*n + k] * B[k*n + j];
}</pre>
```

Multiple ways of parallelization

- choose one loop
- choose two loops
- parallelize all the loops

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Parallelizat	ion			

• doesn't scale well, it is necessary to use big matrices (we need thousands of threads for good GPU utilization)

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Parallelizat	ion			

• doesn't scale well, it is necessary to use big matrices (we need thousands of threads for good GPU utilization)

Parallelization of two loops

• scales well, number of threads grows quadratically w.r.t. n

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Parallelizat	ion			

- doesn't scale well, it is necessary to use big matrices (we need thousands of threads for good GPU utilization)
- Parallelization of two loops
- scales well, number of threads grows quadratically w.r.t. *n* Parallelization using inner loop
  - bad, synchronization needed when writing into C!

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Parallelizat	ion			

• doesn't scale well, it is necessary to use big matrices (we need thousands of threads for good GPU utilization)

# Parallelization of two loops

• scales well, number of threads grows quadratically w.r.t. *n* Parallelization using inner loop

• bad, synchronization needed when writing into C!

Best way is thus to parallelize loops over i and j.

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
First Kern	el			

#### We can form the block and grid as 2D array.

```
__global__ void mmul(float *A, float *B, float *C, int n){
 int x = blockIdx.x*blockDim.x + threadIdx.x;
 int y = blockIdx.y*blockDim.y + threadIdx.y;
 float tmp = 0;
 for (int k = 0; k < n; k++)
 tmp += A[y*n+k] * B[k*n+x];
 C[y*n + x] = tmp;
}</pre>
```

Note similarity to math description – parallel version is more intuitive than the serial one!

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
How to In	nprove It?			

We hit the limit of global memory. GPUs have faster types of memory, can we use them?

For computation of one  ${\it C}$  element, we have to read one row from

A and one column from B, that are in the global memory.

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication ○○○○○●○○○○○
How to In	nprove It?			

We hit the limit of global memory. GPUs have faster types of memory, can we use them?

For computation of one C element, we have to read one row from A and one column from B, that are in the global memory.

Is it really necessary to do that separately for each element of C?

- we read the same A row for all the elements in the same row of C
- we read the same *B* column for all the elements in the same column of *C*
- we can read some data only once from the global memory into the shared memory and then read them repeatedly from the shared memory

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Blockwise	Approach			

If we access the matrix in blocks, we can amortize transfers from the global memory:

- we will compute  $a \times a$  block of C matrix
- we read blocks of the same size of matrices A and B into the shared memory iteratively
- the blocks will be multiplied and added to C
- arithmetic operations to data transfers is a times better

Natural mapping on GPU parallelism

- individual thread blocks will only compute blocks of C matrix
- they have shared memory
- they get synchronized fast
- no inter-block synchronization needed

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication ○○○○○○●○○○
Blockwise	Access			

How big blocks?

- limited by the size of shared memory
- limited by the number of threads that can run on GPU
- if one thread is to compute one element of C, a reasonable block size is  $16 \times 16$ 
  - multiple of warp size
  - one block will have reasonable 256 threads
  - one block needs 2 KB of shared memory
  - the memory will not limit the performance  $(16 \cdot 25.5 = 568 \text{ GFLOPS})$ , which is quite close to 622 GFLOPS)

GPU hardware	Parallelism	Memory Hierarchy	Synchronization	Matrix Multiplication
Algorithm				

# Algorithm schema

- each thread block will have As and Bs in the shared memory
- blocks of A and B matrices will be multiplied iteratively, the results will get accumulated in *Csub* variable
  - threads in a block read blocks into As and Bs simultaneously
  - each thread mutliplies blocks in *As* and *Bs* for its element of *Csub* matrix
- each thread stores one element of the matrix into the *C* in global memory
- Beware of synchronization
  - the blocks need to be read completely before the multiplication starts
  - before we read new blocks, operation on previous data needs to be completed
