Cryptography and Security

# Security engineering – big picture

## Phases

### 1. Requirements

## Activities

Security requirements

Abuse cases

Architectural risk analysis

Security-oriented design

Code review (with tools)

Risk-based security tools

Penetration testing

### 2. Design

### 3. Implementation

### 4. Testing/assurance

Based on Software security by M. Hicks (Coursera): <https://class.coursera.org/softwaresec-002>

# Overview

- Lecture: problems, prevention
  - buffer overflow (stack/heap/type)
  - string formatting problems
  - compiler protection
  - platform protections (DEP, ASLR)
- Labs
  - compiler flags, buffer overflow exercises

# PROBLEM?

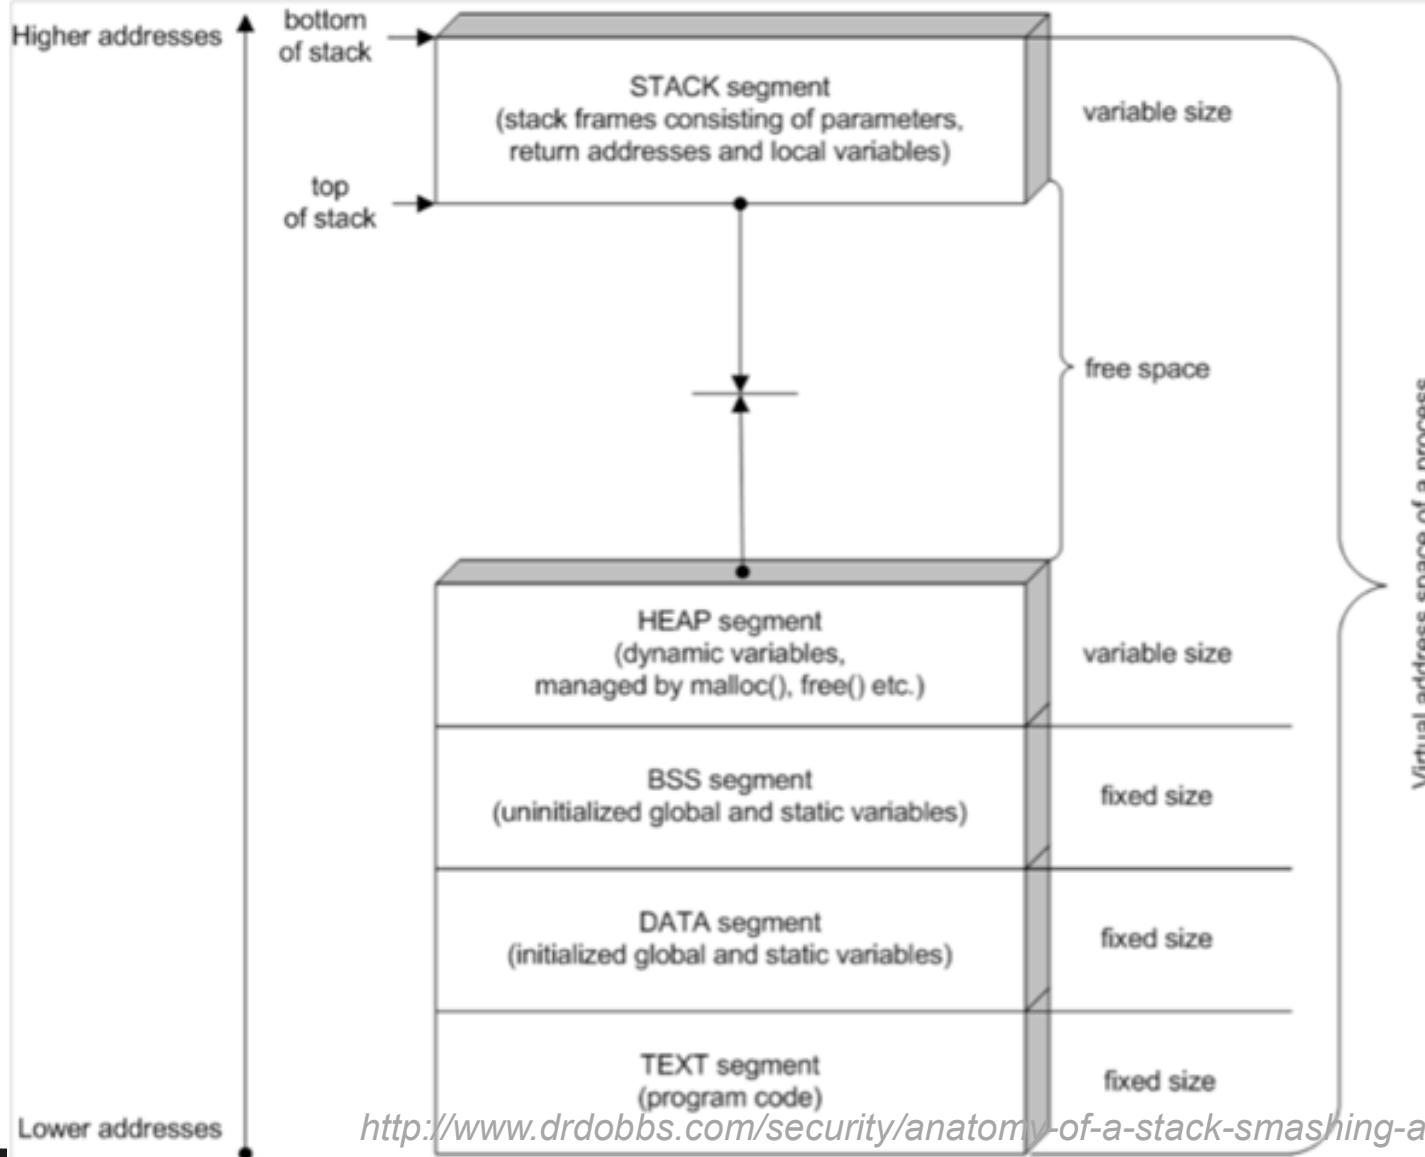

# Motivation problem

- Quiz – what is insecure in given program?
- Can you come up with attack?

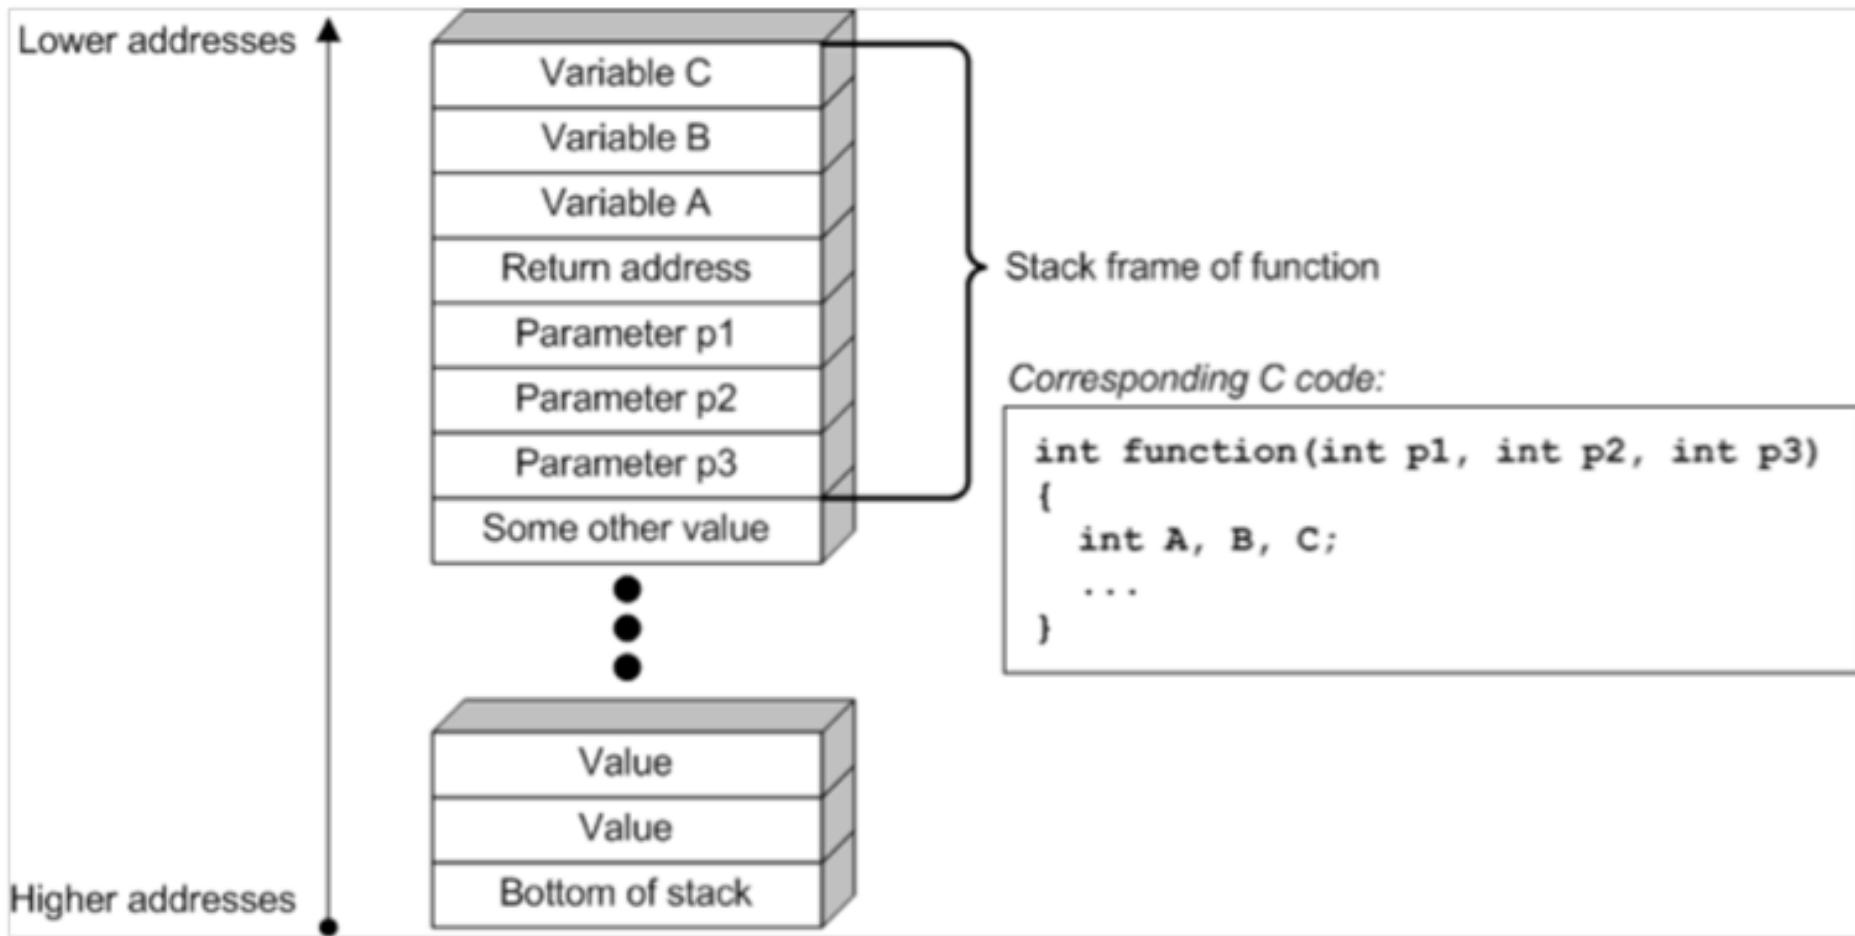

```
#define USER_INPUT_MAX_LENGTH 8
char userName[USER_INPUT_MAX_LENGTH];
gets(userName);
```

- Classic buffer overflow
- Detailed exploitation demo during labs this week

# Process memory layout

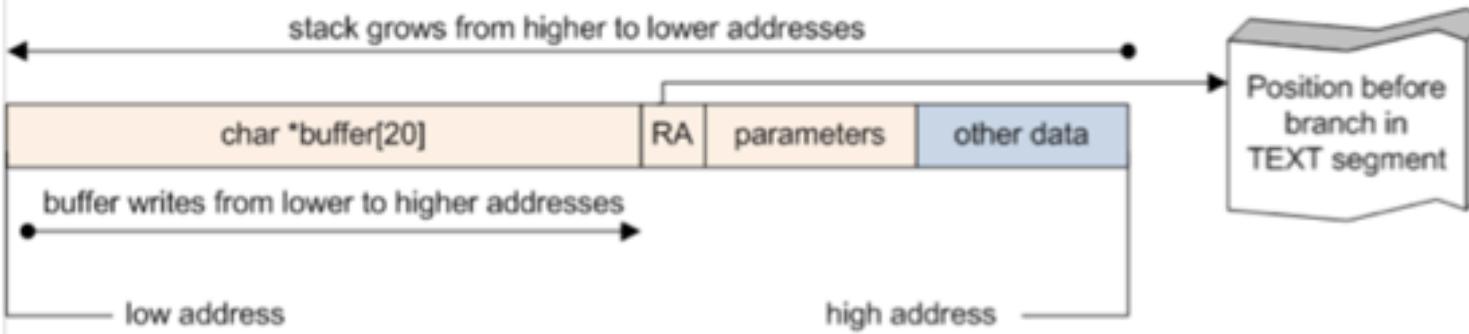

# Stack memory layout

<http://www.drdobbs.com/security/anatomy-of-a-stack-smashing-attack-and-h/240001832#>

# Stack overflow

## Stack before overflow

RA = return address

<http://www.drdobbs.com/security/anatomy-of-a-stack-smashing-attack-and-h/240001832#>

# Memory overflow - taxonomy

1. Buffer overflows
2. Stack overflows
3. Format strings
4. Heap overflows
5. .data/.bss segment overflows

# Type-overflow vulnerabilities - motivation

- Quiz – what is insecure in given program?
- Can you come up with attack?

```
for (unsigned char i = 10; i >= 0; i--) {  
    /* ... */  
}
```

- And what about following variant?
  - Be aware: char can be both signed (x64) or unsigned (ARM)

```
for (char i = 10; i >= 0; i--) {  
    /* ... */  
}
```

# Type overflow – basic problem

- Types are having limited range for the values
  - char: 256 values, int:  $2^{32}$  values
  - add, multiplication can reach lower/upper limit
    - **char** value = 250 + 10 == ?
- Signed vs. unsigned types
  - `for (unsigned char i = 10; i >= 0; i--) /* ... */`
- Type value will underflow/overflow
  - CPU overflow flag is set
  - but without active checking not detected in program
- Occurs also in higher level languages (Java...)

# Type overflow – example with dynalloc

```
typedef struct _some_structure {
    float    someData[1000];
} some_structure;

void demoDataTypeOverflow(int totalItemCount, some_structure* pItem,
                         int itemPosition) {
    // See http://blogs.msdn.com/oldnewthing/archive/2004/01/29/64389.aspx
    some_structure* data_copy = NULL;
    int bytesToAllocation = totalItemCount * sizeof(some_structure);
    printf("Bytes to allocation: %d\n", bytesToAllocation);
    data_copy = (some_structure*) malloc(bytesToAllocation);
    if (itemPosition >= 0 && itemPosition < totalItemCount) {
        memcpy(&(data_copy[itemPosition]), pItem, sizeof(some_structure));
    }
    else {
        printf("Out of bound assignment\n");
        return;
    }
    free(data_copy);
}
```

**Basic idea:**

- Data to be copied into newly allocated mem.
- Computation of required size type-overflow
- Too small memory chunk is allocated
- Copy will write behind allocated memory

# Safe add and mult operations in C/C++

- Compiler-specific non-standard extensions of C/C++
- GCC
  - `__builtin_add_overflow`, `__builtin_mul_overflow` ...  
**bool** `__builtin_add_overflow (type1 a, type2 b, type3 *res)`
  - Result returned as third (pointer passed) argument
  - Returns true if overflow occurs
  - <https://gcc.gnu.org/onlinedocs/gcc/Integer-Overflow-Builtins.html>
- MSVC
  - SafeInt wrapper template (for int, char...)
  - Overloaded all common operations (drop in replacement)
  - Returns SafeIntException if overflow/underflow
  - <https://msdn.microsoft.com/en-us/library/dd570023.aspx>

# Safe add and mult operations in Java

- Java SE 8 introduces extensions to `java.lang.Math`
- `ArithmaticException` thrown if overflow/underflow

```
public static int addExact(int x, int y)
public static long addExact(long x, long y)
public static int decrementExact(int a)
public static long decrementExact(long a)
public static int incrementExact(int a)
public static long incrementExact(long a)
public static int multiplyExact(int x, int y)
public static long multiplyExact(long x, long y)
public static int negateExact(int a)
public static long negateExact(long a)
public static int subtractExact(int x, int y)
public static long subtractExact(long x, long y)
public static int toIntExact(long value)
```

# Format string vulnerabilities - motivation

- Quiz – what is insecure in given program?
- Can you come up with attack?

```
int main(int argc, char * argv[]) {  
    printf(argv[1]);  
    return 0;  
}
```

# Format string vulnerabilities

- Wide class of functions accepting format string
  - `printf("%S", X);`
  - resulting string is returned to user (= potential attacker)
  - formatting string can be under attackers control
  - variables formatted into string can be controlled
- Resulting vulnerability
  - memory content from stack is formatted into string
  - possibly any memory if attacker control buffer pointer

# Information disclosure vulnerabilities

- Exploitable memory vulnerability leading to read access (not write access)
  - attacker learns some information from the memory
- Direct exploitation
  - secret information (cryptographic key, password...)
- Precursor for next step (very important with DEP&ASRL)
  - module version
  - current memory layout after ASRL (stack/heap pointers)
  - stack protection cookies (/GS)

# Format string vulnerability - example

- Example retrieval of security cookie and return address

```
int main(int argc, char* argv[]) {  
    char buf[64] = {};  
    sprintf(buf, argv[1]);  
    return printf("%s\n", buf);  
}
```

argv[1] submitted by an attacker  
E.g., %x%x%x....%x  
Stack content is printed  
Including security cookie and RA

# Non-terminating functions - example

- What is wrong with following code?

```
int main(int argc, char* argv[]) {
    char buf[16];
    strncpy(buf, argv[1], sizeof(buf));
    return printf("%s\n",buf);
}
```

# strncpy - manual

function

## strncpy

<cstring>

```
char * strncpy ( char * destination, const char * source, size_t num );
```

### Copy characters from string

Copies the first *num* characters of *source* to *destination*. If the end of the *source* C string (which is signaled by a null-character) is found before *num* characters have been copied, *destination* is padded with zeros until a total of *num* characters have been written to it.

No null-character is implicitly appended at the end of *destination* if *source* is longer than *num*. Thus, in this case, *destination* shall not be considered a null terminated C string (reading it as such would overflow).

*destination* and *source* shall not overlap (see [memmove](#) for a safer alternative when overlapping).

### Parameters

#### destination

Pointer to the destination array where the content is to be copied.

#### source

C string to be copied.

#### num

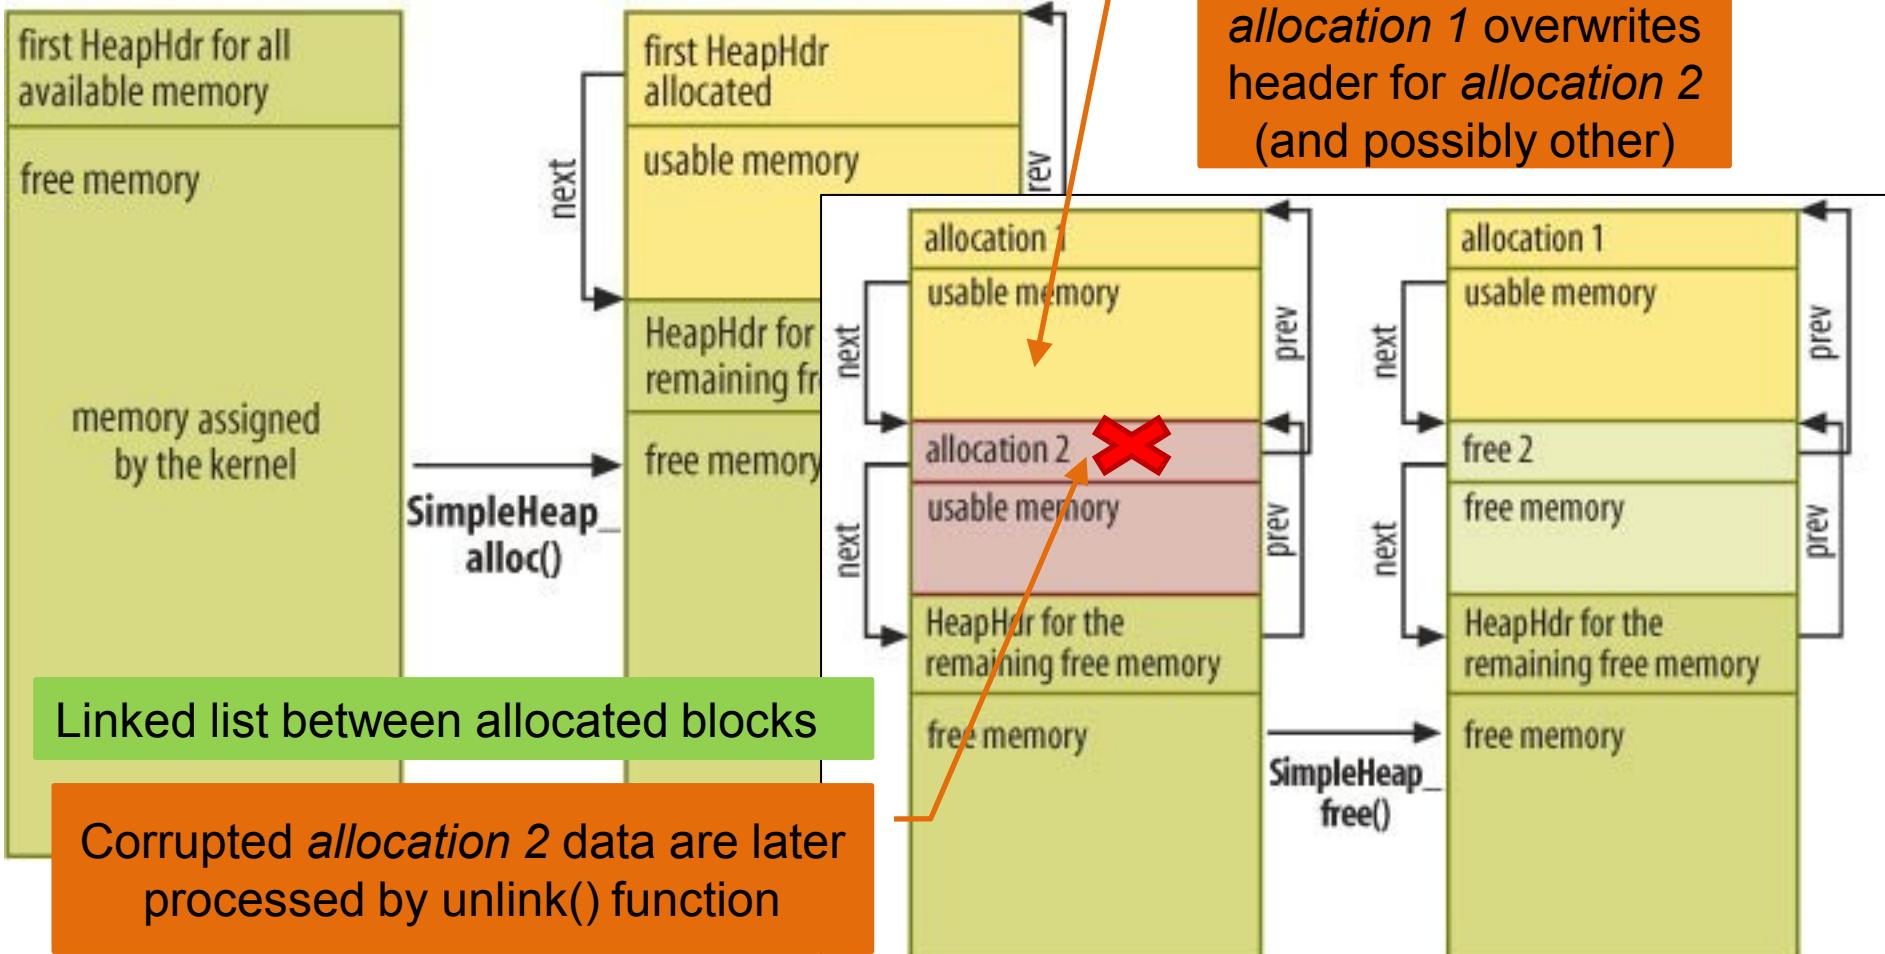

Maximum number of characters to be copied from *source*.  
*size\_t* is an unsigned integral type.

<http://www.cplusplus.com/reference/cstring/strncpy/?kw=strncpy>

# Non-terminating functions for strings

- strncpy
  - snprintf
  - vsnprintf
  - mbstowcs
  - MultiByteToWideChar
  - wcsncpy
  - snwprintf
  - vsnwprintf
  - wcstombs
  - WideCharToMultiByte
- 
- Non-null terminated Unicode string more dangerous
    - C-string processing stops on first zero
    - any binary zero (ASCII)
    - 16-bit aligned wide zero character (UNICODE)

# Heap overflow

# Heap overflow – more details

- Assumption: buffer overflow possible for buffer at heap
- Problem:
  - attacker needs to write his pointer to memory later used as jump
  - no return pointer (jump) is stored on heap (as was for stack)
- Different mechanism for misuse
  - overwrite `malloc` metadata (few bytes before allocated block)
    - only `next`, `prev`, `size` and `used` can be manipulated
    - fake header (`hdr`) for fake block is created
  - let `unlink` function to be called (merge free blocks)
    - fake block is also merged during merge operation
    - `hdr->next->next->prev = hdr->next->prev;`

address in stack that will be interpreted later as jump pointer

address of attacker's code

# SOURCE CODE PREVENTION

# How to detect and prevent problems?

1. Protection on the **source code level**
  - languages with/without implicit protection
    - containers/languages with array boundary checking
  - usage of safe alternatives to vulnerable function (*this lecture*)
    - vulnerable and safe functions for string manipulations
  - proper input checking (*next lectures*)
  - automatic detection by static and dynamic checkers (*next lectures*)
  - security testing, fuzzing (*next lectures*)
2. Protection **by compiler** (+ compiler flags) (*this lecture*)
  - runtime checks introduced by compiler (stack protection)
3. Protection **by execution environment** (*this lecture*)
  - DEP, ASRL...

# How to write code securely (w.r.t. BO) I.

- Be aware of possibilities and principles
- Never trust user's input, always check defensively
- Use safe versions of string/memory functions
- Always provide a format string argument
- Use self-resizing strings (C++ `std::string`)
- Use automatic bounds checking if possible
  - C++ `std::vector.at(i)` instead of `vector[i]`

## How to write code securely (w.r.t. BO) II.

- Run application with lowest possible privileges
- Let your code to be reviewed
- Use compiler-added protection
- Use protection offered by platform (privileges, DEP, ASRL, sandboxing...)

# Secure C library

- Secure versions of commonly misused functions
  - bounds checking for string handling functions
  - better error handling
- Also added to new C standard ISO/IEC 9899:2011
- Microsoft Security-Enhanced Versions of CRT Functions
  - MSVC compiler issue warning C4996, more functions then in C11
- Secure C Library
  - [http://docwiki.embarcadero.com/RADStudio/XE3/en/Secure\\_C\\_Library](http://docwiki.embarcadero.com/RADStudio/XE3/en/Secure_C_Library)
  - <http://msdn.microsoft.com/en-us/library/8ef0s5kh%28v=vs.80%29.aspx>
  - <http://msdn.microsoft.com/en-us/library/wd3wzwts%28v=vs.80%29.aspx>

# Secure C library – selected functions

- Formatted input/output functions
  - **gets\_s**
  - **scanf\_s**, **wscanf\_s**, **fscanf\_s**, **fwscanf\_s**, **sscanf\_s**,  
**vfscanf\_s**, **vfwscanf\_s**, **vscanf\_s**, **vwscanf\_s**,  
**vswscanf\_s**
  - **fprintf\_s**, **fwprintf\_s**, **printf\_s**, **printf\_s**, **snprintf\_s**, **snwprintf\_s**,  
**sprintf\_s**, **swprintf\_s**, **vfprintf\_s**, **vfwprintf\_s**, **vprintf\_s**, **vwprintf\_s**,  
**vsnprintf\_s**, **vsnwprintf\_s**, **vsprintf\_s**, **vswprintf\_s**
  - functions take additional argument with buffer length
- File-related functions
  - **tmpfile\_s**, **tmpnam\_s**, **fopen\_s**, **freopen\_s**
    - takes pointer to resulting file handle as parameter
    - return error code

```
char *gets(
    char *buffer
);

char *gets_s(
    char *buffer,
    size_t sizeInCharacters
);
```

# Secure C library – selected functions

# MSVC Compiler security flags - /GS

- /GS switch (added from 2003, evolves in time)
  - <http://msdn.microsoft.com/en-us/library/8dbf701c.aspx>
  - multiple different protections against buffer overflow
  - mostly focused on stack protection
- /GS protects:
  - return address of function
  - address of exception handler
  - vulnerable function parameters (arguments)
  - some of the local buffers (GS buffers)
- /GS protection is (automatically) added only when needed
  - to limit performance impact, decided by compiler (/GS rules)
  - **#pragma strict\_gs\_check(on)** - enforce strict rules application

/GS is applied in both  
DEBUG and RELEASE  
modes

# Is /GS protection bulletproof?

*Function parameters*

*Function return address (of Y == X)*

*Frame pointer*

**Cookie**

*Exception Handler frame*

*Locally declared variables and buffers*

*Callee save registers*

**Y**

*Function parameters*

*Function return address (of X)*

*Frame pointer*

**X**

**Cookie**

*Exception Handler frame*

*Locally declared variables and buffers*

*Callee save registers*

- Return address of X can be overwritten inside Y
- Incorrect jump is executed only later after X ends
- ...

## /GS – what is NOT protected

- /GS compiler option does not protect against all buffer overrun security attacks
- Corruption of address in vtable
  - (table of addresses for virtual methods)
- Example: buffer and a vtable in an object, a buffer overrun could corrupt the vtable
- Functions with variable arguments list (...)

# GCC compiler - StackGuard & ProPolice

- StackGuard released in 1997 as extension to GCC
  - but never included as official buffer overflow protection
- GCC Stack-Smashing Protector (ProPolice)
  - patch to GCC 3.x
  - included in GCC 4.1 release
  - **-fstack-protector** (string protection only)
  - **-fstack-protector-all** (protection of all types)
  - on some systems enabled by default (OpenBSD)
    - **-fno-stack-protector** (disable protection)

# GCC compiler & ProPolice - example

```
1 #include <string.h>
2
3 void vuln(const char *str)
4 {
5     char buf[20];
6     strcpy(buf, str);
7 }
8
9 int main(int argc, char *argv[])
10{
11    vuln(argv[1]);
12    return 0;
13}
```

<http://www.drdobbs.com/security/anatomy-of-a-stack-smashing-attack-and-h/240001832#>

# GCC -fno-stack-protector

```

1  vuln:

7 }
8
9 int main(int argc, char *argv[])
10{
11    vuln(argv[1]);
12    return 0;
13}

```

# How to bypass stack protection cookie?

- Scenario:
    - long-term running of daemon on server
    - no exchange of cookie between calls
1. Obtain security cookie by one call
    - cookie is now known and can be incorporated into stack-smashing data
  2. Use second call to change only the return address

# Control flow integrity

- Promising technique with low overhead
  - Classic CFI (2005), Modular CFI (2014)
    - avg 5% impact, 12% in worst case
    - part of LLVM compiler (but only for C)
1. Analysis of source code to establish control-flow graph  
(which function can call what other functions)
  2. Assign shared labels between valid caller X and callee Y
  3. When returning into function X, shared label is checked
  4. Return to other function is not permitted

[https://class.coursera.org/softwaresec-002/lecture/view?lecture\\_id=49](https://class.coursera.org/softwaresec-002/lecture/view?lecture_id=49)

# PLATFORM PROTECTIONS

# Data Execution Prevention (DEP)

- *Motto: When boundary between code and data blurs (buffer overflow, SQL injection...) then exploitation might be possible*
- Data Execution Prevention (DEP)
  - prevents application to execute code from non-executable memory region
  - available in modern operating systems
    - Linux kernel > 2.6.8, WinXP SP2, Mac OS X, iOS, Android
  - difference between ‘hardware’ and ‘software’ based DEP

# Hardware DEP

- Supported from AMD64 and Intel Pentium 4
  - OS must add support of this feature (around 2004)
- CPU marks memory page as non-executable
  - most significant bit (63th) in page table entry (NX bit)
  - 0 == execute, 1 == data-only (non-executable)
- Protection typically against buffer overflows
- Cannot protect against all attacks!
  - e.g., code compiled at runtime (produced by JIT compiler) must have both instructions and data in executable page
  - attacker redirect execution to generated code (JIT spray)
  - used to bypass Adobe PDF and Flash security features

## Software “DEP”

- Unrelated to NX bit (no CPU support required)
- When exception is raised, OS checks if exception handling routine pointer is in executable area
  - Microsoft's Safe Structured Exception Handling
- Software DEP is not preventing general execution in non-executable pages
  - different form of protection than hardware DEP

# Return-oriented programming (ROP) I.

- Return-into-library technique (Solar Designer, 1997)
  - <http://seclists.org/bugtraq/1997/Aug/63>
  - method for bypassing DEP
  - no write of attacker's code to stack (as is marked by DEP)
    1. function return address is replaced by pointer of selected standard library function instead
    2. library function arguments are also replaced according to attackers needs
    3. function return will result in execution of library function with given arguments
- Example: system call wrappers like `system()`

# Return-oriented programming (ROP) II.

- But 64-bit hardware introduced different calling convention
  - first arguments to function are passed in CPU registers instead of via stack
  - harder to mount return-into-library attack
- Borrowed code chunks
  - attacker tries to find instruction sequences from any function that pop values from the stack into registers
  - necessary arguments are inserted into registers
  - return-into-library attack is then executed as before
- Return-oriented programming extends previous technique
  - multiple borrowed code chunks (gadgets) connected to execute Turing-complete functionality (Shacham, 2007)
  - automated search for gadgets possible by ROPgadget
  - [https://www.youtube.com/watch?v=a8\\_fDdWB2-M](https://www.youtube.com/watch?v=a8_fDdWB2-M)
  - partially defended by ASLR (but information leakage)

# Address Space Layout Randomization (ASLR)

- Random reposition of executable base, stack, heap and libraries address in process's address space
  - aim is to prevent exploit to reliably jump to required address
  - performed every time a process is executed
  - random offset added to otherwise fixed address
  - entropy of random offset is important (bruteforce)
- Applies to program and also dynamic libraries
- Introduced by Memco software (1997)
  - fully implemented in Linux PaX patch (2001)
  - MS Windows Vista, enabled by default (2007)
  - MS Windows 8, improved entropy (2012)

# ASLR – how much entropy?

- Usually depends on available memory
  - possible attack combination with enforced low-memory situation
- Linux PaX patch (2001)
  - around 24 bits entropy
- MS Windows Vista (2007)
  - heap only around 5-7 bits entropy
  - stack 13-14 bits entropy
  - code 8 bits entropy
  - <http://www.blackhat.com/presentations/bh-dc-07/Whitehouse/Presentation/bh-dc-07-Whitehouse.pdf>
- MS Windows 8 (2012)
  - additional entropy, Lagged Fibonacci Generator, registry keys, TPM, Time, ACPI, new rdrand CPU instruction
  - [http://media.blackhat.com/bh-us-12/Briefings/M\\_Miller/BH\\_US\\_12\\_Miller\\_Exploit\\_Mitigation\\_Slides.pdf](http://media.blackhat.com/bh-us-12/Briefings/M_Miller/BH_US_12_Miller_Exploit_Mitigation_Slides.pdf)

# ASLR entropy in MS Windows 7&8 (2012)

Entropy (in bits) by region	Windows 7		Windows 8		
	32-bit	64-bit	32-bit	64-bit	64-bit (HE)
Bottom-up allocations (opt-in)	0	0	8	8	24
Stacks	14	14	17	17	33
Heaps	5	5	8	8	24
Top-down allocations (opt-in)	0	0	8	17	17
PEBs/TEBs	4	4	8	17	17
EXE images	8	8	8	17*	17*
DLL images	8	8	8	19*	19*
Non-ASLR DLL images (opt-in)	0	0	8	8	24

\* 64-bit DLLs based below 4GB receive 14 bits, EXEs

ASLR entropy is the same for both 32-bit and 64-bit processes

64-bit processes receive much more entropy on Windows 8, especially with

(Microsoft Security Engineering Center), BlackHat USA 2012

# ASRL – impact on attacks

- ASLR introduced big shift in attacker mentality
- Attacks are now based on gaps in ASRL
  - legacy programs/libraries/functions without ASRL support
    - ! /DYNAMICBASE
  - address space spraying (heap/JIT)
  - predictable memory regions, insufficient entropy

# DEP and ASLR should be combined

- “*For ASLR to be effective, DEP/NX must be enabled by default too.*” M. Howard, Microsoft
- /GS combined with /DYNAMICBASE and /NXCOMPAT
  - /NXCOMPAT prevents insertion of new attackers code and forces ROP
  - /DYNAMICBASE randomizes code chunks used later for ROP
  - /GS prevents modification of return pointer used later for ROP
  - /DYNAMICBASE randomizes position of master cookie for /GS
- **Visual Studio → Configuration properties →**
  - Linker → All options
  - C/C++ → All options

# SUMMARY

# The state of memory safety exploits

**Most systems are not compromised by exploits**

- About 6% of MSRT detections were likely caused by exploits [29]
- Updates were available for more than a year for most of the exploited issues [29]

**Most exploits target third party applications**

- 11 of 13 CVEs targeted by popular exploit kits in 2011 were for issues in non-Microsoft applications [27]

**Most exploits target older versions of Windows (e.g. XP)**

- Only 5% of 184 sampled exploits succeeded on Windows 7 [28]
- ASLR and other mitigations in Windows 7 make exploitation costly [30]

**Most exploits fail when mitigations are enabled**

- 14 of 19 exploits from popular exploit kits fail with DEP enabled [27]
- 89% of 184 sampled exploits failed with EMET enabled on XP [28]

**Exploits that bypass mitigations & target the latest products do exist**

- Zero-day issues were exploited in sophisticated attacks (Stuxnet, Duqu)
- Exploits were written for Chrome and IE9 for Pwn2Own 2012

*(Microsoft Security Engineering Center), BlackHat USA 2012*

# Final checklist

1. Be aware of possible problems and attacks
  - Don't make exploitable errors at the first place!
  - Automated protections cannot fully defend everything
2. Use safe versions of vulnerable functions
  - Secure C library (xxx\_s functions)
  - Self-resizing strings/containers for C++
3. Compile with all protection flags
  - MSVC: **/RTC1 , /DYNAMICBASE , /GS , /NXCOMPAT**
  - GCC: **-fstack-protector-all**
4. Apply automated tools
  - BinScope Binary Analyzer, static and dynamic analyzers, vulns. scanners
5. Take advantage of protection in the modern OSes
  - and follow news in improvements in DEP, ASRL...
