

iangulation www.iue.tuwien.ac.at

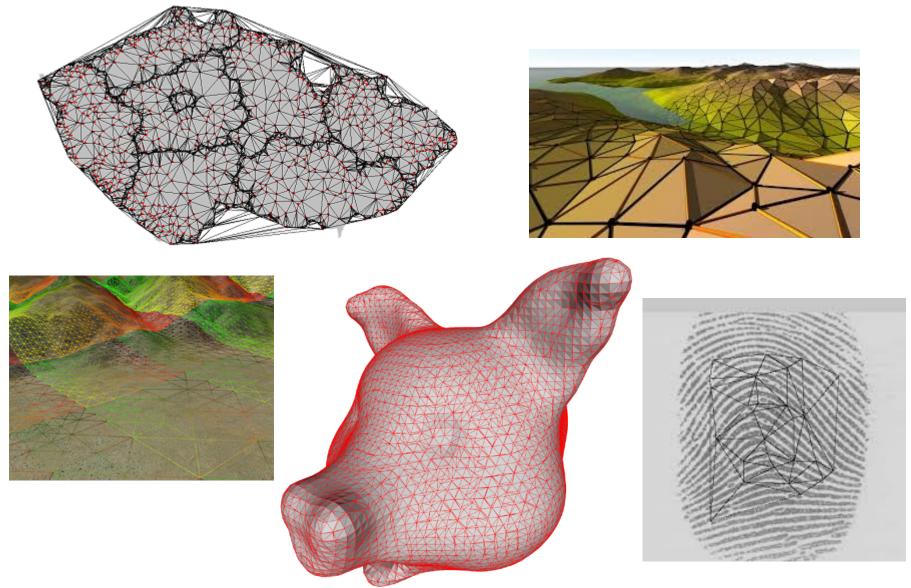

- Dividing a polygon to a set of triangles
- Often with the constraint that each triangle edge is fully shared by two triangles
- In 1925, it was proved that each surface can be triangulated

Usage of triangulation

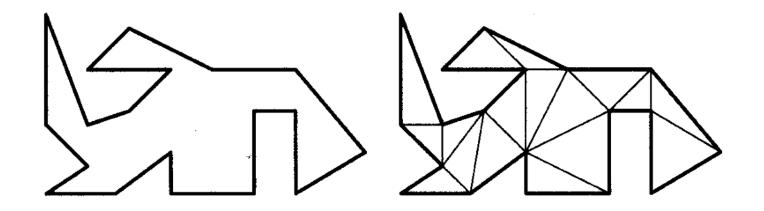

- Cartography, GIS
- Image processing segmentation, pattern recognition
- Creating spatial models from laser scanning
- Spatial data visualization
- Finite element level set method analysis of material structure and properties, simulation
- Robot motion planning
- Simulation of natural phenomena erosion
- Interpolation transfer of point clouds to surfaces
- Biometry fingerprints detection

Usage of triangulation

- Set of triangles $T = T_i$, i = 1, ..., n is considered to be a triangulation when:
 - an arbitrary pair of triangles from T mutually intersects in one common vertex or along a common edge
 - union of triangles from T is a continuous set
- Generally, the input is a continuous polygon which does not have to be necessarily convex and can contain holes

- Triangulation of a simple polygon P = dividing P to triangles by a set of nonintersecting lines, connecting two vertices from P and fully lying inside P
- Triangulation is mostly non-unique

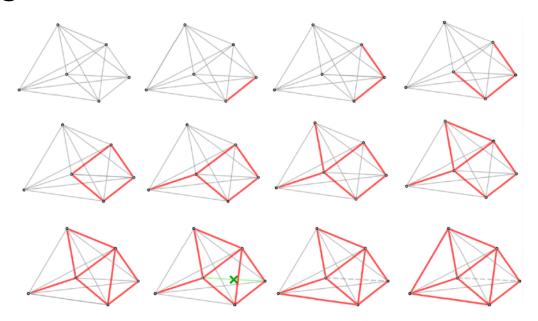

- Triangulation is the basic problem of computational geometry - dividing complex objects to simple ones
- The most simple objects are triangles in 2D (tetrahedra in 3D)

- There are several types of triangulation,
 e.g.:
 - Delaunay triangulation from all existing triangulations, it has the smallest sum of the lenghts of all its edges, it is dual to the Voronoi diagram
 - we will implement it later in the semester

- For a given set of points (or a polygon), there are several possible triangulations. But all of them have the same number of triangles triangulated polygon with n edges has n 2 triangles.
- Some polygons can be triangulated easily e.g., convex ones
- Non-convex polygons have to be first divided to so-called monotone polygons. These can be then easily triangulated.

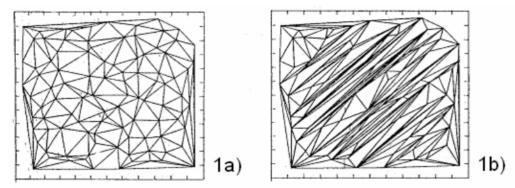

- Naïve approach
- Creates all potential edges, sorts them according their length in an ascending order (the number of these edges is n(n-1)/2)
- The edges are one by one added to the resulting triangulation, we start with the shortest one
- The algorithm ends when the list of edges is empty or when the number of edges in the triangulation is 3n - 6

- Criterion for adding the edge:
 - Edge is added when it does not intersect with any other edge already present in the triangulation

```
repeat for all p_i, i \in [1, n]:
       repeat for j \in [i + 1, n]:
              create edge e = (p_i, p_i)
              for e compute d = dist(p_i, p_i) and store to Q
sort Q according to d
remove Q[0] and add it to T
until Q not empty
       e = pop(Q)
       repeat for all e_i \in T:
              test if e intersects with e_i \in T
       if e does not intersect with any e_i \in T:
              add e to T
```

 Triangles do not have to fulfill any special condition - the triangulation can contain "ugly" triangles

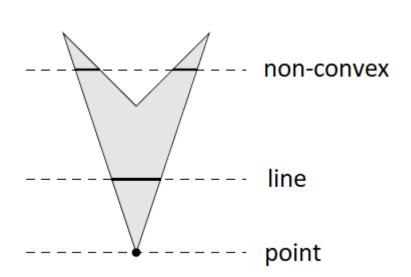

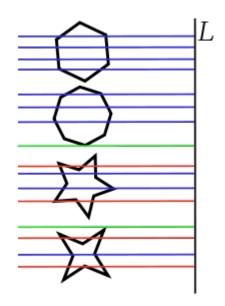

• Complexity $O(n^3)$, can be optimized to $O(n^2 \log n)$

 For simplicity, let's assume that we are triangulating a monotone polygon...

Monotone polygon

 Polygon is monotone when its intersection with each horizontal line is convex (it is empty set, point, or line) - the orientation of the polygon matters!

 1st step: Lexicographically sort the vertices of the convex hull

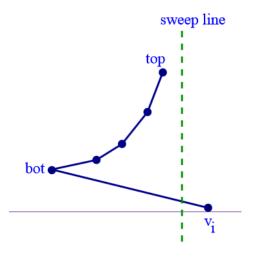

$$p > q \Leftrightarrow p_y > q_y \text{ or } p_y = q_y \text{ and } p_x < q_x$$

 We determine the left and right path (split at minimal and maximal point according to lexicographical sorting) they are stored in two queues

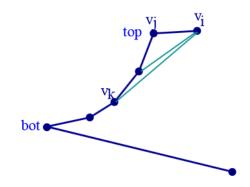

- Algorithm is trying to create new triangle always when the sweep line intersects with a vertex of the polygon
- We use another data structure stack. It will contain vertices above the sweep line (already traversed ones), which were not yet triangulated

```
sort vertices v_1, v_2, ..., v_n lexicographically
put v_1, v_2 to stack
for i = 3 to n:
        if v_i and the top of the stack lie on the same path (left or right)
        add edges v_i v_j, ..., v_i v_k, where v_k is the last vertex forming the "correct" line
                 pop v_i, ..., v_k and push v_i
         else
                 add edges from v_i to all vertices stored in stack and
        remove (pop) them from stack
                 store V_{top}
                 push v_{top} and v_i
```

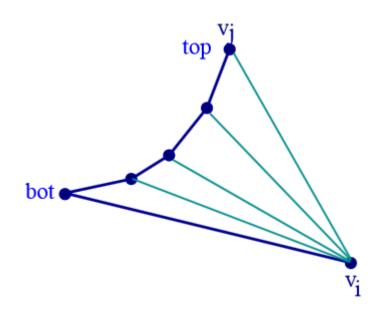

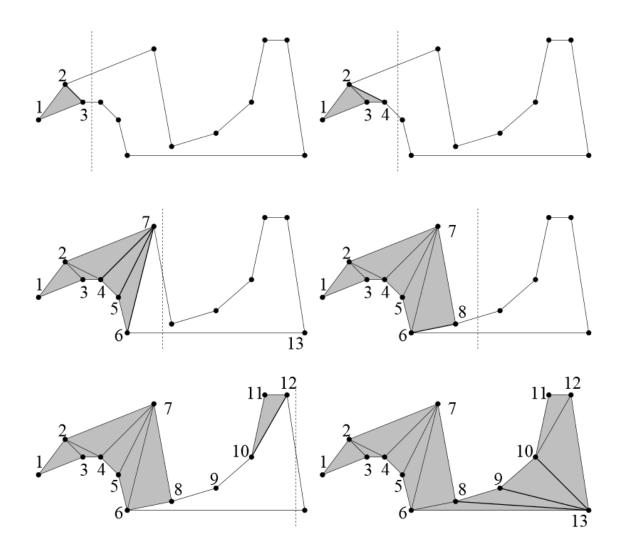

First branch of the *if* condition: Stack will contain (bot, ..., v_k , v_i)

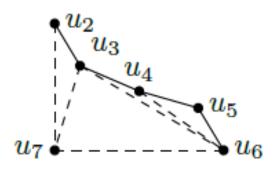

else branch of the if condition:

Stack will contain (v_i, v_i)

Yet another example

$$\begin{bmatrix} u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{4} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{5} \\ u_{4} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{6} \\ u_{4} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{6} \\ u_{4} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{6} \\ u_{3} \\ u_{2} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{8} \\ u_{8} \\ u_{8} \\ u_{8} \end{bmatrix} \rightarrow \begin{bmatrix} u_{7} \\ u_{8} \\ u_{8} \\ u_{8} \\ u_{8} \end{bmatrix} \rightarrow \begin{bmatrix} u_{8} \\ u_{8}$$

Time complexity

- Each vertex is added to the stack only once - when "visited", it is removed from stack
- In each step we add at least one edge
- Total triangulation time: O(n log n)

Your assignment

- Implement the sweep line algorithm for polygon triangulation
- Our input data:
 - Convex hull (created in previous assignments)
 - Arbitrary polygon (has to be added to the basic framework - simple connection of points added by the user to the scene. We connect them in the same order as they were inserted to the scene + connecting the first and last point to close the polygon. We skip the test for monotonity (we assume that the user creates a monotone polygon, if not, we are fine with wrong result <a>>

Your assignment

 Your algorithm should be able to work with both mentioned inputs
