# **PB007 Week 03**

Samuel Sabo

1 Advanced use case diagrams, Textual specification

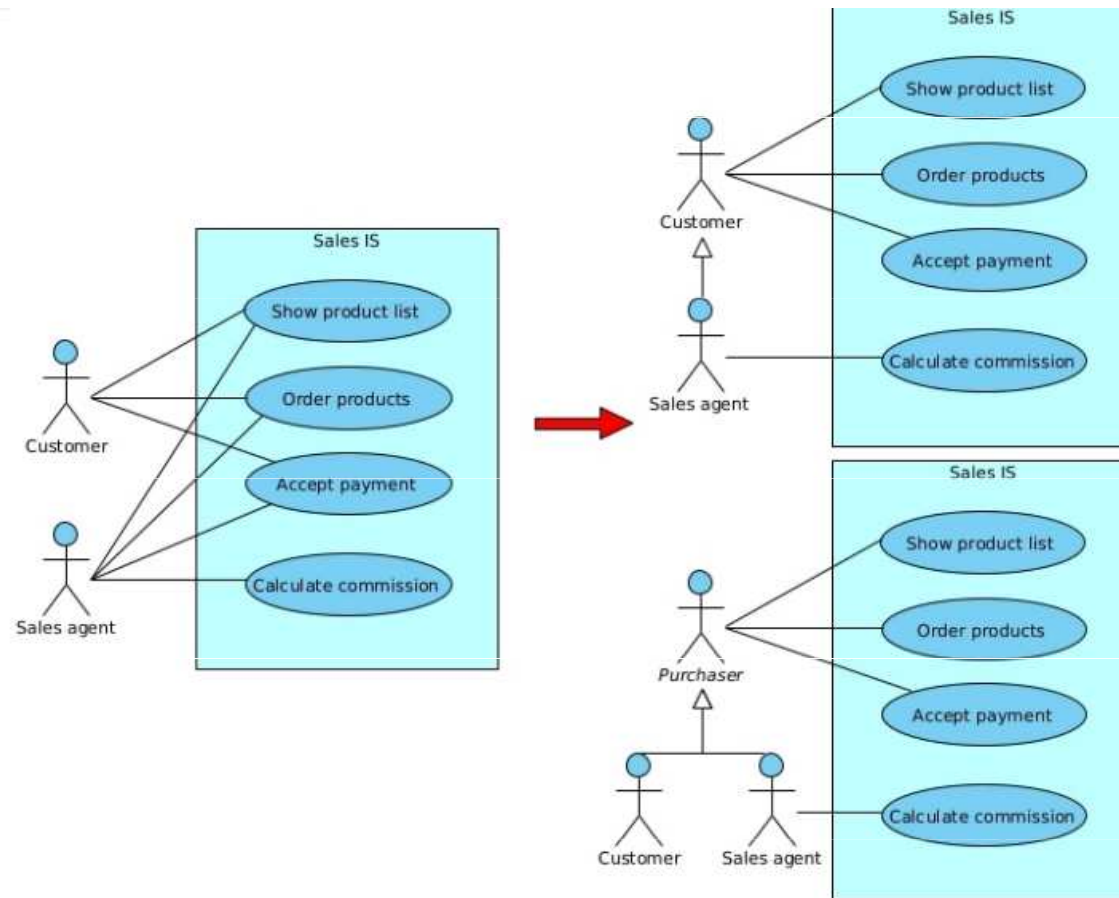

# Relationships in use case diagrams

- In addition to the communication association between actors and use cases, there are other types of possible relationships:
  - actor generalization
  - use case generalization
  - <<include>>
  - <<extend>>

# Actor generalization

- Actor generalization (inheritance) is the relationship between the general and specialized actors
  - General actors are often abstract
  - Specialized actor inherits all roles and relationships of the parent actor
  - Each expected occurrence of the parent actor can be substituted by any of its descendant actors
  - It is usually suitable when multiple actors share some of the use cases

# Actor generalization - example

# Use case generalization

- Use case generalization (inheritance) is the relationship between the general and specialized use cases
  - Specialized use case inherits the properties of its parent and it can add new properties or override inherited ones. Note.: it cannot overload parent's extension points.
  - The text specification of inherited use cases should mark the changes from the parent use case.
  - Parent use case can be abstract (recommended), i.e. it has either no specification or incomplete specification of the event flow

# Use case generalization - example

# <<include>>

- <<include>> allows to extract steps that are repeated in multiple use cases into separate use case.
  - The base use case is incomplete without all the included use cases.
  - The included use case may or may not be complete.
  - It should not be misused for functional decomposition

# <<include>> - example

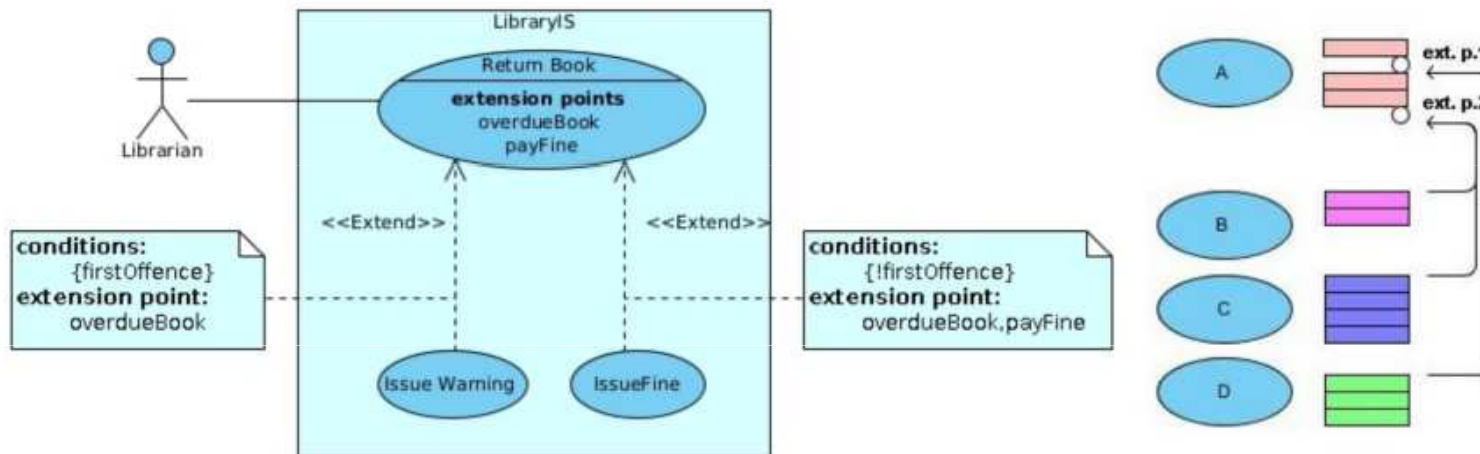

# <<extend>>

- The <<extend>> relationship allows to add a new behaviour into an existing use case.
  - The base use case contains extension points within the flow of events.
  - The extension use case specifies to which extension points it is attached.
  - The base use case does not know about its extension use cases.
  - The extension use case is usually incomplete. It can contain multiple segments, each specifying their extension points.
  - Multiple extension use cases can share the same extension points. In such case, it is appropriate to define conditions to determine which of them should be used in given situation.

# <<extend>> - example

# Textual specification of use cases

- Textual specification of use cases should contain:
  - Name (ID)
  - A brief description
  - The primary actors
  - The secondary actors
  - Preconditions
  - The main flow of events
  - Post-conditions
  - An alternative flow of events

# Flow of events

- Main flow(Primary Scenario) of events is a sequence of steps in the interaction between actors and the system in the ideal case
  - It always starts with an action from the primary actor. Use the form:
    1. The use case begins when, <actor><function>
  - The individual steps should be short, precise and understandable. Use the form:  
<step id><actor/system><action>  
You can modify the flow with IF, FOR, WHILE, GOTO etc.
- The alternative flow represents deviations from the main flow caused by the errors and interruptions. It can be also used to capture more complex branching.

# Flow of events - example

## Update Ticket Status

<b>Use Case ID</b>	UC9
<b>Brief Description</b>	Support Managers updates the information or status of the issue ticket to reflect the work progress on the issue
<b>Primary Actors</b>	Support Technician
<b>Secondary Actors</b>	Issue Reporter
<b>Preconditions</b>	Issue Reporter is logged in the system
<b>Main Flow of Events</b>	<ol style="list-style-type: none"><li>1. Use case starts when <b>Support Technician</b> selects "Update Tickets" option in the menu</li><li>2. <i>INCLUDE</i>(Find Tickets)</li><li>3. <i>IF</i> at least one ticket assigned to the Issue Technician is found<ol style="list-style-type: none"><li>3.1. <b>Support Technician</b> selects one of the tickets from the displayed list</li><li>3.2. <b>System</b> shows detailed information about the issue ticket</li><li>3.3. <b>Support Technician</b> selects the "Edit Status" option.</li><li>3.4. <b>System</b> displays an editable form for the ticket details.</li><li>3.5. <b>Support Technician</b> updates the ticket information or its status.</li></ol></li><li><i>EXTENSION POINT</i>(Ticket is Closed)</li><li>3.6. <b>System</b> stores the changes in the database</li></ol>
<b>Alternative Flows</b>	Issue Reporter can log out at any time
<b>Post-conditions</b>	The status of the issue ticket was updated.

# Task for this week

- Review the initial use case diagram from the previous session. Fix any problems and consider the use of advanced relationships
- Briefly document all use cases. This will help to better understand the project
- Choose 3 use cases (ideally the more complex ones) for detailed textual specification. The selection should be approved by the seminar tutor. The chosen use cases should use different colour in VP
- Submit pdf report to [homework vault](#)
