

# Enzymes I

**General features, cofactors**

© Department of Biochemistry, FM MU, 2013 (J.D.)

# Literature for Biochemistry I

- Lecture files on *is.muni.cz*.
- Tomandl J., Táborská E.: *Biochemistry I – Seminars*. MU, 2012
- Harvey R.A., Ferrier D.R.: *Biochemistry*. 5th ed., Lippincott Williams & Wilkins, 2011.
- Koolman J., Röhm K.H.: *Color atlas of biochemistry*, Thieme, 2013.

# General features of enzymes

**CAUTION:** peptidyltransferase is **ribozyme**

- biocatalysts
- different types of proteins / also RNA (ribozyme)
  - with covalently attached prosthetic group and/or metal cation,
  - oligomeric / multienzyme complexes / associated with membranes etc.
- different distribution in cell and in the body, make isoforms (isoenzymes)
- specific (towards substrate and reaction), highly effective
- work under mild conditions
- *in vivo* - can be regulated in two ways (activity of enzyme, quantity of enzyme)
- *in vitro* - sensitive to many factors

# Enzymes are highly efficient catalysts

- decrease activation energy  $\Rightarrow$  **increase the reaction rate**
- much more efficient than other (inorganic) catalysts
- remain unchanged after reaction
- do not alter equilibrium constant  $K$
- *in vitro* sensitive to many factors

# Enzymes work under mild conditions

- narrow temperature range around **37 °C**
- over 50 °C become denaturated = inactivated
- narrow pH range  $\Rightarrow$  **pH optimum**
- most intracellular enzymes have pH optima around 7
- digestion enzymes function in rather stronger acidic / alkaline environment (pepsin 1-2, trypsin ~ 8)

# Dual specificity of enzymes towards:

## Reaction

catalyze just

**one type of reaction**

## Substrate

work with **one substrate**

(or group of similar substrates)

often stereospecific

# Enzymes are stereospecific catalysts

there are two types of stereospecific conversions:

## 1. non-chiral substrate $\rightarrow$ chiral product<sub>(one enantiomer)</sub>

pyruvate  $\rightarrow$  L-lactate

fumarate  $\rightarrow$  L-malate

---

## 2. chiral substrate<sub>(one enantiomer)</sub> $\rightarrow$ product

L-alanine  $\rightarrow$  pyruvate (D-alanine does not react)

D-glucose  $\rightarrow$  pyruvate (L-glucose does not react)

chiral signal molecule  $\rightarrow$  complex with receptor  $\rightarrow$  biological response

chiral drug<sub>(ant)agonist</sub>  $\rightarrow$  complex with receptor  $\rightarrow$  pharmacological response

# Hydrogenation of pyruvate

when pyruvate is hydrogenated without enzyme (*in vitro*),  
reaction product is the **racemic mixture** of D-lactate and L-lactate:

in reaction catalyzed by lactate dehydrogenase (*in vivo*),  
pyruvate is reduced stereospecifically to **L-lactate** only:

# Non-enzymatic hydration of fumarate

*in vitro* reaction proceeds to racemic D,L-malate

# Enzymatic hydration of fumarate (citrate cycle)

*in vivo* just one enantiomer (L-malate) is produced

## Hydrogenation of D-fructose *in vitro* gives two epimers

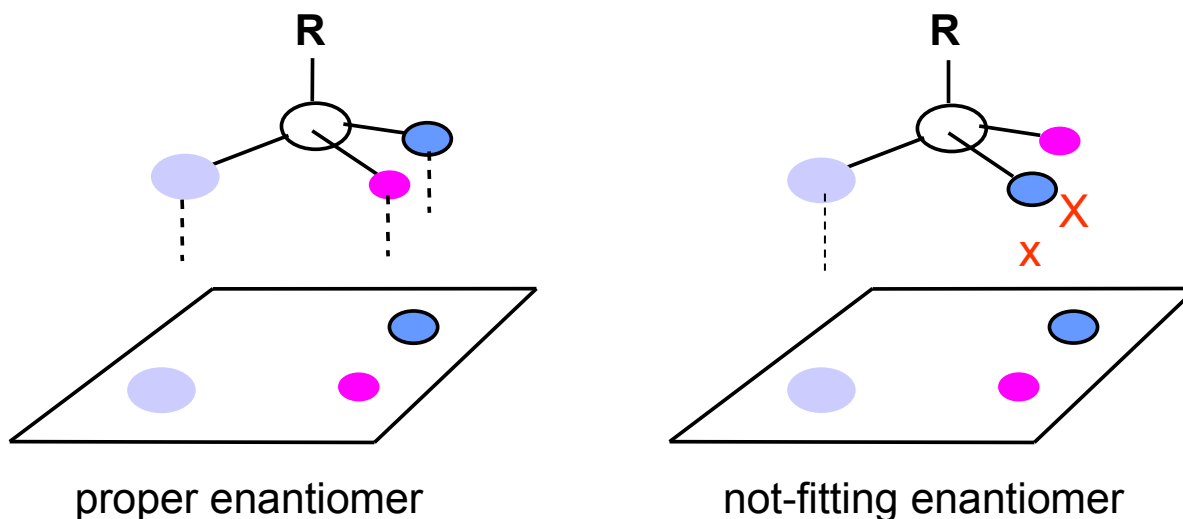

*in vivo*: enzymatic reaction gives just one product (D-glucitol)

## Enzymes or receptors recognize only one enantiomer

If the reactant of enzymatic reaction is a chiral compound, only one of two enantiomers is recognized as the specific substrate.

Chiral substrates/signal molecules are bound to the stereospecific enzymes/receptors at three sites:

see also  
MCH II, p. 13

# Enzyme nomenclature: the ending *-ase*

**Systematic names** identify the enzymes fully with the EC code number, contain information about substrate and type of reaction, not very convenient for everyday use.

**Recommended (accepted) names** are shorter than systematic names, include also some historical names (pepsin, amylase)

EC (abbr. Enzyme Commission) of International Union of Biochemistry (IUB)  
major class number  
    . subclass number  
        . sub-subclass number  
            . enzyme serial number

# Examples of enzyme names

**Recommended name:** alcohol dehydrogenase

**Systematic name:** EC 1.1.1.1 ethanol:NAD<sup>+</sup>-oxidoreductase

**Reaction:** ethanol + NAD<sup>+</sup> → acetaldehyde + NADH + H<sup>+</sup>

**Recommended name:** alanine aminotransferase (ALT)

**Systematic name:** EC 2.6.1.2 L-alanine:2-oxoglutarate-aminotransferase

**Reaction:** L-alanine + 2-oxoglutarate → pyruvate + L-glutamate

# Classification of enzymes: six classes according to reaction type

(each class comprises other subclasses)

Enzyme class	General scheme of reaction
1. Oxidoreductases	$A_{\text{red}} + B_{\text{ox}} \rightleftharpoons A_{\text{ox}} + B_{\text{red}}$
2. Transferases	$A-B + C \rightarrow A + C-B$
3. Hydrolases	$A-B + H_2O \rightarrow A-H + B-OH$
4. Lyases	$A-B \rightleftharpoons A + B$ (reverse reaction: synthases)
5. Isomerases	$A-B-C \rightleftharpoons A-C-B$
6. Ligases (synthetases)	$A + B + ATP \rightarrow A-B + ADP + P_i$

# 1 Oxidoreductases

catalyze the oxidation or reduction of substrate

subclasses:

- **dehydrogenases** catalyze the transfers of two H atoms
- **oxygenases** catalyze the incorporation of one/two O atoms into the substrate (monooxygenases, dioxygenases)
- **oxidases** catalyze transfers of electrons between substrates (e.g. cytochrome *c* oxidase, ferroxidase)
- **peroxidases** catalyze the decomposition of peroxides

Recommended name: lactate dehydrogenase

Systematic name: (*S*)-lactate:NAD<sup>+</sup> oxidoreductase

## 2 Transferases

catalyze the transfer of a group from one to another substrate

subclasses:

- **aminotransferases, methyltransferases, glucosyltransferases**
- **kinases** phosphorylate substrate by the transfer of phosphoryl group  $\text{PO}_3^{2-}$  from ATP (e.g. hexokinases, protein kinases)

**Example:** glucose + ATP  $\rightarrow$  glucose 6-P + ADP

Recommended name: glucokinase

Systematic name: ATP:D-glucose phosphotransferase

# Example: Phosphorylation of glucose

# 3 Hydrolases

catalyze the hydrolytic splitting of esters, glycosides, amides, peptides etc.

subclasses:

- **esterases** (lipases, phospholipases, ribonucleases, **phosphatases**)
- **glycosidases** (e.g. sucrase, maltase, lactase, amylase)
- **proteinases, peptidases** (pepsin, trypsin, cathepsins, caspases/apoptosis, dipeptidases, carboxypeptidases, aminopeptidases)
- **amidases** (glutaminase, asparaginase)
- **ATPases** (split anhydride bonds of ATP)

**Example:**  $\text{glucose 6-P} + \text{H}_2\text{O} \rightarrow \text{glucose} + \text{P}_i$

Recommended name: glucose 6-phosphatase

Systematic name: glucose 6-phosphate phosphohydrolase

# Example: glucose 6-phosphatase

# Compare two antagonistic enzymes

**Glutaminase is amidase which catalyzes  
the deamidation of glutamine**

# ATPase catalyzes the exergonic hydrolysis of phosphoanhydride bond in ATP

Example: muscle contraction

myosine head exhibits ATPase activity, chemical energy of ATP is transformed into mechanical work (actin-myosin contraction)

# Examples of lysosomal hydrolases

<b>Hydrolase</b>	<b>Bond hydrolyzed</b>
Glucosidase	glycoside
Galactosidase	glycoside
Hyaluronidase	glycoside
Arylsulfatase	sulfoester
Lysozyme	glycoside
Cathepsin	peptide
Collagenase	peptide
Elastase	peptide
Ribonuclease	phosphodiester
Lipase	ester
Phosphatase	phosphoester
Ceramidase	amide

# Distinguish: lysozyme      lysosome

## Lysozyme is enzyme

- compound word, **lyso** (Greek *lysis*) + **zyme** (from *enzyme*)
- hydrolase, glycosidase, cleaves  $\beta$ -1,4-glycoside bond in bacterial heteropolysaccharides, antiseptic defense
- occurs in saliva, tears, and other body fluids

## **Lysosome** is **intracellular digestion organelle**

- Greek compound word from *lysis* (to lyse) and *soma* (body)
- typical for animal cells
- acidic pH, contains many acidic hydrolases

# 4 Lyases

catalyze **non-hydrolytic splitting** or **forming** bonds C–C, C–O, C–N, C–S through removing or adding, respectively, a small molecule ( $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{NH}_3$ )

Some frequent recommended names:

- **ammonia lyases** (e.g. histidine ammonia lyase: histidine  $\rightarrow$  urocanate +  $\text{NH}_3$ )
- **decarboxylases** (amino acid  $\rightarrow$  amine +  $\text{CO}_2$ )
- **aldolases** (catalyze aldol cleavage and formation)
- **(de)hydratases** (e.g. carbonate dehydratase:  $\text{CO}_2 + \text{H}_2\text{O} \rightleftharpoons \text{H}_2\text{CO}_3$ )

**Example:** fumarate +  $\text{H}_2\text{O} \rightleftharpoons$  L-malate

Recommended name: fumarate hydratase

Systematic name: (*S*)-malate hydro-lyase (fumarate-forming)

# 5 Isomerases

catalyze intramolecular rearrangements of atoms

examples:

- **epimerases**
- **racemases**
- **mutases**

**Example:** UDP-glucose  $\rightarrow$  UDP-galactose

Recommended name: UDP-glucose 4-epimerase

Systematic name: UDP-glucose 4-epimerase

# 6 Ligases

catalyze the formation of high-energy bonds C–C, C–O, C–N

in the reactions coupled with **hydrolysis of ATP**

Frequent recommended names:

**carboxylases**

**synthetases**

(e.g. glutamine synthetase: glutamate + ATP + NH<sub>3</sub> → glutamine + ADP + P<sub>i</sub>)

**Example:** pyruvate + CO<sub>2</sub> + ATP + H<sub>2</sub>O → oxaloacetate + ADP + P<sub>i</sub>

Recommended name: pyruvate carboxylase

Systematic name: pyruvate:carbon-dioxide ligase (ADP-forming)

# Three enzymes dealing with phosphate

Enzyme (Class)	Reaction scheme / Reaction type
Kinase (Transferase)	$\text{substrate-OH} + \text{ATP} \rightarrow \text{substrate-O-P} + \text{ADP}$ phosphorylation = transfer of phosphoryl $\text{PO}_3^{2-}$ from ATP to substrate
Phosphatase (Hydrolase)	$\text{substrate-O-P} + \text{H}_2\text{O} \rightarrow \text{substrate-OH} + \text{P}_i$ the hydrolysis of phosphoester bond
Phosphorylase (Transferase)	$(\text{glycogen})_n + \text{P}_i \rightarrow (\text{glycogen})_{n-1} + \text{glucose 1-P}$ $\text{inosine} + \text{P}_i \rightarrow \text{hypoxanthine} + \text{ribose 1-P}$ phosphorolysis = the splitting of glycoside bond by phosphate = transfer of glucosyl to inorganic phosphate

## Distinguish:

### Three types of lysis (decomposition of substrate)

<b>Hydrolysis</b>	the decomposition of substrate <b>by water</b> , frequent in intestine: sucrose + H <sub>2</sub> O → glucose + fructose (starch) <sub>n</sub> + H <sub>2</sub> O → maltose + (starch) <sub>n-2</sub>
<b>Phosphorolysis</b> (see previous page)	the cleavage of <i>O/N</i> -glycoside bond <b>by phosphate</b> : (glycogen) <sub>n</sub> + P <sub>i</sub> → (glycogen) <sub>n-1</sub> + glucose 1-P
<b>Thiolysis</b>	the cleavage of C-C bond <b>by sulfur atom</b> of coenzyme A in β-oxidation of FA or ketone bodies catabolism RCH <sub>2</sub> COCH <sub>2</sub> CO-SCoA + CoA-SH → RCH <sub>2</sub> CO-SCoA + CH <sub>3</sub> CO-SCoA CH <sub>3</sub> COCH <sub>2</sub> CO-SCoA + CoA-SH → 2 CH <sub>3</sub> CO-SCoA

# Cofactors of enzymes

- low-molecular non-protein compounds
- many of them are derived from B-complex vitamins
- many of them are nucleotides
- **transfer 2 H or e<sup>-</sup> (cooperate with oxidoreductases)**
- **transfer groups (cooperate with transferases)**
- tightly (covalently) attached – prosthetic groups
- loosely attached – coenzymes (cosubstrates)

# Three different components in enzyme reaction

1. substrate(s)
  2. cofactor
- } react to each other
3. enzyme catalyzes the whole process

## Notes:

- one or two substrates may be involved (dehydrogenation × transamination)
- substrate can be low / high molecular (hexokinase × protein kinase)
- some reactions proceed without cofactor (hydrolysis, isomeration)
- reaction can be reversible or irreversible (dehydrogenation × decarboxylation)

# Cofactors of oxidoreductases

Oxidized form	Reduced form	The function of cofactor
NAD <sup>+</sup>	NADH+H <sup>+</sup>	NAD <sup>+</sup> acceptor of 2H
NADP <sup>+</sup>	NADPH+H <sup>+</sup>	NADPH+H <sup>+</sup> donor of 2H
FAD	FADH <sub>2</sub>	FAD acceptor of 2H
Dihydrobiopterin (BH <sub>2</sub> )	tetrahydrobiopterin (BH <sub>4</sub> )	BH <sub>4</sub> donor of 2H
Molybdopterin <sub>oxid</sub>	molybdopterin <sub>red</sub>	electron transfer
Lipoate (-S-S-)	dihydrolipoate (2 -SH)	antioxidant / transfer of acyl
Ubiquinone (Q)	ubiquinol (QH <sub>2</sub> )	transfer of 2 electrons + 2 H <sup>+</sup>
Heme-Fe <sup>3+</sup>	heme-Fe <sup>2+</sup>	transfer of 1 electron
Non-heme-S-Fe <sup>3+</sup>	non-heme-S-Fe <sup>2+</sup>	transfer of 1 electron
Glutathione <sub>oxid</sub> (G-S-S-G)	glutathione <sub>red</sub> (GSH)	2 GSH donor of 2H

# NAD<sup>+</sup> is the cofactor of dehydrogenases, derivative of nicotinamide (vitamin)

- NAD<sup>+</sup> is oxidant – takes off **2 H** from substrate

- one H adds as **hydride ion (H<sup>-</sup>)**

into *para*-position of pyridinium cation of NAD<sup>+</sup>

- NAD<sup>+</sup> + H<sup>-</sup> = NADH = equivalent of two electrons
- the second H is released as **proton (H<sup>+</sup>)** and  
binds to enzyme molecule

# $\text{NAD}^+$ (nicotinamide adenine dinucleotide)

addition of hydride anion

# Redox pair of cofactor

oxidized form  $\text{NAD}^+$

aromatic ring

tetravalent nitrogen

positive charge on nitrogen

reduced form  $\text{NADH}$

aromaticity **totally** disturbed

trivalent nitrogen

electroneutral species

**high-energy compound**

# Dehydrogenation by $\text{NAD}^+$

- typical substrate groups:
- primary alcohol  $-\text{CH}_2\text{-OH}$
- secondary alcohol  $>\text{CH-OH}$
- secondary amine  $>\text{CH-NH}_2$
- **double bond** ( $\text{C=O}$ ,  $\text{C=N}$ ) is produced

# NAD<sup>+</sup> dehydrogenations form a double bond

Substrate	Product
primary alcohol	aldehyde
secondary alcohol	ketone
aldehyde hydrate	carboxylic acid
hemiacetal	ester
cyclic hemiacetal	lactone
hydroxy acid	oxo acid
amino acid	imino acid

compare  
Med. Chem. II  
Appendix 3

# Dehydrogenation of ethanol (alcohol dehydrogenase)

# Dehydrogenation of glutamate (glutamate dehydrogenase)

glutamate

2-imino glutarate

# **NAD<sup>+</sup>-dependent enzymes are called pyridine dehydrogenases**

- **Citrate cycle**
  - isocitrate dehydrogenase
  - 2-oxoglutarate dehydrogenase
  - malate dehydrogenase
- **Glycolysis**
  - glyceraldehyde 3-P dehydrogenase
  - lactate dehydrogenase
- **Oxidation of ethanol**
  - alcohol dehydrogenase
  - acetaldehyde dehydrogenase

# Reduced cofactor NADPH+H<sup>+</sup> is hydrogenation agent

- donor of 2 H in hydrogenations
- cofactor of **reducing syntheses** (FA, cholesterol)
- regeneration of glutathione (GSH) in erythrocytes
- cofactor of **hydroxylation reactions:**

cholesterol → → bile acids

calcitriol → → calcitriol

xenobiotic → hydroxylated xenobiotic

- general scheme of hydroxylation:

# FAD is cofactor of flavin dehydrogenases, derivative of riboflavin (vitamin B<sub>2</sub>)

- flavin adenine dinucleotide
- dehydrogenation of -CH<sub>2</sub>-CH<sub>2</sub>- group
- **two** H atoms are attached to **two** nitrogens of riboflavin  
(N-1 and N-10)
- $\text{FAD} + 2\text{H} \rightarrow \text{FADH}_2$

# FAD (flavin adenine dinucleotide)

dimethylisoalloxazine

the sites for accepting  
two H atoms

ribitol

diphosphate

adenine

ribose

# Redox pair of cofactor

oxidized form FAD

aromatic system

electroneutral species

reduced form FADH<sub>2</sub>

aromaticity **partially** disturbed

electroneutral species

high-energy compound

# Dehydrogenation of succinate to fumarate (flavin dehydrogenase)

# Tetrahydrobiopterin (BH<sub>4</sub>) is a cofactor of hydroxylations

tetrahydropteridin

guanine

- made in the body from GTP
- **donor of 2H**
- oxidized to dihydrobiopterin (BH<sub>2</sub>)

# Redox pair of cofactor

tetrahydrobiopterin  
(BH<sub>4</sub>)

dihydrobiopterin  
(BH<sub>2</sub>)

# Hydroxylation of phenylalanine

# Coenzyme Q (ubiquinone)

- derivative of 1,4-benzoquinone
- cyclic diketone, not aromatic
- component of respiratory chain
- gradually accepts electron and proton (2x)
- reduced to semiubiquinone and ubiquinol

# Reversible reduction of ubiquinone

ubiquinone

(non-aromatic cycl. diketone)

semiubiquinone

(aromatic ring + radical)

ubiquinol

(diphenol)

electron (e<sup>-</sup>) and proton (H<sup>+</sup>) have different origin:

electron comes from reduced cofactors, H<sup>+</sup> from matrix of mitochondria

R = long polyisoprenoid chain  $\Rightarrow$  lipophilic character

# Heme of various cytochromes

- transfers just 1 electron
- cytochromes are hemoproteins
- components of respiratory chain or other heme enzymes (cyt P-450)
- reversible redox reaction:  $\text{Fe}^{2+} \rightleftharpoons \text{Fe}^{3+}$

## Non-heme iron ( $\text{Fe}_2\text{S}_2$ cluster) transfers electron in R.CH.

oxidized state

reduced state

just one iron cation changes oxidation number

# Molybdopterin (formula in Seminars)

## Xanthine oxidase catalyzes the oxygenation of purine bases (catabolism)

hypoxanthine

xanthine

uric acid

side product:  $\text{H}_2\text{O}_2$

# Molybdopterin

**Sulfite oxidase:  
sulfate is catabolite from cysteine**

cysteine

plasma  
urine

acidify  
plasma  
urine

reduce Mo

**Redox pair lipoate/dihydrolipoate is antioxidant system.**  
**It is also involved in the acyl transfer** (see later)

# Glutathione (GSH)

- tripeptide
- $\gamma$ -glutamyl-cysteinyl-glycine
- cofactor of glutathione peroxidase (contains selenocysteine)
- reduces  $\text{H}_2\text{O}_2$  to water
- $2 \text{G-SH} + \text{H-O-O-H} \rightarrow \text{G-S-S-G} + 2 \text{H}_2\text{O}$

Remember:

The -SH compounds have generally reducing properties.

# Dehydrogenation of two GSH molecules

2

# Vitamins and cofactors of transferases

Vitamin	Cofactor	Transferred group
Pyridoxin	pyridoxal phosphate	-NH <sub>2</sub> (transamination)
(Made in body)	ATP	-PO <sub>3</sub> <sup>2-</sup> (phosphoryl)
(Made in body)	PAPS	-SO <sub>3</sub> <sup>2-</sup>
Biotin	carboxybiotin	CO <sub>2</sub>
Pantothenic acid	CoA-SH	acyl
(Made in body)	dihydrolipoate	acyl
(Methionine)	SAM	-CH <sub>3</sub>
Folate	tetrahydrofolate	C <sub>1</sub> groups
Cyanocobalamin	methylcobalamin	-CH <sub>3</sub>
Thiamin	thiamin diphosphate	residue of oxo acid

# Pyridoxal phosphate is the cofactor of transamination and decarboxylation of AA

# ATP is the cofactor of kinases (phosphorylation agent)

# Phosphorylation of substrate

substrate

ATP (4<sup>-</sup>)

CAUTION: creatine kinase (CK)  
phosphorylation on nitrogen (the bond N-P)

kinase

phosphorylated substrate

ADP (3<sup>-</sup>)

# PAPS is sulfation agent

- 3'-phosphoadenosine-5'-phosphosulfate
- mixed anhydride of  $\text{H}_2\text{SO}_4$  and  $\text{H}_3\text{PO}_4$
- esterification of hydroxyl groups by sulfuric acid = sulfation
- sulfated sphingoglycolipids
- sulfated glycosaminoglycans (heparin, chondroitin sulfate, keratan sulfate)

# Carboxybiotin

- cofactor of carboxylation reactions
- carboxylation of biotin needs ATP

# Carboxybiotin is the cofactor of carboxylation reactions

pyruvate

pyruvate carboxylase

+

oxaloacetate

# Distinguish: Decarboxylation vs. Carboxylation

Cofactor	Decarboxylation (does not require energy)
Thiamin-diP	pyruvate $\rightarrow$ acetyl-CoA + CO <sub>2</sub> 2-oxoglutarate $\rightarrow$ succinyl-CoA + CO <sub>2</sub>
Pyridoxal-P	amino acid $\rightarrow$ amine + CO <sub>2</sub>
None	acetoacetate $\rightarrow$ acetone + CO <sub>2</sub> (non-enzymatic, spontaneous)
Cofactor	Carboxylation (requires energy)
Biotin	pyruvate + CO <sub>2</sub> + ATP $\rightarrow$ oxaloacetate acetyl-CoA + CO <sub>2</sub> + ATP $\rightarrow$ malonyl-CoA propionyl-CoA + CO <sub>2</sub> + ATP $\rightarrow$ methylmalonyl-CoA $\rightarrow$ succinyl-CoA carboxylations (ATP) in the catabolism of Val, Leu, Ile
Phylloquinone (vitamin K)	protein-glutamate + O <sub>2</sub> + vit K <sub>red</sub> + CO <sub>2</sub> $\rightarrow$ protein- $\gamma$ -carboxyglutamate posttranslational carboxylation of glutamate $\rightarrow$ hemostasis
None	Hb-NH <sub>2</sub> + CO <sub>2</sub> $\rightarrow$ Hb-NH-COOH (unstable Hb-carbamate, spontaneous)

# Coenzyme A (CoA-SH)

- transfers acyl
- attached to sulfur atom
- **thioester bond**
- acyl-CoA is activated acyl
- e.g. acetyl-CoA

# Coenzyme A

# Lipoate (lipoamide)

part of the 2-oxo acid dehydrogenase complex (see the following lectures)

it is oxidant of a group carried by thiamine diphosphate (TDP),

binds the resulting acyl as thioester and transfers the acyl to coenzyme A:

# S-Adenosylmethionine (SAM)

- „active methyl“, trivalent sulfur  $\Rightarrow$  **sulfonium cation**
- cofactor of methylation reactions:
  - ethanolamine  $\rightarrow$  choline (3 methylation)
  - guanidine acetate  $\rightarrow$  creatine
  - noradrenaline  $\rightarrow$  adrenaline ..... and many others
- side product is **homocysteine**
- remethylation of homocysteine needs methyl-FH<sub>4</sub> + B<sub>12</sub> cofactor  
(see Seminars)

# *S*-Adenosylmethionine (SAM)

**Folic acid is vitamin.**

**In the body, it is hydrogenated to 5,6,7,8-tetrahydrofolate.**

**Tetrahydrofolate ( $\text{FH}_4$ ) is cofactor for the transfer of  $\text{C}_1$  groups**

# C<sub>1</sub> Groups transferred by FH<sub>4</sub>

compare scheme

Seminars, p. 26

Oxidation number of C	Formula	Name	Metabolic Origin / Comment
-III	-CH <sub>3</sub>	methyl	reduction of methylene-FH <sub>4</sub> (from serine, glycine) methyl-FH <sub>4</sub> cooperates with B <sub>12</sub> cofactor in methylation
-II	-CH <sub>2</sub> -	methylene	catabolism of serine, glycine used in synthesis of dTMP → DNA
-I	-CH=	methenyl	deamination of formimino-FH <sub>4</sub> (from histidine) used in synthesis of purine bases
+I	-CH=O	formyl	catabolism of tryptophan → formiate → formyl used in synthesis of purine bases
+I	-CH=NH	formimino	catabolism of histidine

# B<sub>12</sub> vitamin is cyano or hydroxocobalamin

R = CN or OH  
corrin cycle

hydroxocobalamin is used in the treatment of cyanide poisoning, it binds cyanide ions to nontoxic cyanocobalamin

**B<sub>12</sub> cofactor is methyl or deoxyadenosylcobalamin,  
it is needed for two reactions in the body**

1. homocysteine  $\xrightarrow{\text{FH}_4 / \text{B}_{12}}$  methionine  
methylation of homocysteine (regeneration of methionine)
2. homocysteine  $\rightarrow \rightarrow$  propionyl-CoA  $\xrightarrow{\text{B}_{12}} \rightarrow$  succinyl-CoA

# Compare: Four different cofactors of methylations

Cofactor	Origin of methyl	Examples of methylation reactions
SAM	methionine	ethanolamine → choline guanidine acetate → creatine noradrenaline → adrenaline methylation of DNA (regulation of gene expression) methylation of bases in tRNA / mRNA (guanine-N <sup>7</sup> = cap) inactivation of catecholamines (COMT): <ul style="list-style-type: none"> <li>• dopamine → methoxytyramine</li> <li>• noradrenaline → normetanephrine</li> <li>• adrenaline → metanephrine</li> </ul> methylation of xenobiotics (II. phase - conjugation)
methyl-FH <sub>4</sub>	methylene-FH <sub>4</sub>	} homocysteine → methionine
methyl-B <sub>12</sub>	methyl-FH <sub>4</sub>	
methylene-FH <sub>4</sub>	serine, glycine	dUMP → dTMP dUMP + methylene-H <sub>4</sub> F → dTMP + H <sub>2</sub> F (thymidylate synthase)

**Thiamin is vitamin B<sub>1</sub>**

**Thiamin diphosphate (TDP) is cofactor**

### **Oxidative decarboxylation of some 2-oxo acids**

- pyruvate → acetyl-CoA
- 2-oxoglutarate → succinyl-CoA (citrate cycle)
- 2-oxo acids in the catabolism of branched amino acids (Val, Leu, Ile)

### **Transketolase reactions in pentose cycle**

- ribose-5-P + xylulose-5-P ⇌ glyceraldehyde-3-P + sedoheptulose-7-P
- xylulose-5-P + erythrose-4-P ⇌ fructose-6-P + glyceraldehyde-3-P

# Thiamin diphosphate (TDP) is cofactor in the oxidative decarboxylation of pyruvate

attachment of pyruvate and its decarboxylation

## In human body, a number of non-enzymatic reactions proceeds

- decarboxylation of acetoacetate → acetone
- catabolism of creatine → creatinine (dehydration + cyclization)
- glycation / carbamylation / nitrosylation / nitration of proteins
- the reactions of reactive oxygen species (e.g. lipoperoxidation)
- spontaneous oxidation of hemoproteins (hemoglobin → methemoglobin)
- spontaneous oxidation of urobilinogens to urobilins (large intestine)
- condensation of amines with carbonyl compounds to heterocyclic derivatives
  - dopamine + pyruvate → salsolinol (neurotoxin ?)
  - tryptamine + pyruvate → harmaline
  - dopamine + dihydroxyphenylacetaldehyde → tetrahydropapaveroline
- binding ligands to proteins:
  - bilirubin + albumin → bilirubin-albumin complex
  - CO + hemoglobin → carboxyhemoglobin
- the interactions of macromolecules:
  - antigen + antibody → immuno complex
