

Bone and joint diseases

December 12, 2017

Bone properties

- Bones
 - stiff
 - do not bend when loaded.
 - flexible - absorb the energy imposed by loading as potential energy by elastic then plastic deformation.
 - Structural failure may occur if bones deform too little or too much.
- High remodeling reduces the mineral content of bone, resulting in loss of stiffness.

Bone properties

- Age- and menopause-related abnormalities in bone remodeling produce loss of material and structural properties.
- Sex hormone deficiency
 - increases the volume of bone resorbed
 - reduces the volume of bone formed.
- The contributions made by differences in material composition, tissue mineral content, collagen type and cross-linking structure (bone size, cortical thickness and porosity, trabecular number, thickness, connectivity), and other factors (microdamage burden, osteocyte density) to sex and racial differences in bone fragility remain poorly defined.

Skeletal fragility

Skeletal fragility can result from:

- failure to produce a skeleton of optimal mass and strength during growth;
- excessive bone resorption resulting in decreased bone mass and microarchitectural deterioration of the skeleton;
- and an inadequate formation response to increased resorption during bone remodeling.

Bone remodeling

- **Osteoclast activation**
- **Resorption phase**- due to osteoclast activation- short period
- **Reverse phase**- bone surface is covered by mononuclear cell
- **Formation phase**- osteoblast production in bone matrix - long.

Bone cells

Osteoblasts

the surface of the rising / remodeling bone, less well within the relatively passive adult. **synthesize and store the bone matrix**, mineralize it, gradually convert to osteocytes. the surface binds alkaline phosphatase, mineralization matrix.

Osteoclasts

at sites of active erosion on the surface of the bone, in so-called resorptive wells. many lysosomes with high acid phosphatase activity. phagocytes collagen and other organic components of the matrix.

Osteocytes

the main component of the adult bone, scattered in the lakes, interconnecting the protuberances create a complex cellular network. their average life is estimated at 25 years, death resolves resorption.

Regulation of osteoclast formation and activity

Ratiz, L. G. J. Clin. Invest. 2005;115:3318-3325

Copyright ©2005, American Society for Clinical Investigation

Osteoclasts activation

- Regulation of osteoclast formation and activity.
 - contact between cells of the osteoblast and osteoclast lineages.
 - to stimulate differentiation and proliferation of hematopoietic progenitors, which then express RANK as preosteoclasts.
 - Osteoclast differentiation and activity are stimulated by RANK/RANKL interaction, and
 - this interaction can be blocked by soluble OPG.

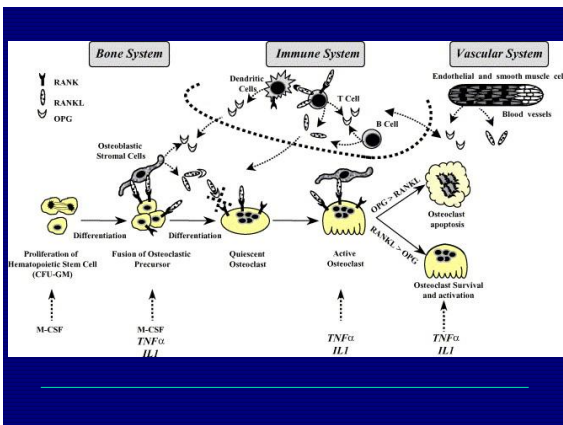

Ligand for receptor activator nuclear factor- kappa B ligand (RANKL) a osteoprotegerin (OPG) as final effector cytokines in malignant skeletal diseases (to the previous picture).

- 1) Interaction RANKL with RANK supports differentiation and activation of osteoclasts
- 2) Activated osteoclasts cause humoral hypercalcemia in malignant tumors, osteolytic metastases, pathological fractures and in pain-related malignancies.
- 3) OPG functions as receptor neutralizing RANKL which obstructs its ligation with RANK.
- 4) many growth factors, cytokines, hormones converge at the level of RANKL and OPG and regulate differentiation and activation of osteoclasts. IL-1 and TNF support production of RANKL and OPG, while PTH, PTHrP and glucocorticoids increase production of RANKL, but decrease OPG production
- 5) to some extent, IL-1 and TNF are able to modulate differentiation and activation of osteoclasts independently on RANKL and RANK.

OPG/RANK/RANKL as a common effector in bone immune system and a vascular system (to the previous figure)

- OPG, RANK and RANKL are selectively produced by many cell types in different tissue: lymphocytes, osteoblasts and endothelial cells.
- RANKL is functioning as a survival factor for dendritic cells and as a osteoclastogenic factor after RANK ligation.
- OPG inhibits osteolysis and blocks RANKL/RANK interaction.
- OPG/RANKL/RANKL triad is considered a osteoimmunomodulating complex.

Osteoclasts activation

- Under pathologic conditions, inflammatory and malignant cells can increase osteoclastogenesis by producing soluble or membrane-bound M-CSF and RANKL as well as PTH-related protein (PTHrP), cytokines, and prostaglandins.

Parathyroid Hormone Relation Peptide (PTHrP)

- PTHrP was discovered as mediator of syndrome "humoral hypercalcemia of malignancy" (HHM).
- During the syndrome in different type of cancer (in absence of metastases) similar compounds to PTH are produced which is related to:
 - Hypercalcemia
 - Hypophosphatemia
 - Increased cAMP excretion by urine
- The effects are similar to those caused by PTH; no PTH levels are detected.

Genetic families of PTH and PTHrP: PTHrP, PTH and TIP39 are probably members of the same genetic family. Their receptors PTH1R and PTH2R are 7 transmembrane G protein-coupled receptors.

Production of PTHrP regulated by growth factor (GF) in tumor states. Tumor cells are able to be stimulated at a distance (outside the bone) by autocrine growth factors to an increased production of PTHrP. It reaches via circulation the bone tissue and supports bone resorption. Metastatic tumor cells in the bone are able to secrete PTHrP supporting bone resorption and paracrine growth factors which further support PTHrP production.

Gene	Mutation	Disease
RANK	18 bp duplication	Familial expansile osteolysis
	27 bp duplication	Early onset Paget's disease
	15 bp duplication	Expansile skeletal hyperphosphatasia
RANKL	Deletion of amino acids 145-177	Autosomal recessive osteopetrosis
	A single nucleotide change (596T>A) in exon 8 of both alleles	Autosomal recessive osteopetrosis
	Deletion of two nucleotides (828_829delCG)	Autosomal recessive osteopetrosis
OPG	Deletion making OPG inactive	Juvenile Paget's disease
	20 bp deletion resulting in premature termination of OPG translation	Juvenile Paget's disease

Cytokines, prostaglandins

- There is evidence that polymorphisms of IL-1, IL-6, TNF- α and their receptors can influence bone mass in humans.
- Prostaglandins have both stimulatory and inhibitory actions; the predominant effect of PGE₂, which is the major prostaglandin produced by bone cells, is to stimulate both resorption and formation.
 - Prostaglandins, particularly PGE₂, are produced by bone cells largely through the action of inducible cyclooxygenase 2 (COX2).
 - COX2 is induced by most of the factors that stimulate bone resorption and thus may enhance the response to these agents. Treatment with COX inhibitors blunts the response to impact loading and fluid shear stress, indicating that prostaglandins play an important role in the response on mechanical forces, and this may be enhanced by estrogen. In epidemiologic studies, small increases in BMD and decreases in fracture risk have been reported in individuals using NSAIDs.

Cytokines, prostaglandins, NO, and leukotrienes

- NO is produced by bone cells and is a cofactor for the anabolic response to mechanical loading. However, unlike prostaglandins, NO may inhibit bone resorption, perhaps by increasing OPG production.
- Leukotrienes, the products of lipoxygenase, can affect bone by stimulating resorption and inhibiting formation.

Estrogen influence on bone state

- Estrogen is critical for
 - epiphyseal closure in puberty in both sexes and
 - regulates bone turnover in men as well as women.
- Estrogen has a greater effect than androgen in inhibiting bone resorption in men, although androgen may still play a role.
- Estrogen may also be important in the acquisition of peak bone mass.
- Osteoporosis in older men is more closely associated with low estrogen than with low androgen levels.

Central role of estrogen deficiency - today

- An increase in bone resorption, and not impaired bone formation, appears to be the driving force for bone loss in the setting of estrogen deficiency.
- The rapid and continuous bone loss that occurs for several years after the menopause indicate an impaired bone formation response, since in younger individuals going through the pubertal growth spurt, even faster rates of bone resorption can be associated with an increase in bone mass.
- However, the increased bone formation that normally occurs in response to mechanical loading is diminished in estrogen deficiency, suggesting estrogen is both anti-catabolic and anabolic.

Remodelling of bones. Estrogen action places (i)

Raisz, L. G. J. Clin. Invest. 2005;115:3318-3325

Collagen abnormalities

- A polymorphism of the first intron of the gene coding for the type I collagen 1 chain and increased levels of homocysteine can influence fracture risk independent of BMD (bone mass density).
 - This may be due to differences in helix formation or cross-linking of collagen, challenging the concept that mineral and matrix composition are normal in osteoporosis and that only structural abnormalities account for skeletal fragility.

Calcium

Calcium, vitamin D, and parathyroid hormone

- The active 1,25 dihydroxy vitamin D (calcitriol),
 - optimal intestinal absorption of calcium and phosphorus,
 - exerts a tonic inhibitory effect on parathyroid hormone (PTH) synthesis,
 - dual pathways that can lead to secondary hyperparathyroidism.
- Vitamin D deficiency and secondary hyperparathyroidism can contribute to
 - accelerated bone loss and
 - increasing fragility, but also to
 - neuromuscular impairment that can increase the risk of falls.

Vitamin D

- ❑ Sunscreens, especially those with SPF ratings greater than 8, effectively block synthesis of vitamin D in the skin.
- ❑ **Vitamin D toxicity:** Excessive exposure to sunlight does not lead to overproduction of vitamin D. Vitamin D toxicity is inevitably the result of overdosing on vitamin D supplements. Ingestion of milligram quantities of vitamin D over periods of weeks or months can be severely toxic to humans and animals.

Regulation of gene expression by VDR

Vitamin D - consequences

- ❑ Deficit and insufficiency of vitamin D = global health problem.
- ❑ High risk for acute and chronic disease, as
 - Infection diseases
 - Autoimmune diseases
 - DM type I and II
 - High risk of atherosclerosis
 - Some tumor types (colorectal carcinoma, breast and prostate cancer, ovarian cancer)
 - Cognitive dysfunction
 - Infertility
 - Gravidity and around delivery complications

Pludowski P et al. Vitamin D effects on musculoskeletal health, immunity, autoimmunity, cardiovascular disease, cancer, fertility, pregnancy, dementia and mortality—A review of recent evidence. *Autoimmunity Reviews*, Volume 12, Issue 10, August 2013, Pages 976-989

Calcitonin

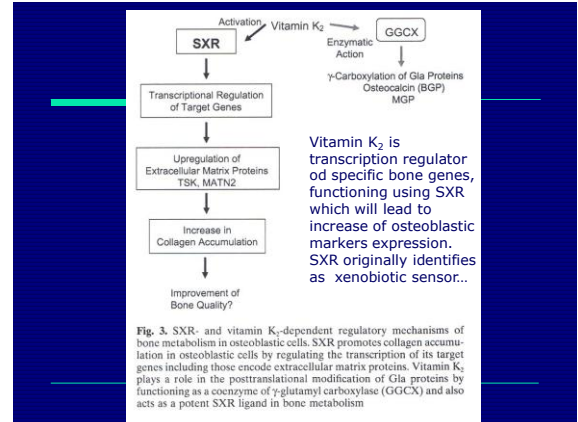

- ❑ Calcitonin is a hormone known to participate in calcium and phosphorus metabolism. Its main role is to increase calcium deposition in bones.
- ❑ In mammals, **the major source of calcitonin is from the parafollicular or C cells in the thyroid gland**, but it is also synthesized in a wide variety of other tissues, including the lung and intestinal tract.
- ❑ Calcitonin is a 32 amino acid peptide cleaved from a larger prohormone. It contains a single disulfide bond, which causes the amino terminus to assume the shape of a ring.
- ❑ Alternative splicing of the calcitonin pre-mRNA can yield a mRNA encoding calcitonin gene-related peptide; that peptide appears to function in the nervous and vascular systems. The calcitonin receptor has been cloned and shown to be a member of the seven-transmembrane, G protein-coupled receptor family.

Calcitonin

- ❑ **The most prominent factor controlling calcitonin secretion is the extracellular concentration of ionized calcium.**
- ❑ Elevated blood calcium levels strongly stimulate calcitonin secretion, and secretion is suppressed when calcium concentration falls below normal.
- ❑ A number of other hormones have been shown to stimulate calcitonin release in certain situations, and nervous controls also have been demonstrated.

Vitamin K and bones

- o cofactor for γ -carboxylase, enzyme which catalyses conversion of specific residuals of glutamic acid to Gla residuals
- o γ -carboxylation of proteins of bone matrix which contain Gla as **MGP (= matrix Gla protein) a osteocalcin**.
 - o Uncompleted γ -carboxylation of osteocalcin and MGP during vitamin K decrease lead to osteoporosis and high risk of fractures.
- o stimulates synthesis of osteoblastic markers and bone deposition.
- o decreases bone reabsorption by inhibition of osteoclasts formation and by decrease of their resorbition activity.
- o Vitamin K₂ treatment induces osteoclast apoptosis, but inhibits osteoblasts apoptosis which is leading to increased bone formation.
- o Vitamin K₂ supports osteocalcin expression (increases its mRNA) which can be further modulated by 1, 25-(OH)₂ vitamin D₃

Local and systemic growth factors

- Remodeling imbalance, characterized by an impaired bone formation response to increased activation of bone remodeling, is an essential component of the pathogenesis of osteoporosis. This may be due, in part, to an age-related decrease in the capacity of osteoblasts to replicate and differentiate. However, it seems likely that specific defects in the production or activity of local and systemic growth factors will also contribute to impaired bone formation.

Metabolic bone diseases

- Osteoporosis
 - (estrogen deficiency, glucocorticoids increase, vitamin K2 deficiency?)
- Osteodystrophy
 - (primary and secondary hyperparathyroidism)
- Ostemalacia/ rickets
 - vitamin D deficiency)

Metabolic bone diseases

- Osteoporosis remains the most common metabolic abnormality of bone. It has been described as "a silent epidemic" affecting one in two women and one in five men, older than 50 years of age, during their lifetime.
- It is now defined as a systemic skeletal disease characterized by low bone mass and micro-architectural deterioration of bone resulting in fractures with little or no trauma.

Osteoporosis

- The bone mass of an individual in later life is a result of the peak bone mass accrued during intrauterine life, childhood, and puberty, as well as the subsequent rate of bone loss.
- Although genetic factors strongly contribute to peak bone mass, environmental factors in intrauterine life, childhood, and adolescence modulate the genetically determined pattern of skeletal growth.

Osteoporosis

- is a skeletal disease characterised by low bone mass and microarchitectural deterioration with a resulting increase in bone fragility and hence susceptibility to fracture.
- Caucasian population: about 50% of women and 20% of men older than 50 years will have a fragility fracture in their remaining lifetime.

Etiopathogenesis of osteoporosis

- complex interactions among local and systemic regulators of bone cell function.
- The heterogeneity of osteoporosis may be due to
 - differences in the production of systemic and local regulators,
 - changes in receptors,
 - signal transduction mechanisms,
 - nuclear transcription factors, and
 - enzymes that produce or inactivate local regulators.
- Since the first human osteoporosis study indicated an association among bone mass, fragility, and polymorphisms in the *vitamin D receptor (VDR)* gene, more than 30 candidate genes have been reported that might influence skeletal mass and fragility.
- Since osteoporosis is a complex, polygenic disorder, the contributions of specific gene polymorphisms are likely to be relatively small, but may still be clinically important.

Osteoporosis - causes

- Glucocorticoids excess
- Estrogene deficiency
- Vitamin K2 deficiency?

Osteoporosis induced by cortisol

- Cortisol modifies proliferative and metabolic activities of bone cells
- Cortisol inhibits osteoblastogenesis
- Reduces half-life time of osteoblasts which is leading to decreased bone formation

Common adverse effects of glucocorticoid therapy- glucocorticoid-induced osteoporosis

- Glucocorticoid-induced osteoporosis is the most common type of iatrogenic osteoporosis and a frequent cause of secondary osteoporosis.
- An estimated 50% of patients taking glucocorticoids for longer than 6 months will develop secondary osteoporosis.
- The absolute risk for glucocorticoid-induced osteoporosis is higher in patients aged 65 years or older given their baseline age-related fracture risk, although the relative risk of fracture related to glucocorticoid use may be even higher in patients under 65.

Cortisol generally antagonizes insulin ...

Osteomalacia and rickets

- Classically, the deficiency of vitamin D, essential for the absorption of calcium, has been the major cause of rickets in the child and osteomalacia in the adult
- resulting in absence or delay in the mineralization of growth cartilage or newly formed bone collagen.

Osteomalacia and rickets

- A consequence of a low serum phosphate and normal serum calcium.
- Two such conditions are *x-linked hypophosphatemic rickets/osteomalacia* and *oncogenic osteomalacia*.
- When present, the signs of rickets and osteomalacia in the low serum phosphate states are indistinguishable from the classic hypocalcemic states.

X-linked hypophosphatemic osteomalacia

- The condition is characterized by low tubular reabsorption of phosphate in the absence of secondary hyperparathyroidism.
- X-linked hypophosphatemia occurs in about 1 in 25,000 and is considered the most common form of genetically induced rickets.

Oncogenic osteomalacia

- Oncogenic osteomalacia is a paraneoplastic syndrome in which a bone or soft tissue tumor or tumor-like lesion induces hypophosphatemia and low vitamin D levels that reverse when the inciting lesion is resected.

Oncogenic osteomalacia

- **Phosphatonin**
 - a humoral factor,
 - has been identified in clinical and experimental studies as being responsible for the serum biochemical changes.
 - causes hyperphosphaturia by inhibiting the reabsorption of phosphate by the proximal renal tubules.
- Fibroblast growth factor 23, phosphate-regulating gene with homologies to endopeptides located on the 'x' chromosome (PHEX) and matrix extracellular phosphoglycoprotein (MEPE) are candidates proposed for the production of phosphatonin and the altered pathophysiology in oncogenic osteomalacia.

	Calcium Deprivation	Calcium Loading
Parathyroid hormone	Secretion stimulated	Secretion inhibited
Vitamin D	Production stimulated by increased parathyroid hormone secretion	Synthesis suppressed due to low parathyroid hormone secretion
Calcitonin	Very low level secretion	Secretion stimulated by high blood calcium
Intestinal absorption of calcium	Enhanced due to activity of vitamin D on intestinal epithelial cells	Low basal uptake
Release of calcium and phosphate from bone	Stimulated by increased parathyroid hormone and vitamin D	Decreased due to low parathyroid hormone and vitamin D
Renal excretion of calcium	Decreased due to enhanced tubular reabsorption stimulated by elevated parathyroid hormone and vitamin D; hypocalcemia also activates calcium sensors in loop of Henle to directly facilitate calcium reabsorption	Elevated due to decreased parathyroid hormone-stimulated reabsorption.
Renal excretion of phosphate	Strongly stimulated by parathyroid hormone; this phosphaturic activity prevents adverse effects of elevated phosphate from bone resorption	Decreased due to hypoparathyroidism
General Response	Typically see near normal serum concentrations of calcium and phosphate due to compensatory mechanisms. Long term	Low intestinal absorption and enhanced renal excretion guard against development of hypercalcemia.

Articular diseases

- irreversible destruction of the cartilage, tendon, and bone that comprise synovial joints
 - rheumatoid arthritis (RA) and
 - osteoarthritis (OA).
- While cartilage is made up of proteoglycans and type II collagen, tendon and bone are composed primarily of type I collagen.

Rheumatoid Arthritis

- The prevalence of rheumatoid arthritis in most Caucasian populations approaches 1% among adults 18 and over and increases with age, approaching 2% and 5% in men and women, respectively, by age 65
- The incidence also increases with age, peaking between the 4th and 6th decades
- Both prevalence and incidence are 2-3 times greater in women than in men
- Monozygotic twins 13.5% vs dizygotic twins 3.5%

“One must from time to time attempt things that are beyond one’s capacity.”

—Pierre-Auguste Renoir

Rheumatoid Arthritis

- Rheumatoid arthritis is an autoimmune disease affecting the joints, tendons, and bones, resulting in inflammation and destruction of these tissues.

- The term ‘arthritis’ is used to denote clinically apparent soft tissue swelling or fluid (not bony overgrowth alone).

Rheumatoid Arthritis

- Description
 - Morning stiffness
 - Arthritis of 3 or more joints
 - Arthritis of hand joints
 - Symmetric arthritis
 - Rheumatoid nodules
 - Serum rheumatoid factor
 - Radiographic changes

- having rheumatoid arthritis – positive 4 of 7 criteria, with criteria 1-4 present for at least 6 weeks

Functional Presentation and Disability of RA

- In the initial stages of each joint involvement, there is warmth, pain, and redness, with corresponding decrease of range of motion of the affected joint
- Progression of the disease results in reducible and later fixed deformities
- Muscle weakness and atrophy develop early in the course of the disease in many people

Rheumatoid Arthritis

- Pathogenesis of RA
 - complex interaction between genetic and environmental factors and
 - the repeated activation of innate and adaptive immune system
 - evolves into the breakdown of immune tolerance, aberrant autoantigen presentation and antigen-specific T and B cells activation.
- Genetic factors have an important role in the susceptibility to rheumatoid arthritis
 - HLA-DRB

First step – joint disease?

- Although the synovium is the principal site of pathology in the established phase of disease, it may not be the site where the disease is initiated.
- Systemic immune abnormalities in individuals without joint symptoms, and a lack of immune infiltrates in the synovium during the earliest phase before clinical signs and symptoms of arthritis, point to other tissues being important in the initiation of adaptive immune reactions.
- Important tissues for research include bone marrow, lymph nodes, the gut, periodontal tissue, the lung and the neuroendocrine system.

RA without clinical arthritis

- An initial phase, characterised by systemic autoimmunity without synovial inflammation, may be followed by a shorter phase during which asymptomatic synovitis is present.

RA progression

- events culminate in synovial inflammation, hyperplasia and bone destruction leading to joint swelling and deformity and to systemic inflammation.

Clinical Presentation of RA

Latins KM, et al. The Washington ManualTM Rheumatology Subspecialty Consult. Philadelphia, Pa: Lippincott Williams & Wilkins; 2004.

RA progression

□ Early Pannus

- Granulation, inflammation at synovial membrane, invades joint, softens and destroys cartilage

RA progression

Mod advanced Pannus

- joint cartilage disappears, underlying bone destroyed, joint surfaces collapse

Fibrous Ankylosis

- Fibrous connective tissue replaces pannus; loss of joint motion

Bony Ankylosis

- Eventual tissue and joint calcification

Subcutaneous nodules
(disappear and appear without warning)

Diagnostic Tools in Rheumatoid Arthritis

- Rheumatoid factor
- Anti-CCP antibodies
- Plain X-ray
- MRI
- Ultrasound

Rheumatoid Factor

- Antibody directed against the Fc portion of IgG
- Present in approximately 80% of RA patients
 - Sensitivity for RA is ~80%
 - Specificity is 85-95%
- May be involved in disease pathogenesis
- Higher levels tend to be associated with poorer prognosis
- Found in other conditions, especially Hepatitis C

Anti-Cyclic Citrullinated Peptide (CCP) Antibodies in RA

- Anti-citrulline Abs produced in RA synovium
- Early RA Diagnosis
 - sensitivity 48%; specificity 96%
 - seen in 2% of pts with other autoimmune diseases and infections (vs. 14% for RF)
 - less than 1% of healthy controls
- Predicts erosive disease PPV - 63% and NPV - 90%
- Present years before the onset of symptoms, 34% of blood samples obtained 2.5 yr before onset of symptoms (vs. 1.8% of controls)

Plain X-ray

Magnetic Resonance Imaging as a Diagnostic Tool

Erosions Detected:
X-rays vs MRI (%)

McQueen FM et al. *Ann Rheum Dis*. 1999;58:156-163.
McQueen FM et al. *Ann Rheum Dis*. 1998;57:350-356.

Ultrasound as a Diagnostic Tool

Keen et al. *Rheum Dis Clin N Am* 31 (2005) 699-714

Features Related to Poor Outcomes

- Extra-articular disease
- High rheumatoid factor titer, positive anti-CCP antibody
- Poor functional status
- Involvement of multiple joints
- Radiographic erosions
- Sustained elevation of acute-phase reactants (eg, ESR)
- Low socioeconomic status/educational level
- Increased genetic risk of developing RA plus smoking

Alroy JH et al. *Ann Rheum Dis*. 1994;53:765-781. Pincus T, et al. *Scellings' Clin Rheumatol* 1992;8:131-131. Pusek DE. *Rheum Dis Clin North Am*. 1994;20:309-319. Padyukov L, et al. *Arthritis Rheum*. 2004;50:3085-3092.

Complications of Rheumatoid Arthritis

Complications:

- Carpal tunnel syndrome, Baker's cyst, vasculitis, subcutaneous nodules, Sjögren's syndrome, peripheral neuropathy, cardiac and pulmonary involvement, Felty's syndrome, and anemia

RA is a Multisystem Disease

Rheumatoid arthritis: episcleritis

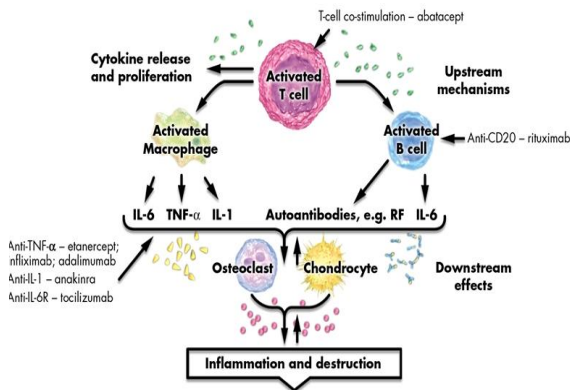

Treatment before the BIOLOGICS

- NSAIDs for stiffness
- Corticosteroids for inflammation and to suppress the autoimmunity
- Disease Modifying Anti rheumatic Drugs (DMARDs)
 - Drug of choice -Methotrexate 7.5-25mg weekly
 - But also Cyclosporine, Azathioprine, cyclophosphamide

Monoclonal antibodies and RA

- Tumor Necrosis (alpha) Inhibitors 5 FDA approved
 - Infliximab (Remicaid) an infusion
 - Etanercept (Enbrel) against soluble TNF receptors
 - Adalimumab (Humira) against soluble and membrane bound TNF receptors
 - Certolizumab (Cimza) pegylated
 - Golimumab (Simponi)
- Rituximab (rituxan) anti CD20 B cells
- Abatacept anti Costimulation blocking CD80/86 CD28
- Anakinra (Kineret) anti IL 1 receptor LOW EFFECT
- Tocilizumab (Actemra) anti IL 6

RA Therapies: The Next Generation

- Biosimilars
- Anti-IL-6 receptor
 - Sarilumab
- Anti-IL-17A
 - Secukinumab
- Anti-IL-20
- Anti-CD22
 - Epratuzamab
- Chemokine inhibitor: CCX354-L2
- PDE4 inhibitor: aprimilast

Seronegative Spondyloarthropathy

- Consist of a group of related disorders that include Reiter's syndrome, ankylosing spondylitis, psoriatic arthritis, and arthritis in association with inflammatory bowel disease
- Occurs commonly among young men, with a mean incidence between ages 25 and 34
- The prevalence is about 1%
- The male-to-female ratio approaches 4 to 1 among adult Caucasians
- Genetic factors play an important role in the susceptibility to each disease

Seronegative Spondyloarthropathy

- The spondyloarthropathies share certain common features, including the absence of serum rheumatoid factor, an oligoarthritis commonly involving large joints in the lower extremities, frequent involvement of the axial skeleton, familial clustering, and linkage to HLA-B27
- These disorders are characterized by inflammation at sites of attachment of ligament, tendon, fascia, or joint capsule to bone (enthesopathy)

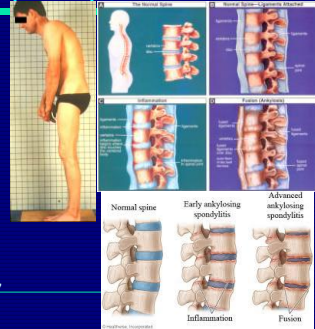

Sacroiliitis

- Sacroiliitis is an inflammation of the sacroiliac joint.
 - Symptoms usually include a fever and reduced range of motion.
- Picture of individual with – sacroiliitis and Ankylosing Spondylitis. The arrows point to the inflamed and narrowed SI joints. They are white due to bony sclerosis around the joints

Ankylosing Spondylitis

- Chronic disease that primarily affects the spine and may lead to stiffness of the back.
- The joints and ligaments become inflamed. The joints and bones may fuse.
- The effects are inflammation and chronic pain and stiffness in the lower back that usually starts where the lower spine is joined to the pelvis or hip.
- Diagnosis: X-rays, and blood tests for HLA-B27 gene

Psoriatic Arthritis

- Causes pain and swelling in some joints and scaly skin patches on some areas of the body.
- The symptoms are:
 - About 95% of those with psoriatic arthritis have swelling in joints outside the spine
 - Silver or grey scaly spots on the scalp, elbows, knees and/or lower end of the spine.
 - Pain and swelling in one or more joints
 - Swelling of fingers/toes that gives them a "sausage" appearance.

Degenerative Joint Disease (Osteoarthritis)

- is characterized by progressive loss of cartilage and reactive changes at the margins of the joint and in the subchondral bone
- The disease usually begins in one's 40s
- Prevalence increases with age and the disease becomes almost universal in individuals aged 65 and older
- Primarily affects weight-bearing joints such as the knees, hips, and lumbosacral spine

Degenerative Joint Disease

- In early disease, pain occurs only after joint use and is relieved by rest
- As the disease progresses, pain occurs with minimal motion or even at rest
- Nocturnal pain is commonly associated with severe disease

Diseases of Muscles

- **Myopathies:** disorders of muscle fibres
- **Dystrophy:** a genetic myopathy.
- **Neurogenic:** interference with nerve supply.
- **Bilateral & symmetrical:** myopathy
- **Asymmetric:** neurogenic.

Classification

Inherited

- Muscular dystrophies
- Myotonic dystrophy
- Congenital myopathies
- Metabolic myopathies
- Channelopathies

Acquired

- Endocrinopathies
- Drug induced
- Idiopathic inflammatory myopathy
- Metabolic myopathy
- Myasthenia Gravis /LEMS

Muscular dystrophy

- Muscular dystrophy is a heterogeneous group of **inherited** disorders recognized by **progressive degenerative** muscle **weakness** and **loss** of muscle tissue (started in childhood).
- Affect muscles **strength** and **action**.
- **Generalized** or **localized**.
- Skeletal muscle and other organs may involve

- **Limitation:** Difficulties with walking or **M**aintaining posture, **M**uscle spasms. **N**eurological, **B**ehavioral, **C**ardiac, or other **F**unctional limitations.

Muscular Dystrophy

Causes

- Inheritance
- Dominant genes
- Recessive gene

Depends on the age when symptoms appear, and the types of symptoms that develop.

- It is estimated that between 50,000 -250,000 are affected annually. 1 per 3500 live male births

1- X-Linked Muscular Dystrophy (Duchenne Muscular Dystrophy- DMS)

2- Becker Muscular Dystrophy- BMS

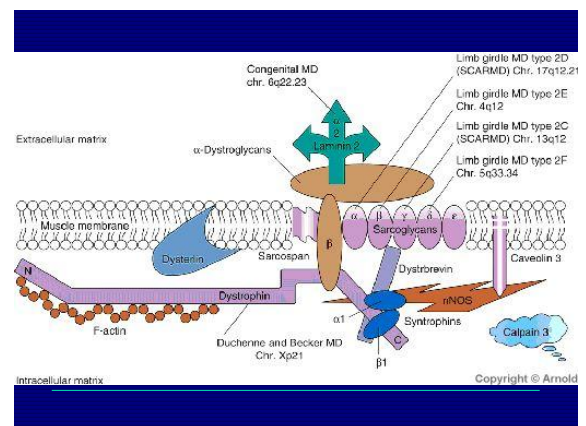

3- Myotonic Dystrophy.

4- Other Muscular Dystrophies:

Less common, share many features with DMS, BMS, affect certain muscle groups (**Fascioscapulohumeral muscular dystrophy; autosomal dominant\Oculopharyngeal muscular dystrophy; autosomal dominant, Congenital muscular dystrophies; autosomal recessive etc..**).

DMD, BMD

- 1- Caused by abnormalities in **DMD**, a gene that is located in the Xp21 region→ It encodes a **427-kD** protein named **dystrophin**.
- 2- The genetic abnormalities are deletions with point mutations accounting for the rest.
- Approximately two thirds of the cases are familial, and the remainder represent new mutations.
- **Dystrophin** is a cytoplasmic protein located adjacent to the sarcolemmal membrane in myocytes, it is concentrated at the plasma membrane over Z-bands, where it forms a strong mechanical link to cytoplasmic actin.
- **dystrophin and the dystrophin-associated protein complex** form an interface between the intracellular contractile apparatus and the extracellular connective tissue matrix → **transferring the force of contraction to connective tissue**.
- **The absence of dystrophin** → myocyte degeneration

Myotonic dystrophy

- 1- Inherited as an autosomal dominant trait → a \w a CTG trinucleotide repeat expansion on chromosome 19q13.2-q13.3 → affect the mRNA for the dystrophin myotonia protein kinase (DMPK) → sustained involuntary contraction of a group of muscles & stiffness.

DMD, BMD and others

Type	Onset Age (years)	Clinical Features	Other organ systems involved
Duchenne	Before 5	1. Progressive weakness of girdle muscles. 2. unable to walk after age 12 3. progressive kyphoscoliosis 4. Respiratory failure in 2 nd or 3 rd decade.	Cardiomyopathy Mental impairment
Becker 5-25yr	early childhood to adult	1. Progressive weakness of girdle muscles 2. able to walk after age 15. 1.3. respiratory failure may develop by 4 th grade	Cardiomyopathy
Emery-Dreifuss	Childhood to adult	Elbow contractures, humeral and perineal weakness	Cardiomyopathy
Limb-Girdle	early childhood to adult	Slow progressive weakness of shoulder and hip girdle muscles	Cardiomyopathy

Distribution of onset of muscle weakness

- A. Typical proximal (limb-girdle) distribution of a myopathic disorder (DMD)
- B. More distal (glove and stocking) distribution of a neurogenic disorder (SMA)
- C. FSH – own distribution
- D. SP - own distribution

Myasthenia Gravis - MG

- is a muscle disease caused by immune-mediated loss of acetylcholine receptor.
- Prevalence:** of about 30 in 100,000 persons.
- Age:** < 40 yrs of life.
- Sex:** commonly affect female > male, in older equally.
- Evidence** based nearly all cases: decrease in the number of muscle acetylcholine receptors (**AChRs**), and circulating antibodies to the **AChR** are present in nearly all cases.
- Risk-** thymic abnormalities are common in these patients

MG - autoimmunity

- Autoantibodies against the AChR lead to loss of functional AChRs at the neuromuscular junction by:
 - (1) Fixing complement and causing direct injury to the postsynaptic membrane.
 - (2) Increasing the internalization and degradation of the receptors.
 - (3) Inhibiting binding of acetylcholine.
- Outcomes:**
 - A) Electrophysiologic studies are notable for diminished.
 - B) Sensory as well as autonomic functions are not affected

Thank you for your attention
