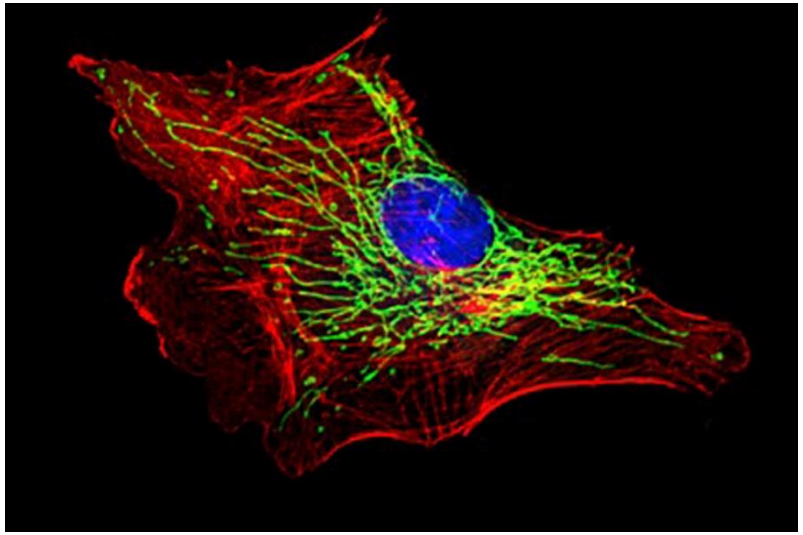
Mitochondria



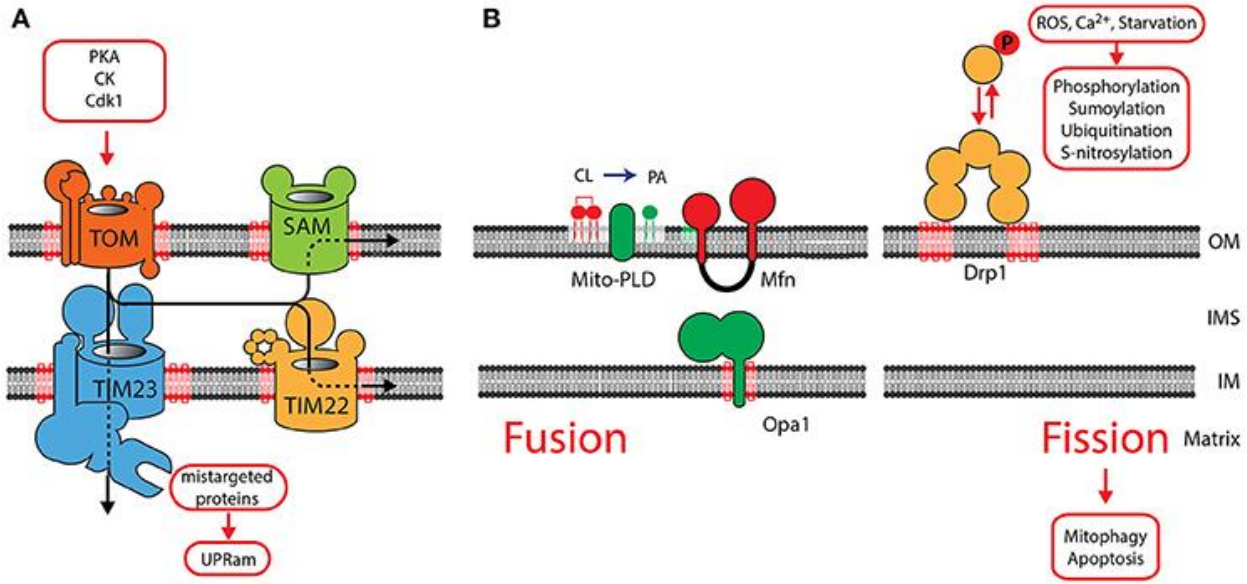
Mitochondrial network

- production of ATP for cellular energy needs
- metabolism of amino acids
- regulation of the redox state of cells
- heme synthesis
- differentiation and activation processes of immune cells
- crucial functions in the cell death program

MUNI MED

Mitochondrial fusion and fission

- processes occur in response to various extra- or intracellular changes
- changes in nutrient supply, energy or redox status, during cell differentiation in a cell-type dependent manner

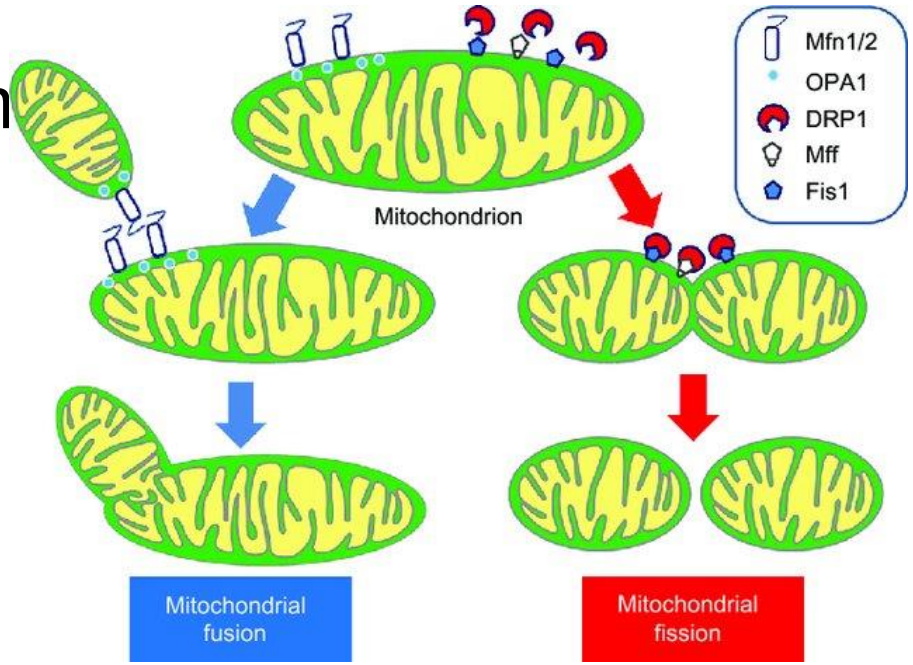


Front. Cell Dev. Biol., 2017

MUNI MED

Mitochondrial fusion and fission

- response to metabolic/pathogenic condition
- FUSION = autonomously integrate
- 1. fusion of the outer membrane between 2 adjacent mitochondria
  - mediated by mitofusin 1 and 2
- 2. fusion of the inner membrane
  - cardiolipin, dynamin-like GRPase optic atrophy (OPA)
- important for maintenance of mitochondrial DNA integrity and cellular respiration

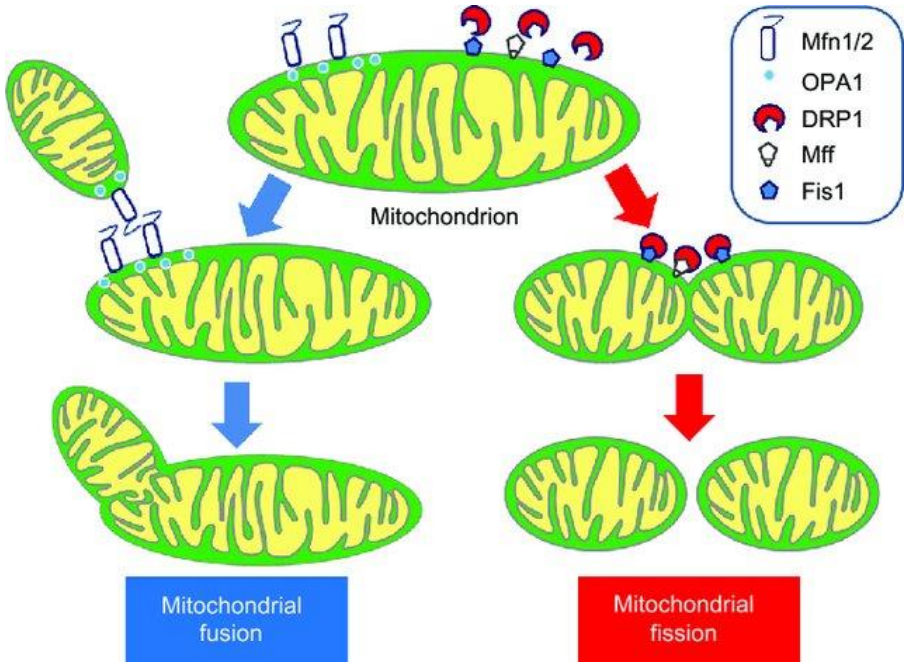


Research Reports in Clinical Cardiology 2014(default):111

MUNI MED

Mitochondrial fusion and fission

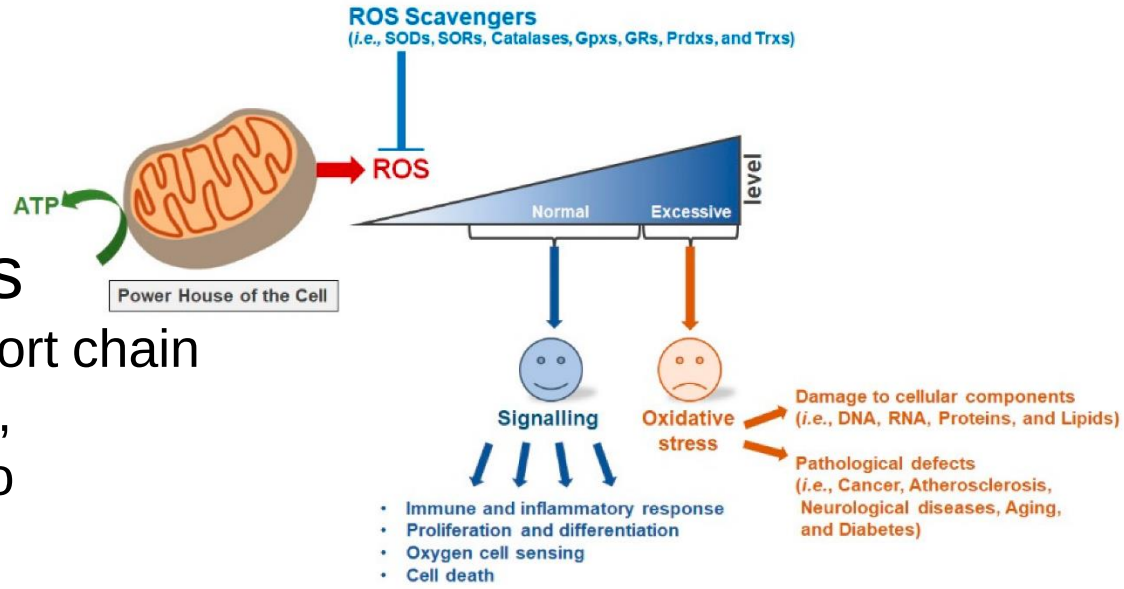
- FISSION
- important to allow inheritance of mitochondria by daughter cells during cell division
- when damaged and deleted - damaged mitochondria facilitates their removal by mitophagy



Research Reports in Clinical Cardiology 2014(default):111

MUNI MED

Mitochondria and ROS



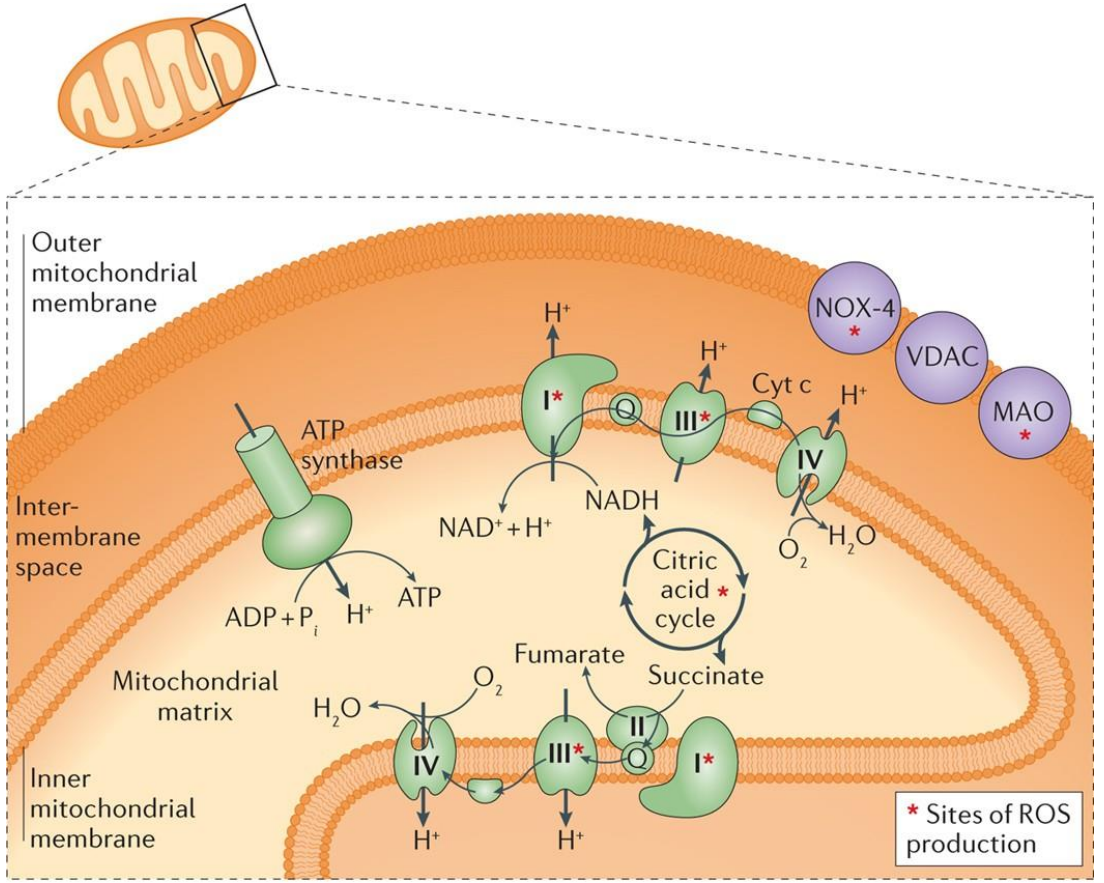
Int. J. Mol. Sci. **2019**, *20*(18), 4407

- production of reactive oxygen species
  - generated by mitochondria via the electron transport chain
  - byproduct during mitochondrial energy production, consequence of fatty acid β-oxidation, exposure to radiation, light, metals, and redox drugs
- ROS function:
  - second messengers in various signaling pathways
    in immune cells: Ca^{2+}-NFAT signaling pathway, which is critical in T cell activation.
  - ROS can also damage bacterial pathogens, but
- if produced excessively - damage the producing cell or neighboring cells.

MUNI MED

Sites of ROS production

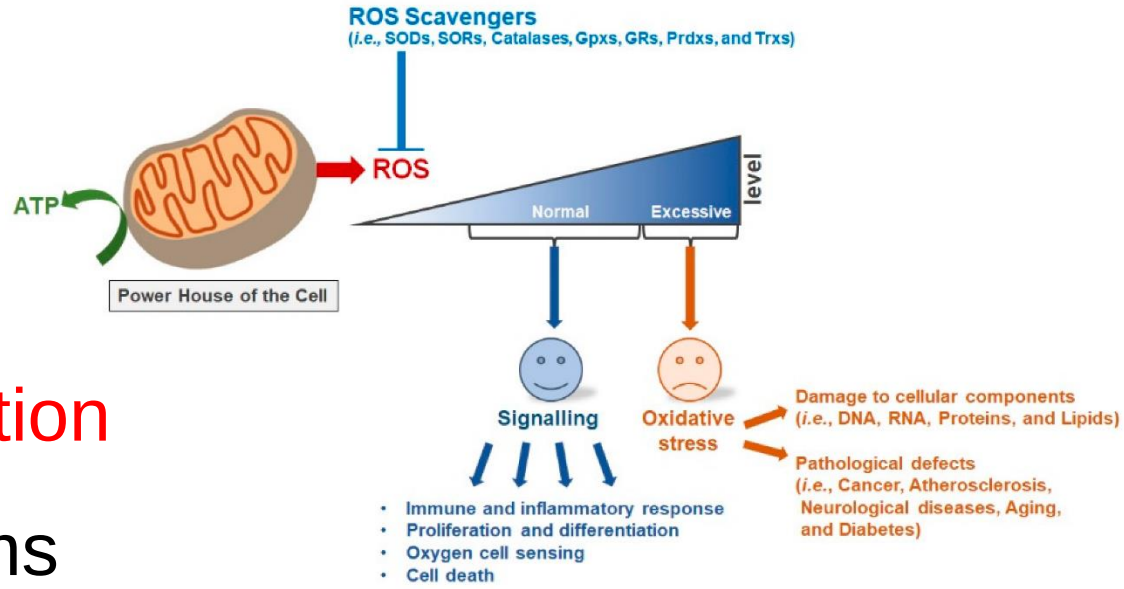
- mitochondrial ROS (mROS) are basically produced as byproducts of this bioenergetic metabolism
  - Cyt c, cytochrome *c*; MAO, monoamine oxidase; NOX-4, NADPH oxidase 4; VDAC, voltage-dependent anion channel



Nature Reviews | Cardiology

MUNI MED

Oxidative stress



Int. J. Mol. Sci. **2019**, *20*(18), 4407

- result of imbalance between

ROS production and antioxidation

- pathological defects in living organisms
  - cancer, atherosclerosis, neurological diseases, aging, and diabetes, damage of cellular components (DNA, RNA, lipids, and proteins)
- non-enzymatic defense:
  - flavonoids, vitamins (A, C, and E), and glutathione
- enzymatic antioxidants:
  - Superoxide dismutase (SOD), superoxide reductase, catalase, glutathione peroxidase, glutathione reductase, peroxiredoxins (Prdxs), and thioredoxins (Trx)

MUNI MED

Effect of mitochondria in immune reaction

- mitochondrial DAMPs
  - in extracellular space and circulation.
- mitochondrial proteins
  - FRP receptors - production of chemoattractants.
- mitochondrial ROS
  - intracellular signaling, damage cells.
- mitochondrial ATP and cardiolipin
  - activate the NLRP3 inflammasome or TLR4 - production of pro-inflammatory cytokines.
- mitochondrial DNA
  - activate TLR9, NLRP3 inflammasomes or the cGAS pathway - production of pro-inflammatory cytokines.

MUNI MED

Mitochondrial dysfunction and heart

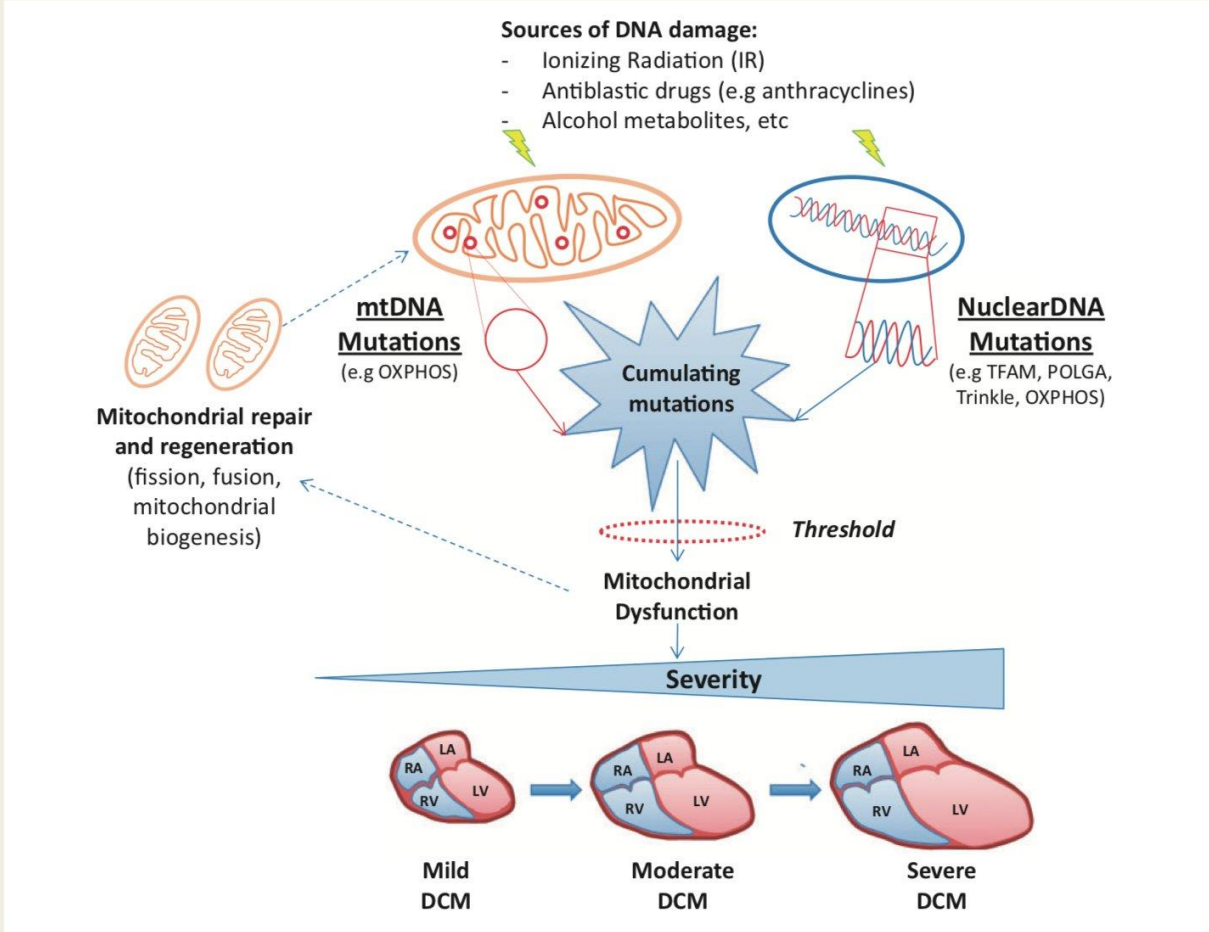

Figure 4 The interaction between DNA defects and failing of mitochondrial repair systems promotes the genesis of mitochondrial DCM. The exposure of cardiomyocytes to ionizing radiation (IR), antiblastic drugs, alcohol metabolites, and many other sources of DNA damage leads to mutations in both mitochondrial and nuclear genes coding for mitochondrial proteins. When the number of gene defects overcomes cellular tolerance, mitochondria can recruit a complex pathway of self-repair and regeneration. As the above mechanisms fail, defects tend to accumulate further, leading at the end to mitochondrial dysfunction.

Inflammation

Inflammation
Acute fase reaction
Cytokines, chemokines

Inflammation

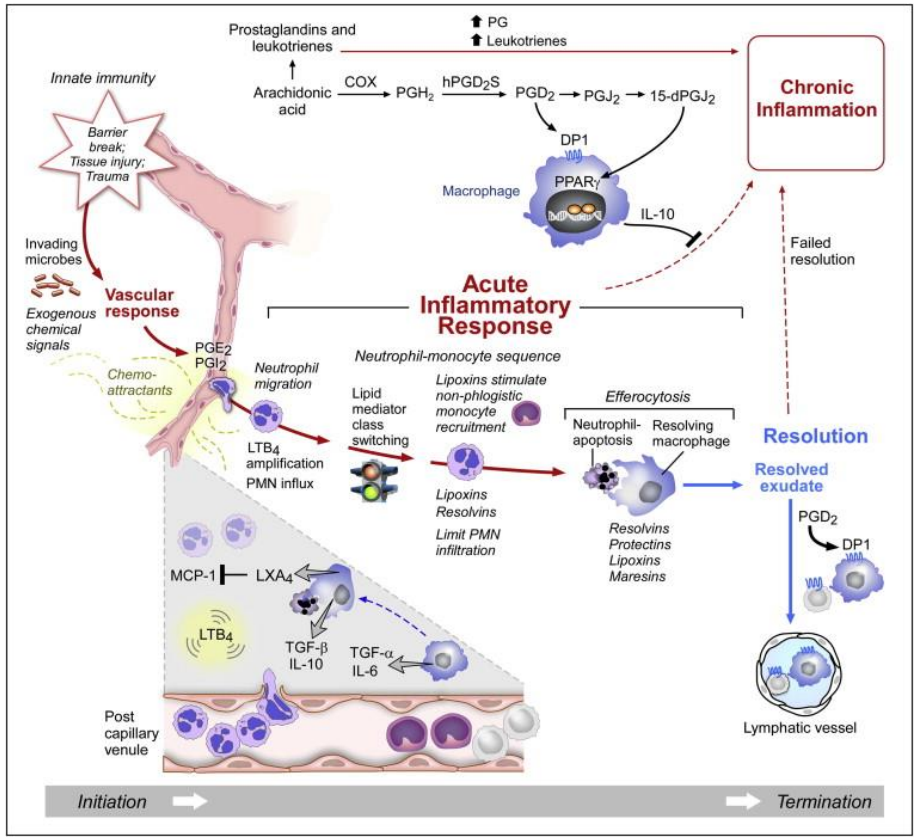
→ Inflammation is the response of living tissue to damage.

→The acute inflammatory response has 3 main functions:

→The affected area is occupied by a transient material called the acute inflammatory exudate. The exudate carries proteins, fluid and cells from local blood vessels into the damaged area to mediate local defences.

→If an infective causative agent (e.g. bacteria) is present in the damaged area, it can be destroyed and eliminated by components of the exudate.

→The damaged tissue can be broken down and partially liquefied, and the debris removed from the site of damage.



MUNI MED

Inflammation

- In all these situations, the inflammatory stimulus will be met by a series of changes in the human body; it will induce production of certain cytokines and hormones, which in turn will regulate haematopoiesis, protein synthesis and metabolism.
- Most inflammatory stimuli are controlled by a normal immune system. The human immune system is divided into two parts which constantly and closely collaborate - the innate and the adaptive immune system.

MUNI
MED

Inflammation – innate system

- The innate system reacts promptly without specificity and memory. Phagocytic cells are important contributors in innate reactivity together with enzymes, complement activation and acute phase proteins.

- When phagocytic cells are activated, the synthesis of different cytokines is triggered. These cytokines are not only important in regulation of the innate reaction, but also for induction of the adaptive immune system. There, specificity and memory are the two main characteristics.

MUNI
MED

Inflammation – adaptive immune response

– In order to induce a strong adaptive immune response, some lymphocytes must have been educated to recognize the specific antigen on the antigen-presenting cell (APC) in context of self major histocompatibility molecules. The initial recognition will mediate a cellular immune reaction, production of antigen-specific antibodies or a combination of both. Some of the cells, which have been educated to recognize a specific antigen will survive for a long time with the memory of the specific antigen intact, rendering the host "immune" to the antigen.

MUNI
MED

Differences between innate (non-specific) and specific (adaptive) immunologic reaction of organism

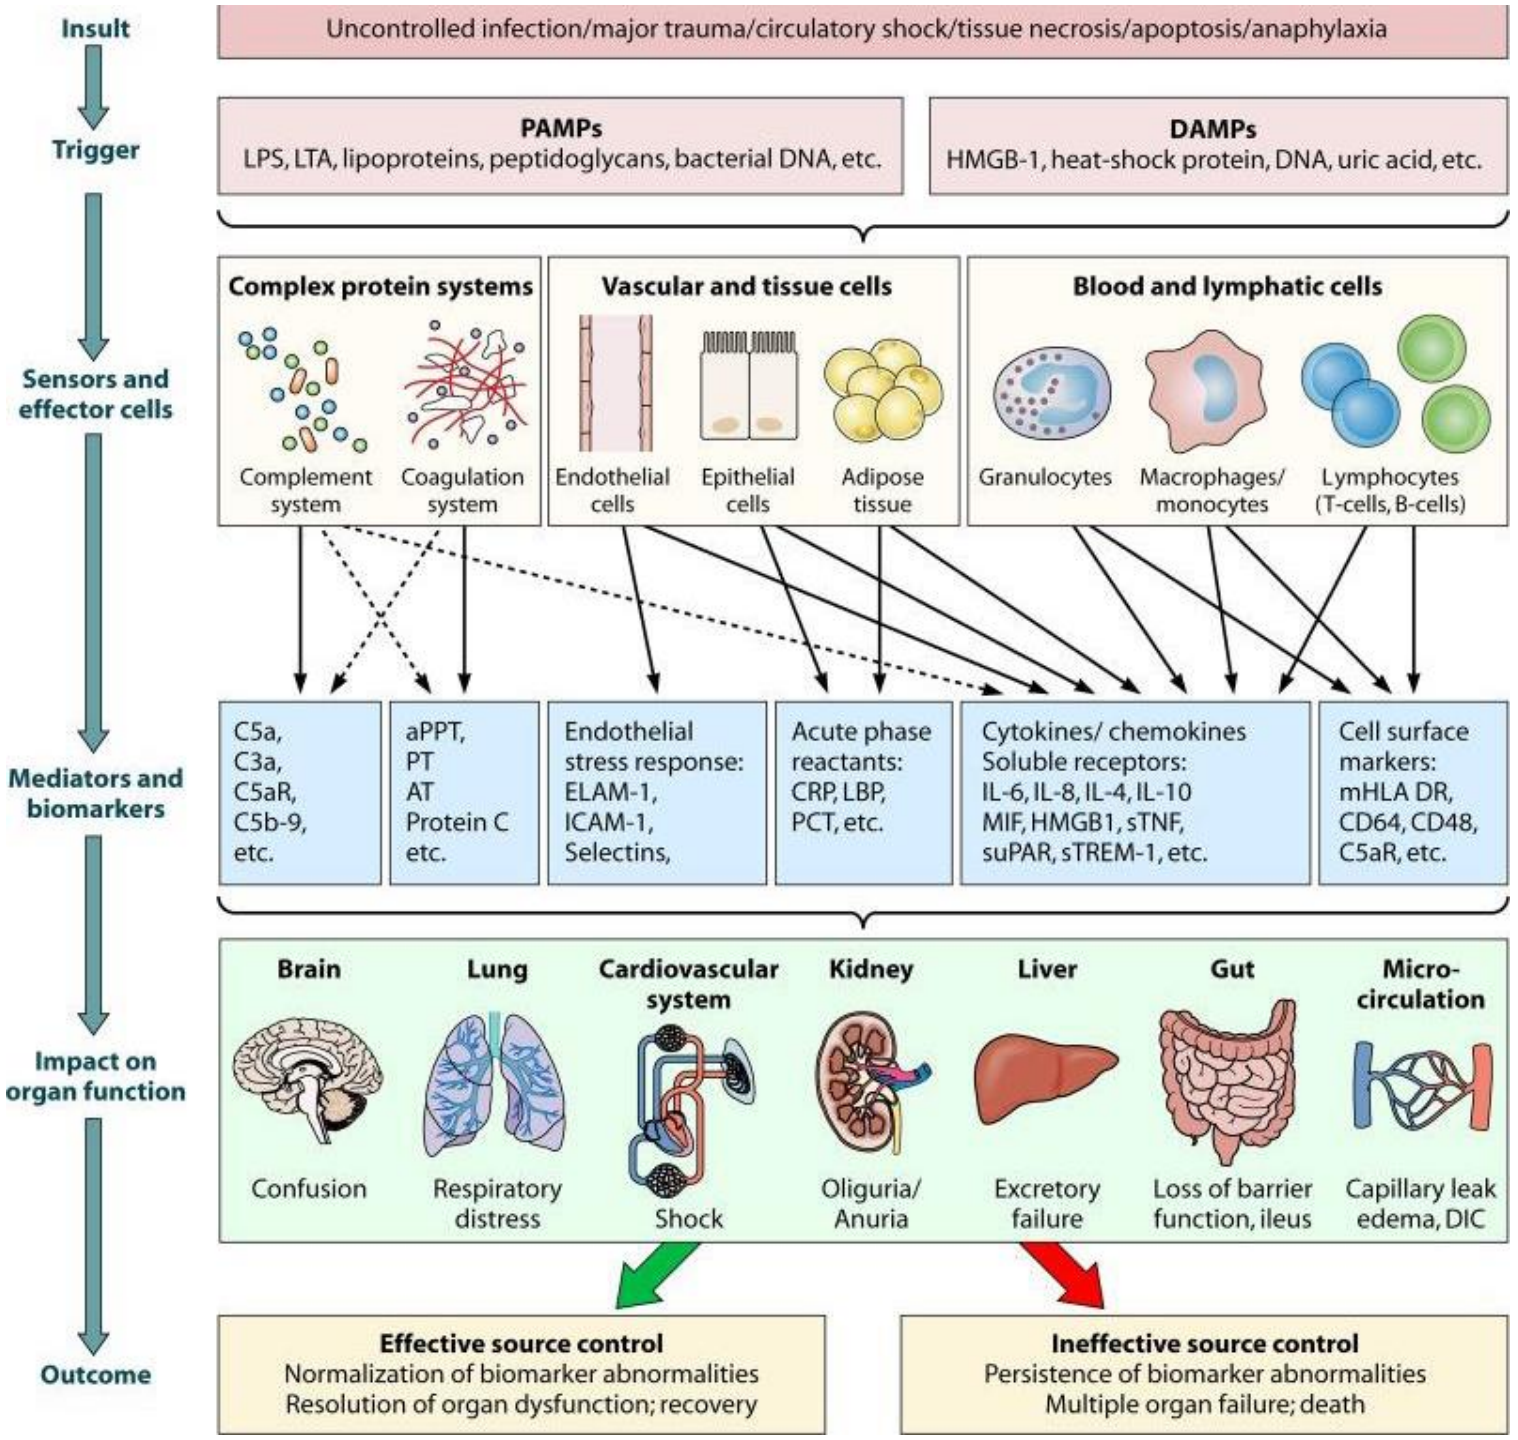
Non-specific Immunity

- Response is antigen-independent
- There is immediate maximal response
- Non-antigen-specific
- Exposure results in no immunologic memory

Specific Immunity

- Response is antigen-dependent
- There is a lag time between exposure and maximal response
- Antigen-specific
- Exposure results in immunologic memory

MUNI MED

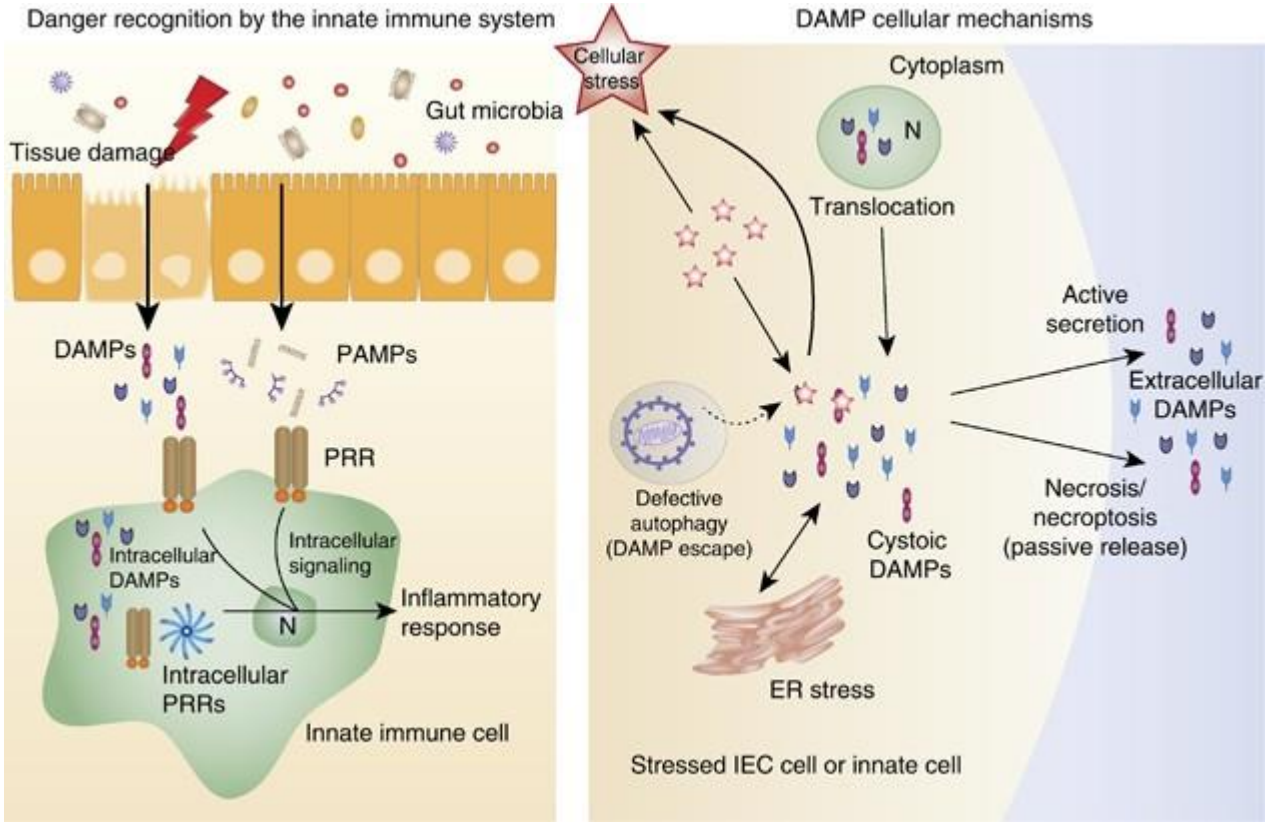


Clin Microbiol Rev. 2012 Oct; 25(4): 609–634.

MUNI MED

Danger recognition by the innate immune system

- PRRs such as TLR, NLR, and RAGE sense danger associated with infection via recognition of evolutionarily conserved PAMPs on pathogens or sterile injury via recognition of DAMPs.
- Activation of cell surface or intracellular PRRs leads to intracellular signaling and inflammatory responses

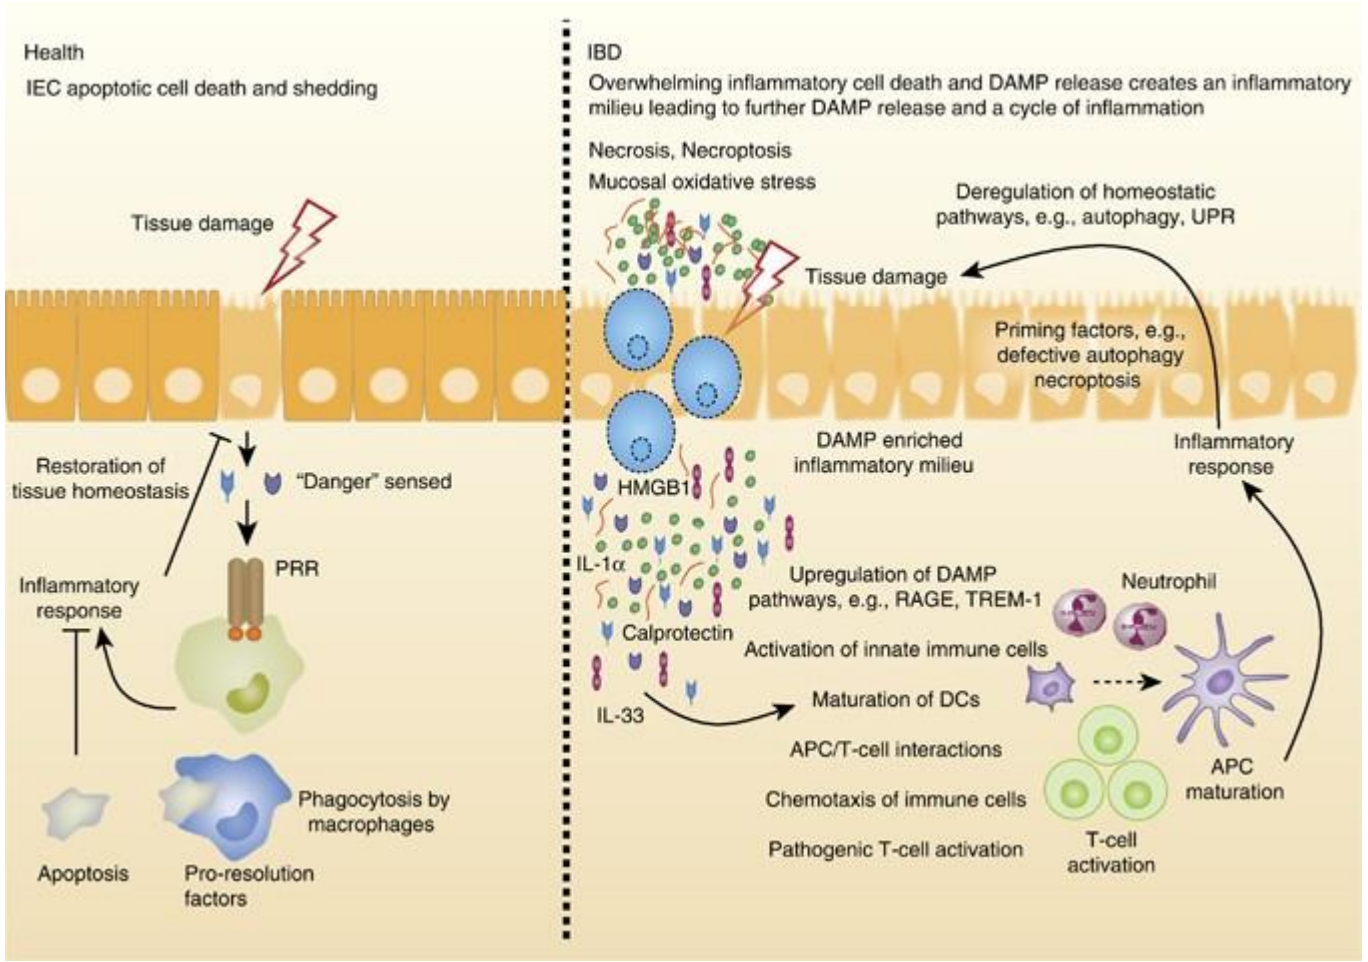


Mucosal Immunology **volume 9**, pages567–582 (2016)

MUNI MED

Contribution of DAMPs to inflammatory response in IBD

– nonapoptotic cell death, mucosal oxidative stress, and deregulation of homeostatic pathways lead to overwhelming release of DAMPs, creating a proinflammatory milieu



Mucosal Immunology **volume 9**, pages567–582 (2016)

MUNI MED

Causes of Inflammation

- infectious inflammatory stimuli (viruses, bacteria, fungi and parasites)
- by non-infectious inflammatory stimuli, as in rheumatoid arthritis and graft-versus host disease
- by tissue necrosis as in cancer
- by burns and toxic influences caused by drugs or radiation

MUNI
MED

Types of inflammation

- Acute
- Chronic

- Local
- Systemic

MUNI
MED

General and local clinical symptoms of the acute phase reaction

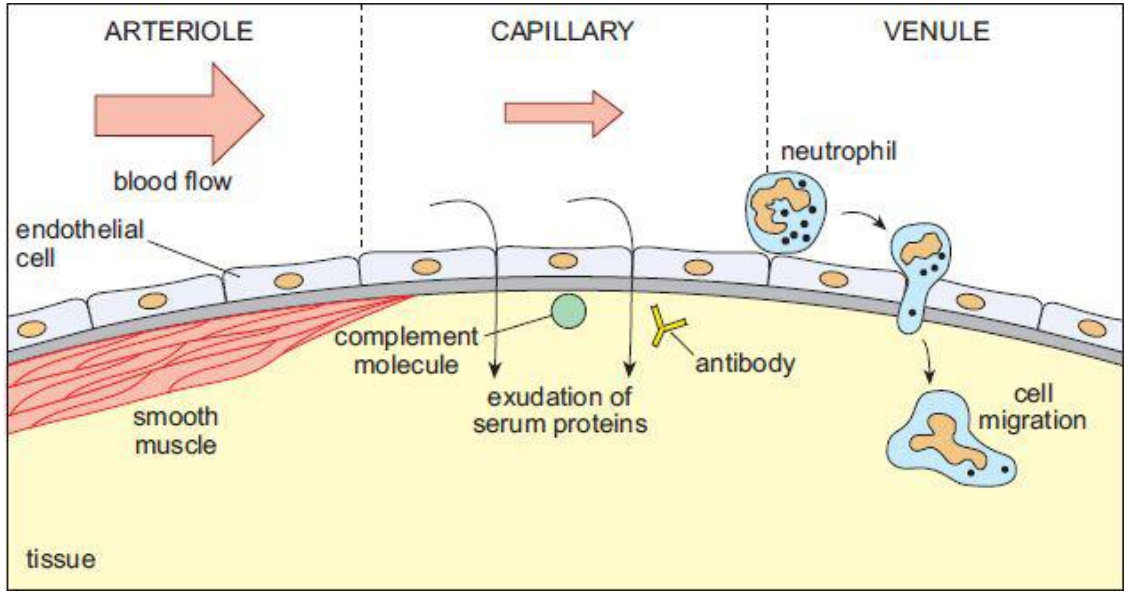
Local symptoms	General symptoms
calor	fever
rubor	tachycardia
dolor	hyperventilation
tumor	tiredness
functio laesa	Loss of appetite

MUNI
MED

Local Inflammation

The acute inflammatory response involves three processes:

- changes in vessel caliber (= vasodilation) and, consequently, slower blood flow
- increased vascular permeability and formation of the fluid exudate
- formation of the cellular exudate by emigration of the neutrophil polymorphs into the extravascular space.



MUNI MED

Early Stages

The steps involved in the acute inflammatory response are:

- Small blood vessels adjacent to the area of tissue damage initially become dilated with increased blood flow, then flow along them slows down.
- Endothelial cells swell and partially retract so that they no longer form a completely intact internal lining.
- The vessels become leaky, permitting the passage of water, salts, and some small proteins from the plasma into the damaged area (exudation). One of the main proteins to leak out is fibrinogen.
- Circulating neutrophil polymorphs initially adhere to the swollen endothelial cells (margination), then actively migrate through the vessel basement membrane (emigration), passing into the area of tissue damage.
- Later, small number of blood monocytes (macrophages) migrate in a similar way, as do lymphocytes.

MUNI
MED

Systemic manifestation of inflammation

- **Increase of body temperature (fever)**
- **Acute phase reaction**

MUNI
MED

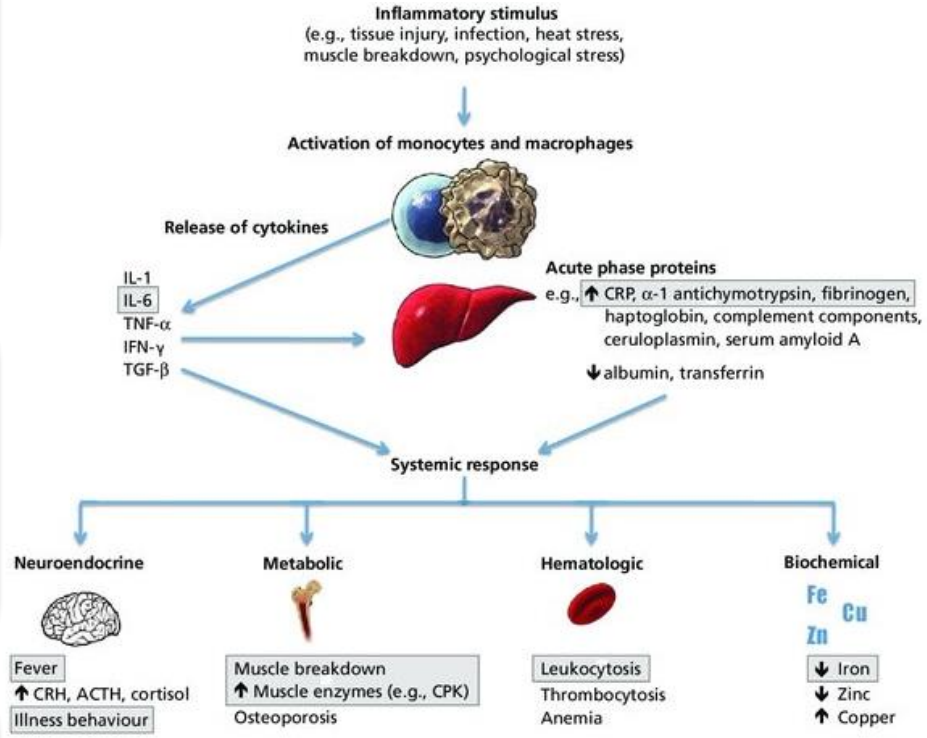
Acute phase reaction

The acute phase reaction is the body's first-line inflammatory defense system, functioning without specificity and memory, and in front of, and in parallel with, the adaptive immune system.

In the acute phase reaction, several biochemical, metabolic, hormonal and cellular changes take place in order to fight the stimulus and re-establish a normal functional state in the body.

An **increase in the number of granulocytes** will increase the phagocytotic capacity, an increase in scavengers will potentiate the capability to neutralize free oxygen radicals, and an increase in metabolic rate will increase the energy available for cellular activities, despite a reduced food intake.

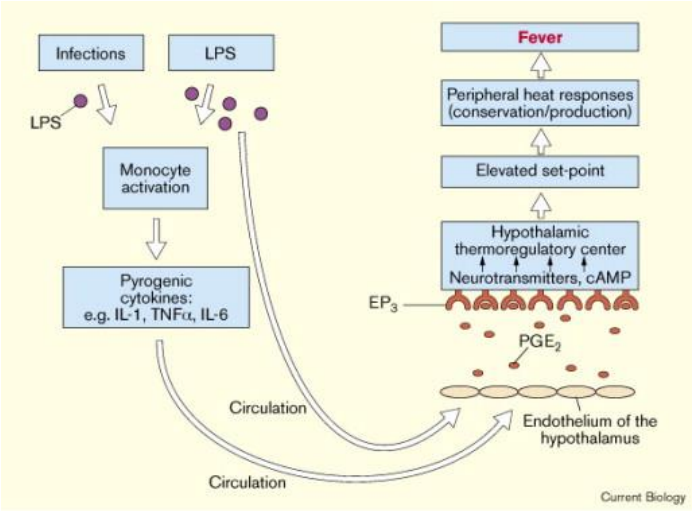
Some of these changes can explain the symptoms of an acute phase reaction, which are typically fever, tiredness, loss of appetite and general sickness, in addition to local symptoms from the inducer of the acute phase.



Canadian Medical Association Journal 182(18):E834-8

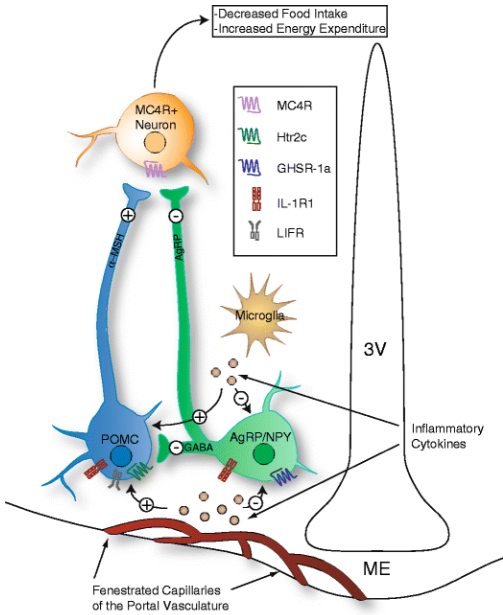
MUNI MED

Systemic effects of acute/chronic inflammation



→ Pyrexia

Polymorphs and macrophages produce compounds known as endogenous pyrogens, which act on the hypothalamus to set the thermoregulatory mechanisms at a higher temperature. Release of endogenous pyrogen is stimulated by phagocytosis, endotoxins and immune complexes.



Mol Cancer Res; 11(9); 967–72. ©2013 AACR.

→ Constitutional symptoms

Constitutional symptoms include malaise, anorexia and nausea. Weight loss is common when there is extensive chronic inflammation.

→ Local or systemic lymph node enlargement commonly accompanies inflammation, while splenomegaly is found in certain specific infections (e.g. malaria, infectious mononucleosis).

MUNI MED

Systemic effects of inflammation

Haematological changes

- Increased erythrocyte sedimentation rate. An increased erythrocyte sedimentation rate is a non-specific finding in many types of inflammation.

- Leukocytosis.
  - Neutrophilia occurs in pyogenic infections and tissue destruction;
  - eosinophilia in allergic disorders and parasitic infection;
  - lymphocytosis in chronic infection (e .g. tuberculosis), many viral infections and in whooping cough; and
  - monocytosis occurs in infectious mononucleosis and certain bacterial infections (e.g. tuberculosis, typhoid).

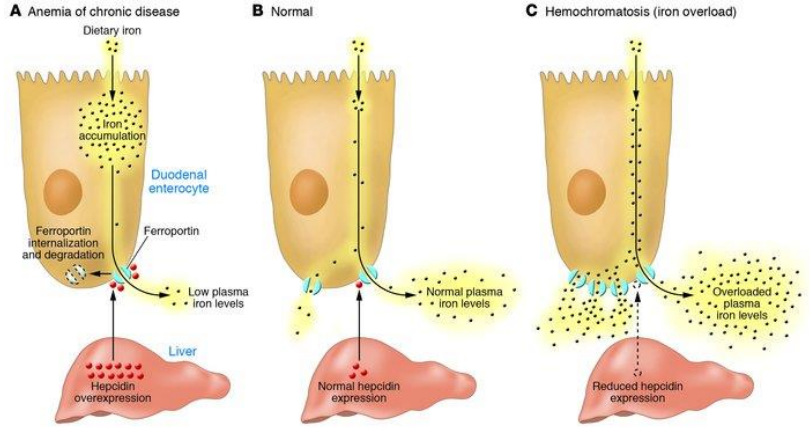
- Anaemia.
  - blood-loss in the inflammatory exudate (e.g. in ulcerative colitis),
  - haemolysis (due to bacterial toxins), and
  - 'the anemia of chronic disorders' due to toxic depression of the bone marrow.

Amyloidosis

- Longstanding chronic inflammation (for example, in rheumatoid arthritis, tuberculosis and bronchiectasis), by elevating serum amyloid A protein (SAA), may cause amyloid to be deposited in various tissues resulting in secondary (reactive) amyloidosis.

MUNI MED

Difference between anaemia of chronic disease and iron-deficiency anaemia



J Clin Invest. 2007;117(7):1755-1758. https://doi.org/10.1172/JCI32701.

	Anemia of Chronic Diseases	Iron Deficiency Anemia
Seru Iron	Reduced	Reduced

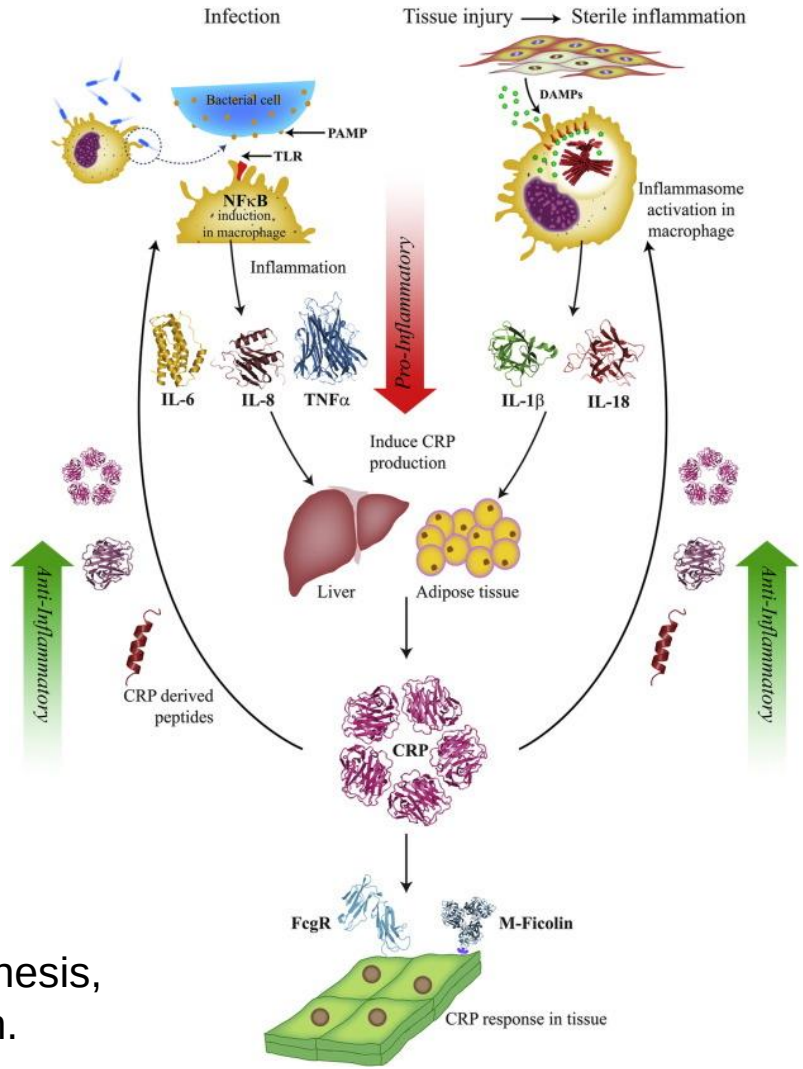
Transferrin Saturation	Reduced	Reduced
Ferritin	Normal to increased	Reduced
Soluble transferrin receptor	Normal	Increased
Cytokine level	Increased	Normal
Hepcidin	Increased	Reduced
Bone marrow iron stores	Normal to increased	Reduced
Ery	Normal, microcytes	Microcytes

Acute phase proteins

- Induction of the acute phase reaction - changes in synthesis of many proteins in the liver
  - measured in plasma.

- Regulation of protein synthesis - at the level of both transcription (DNA, RNA) and translation to protein.
  - The cells have intricate systems for up- and down-regulation of protein synthesis, initiated by a complex system of signals induced in the acute phase reaction.



Biotechnology Advances Volume 34, Issue 3, May–June 2016

MUNI MED

Acute phase proteins

Function related to

- limiting the negative effects of the acute phase stimulus

or

- repair of inflammatory induced damage.

Examples are enzyme inhibitors limiting the negative effect of enzymes released from neutrophils, scavengers of free oxygen radicals, increase in some transport proteins and increased synthesis and activity of the cascade proteins such as coagulation and complement factors.
The protein synthesis may be upregulated even if plasma levels are normal, due to increased consumption of acute phase proteins.

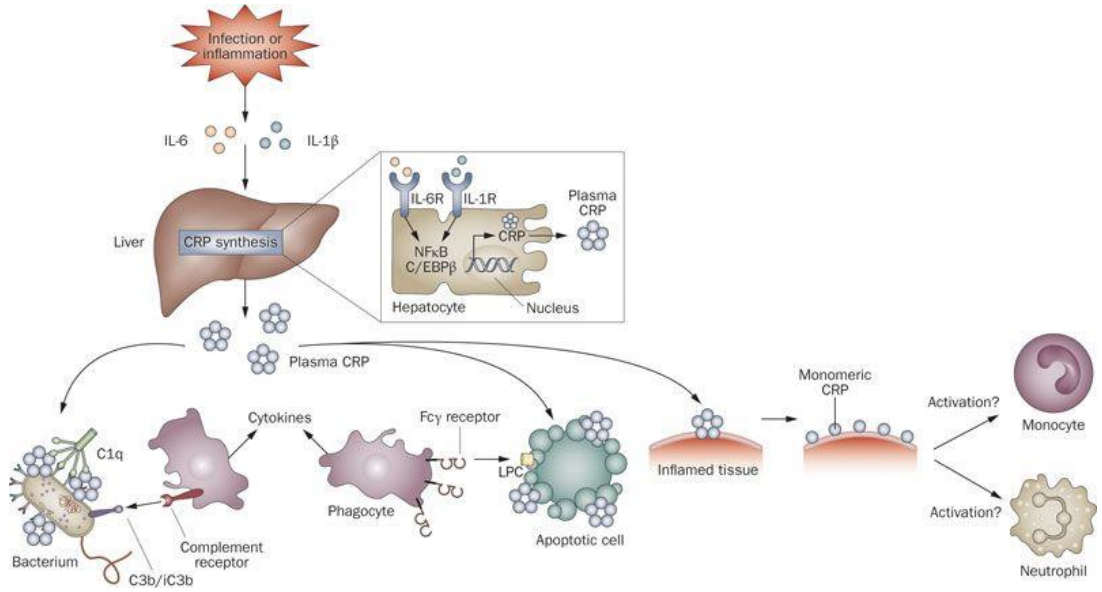
Biochemistry and physiology of the acute phase reaction

– **CRP** is a major acute phase protein acting mainly through Ca2+-dependent binding to, and clearance of, different target molecules in proteins, having evolved almost unchanged from primitive to advanced species.



Nature Reviews Rheumatology **volume 7**, pages282–289 (2011)

microbes, cell debris and cell nuclear material.

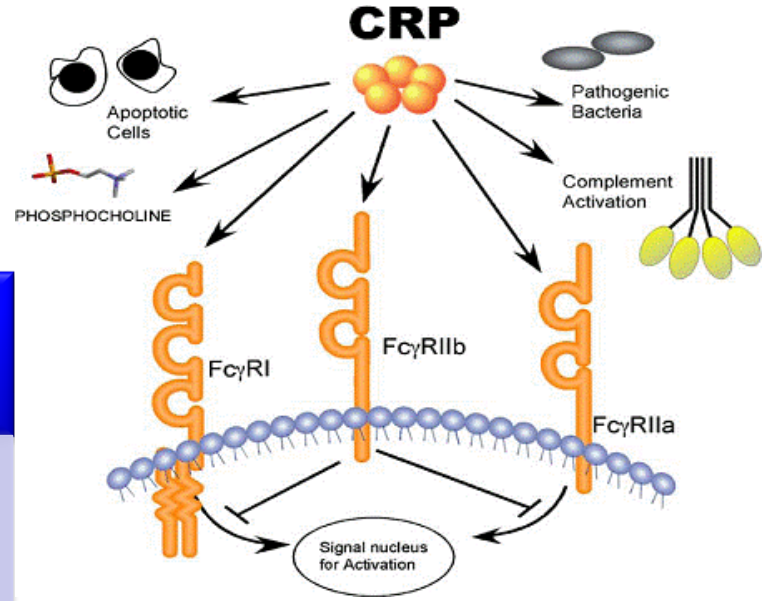
In an acute phase reaction there may be a more than 1000-fold increase in the serum concentration of CRP. CRP is regarded as an important member of the family of acute phase, having evolved almost unchanged from primitive to advanced species.

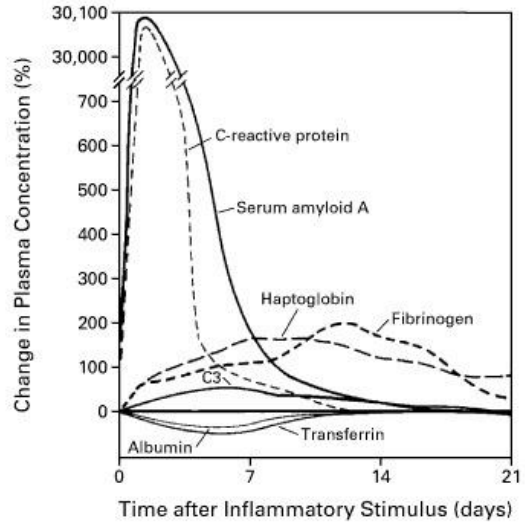
MUNI MED

C-reactive protein

Most functions of CRP are easily understood in the context of the body's defenses against infective agents.

- The bacteria are opsonized by CRP and increased phagocytosis is induced.
- CRP activates complement with the split product being chemotactic, increasing the number of phagocytes at the site of infection. Enzyme inhibitors protect surrounding tissue from the damage of enzymes released from the phagocytes.
- CRP binds to chromatin from dead cells and to cell debris which are cleared from the circulation by phagocytosis, either directly or by binding to Fc-, C3b- or CRP-specific receptors. Platelet aggregation is inhibited, decreasing the possibility of thrombosis.
- CRP binds to low density lipoprotein (LDL) and may clear LDL from the site of atherosclerotic plaques by binding to cell surface receptors on phagocytic cells.





N Engl J Med 1999; 340:448-454
DOI: 10.1056/NEJM199902113400607

MUNI MED

Biologically active products of complement activation

Chemotactic factors

C5a and MAC (membrane attack complex C5b67) are both chemotactic. C5a is also a potent activator of neutrophils, basophils and macrophages and causes induction of adhesion molecules on vascular endothelial cells.

Opsonins

C3b and C4b in the surface of microorganisms attach to C-receptor (CR1) on phagocytic cells and promote phagocytosis.

Other biologically active products of C activation

Degradation products of C3 (iC3b, C3d and C3e) also bind to different cells by distinct receptors and modulate their function.

MUNI MED

Biologically active products of complement activation

Activation of complement results in the production of several biologically active molecules which contribute to resistance, anaphylaxis and inflammation.

Kinin production

C2b generated during the classical pathway of C activation is a prokinin which becomes biologically active following enzymatic alteration by plasmin.

Anaphylotoxins

C4a, C3a and C5a (in increasing order of activity) are all anaphylatoxins, which cause basophil/mast cell degranulation and smooth muscle contraction.

MUNI MED

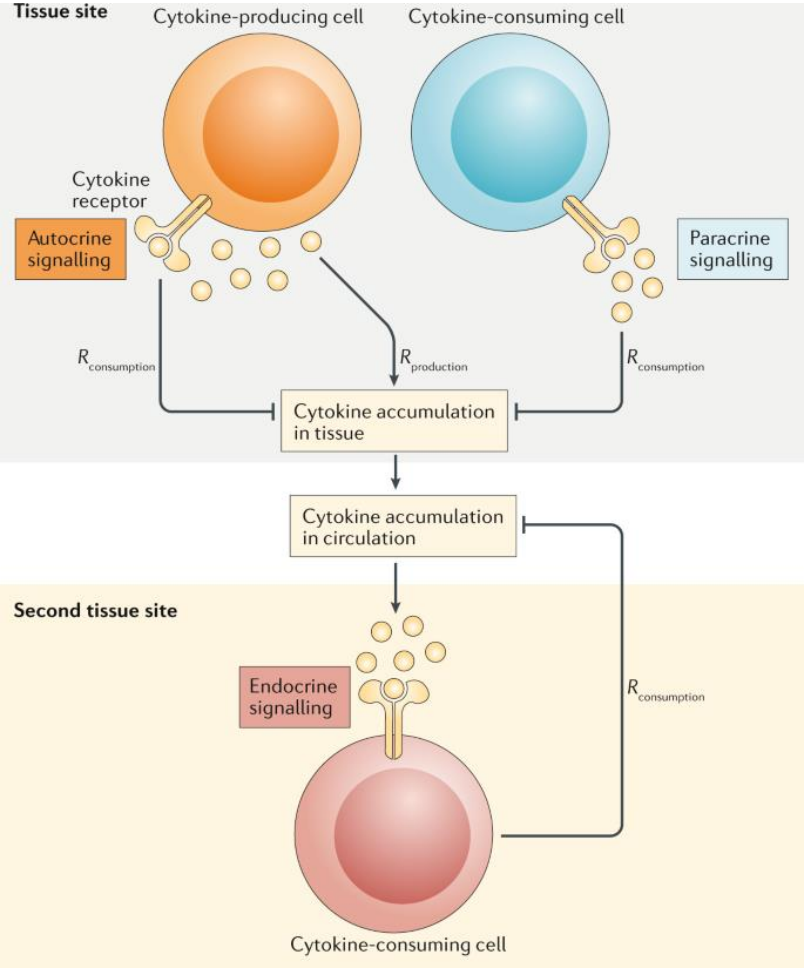
Negative proteins of acute phase

- Decreases in albumin, transferrin, cortisol-binding globulin, transthyretin and vitamin A binding protein temporarily lead to an increased supply of free hormones, which usually bind to these proteins.

- Transthyretin (pre-albumin binding thyroxine, transports thyroid hormones from the plexus choroideus to the cerebrospinal fluid) inhibits the production of IL-1β by monocytes and endothelial cells. Its decline can thus be considered as a pro-inflammatory mechanism. These changes in blood protein profiles appear to be partly related to muscle starvation and catabolism. It is also an offer of amino acids for the production of positive acute phase proteins.

Cytokines

- generic name for a diverse group of soluble proteins and peptides
- act as humoral regulators at nano- to picomolar concentrations under normal or pathological conditions
- modulate the functional activities of individual cells and tissues.
- These proteins also mediate interactions between cells directly and regulate processes taking place in the extracellular environment.



Nature Reviews Immunology **volume 19**, pages205–217(2019)

MUNI MED

Cytokine network

→This term essentially refers to the extremely complex interactions of cytokines by which they induce or suppress their own synthesis or that of other cytokines or their receptors, and antagonize or synergies with each other in many different and often redundant ways.

→These interactions often resemble Cytokine cascades with one cytokine initially triggering the expression of one or more other cytokines that, in turn, trigger the expression of further factors and create complicated feedback regulatory circuits.

→Mutually interdependent pleiotropic cytokines usually interact with a variety of cells, tissues and organs and produce various regulatory effects, both local and systemic.

Chemokines

- ✓Generic name given to a family of pro-inflammatory activation-inducible cytokines. These proteins are mainly chemotactic for different cell types.
- ✓All chemokines possess a number of conserved cysteine residues involved in intramolecular disulfide bond formation, which allows chemokines to be grouped into families according to the presence or absence of one or more conserved cysteine residues.

MUNI
MED

Chemokines

- According to their mode of expression and function, chemokines have been categorized as inflammatory chemokines and homeostatic chemokines.
  - Inflammatory chemokines are expressed usually by leukocytes or related cells only upon cell activation. These factors mediate emigration of leukocytes.
  - Homeostatic chemokines are expressed constitutively and are involved usually in relocation of lymphocytes or other cell types.
  - Dual-function chemokines can act as inflammatory cytokines or homeostatic cytokines.

Wound healing

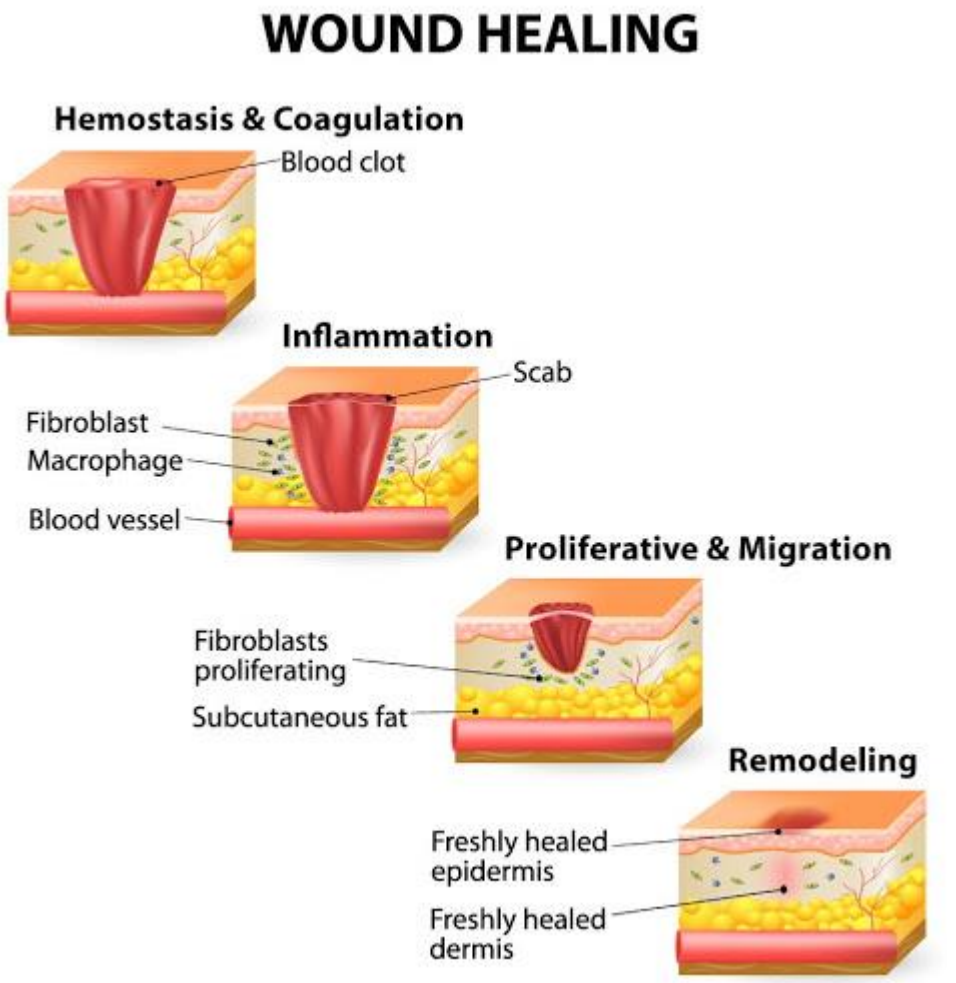
Wound healing

- Wound healing is the process of repair that follows injury to the skin and other soft tissues.
- Healing is the interaction of a complex cascade of cellular events that generates resurfacing, reconstitution, and restoration of the tensile strength of injured tissue.
- Under the most ideal circumstances, healing is a systematic process, traditionally explained in terms of 3 classic phases: inflammation, proliferation, and maturation.

MUNI
MED

Wound healing

- **The inflammatory phase**:
  - a clot forms and cells of inflammation debride injured tissue.
- **The proliferative phase**:
  - epithelialization, fibroplasia, and angiogenesis occur; additionally, granulation tissue forms and the wound begins to contract.
- **The maturation phase**:
  - Collagen forms tight cross-links to other collagen and with protein molecules, increasing the tensile strength of the scar.

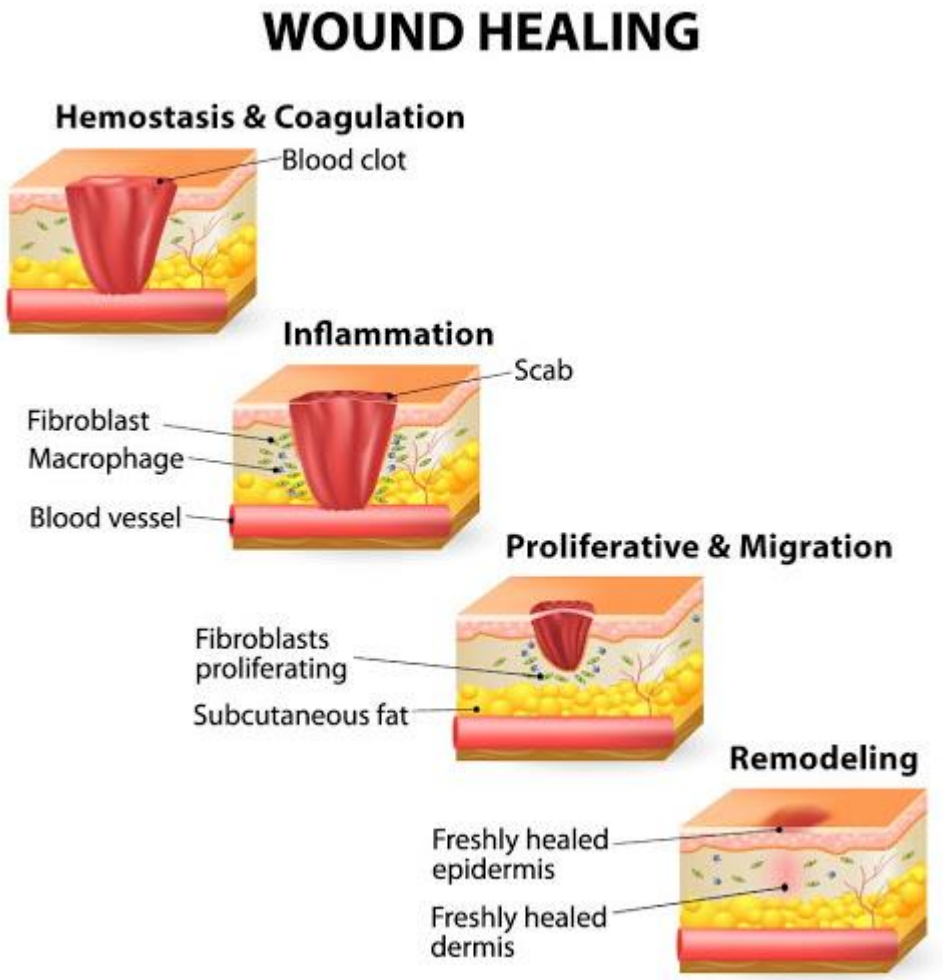


MUNI MED

I. Inflammatory Phase

Immediate to 2-5 days

- **Hemostasis**
  - Vasoconstriction
  - Platelet aggregation
  - Clot formation
- **Inflammation**
  - Vasodilation
  - Phagocytosis
- Fibrin products
  - essential to wound healing and
  - primary component of the wound matrix into which inflammatory cells, platelets, and plasma proteins migrate.
  - Removal of the fibrin matrix impedes wound healing.

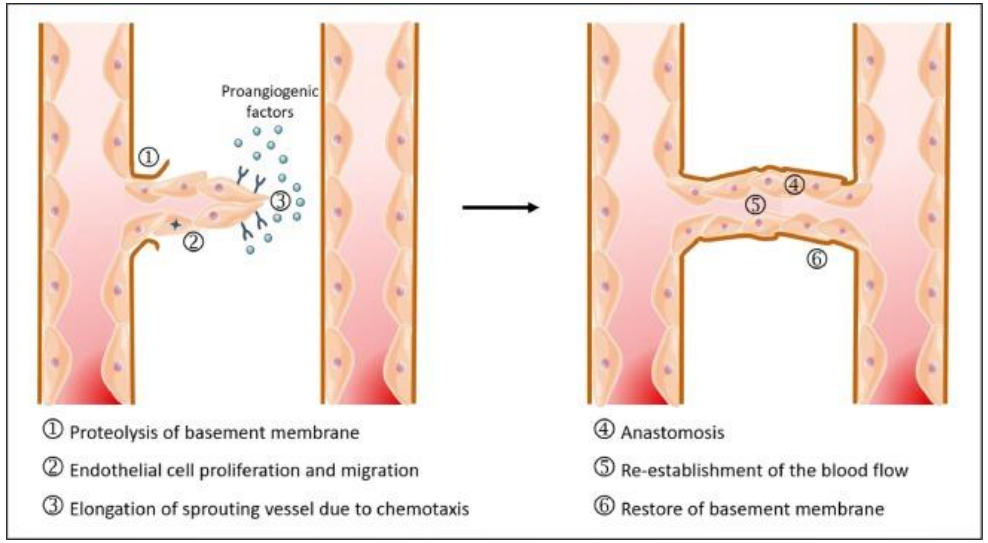


MUNI MED

II. Proliferative Phase

2 days to 3 weeks

- **B) Granulation**
  - Fibroblasts lay bed of collagen - scaffold for migration and further fibroblast proliferation
- **C) Contraction**
  - Wound edges pull together to reduce defect
- **D) Epithelialization**
  - Crosses moist surface
  - Cell travel about 3 cm from point of origin in all directions



Journal of Theoretical Biology 459, 2018, 1-17

vascular network is also re-established through **angiogenesis**

- main regulator of angiogenesis is the vascular endothelial growth factor (VEGF) family, which includes VEGF-A, VEGF-B, VEGF-C, VEGF-D and placental growth factor (PlGF)

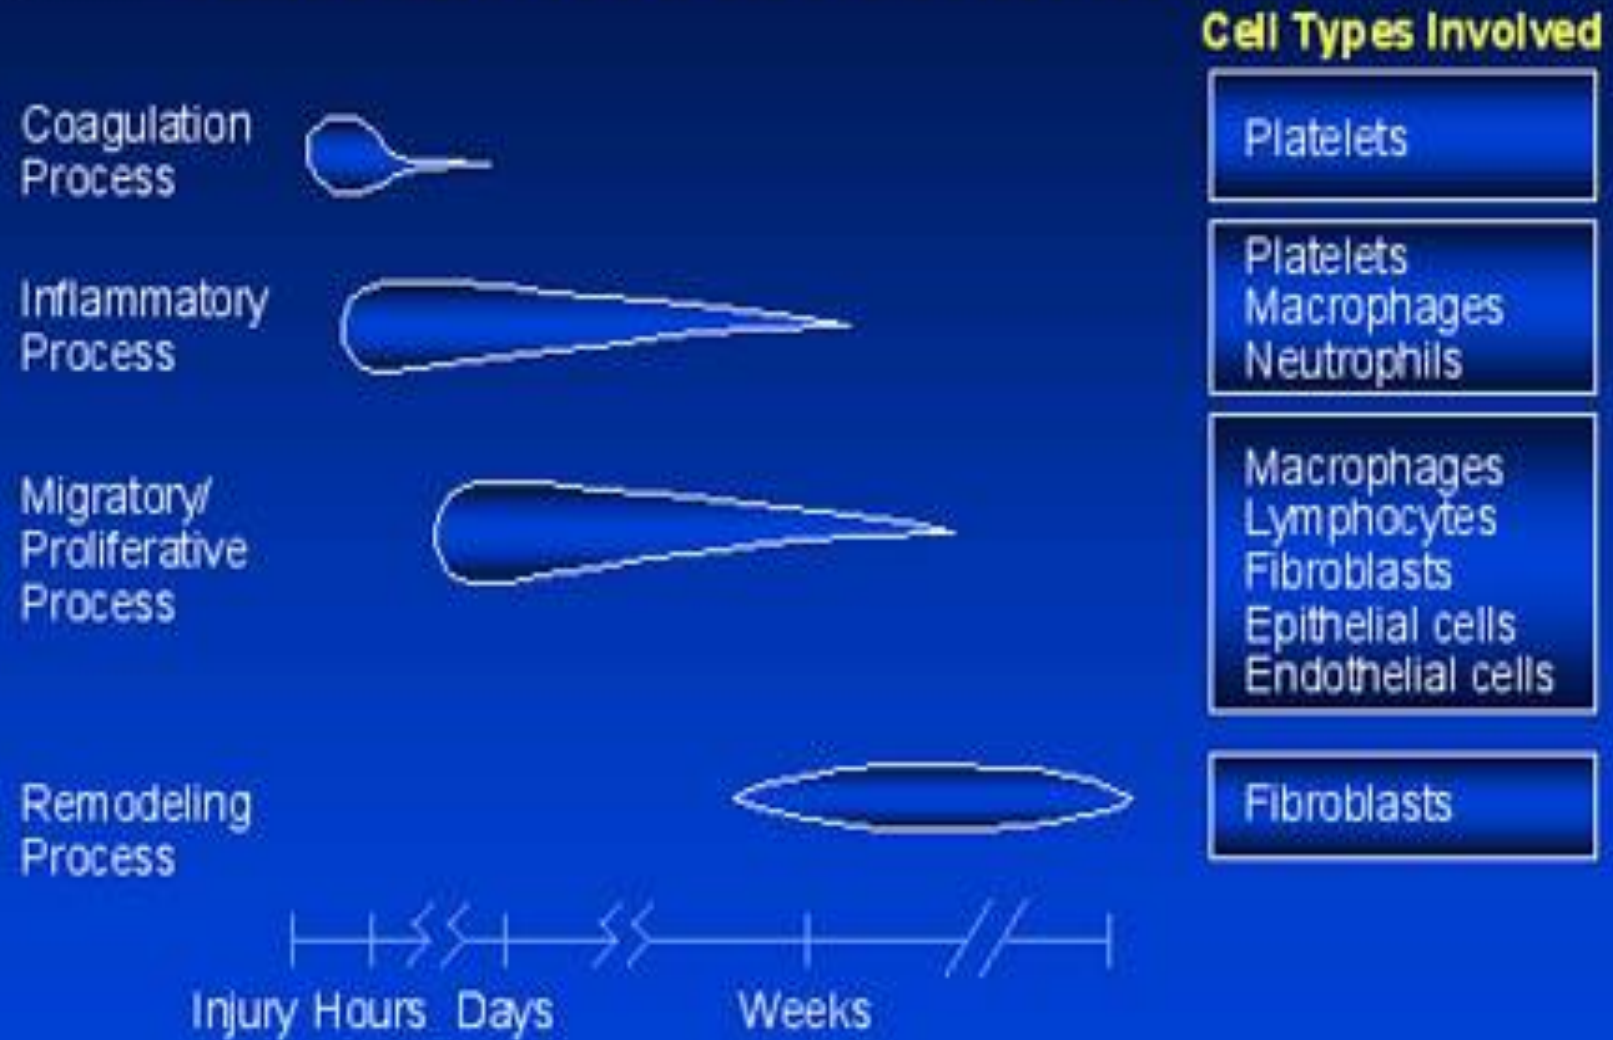
MUNI MED

III. Maturation Phase

- During the maturation phase, fibroblasts leave the wound and collagen is remodeled into a more organized matrix.
- Tensile strength increases for up to one year following the injury. While healed wounds never regain the full strength of uninjured skin, they can regain up to 70 to 80% of its original strength.

MUNI
MED

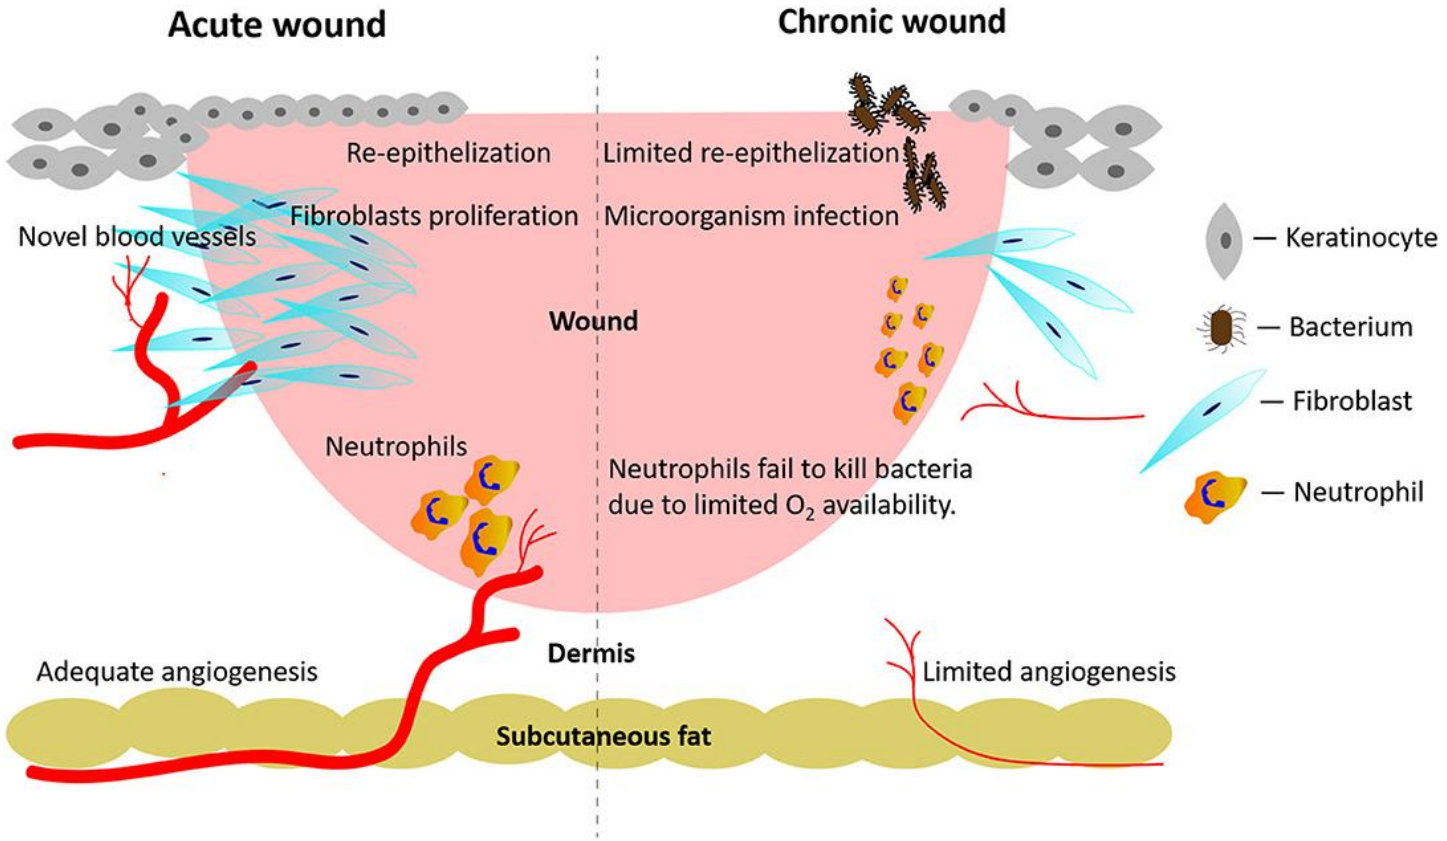
COMPONENTS OF WOUND HEALING



Kane DP, Krasner D. In: *Chronic Wound Care*. 2nd ed. Health Management Publications Inc; 1997:1-4.

Acute vs. chronic wound

- Acute wounds
  - adequate angiogenesis promotes re-epithelialization, fibroblasts' proliferation, and neutrophils' anti-infection activities.
- Chronic wounds
  - persistent local bacterial infections hinder the formation of novel blood vessels. The restricted angiogenesis hampers fibroblasts' proliferation and the neutrophils' anti-infection activities.



Front. Bioeng. Biotechnol., 11 June 2020
