BIOLOGY

Introduction

Obr. 1. Dýchací řetězec

Josef Skopalík, Ph.D.

Short summary of BIOLOGY in next 12 weeks

September 2022 Introduction. Microscopy and another visualisation methods
Cell – definition, development of cells (bacteria, plant, animal).
Eukaroyte / Prokaryote
Basic internal structure and bioenergetics of different cells

October 2022 Structure of biological membranes - basal cell bioenergetic.
Transport of ion and another bioactive compound.
Organelles and illness connected to organelles.
Organelles and clinical target in organelless.

November 2022 Cell signaling and Cell cycle.
– clicnical aspect for Cancer and Regeneration medicine
Biologie of human immune system. Pathological state
in immune systém and basic clinical strategy.
Cell division (Types of Division in PROKARYOTE and EUKARYOTE).
Mitosis and Meiosis. Gene transcription. Genome. MENDEL genetics.
Mutation and cancer

October 2022 Modern trends in cell biology and genetics

Why medical and pharmaceutical worker need BIOLOGY a CELL BIOLOGY:

- We should take not only **macroscopical experience** and statistic form curative effects from set of patient in previous time
- We need also basic idea about structure of tissue and cells and about activity of **bioactive molecules in this microstructure**
- Many new pharma-compounds arte tested on **cells IN VITRO** (Evidence based science – before clincila tests)

Biology

/ Lecture 1 /

- Visualization technique
- Cell and tissue definition

What is visibility?

And what visibility is needed in medicine? :

Analogy:

If we fight against “forest disaster“, sometimes we need technique for macroscopic visibility, sometimes for detail (microscopic) visibility

Good objective visualisation = key step for good fighting

And what visibility is needed in medicine? :

Analogy:

If we fight against “**medical** disaster“, sometimes we need technique for macroscopic visibility, sometimes for detail (microscopic) visibility

Good objective visualisation = key step for good fighting

The human and animal body is not a „bag of sugar water with small soul inside“, however exact description of body and tissue structure had to wait to first „science-man“ **Aristotle** (384–322 BC). Before Aristotle, many Greek philosophers had speculated compartments of body and live organisms but their theorizing was unsupported by empirical investigation.

TABLE 1-1 HISTORICAL LANDMARKS IN DETERMINING CELL STRUCTURE

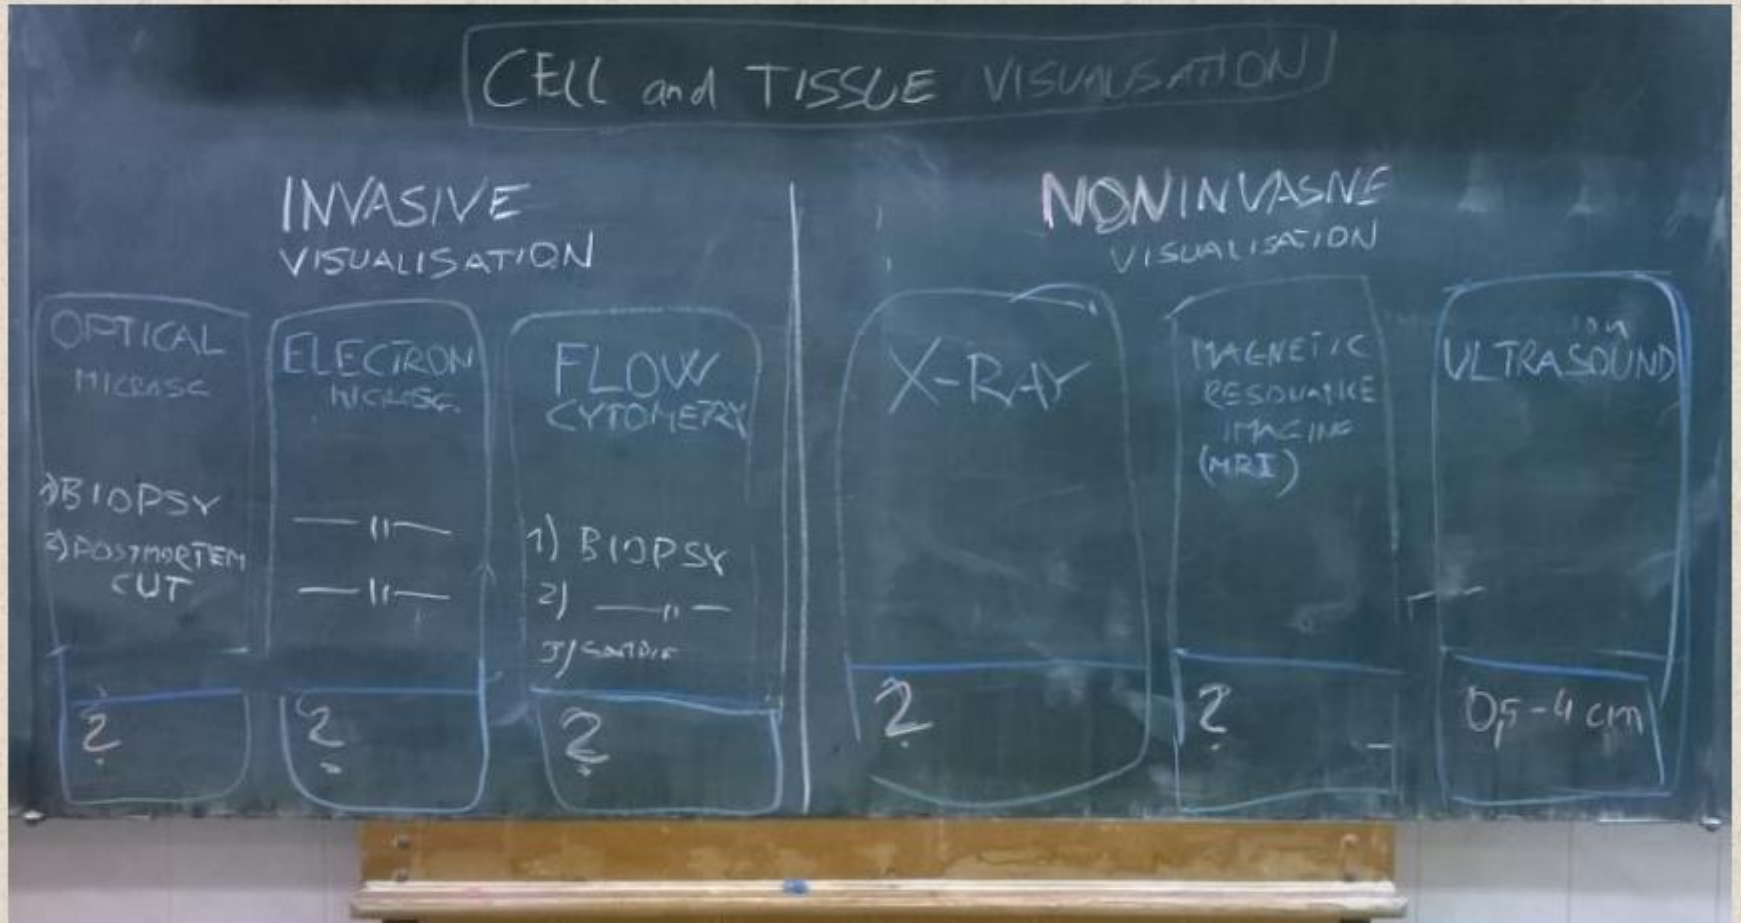

1665	Hooke uses a primitive microscope to describe small chambers in sections of cork that he calls “cells.”
1674	Leeuwenhoek reports his discovery of protozoa. Nine years later, he sees bacteria for the first time.
1833	Brown publishes his microscopic observations of orchids, clearly describing the cell nucleus.
1839	Schleiden and Schwann propose the cell theory, stating that the nucleated cell is the universal building block of plant and animal tissues.
1857	Kölliker describes mitochondria in muscle cells.
1879	Flemming describes with great clarity chromosome behavior during mitosis in animal cells.
1881	Cajal and other histologists develop staining methods that reveal the structure of nerve cells and the organization of neural tissue.
1898	Golgi first sees and describes the Golgi apparatus by staining cells with silver nitrate.
1902	Boveri links chromosomes and heredity by observing chromosome behavior during sexual reproduction.
1952	Palade, Porter, and Sjöstrand develop methods of electron microscopy that enable many intracellular structures to be seen for the first time. In one of the first applications of these techniques, Huxley shows that muscle contains arrays of protein filaments—the first evidence of a cytoskeleton.
1957	Robertson describes the bilayer structure of the cell membrane, seen for the first time in the electron microscope.
1960	Kendrew describes the first detailed protein structure (sperm whale myoglobin) to a resolution of 0.2 nm using X-ray crystallography. Parutz proposes a lower-resolution structure for hemoglobin.
1965	Christian de Duve and his colleagues use a cell-fractionation technique to separate peroxisomes, mitochondria, and lysosomes from a preparation of rat liver.
1968	Petrán and collaborators make the first confocal microscope.
1970	Frye and Edidin use fluorescent antibodies to show that plasma membrane molecules can diffuse in the plane of the membrane, indicating that cell membranes are fluid.
1974	Lazarides and Weber use fluorescent antibodies to stain the cytoskeleton.
1994	Chalfie and collaborators introduce green fluorescent protein (GFP) as a marker to follow the behavior of proteins in living cells.

Cell definition

The cell is the structural and functional elementary unit of all living organisms, conserving the features of the organism, having the ability of self-control, self-regulation, and self-reproduction, being the result of a long time of evolution

In cell biology, an **organelle** is a specialized subunit, usually within a cell, that has a specific function. The name **organelle** comes from the idea that these structures are parts of cells, as **organs** are to the body, hence **organelle**, the suffix -elle being a diminutive.

We can divide the technique via the invasivity or the non-invasivity:

Homework: 1) ad resolution to your exercisebook (information are on following pages)

Each technique have some advantages and disadvantages:

For example Hematoma of leg

Hematoma
by microscopy
(focused inside the muscle)

Microscopic view of organized hematoma showing angiogenesis (arrows), fibrosis (white asterisk) and extravasated red blood cells (black asterisk) (hematoxylin and eosin staining, original magnification, $\times 400$).

Hematoma
by X-RAY CT

Hematoma
by NMRI

Hematoma
by Ultra Sound

For medical and pharmacological curative strategy we need mostly combination of all these techniques.

MAGNIFICATION and RESOLUTION

of visualisation machine (microscopes, ultrasound, telescopes...)

- RESOLUTION (or sometimes RESOLVING POWERS) is defined as the ability of a microscope (or another machine) to **distinguish two close together entities** as being **separate**. An example of resolving power is how well a microcope can show two bacteria as two separated circles.

- For example school microscope : 0,1mm distance of bacterias resolve, but 0,01mm long
- dot. bacteria which are in contact are visited as one small

- RESOLUTION of microscope - similar to screen definition of resolution in home TV or PC)

High resolution = there is visibility of two leaflet

Low resolution = there is not, two leaflet seems like one violet flag

- **MAGNIFICATION** of any optical machine can be defined by two ways:

- Standart magnification
- Anglular magnification (mostly for LENS)

$$M = \frac{L \text{ of visualised object}}{L \text{ of real object}}$$

$$\frac{50}{5} = 10$$

$$m \equiv \frac{\theta}{\theta_0} = \frac{\text{angle with lens}}{\text{angle without lens}}$$

Both of them are comparable and recomputable

Typical resolution of traditional microscopes

MAGNIFICATION

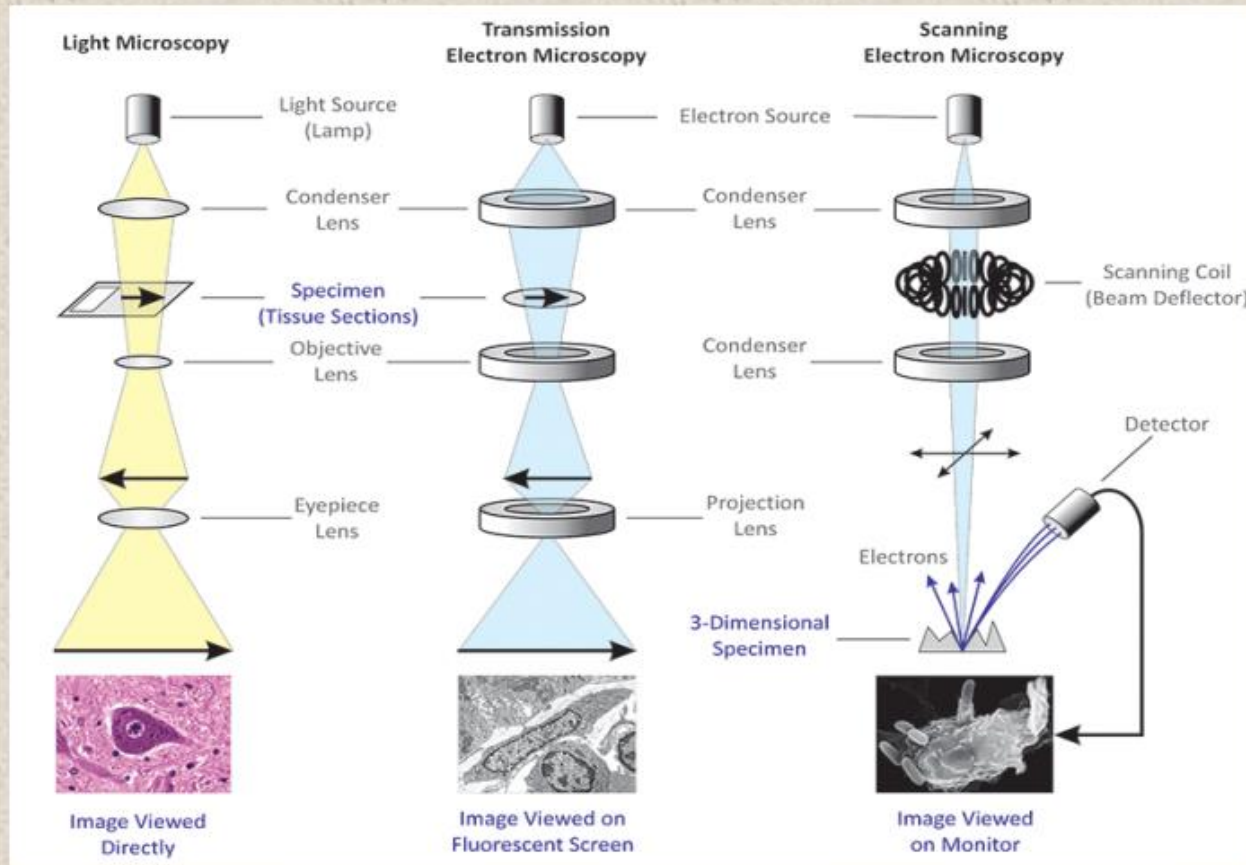

Object

RESOLUTION

Basic construction of microscopies: **Learn!! Will be also in final test !**

OPTICAL and **ELECTRON**

Resolution

200 nm

0.1 nm

0.5 nm

Magnific.

~ $\times 2000$

$\times 50 \sim \times 1,500,000$

$\times 10 \sim \times 1,000,000$

!! IMPORTANT VOCABULARY

of microscope components (will be used in 3 excersise at october !!!) **and will be also in final test**

Light Microscope

- Uses **light** rays

How we can upgrade some structure of cells for better contrast ?
Use staining.

1) **Traditional Histochemistry Staining** (used chemicals which have specific affinity to some part of cell or tissue, for example DNA, collagen etc.

2) **Antibody staining** (best way: primary and secondary antibody which makes some structure fluorescent)

Practical exercise 1

MICROSCOPE

Basic aims:

- 1) Be friendly with school optical microscope.
- 2) Be prepared to read magnification of objectives
- 3) Be prepared to focus the microscope and draw the cell structure which is visible in microscope

For basic background vocabulary:

Practical exercise 1

MICROSCOPE

Basic aims:

4) Be friendly with recomputing of

mm um nm (mili ... micro ... nano meter)

5) Be prepared to tip, which visualization machine produce this scans:

6) Have a idea about resolution of machines

Additional very good short movie about tomography:

CT and MRI are very sophisticated technical apparatus, where great physical theoretic background is needed from quantum physics and nuclear physics theory. Very illustrative videos for medical and biological workers is here:

CT image quality and

Biology

LECTURE 2

Cell and the subcellular structures

Prokaryota / Eukaryota

Cells from Animal / Human / Bacteria

- Medicinal experts should have good overview not only about human cells, but also about another **historical cells** (bacteria + archaea = PROKARYOTA) and **viruses** because their interaction with human body is critical for development of many pathologies (flu, diabetic wound, pathology of intestine microorganism, ...aerobic or anearobic environment could induce different bacterial activity etc)

PROKAROYTE vs. EUKAROYTES

Prokaryotic Cells

Eukaryotic Cells

The Prokaryotic Cell

Of all the types of cells revealed by the microscope, *bacteria* have the simplest structure and come closest to showing us life stripped down to its essentials. Indeed, a bacterium contains essentially no organelles—not even a nucleus to hold its DNA. This property—the presence or absence of a nucleus—is used as the basis for a simple but fundamental classification of all living things. Organisms whose cells have a nucleus are called eukaryotes (from the Greek words *eu*, meaning “well” or “truly,” and *karyon*, a “kernel” or “nucleus”). Organisms whose cells do not have a nucleus are called prokaryotes (from *pro*, meaning “before”).

The Eukaryotic Cell

Eukaryotic cells, in general, are bigger and more elaborate than bacteria and archaea. Some live independent lives as single-celled organisms, such as amoebae and yeasts ([Figure 1–13](#)); others live in multicellular assemblies. All of the more complex multicellular organisms—including plants, animals, and fungi—are formed from eukaryotic cells. By definition, all eukaryotic cells have a nucleus. But possession of a nucleus goes hand-in-hand with possession of a variety of other organelles,

Prokaryota role in evolution

- ✘ Scientists use fossils to study evidence of early life on Earth.
 - ✚ **Fossil:** the preserved or mineralized remains or imprints of an organism that lived long ago.
 - ✚ The oldest fossils **are 3.5 billion year old prokaryotes.**
- ✘ Some of the first prokaryotes were marine cyanobacteria.
 - ✚ **Cyanobacteria:** photosynthetic prokaryotes
 - ✘ Helped release oxygen gas into oceans, and eventually the air.

Eukaryota

- developing organelles via historical ages

Date (million years ago)	Organisms	Events	Atmospheric oxygen (~%)
3800	Prokaryote chemoautotrophs	Origin of life	0
3500–3000	Prokaryote heterotrophs; precursors of cyanobacteria. Stromatolites. Sulfur bacteria	Beginning of <u>photosynthesis</u>	Traces
2100	Filamentous spirally curled organisms, (Grypania)	Major land masses; shallow seas, Iron deposits, BIFs	0.1%
2000	Cyanobacteria tolerant to O ₂	Sterols in bitumen (fossil organisms)	0.2%
1700	Spheromorph Acritarchs, primitive unicellular eukaryotes	Atmosphere oxidising Endosymbiosis. <u>Aerobic respiration</u>	0.3%
1200	Red algae and metaphytes	Large cells. Endosymbiosis. Aerobic respiration. Meiosis. Genetic recombination	0.5%
1000–550	Various primitive multicellular eukaryotes in precambrian fossils, some mineralized. Green algae dominant. Early land plants	Fossils and tracks. Oxygen and ozone accumulating	1–4%
450–present	Full flourishing multicellular <u>eukaryotes</u> ; land living organisms	<u>Ozone layer completed.</u> Crust movements more pronounced. Super continents formed. Ocean basins altered	10–21%

Cells vary enormously in appearance and Function

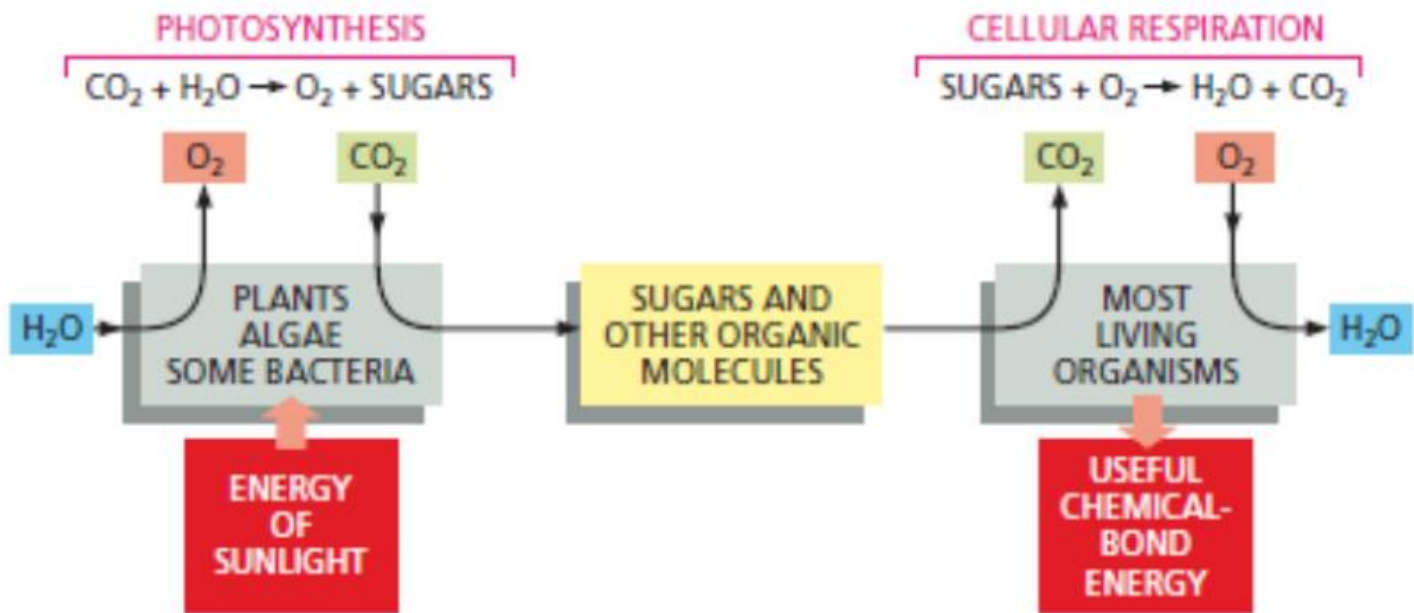

Figure 1-1 Cells come in a variety of shapes and sizes. Note the very different scales of these micrographs. (A) Drawing of a single nerve cell from a mammalian brain. This cell has a huge branching tree of processes, through which it receives signals from as many as 100,000 other nerve cells. (B) *Paramecium*. This protozoan—a single giant cell—swims by means of the beating cilia that cover its surface. (C) *Chlamydomonas*. This type of single-celled green algae is found all over the world—in soil, fresh water, oceans, and even in the snow at the top of mountains. The cell makes its food like plants do—via photosynthesis—and it pulls itself through the water using its paired flagella to do the breaststroke. (D) *Saccharomyces cerevisiae*. This yeast cell, used in baking bread, reproduces itself by a process called budding. (E) *Helicobacter pylori*. This bacterium—a causative agent of stomach ulcers—uses a handful of whiplike flagella to propel itself through the stomach lining. (A, copyright Herederos de Santiago Ramón y Cajal, 1899; B, courtesy of Anne

However biologist during centuries of modern science made basic identification of basal cell principles:

Fundamental principles of all known cells are:

(A) CHEMICAL MACROMOLECULES and STRUCTURE

(B) BIOENERGETIC

Ha ha ha
our cells are different

Essential Concepts

- Cells are the fundamental units of life. All present-day cells are believed to have evolved from an ancestral cell that existed more than 3 billion years ago.
- All cells are enclosed by a plasma membrane, which separates the inside of the cell from its environment.
- All cells contain DNA as a store of genetic information and use it to guide the synthesis of RNA molecules and proteins.
- Cells in a multicellular organism, though they all contain the same DNA, can be very different. They turn on different sets of genes according to their developmental history and to signals they receive from their environment.
- Animal and plant cells are typically 5–20 μm in diameter and can be seen with a light microscope, which also reveals some of their internal components, including the larger organelles.c

The electron microscope reveals even the smallest organelles, but specimens require elaborate preparation and cannot be viewed while alive.

- Specific large molecules can be located in fixed or living cells with a fluorescence microscope.
- The simplest of present-day living cells are prokaryotes: although they contain DNA, they lack a nucleus and other organelles and probably resemble most closely the ancestral cell.
- Different species of prokaryotes are diverse in their chemical capabilities and inhabit an amazingly wide range of habitats. Two fundamental evolutionary subdivisions are recognized: bacteria and archaea.
- Eukaryotic cells possess a nucleus and other organelles not found in prokaryotes. They probably evolved in a series of stages, including the acquisition of mitochondria by engulfment of aerobic bacteria and (for plant cells) the acquisition of chloroplasts by engulfment of photosynthetic bacteria.
- The nucleus contains the genetic information of the eukaryotic organism, stored in DNA molecules.

Schematic Structure of a Membrane Lipid

Schematic Structure of a Lipid Bilayer

- The phospholipids are the critical units of the cell membranes protecting the cells. These units are also responsible for the sustainability of the cells. The inflow and outflow of different biomolecules are controlled by the cell membrane. In fact, these units also host a flexible gate for the entry and exit of the organic molecules.

Due to the excellent structure, the prime phospholipid function is a selective passage.

. These units are also floating and moving. It gives the cell membrane a quasi-fluid structure letting them execute this function. The cell membranes have specific channels for various organic compounds such as proteins, fats, steroids, carbohydrates,

NOTES TO DIFUSION

	Heat Flow	Charge Flow	Mass Flow
1) Flux	Heat Flux q ($J\ m^{-2}\ s^{-1}$)	Charge Flux j (Current density) ($A\ m^{-2}$ & $C\ m^{-2}\ s^{-1}$)	Mass Flux j ($kg\ m^{-2}\ s^{-1}$, $mol\ m^{-2}\ s^{-1}$)
2) Gradient	Temperature Gradient $\frac{dT}{dx}$	Electric Potential Gradient $\frac{dV}{dx}$	Concentration Gradient $\frac{dc}{dx}$
3. Law	Fourier's Law of Heat Conduction $q = -k \left(\frac{dT}{dx} \right)$	Ohm's Law $j = -\sigma \frac{dV}{dx}$	Fick's First Law $j = -D \frac{dc}{dx}$
4. Material Property	Thermal conductivity k ($W\ m^{-1}\ K^{-1}$)	Electrical Conductivity σ ($S\ m^{-1}$ & $\Omega^{-1}\ m^{-1}$)	Diffusivity or Diffusion coefficient ($m^2\ s^{-1}$)
5. Year	1857	1827	1855

DIFUSION in simple basin (without any membrane)

- Red molecules are dropped to water.

What will be happen?

later

and finally

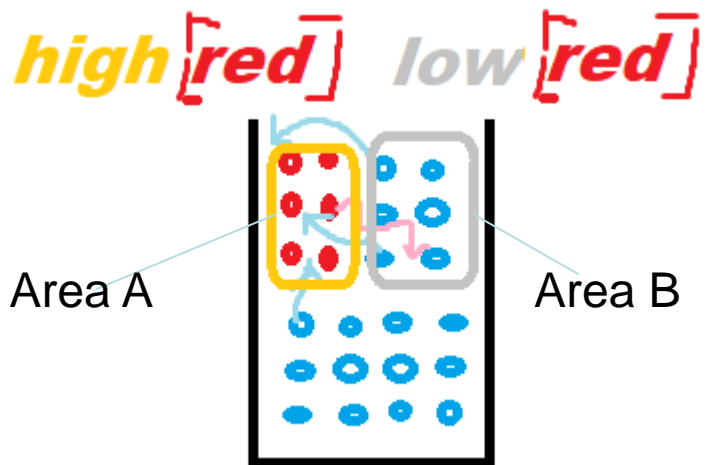

concentration of RED and WATER

are finally homogenous

- Why RED and WATER molecule diffuse?

there exist place with high concentration and

near place with low concentration . This gradient of concentration caused the molecule movement

This movement is quantified by FICK LAW

$$J = S \cdot D \cdot \text{grad}[\text{red}]$$

where S is the “contacting area of drop (area with red molecules)”

D is special physical constant for this type of molecules (will be shown in next pages)

$\text{grad}[\text{red}]$ is gradient of concentration in place A and place B
(if concentration is the same, there is gradient = 0 and no movement of molecules)

- However the same situation can be seen also from opposite site of view:

ALSO WATER MOLECULES are driven from place B (high concentration of WATER to A (low concentration of water)

$$J = S \cdot D \cdot \text{grad}[w]$$

DIFUSION in basin with the membrane

Variant 1: Membrane is permeable **only** for RED

THE PHYSICAL FORCE FOR MOVEMENT OF RED MOLECULES are the same like in basin without membrane.

Concentration of RED and WATER will be finally homogenous in both compartments.

Variant 2: Membrane is permeable **only** for WATER

Water is moving through the membrane and „wants to made“ oncentration of „RED so much low as possible“ (idealy press to zero = total water).

In some time it is stoped in ekvilibrum (because of external presure)
