## ANALYTICAL CHEMISTRY

prof. Viktor Kanický, Analytická chemie I

### Analytical chemistry

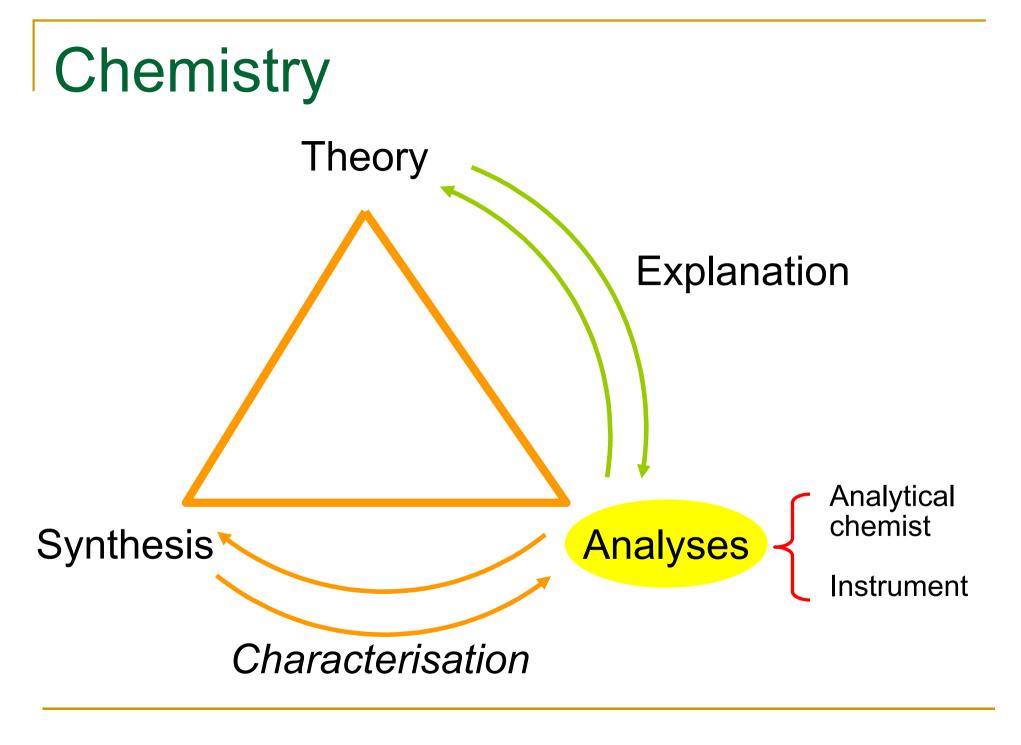

- ανάλυσις = analysis
- Material ⇒ decomposition ⇒ A, B, C ⇒ identification
- Science : Analytical Chemistry(ACH)
- Methodology: Chemical Analysis
- Analytical chemistry is the science of creation and evaluation of analytical signals carrying information about the chemical composition of the sample
- Analytical Chemistry
  - qualitative  $\Rightarrow$  EVIDENCE (WHAT?)
  - ☐ quantitative⇒ DETERMINATION? (HOW MUCH)

## History of Analytical Chemistry

- Egypt, China, Indie, Greece (Demokritos, Platon, Aristoteles, (5.-4. st. BC), Middle Ages– alchemists
- analysis
  - "dry" reaction in solid phase (heating of solids metallurgy)
  - "wet" in solution
- fundamentals
  - R. Boyle 17. century
  - □ J. Dalton 18.-19. century
  - A. L. Lavoisier 18. century
  - Fresenius (19. st.): separation and identification of cations using hydrogen sulphide
  - Instrumental methods: spectral analysis, Bunsen a Kirchhoff (19.cent.)
  - J. Heyrovský: polarography, Nobel Prize1959

## Methodology of analytical chemistry

- Analytical approach in Science and Humanities
  - Partition of problem into particular simpler parts, solution of these partial tasks and combining of individual information for understanding of the whole
    - Decomposition of material into chemical species  $\Rightarrow$  molecules, atoms, ions
      - Х
    - Analysis by physical methods
       study of matter in solid state, without decomposition, dissolution
- Computer Based Analytical Chemistry (COBAC)
- ACH is a scientific discipline that develops and applies methods, instruments and strategies to gather information on the composition and nature of matter in space and time

# Classification of analytical methods according to principle

- Chemical methods (chemical reactions)
  - Gravimetry
  - Volumetry (titrimetry)
- Physico-chemical methods
  - Spectroscopic (radiations, particles electrons, ions)
  - Separation (separation of comonents in time and space between two phases)
  - Electrochemical (electrode processes)
- Biochemical methods (enzymes, microorganisms)

# Classification of analytical methods according to object of analysis

#### Material (examples)

- water, geological, metallurgical, ceramics, building, environmental, pharmaceutical, foodstuff, clinical
- Determined component type analyte (examples):
  - Elemental analysis of samples with inorganic and organic matrix
  - Analysis of organic compounds
  - Determination of radioactive isotopes
- Analyte content
  - Total analysis (main constituents,  $\Sigma$ =100%)
  - trace(μg/g) and ultratrace(ng/g, pg/g) analysis
- Sample size (g, mg, μg, ng, μl, nl)

### Elemental analysis

- Elemental analysis enables:
  - verification of the presence of the element (<u>qualitative analysis</u>)
  - determination of elemental concentration/content (<u>quantitative</u> <u>analysis</u>)
  - identification of structure, in which the element is present (<u>structural</u> <u>analysis</u>)
  - identification of compound, in which the element is bound (speciation)

#### WHOWHO analysis

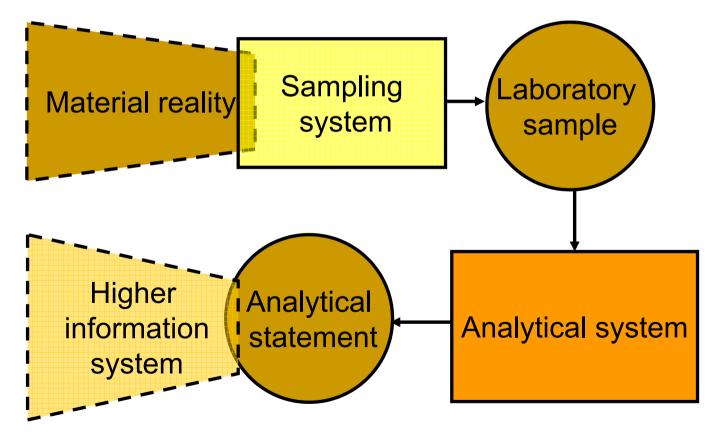

- what (qualitative)
- how much (quantitative)
- where (structure)
- how bound (speciation)
- The aim is to find structure vs properties relation

### General procedure for analysis

- Sampling
  - Representative sample
  - Homogeneous sample
- Sample transfer to a form suitable for analysis
  - Decomposition, dissolution, pressing of powdered samples
  - Separation of components (from matrix, separation of individual analytes), concentration of constituents
- Analytical signal measurement
  - mass, volume, flow of electromagnetic radiation or ions, electrochemical potential, current, charge, conductivity
- Data evaluation
  - Mean value, standard deviation, error, uncertainties, validation
- Conclusions, analytical report

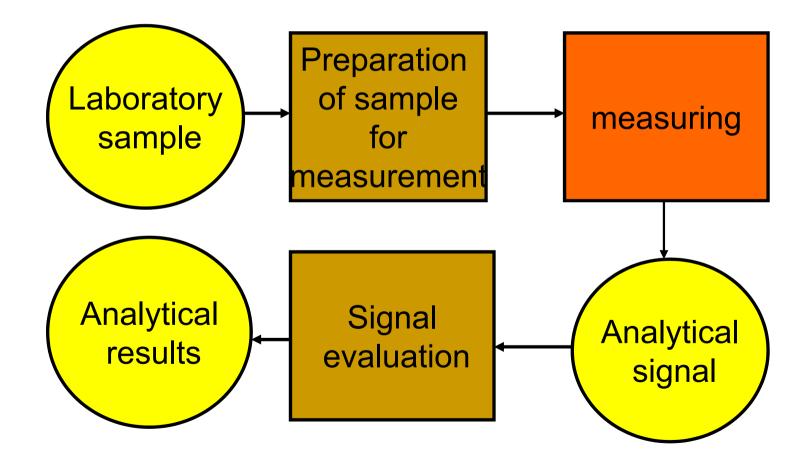

### Analytical system

- Analytical system is a subsystem of higher information system
- Sampling system and analytical system

### Analytical system

Scheme of analytical process

### Analytical signal

 Analytical chemistry is the science of creation and evaluation of the analytical signal (AS), carrying information about the chemical composition of the sample

#### AS has two aspects - dimensions:

- Position (wavelength of radiation, half-wave potential), corresponding to quality (WHAT?)
- Magnitude, intensity (radiant flux, limiting diffusion current, corresponding to quantity (HOW MUCH?)
- Analytical signal intensity is generally a function of concentration of determined analyte c<sub>A</sub>, concentration of other components c<sub>zi</sub>, and a number of variables p<sub>j</sub> (insrumental parameters, reagents)

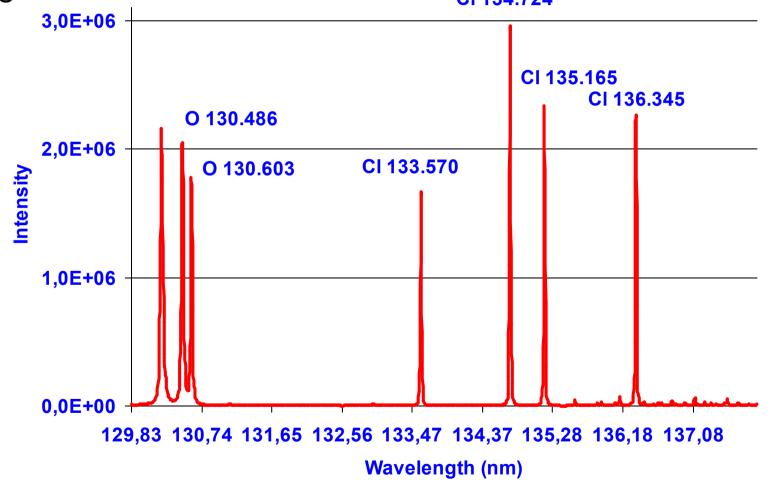

$$S = S(c_A, c_{zi}, p_j)$$

#### Generating of analytical signal in optical atomic emission spectrometry (OES) and mass spectrometry (MS)

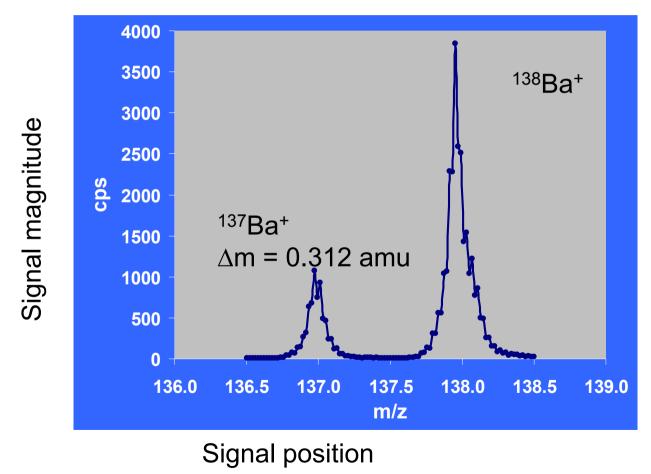

## Atomic (optical) emission spectromety in inductively coupled plasma ICP-AES, ICP-OES

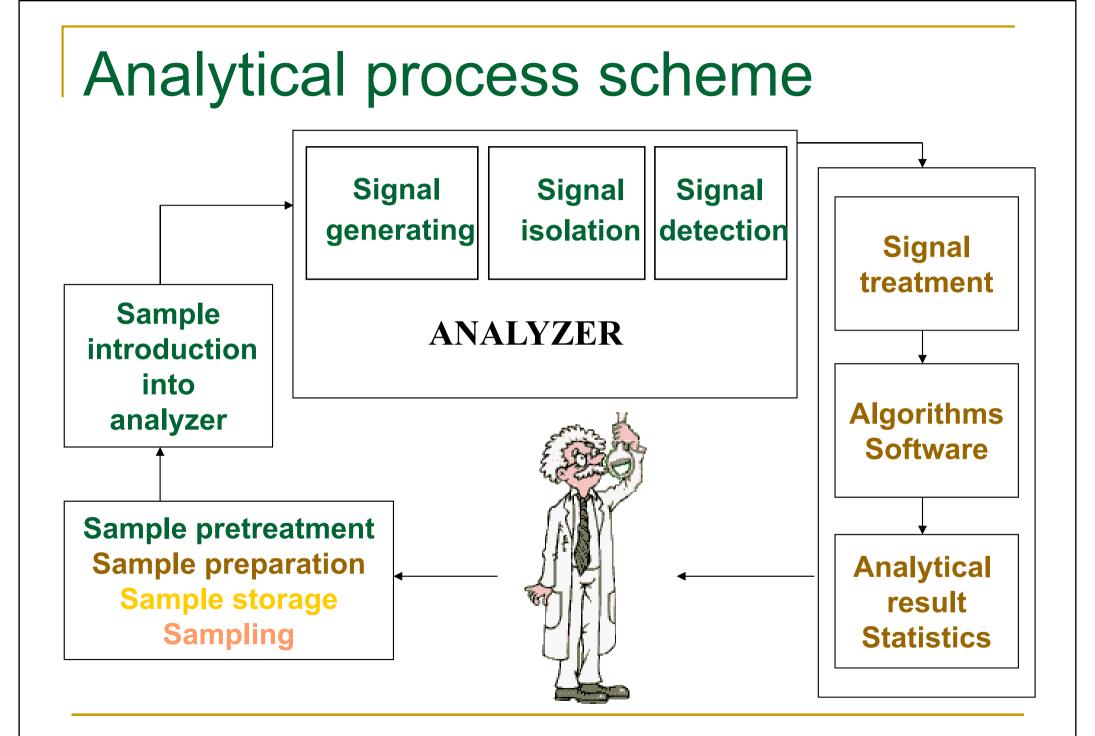

Atomic (line) emission spectrum of chlorine and oxygen in UV region

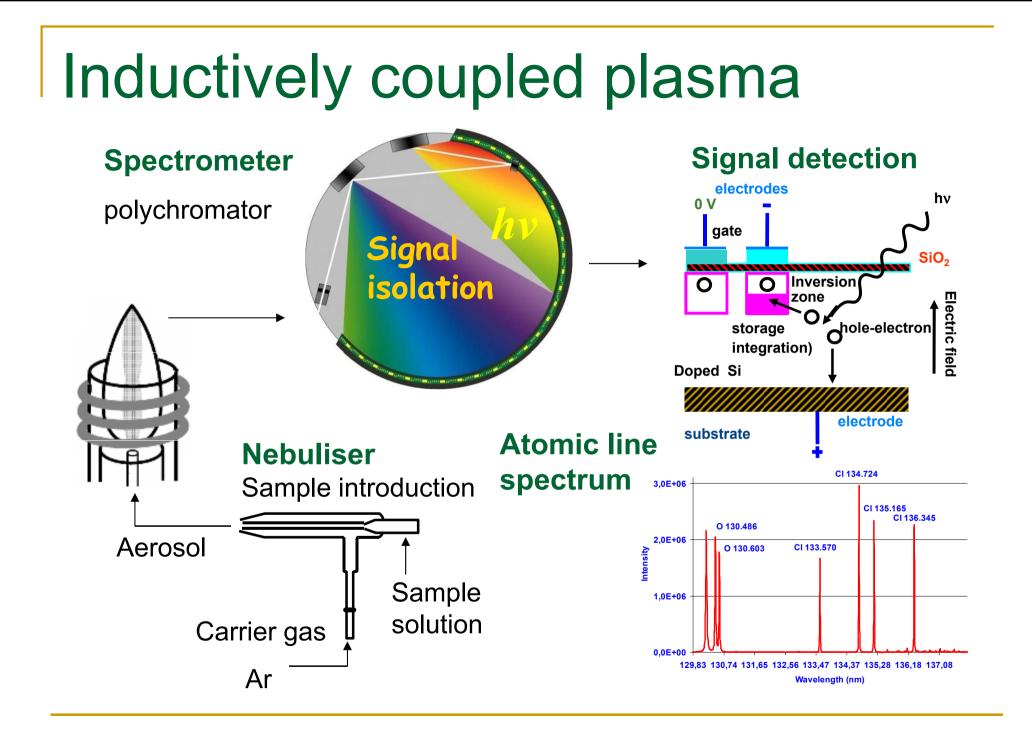

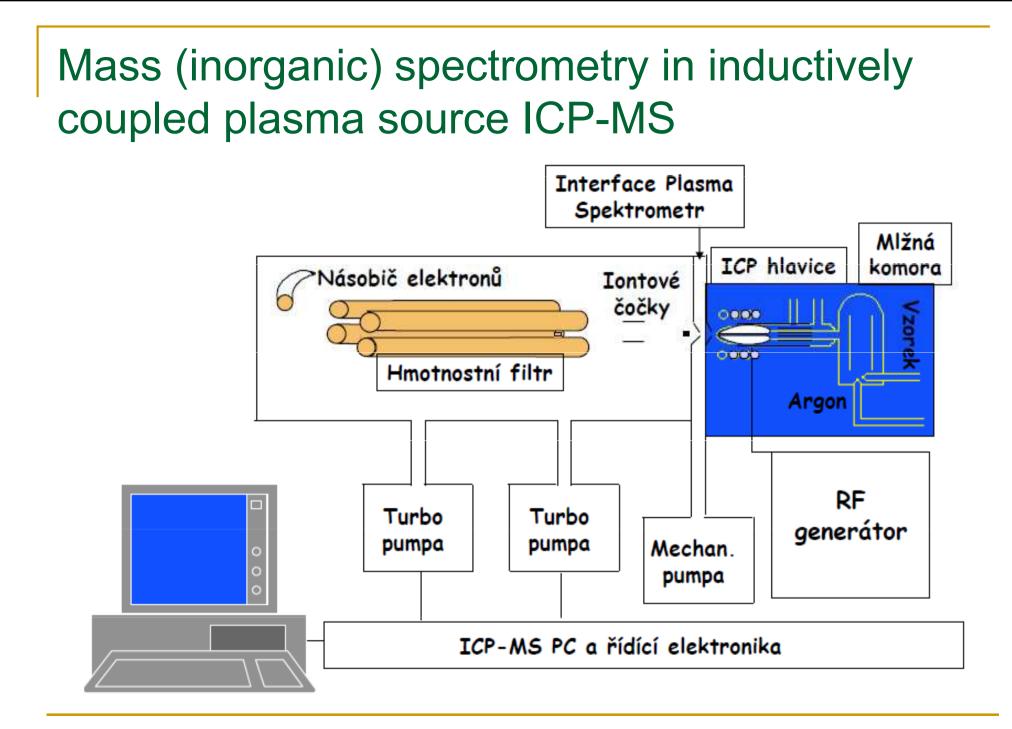

#### Mass spectrometry ICP-TOF-MS

- Resolution m/z: <sup>137</sup>Ba<sup>+</sup> a <sup>138</sup>Ba<sup>+</sup>
- Mass spectrum

### Analytical method

- Sampling and sample storage, preservation of representative material
- Processing of the part of the sample for quantitative analysis
- Determination
- Calculation of results

#### **DEFINITION (ISO 3534)**

- random error = component of measurement error, which changes in the course of repeated measurements in an unpredictable way
- systematic error, bias = component of measurement error, which does not change in the course of repeated measurements or changes in a predictable way

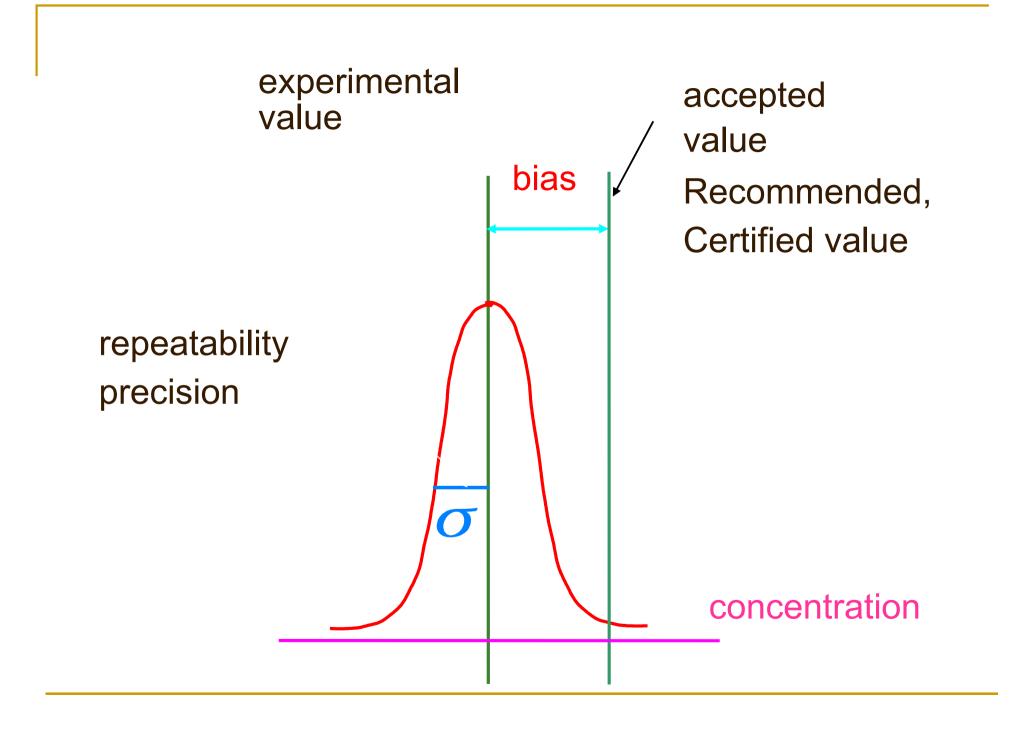

### Analytická metoda

#### DEFINICE (ISO 3534)

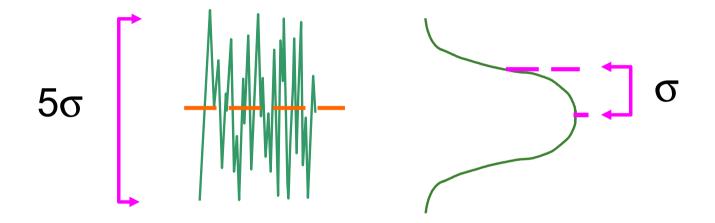

- precision = tightness of agreement between the results obtained with the repeated use of the same experimental procedure under defined conditions (random error)
  - Repeatability
  - Reproducibility
- trueness = tightness of agreement between the "true (actual) value" and the mean value of measured results (systematic error, bias)
- accuracy = method is accurate if it is satisfied at the same time precision and trueness of the results

#### Repeatability

- Repeatability represents random fluctuations of the measured values of the analytical signal (or results) around the mean value within one experiment (a series of replicates)
- Cause of fluctuations is noise: in case of emission spectrometry example:
  - shot noise (photons)
  - flicker noise (sample introduction noise)
  - detector noise
- Repeatability is usually expressed as standard deviation (SD) or relative standard deviation (RSD)

## Standard deviation and fluctuation peak - peak

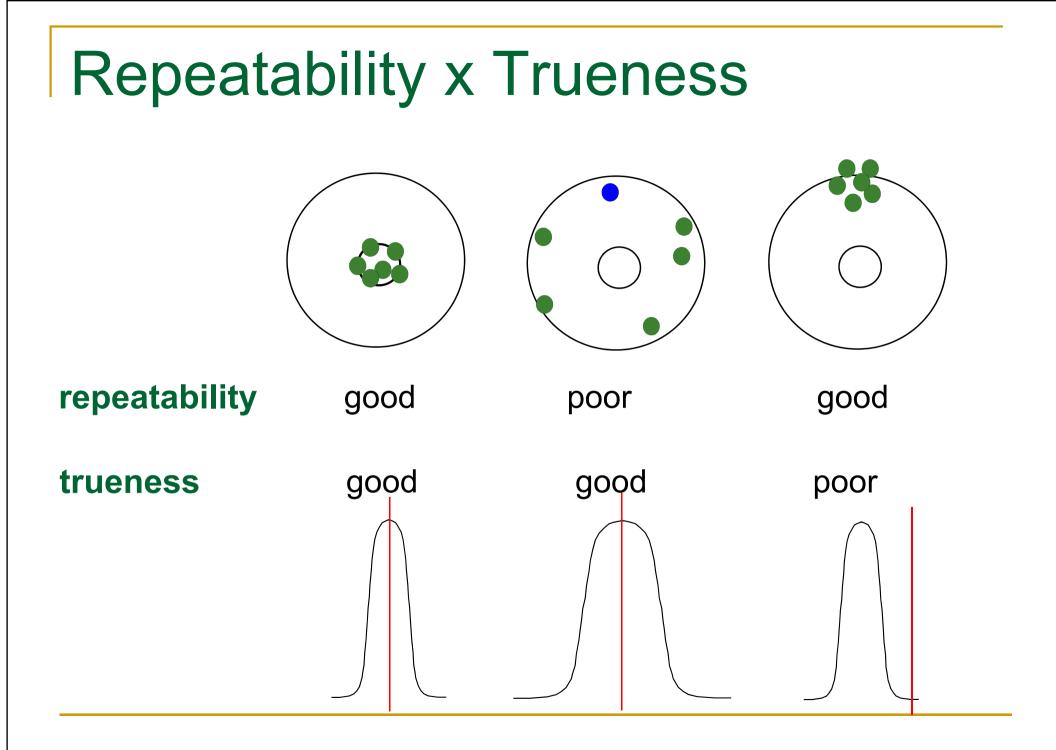

5  $\sigma$  includes 99% of the population

For mean value 100 and standard deviation 1 are fluctuations between 97.5 and 102.5

#### Reproducibility

- Principle as in the case of repeatability, in addition, one other parameter changes
- Reproducibility may be:
  - Between laboratories
  - Between operators in one laboratory
  - Between analyzers
  - In different days
  - etc...

#### Parameters of data sets

- Arithmetic mean = mean value of Gaussian = normal distribution, n values  $\overline{X} = \sum_{i=1}^{n} \frac{X_i}{n}$
- Sample standard deviation = dispersion parameter of the sample set, for n > 7  $s = \sqrt{\frac{1}{n-1} \left[ \sum_{i=1}^{n} (X_i - \overline{X})^2 \right]}$
- median = mean value insensitive to outliers
  - For odd *n* the median of a set of values arranged by size  $X_1, ... X_{(n+1)/2}, ... X_n$  is equal to the middle value of the series:

$$\tilde{X} = X_{(n+1)/2}$$

• For even *n* the median is equal to arithmetic mean of the central pair  $\widetilde{X} = \frac{1}{2}(X_{n/2} + X_{n/2+1})$ 

#### Parameters of data sets - Span

Standard deviation  $s_R$  of data set for  $n \le 7$ 

is calculated from the span of values:

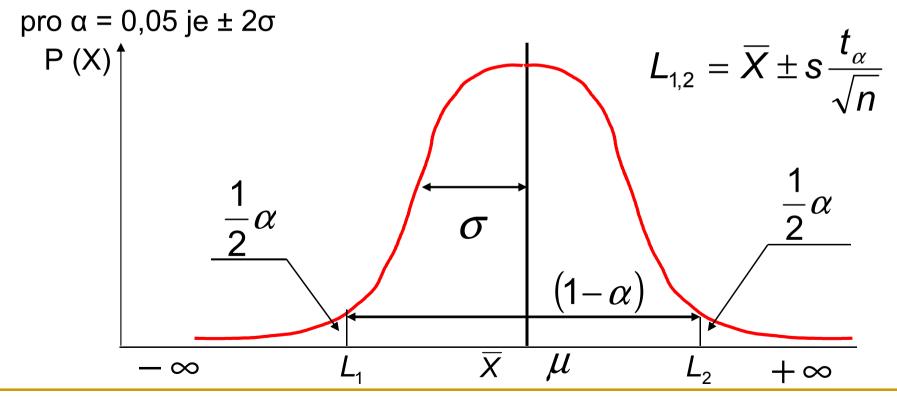

$$s_R = k_n \cdot R$$

$$R = X_{\rm max} - X_{\rm min}$$

## Level of significance and confidence interval of mean

 A level of significance indicates the probability that the true parameter value does not lie within the 100(1- α)% interval

 Confidence interval L<sub>1,2</sub> of the mean X on the level of significance α is an interval, in which the true value μ lies with probability (1- α)

#### Trueness

Standard deviation s is estimate of σ

### Statistical testing

- Comparison of results of analyses
- null hypothesis: the assumption that between the compared values is no other difference than that which can be explained by the presence of random errors
- null hypothesis H<sub>0</sub> is rejected if the actual difference exceeds a critical value that corresponds to the pre-selected significance level α
- risk that we reject the correct null hypothesis is called the error of the 1<sup>st</sup> kind and is given by the significance level α
  - $P_1 = 1 \alpha$  is the probability that we accept the correct null hypothesis

#### **Test of Trueness**

Student test (Gosset), trueness:

$$t = \frac{\left|\overline{X} - \mu\right|}{s/\sqrt{n}}$$
 if  $t \ge t_{krit}(v, \alpha)$  n > 7

 for the number of degrees of freedom v = n-1 and the chosen significance level α, e.g. α = 0.05 for P = 95%, then the difference is statistically significant

#### Test of Trueness using span

Lord test

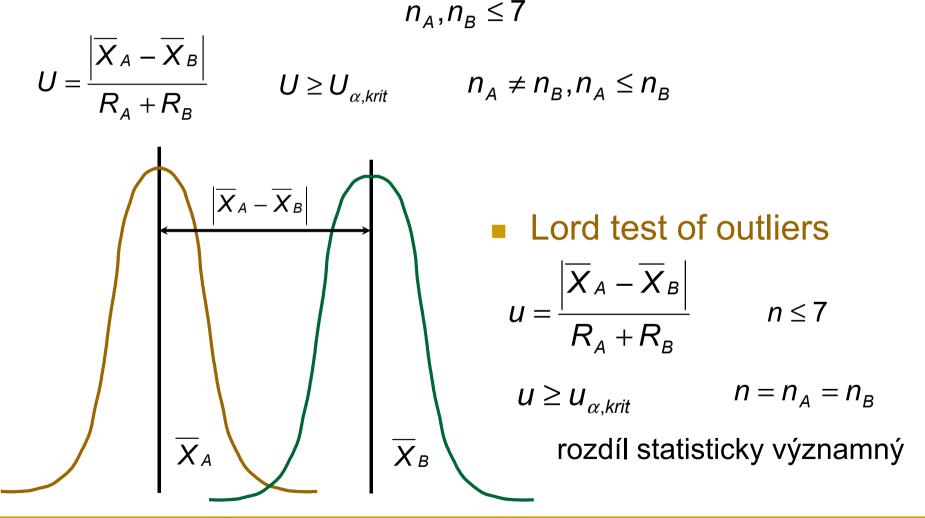

*n* ≤ 7

$$u_n = \frac{\left|\overline{X} - \mu\right|}{R}$$

 $u_n \ge n_{krit}(n, \alpha) \longrightarrow$  statistically significant difference

#### **Correspondence of results**

Moore test of outliers

#### **Correspondence of results**

test of averages (Student test)

$$\overline{X}_{A}, \overline{X}_{B}, n_{A}, n_{B} \qquad v = n_{A} + n_{B} - 2 \quad n_{A}, n_{B} \ge 7$$
$$S_{A} \approx S_{B}$$

□ If the value *t* is greater than the critical value  $t_{krit}$ , the difference in averages is statistically significant:

$$t = \frac{\left|\overline{X}_{A} - \overline{X}_{B}\right|}{S} \cdot \sqrt{\frac{n_{A} \cdot n_{B}}{n_{A} + n_{B}}} \qquad t \ge t_{krit}(\alpha, \nu)$$
$$S^{2} = \frac{\sum_{i} \left(X_{iA} - \overline{X}_{A}\right)^{2} + \sum_{i} \left(X_{iB} - \overline{X}_{B}\right)^{2}}{n_{A} + n_{B} - 2}$$

#### **Correspondence of results**

test of averages (Studentův test)

$$n = n_A = n_B$$

$$t = \frac{\left|\overline{X}_{A} - \overline{X}_{B}\right|}{\sqrt{\left(S_{A}^{2} + S_{B}^{2}\right)}} \cdot \sqrt{(n-1)} \qquad t \ge t_{krit}(\alpha, \nu)$$

 If t is greater than the critical value, then the difference is statistically significant

#### **Exclusion of outliers**

T-test; Grubbs test for n > 7

$$X_1 \le X_2 \le \dots \le X_n$$
  $T_1 = \frac{\overline{X} - X_1}{S_n}$   $T_n = \frac{X_n - \overline{X}}{S_n}$ 

 $T_1, T_n \ge T_{krit}(\alpha, n) \implies \text{extreme values are outliers}$ 

### **Exclusion of outliers**

• Q-test; Dean-Dixon test for  $n \le 7$ 

× /

$$X_1 \le X_2 \le \dots \le X_n$$

$$Q_1 = \frac{X_2 - X_1}{R} \qquad \qquad Q_n = \frac{X_n - X_{n-1}}{R} \qquad \qquad 3 \le n \le 7$$

if

$$Q_1, Q_n \ge Q_{krit}(\alpha, \nu)$$

Then are  $Q_1 a Q_n$  outliers

## Types of analytical methods

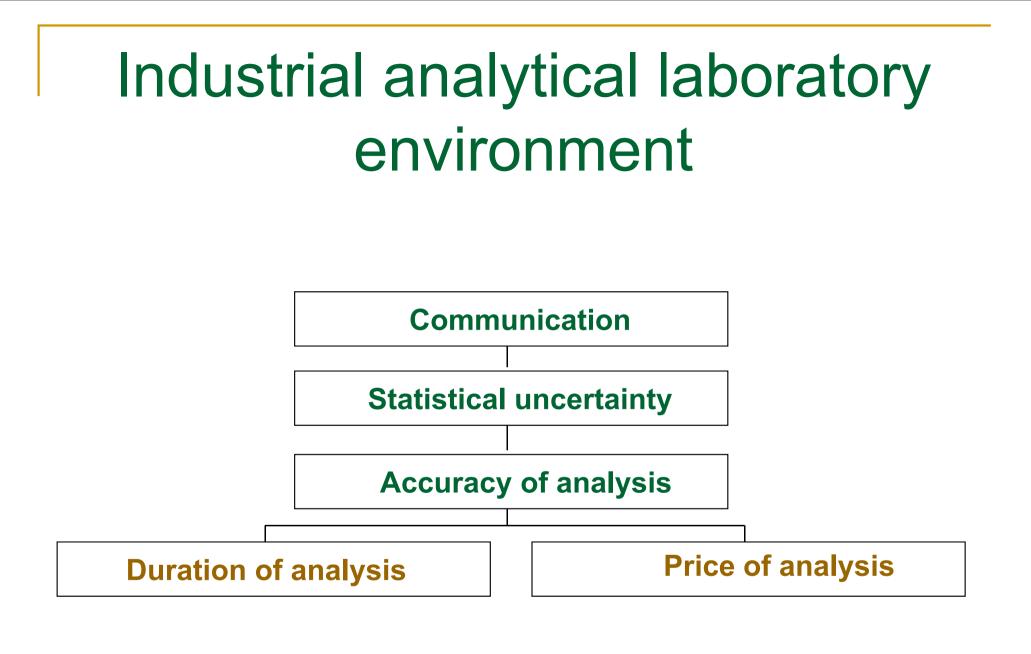

- ISO Guide 32 proposal classifies methods of chemical analysis according to calibration procedure:
  - Absolute methods (calculable methods) result can be calculated on the basis of relations resulting from chemical and physical laws, using measured values (titrimetry, gravimetry, coulometry)
  - Relative methods analyzed sample is compared with a set of calibration samples with known contents using the detection system, which has a linear response to the concentration of fixed components
    - differences between calibration and analyzed samples do not affect the signal in comparison with the magnitude of uncertainty
    - samples before measurement can be adjusted (adjustment of the matrix of calibration samples to the matrix of analyzed samples, elimination of interferences)

## Types of analytical methods

- Comparative methods analyzed sample is compared with a set of calibration samples with known contents using the detection system, which responds not only to the fixed component, but also to change the composition of the matrix
  - calibration of such a method requires use of certified reference materials (CRM)
  - it is a quick method to control technological processes (wavedispersive X-ray fluorescence spectrometry in the production of steel, alloys, oxide powder, ceramic materials, etc.)

## Analytical chemist

- 80% in industrial laboratories, the analytical chemist is a solver of problems and issues
- good theoretical knowledge of the methods used and the ability to develop experimental techniques and to select relevant, the optimal method
- development of specialized analytical procedures for analysis of routine and unique, unusual samples, communication with experts from other disciplines to obtain information about analyzed materials, the ability to choose a compromise between the cost analysis and its accuracy

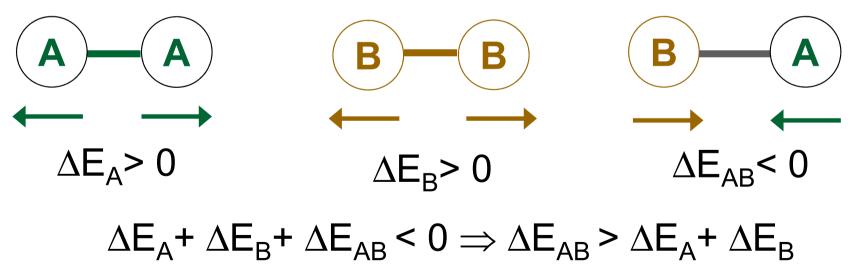

### Method of analytical problem solving

- knowledge of chemistry of the problem
- knowledge of sampling and sample processing
- use of suitable separation methods
- use of proper calibration and standards
- selection of the best methods for measuring the analytical signal

### Theoretical Foundations of Analytical Chemistry

- Dissolving of substances and solutions
  - solution: solid, liquid, gaseous
  - Analytical chemistry– liquid solvents
  - dissolution = overcoming of intermolecular forces between particles
  - Dissolution of A = dispersion of A in a solvent B

## Nature of intermolecular forces and dissolution

Substance to be dissoleved	solvent	Nature of intermolecular forces	solubility
electrolyte	polar	similar	(+)
electrolyte	nonpolar	diffrenet	-
nonelectrolyte	polar	diferent	-
nonelectrolyte	nonpolar	similar	(+)

## Dissolution

Relative permitivity  $\approx \epsilon_R$  dielectric constant dipole momentD

- Nonpolar solvents
  - van der Waals forces
  - Solid nonelectrolytes:
    - Solubility is given (to10<sup>-3</sup> mol/l) ∆H<sub>t</sub>= latent heat of melting ≈ increasing of distances between particles, dispersion
  - $\hfill\square$  Liquids: miscibility according to  $\epsilon_{R}$
  - Gases- nonpolar molecules: O<sub>2</sub>, N<sub>2</sub>, H<sub>2</sub>, CH<sub>4</sub> better soluble in n-pentane and n-hexane than in water

## Dissolution

#### Polar solvents

- Electrostatic forces
- $H_2O: D = 1,84; \epsilon_R = 80$
- shielding of attractive forces between ions in solution
  - Ionic compounds : dissociation

 $M^+A^- \rightarrow M(H_2O)^+_x + A(H_2O)^-_y$ 

- Degree of dissociation  $\alpha$ , conductivity, strong electrolytes, conc.  $\times$  activity
- Polar compounds: ionization+ dissociation:

 $\mathsf{H}^{(+)}\text{-}\mathsf{CI}^{(\text{-})}\text{+}\mathsf{H}^{(+)}\text{-}\mathsf{O}^{(\text{-})}\text{-}\mathsf{H}^{(+)} \to \mathsf{H}_3\mathsf{O}^+\mathsf{CI}^{\text{-}} \to \mathsf{H}_3\mathsf{O}^+\text{+}\mathsf{CI}^{\text{-}}$ 

- Solid electrolyte
  - Ions in crystal lattice
  - Polar molecules
- Energy necessary for disruption of chemical bond
  - □ Gain by hydration of ions  $\Rightarrow$  solubility  $\approx \Delta E$  (bond strength, hydration)
- Bond strength in ionic compounds
  - Lattice energy U = f(z, r, k), z = charge, r = ion radius, k = coordination number
- U = const× $z^2/r_0$  for similar ions,  $r_0 = r_K + r_A$

 $r_K$ ,  $r_A$ - crystallographic values ⇒ influence of particular ions (dU/dr) = const ×( $z^2/r_0^2$ ) = const ×( $z/r_0$ )<sup>2</sup> square of ionic potential, changes in series of similar compounds

- Hydration energy of ions E<sub>H</sub> is proportional to:
  - □ bond strength between ion and water molecule (dipole)  $\approx z^2/r$
  - number of coordinated water molecules
- Ions bound molecules of H<sub>2</sub>O the stronger, the greater is z and smaller r
- Change of  $E_H \approx \text{const} \times (z^2/r^2) \approx z/r$

- Ionic potential z/r decreases (z decreases, r increases) ⇒ U, E<sub>H</sub> decrease, hydration energy decreases slower, because at higher r number of coordinated water molecules increases (compensation of the decrease)
- Solubility of ionic compounds depends on balance E<sub>H</sub> + U
  - ionization (dissociation) = endothermal process, U > 0
  - hydration = exothermal process,  $E_H < 0$
- Compound dissolve:
  - well, if  $E_H + U < 0$ ,  $(U < |E_H|)$
  - with difficulty, if  $E_H + U > 0$ ,  $(U > | E_H |)$
- Solubility of fluorides of alkali metals increases LiF  $\Rightarrow$  CsF, because U decreases from Li  $\rightarrow$  Cs steeper than E<sub>H</sub> (decrese of E<sub>H</sub> is hindered by growth of coordinated molecules H<sub>2</sub>O (Li<sup>+</sup> 4 H<sub>2</sub>O, Cs<sup>+</sup> 8 H<sub>2</sub>O)

- Solubility of salts of small ion (Li<sup>+</sup>, Na<sup>+</sup>, F<sup>-</sup>) increases with decrease of z/r of counterion:
  - □ LiF < LiCl = LiBr < Lil
  - NaF < NaCl < NaBr < Nal</p>
  - LiF < NaF < KF < CsF</p>
- Solubility of salts of big ion (Cs<sup>+</sup>, I<sup>-</sup>) diminishes with decrease of z/r of counterion
  - $\Box \quad CsF > CsCl > CsBr > Csl$
  - Lil > Nal > Kl > Rbl > Csl
- Solubility of salts of medium-size ion (K<sup>+</sup>, Rb<sup>+</sup>, Cl<sup>-</sup>, Br<sup>-</sup>) at first with decrease of z/r diminishes and then slightly increases or remains constant:
  - □ KF > KCI > KBr > KI
  - $\Box RbF > RbCI > RbBr < RbI$
  - LiCl > NaCl > KCl < RbCl < CsCl
- $OH^{-} = small ion \Rightarrow Mg(OH)_{2} < Ca(OH)_{2} < Sr(OH)_{2} < Ba(OH)_{2}$
- Ionic potential:
   3,08
   2,02
   1,77
   1,48
- Big ions:  $PO_4^{3-}$ ,  $SO_4^{2-}$ ,  $S_2O_3^{2-}$ ,  $SiF_6^{2-}$ ,  $CrO_4^{2-}$ ,  $IO_3^{-}$ ,  $NO_3^{-}$ :  $\Rightarrow$ 
  - □  $Mg^{2+} > Ca^{2+} > Sr^{2+} > Ba^{2+}$  (in this sense decreases z/r of cations)

Effect of electron shell – example Pb<sup>2+</sup> a Tl<sup>+</sup>:

Pb <sup>2</sup>	2	8	18	32	2	PbS	PbCrO <sub>4</sub>	Pbl <sub>2</sub>	PbCl <sub>2</sub>
TI+	2	8	18	32	2	TI <sub>2</sub> S	Tl <sub>2</sub> CrO <sub>4</sub>	TII <sub>2</sub>	TICI

- Similarity of Rb<sup>+</sup> s Tl<sup>+</sup>
   Soluble bydrovides PbOH, TIOH and, corbonates Pb CO
  - Soluble hydroxides RbOH, TIOH and carbonates  $Rb_2CO_3$ ,  $TI_2CO_3$
  - □ Little soluble  $Rb_2$ [ PtCl<sub>6</sub>], Tl<sub>2</sub>[ PtCl<sub>6</sub>]
- exception: F<sup>-</sup>: CaF<sub>2</sub> < SrF<sub>2</sub> < MgF<sub>2</sub> < BaF<sub>2</sub> (small ion)
- exception:  $CO_3^{2-}$ :  $Mg^{2+} > Ca^{2+} > Ba^{2+} > Sr^{2+}$  (big ion)
- exception:  $C_2O_4^{2-}$ :  $Ca^{2+} > Sr^{2+} > Ba^{2+} > Mg^{2+}$  (big ion)
- Effect of z/r on solubility of salts of cations of transition elements is limited
  - Prevails influence of unoccupied d-orbitals (ligand field, stabilization energy)

- Electrolytes with polar covalent bound
- Strength is higher then corresponds to ionic attraction
- The smaller the difference of electronegativities the stronger the bond and lower solubility
- example: according to z/r the AgCl solubility should be comparable with that of KCl, generally of halogenides, but AgF only is well soluble

## Theoretical fundamentals of analytical chemistry

- Analytical reactions:
  - Sample treatment (decomposition)
  - Separation and preconcentration of analytes in solution
  - determination
- Evaluation of chemical reation:
  - Thermodynamic criterion
  - Kinetic criterion
  - Chemical thermodynamics change of energy
  - Chemical kinetics reaction path, mechanism, reaction rate
- Analytical reaction occurs (in solutions)
  - At constant pressure
  - At constant temperature
- Change of energy content = change of Gibbs energy
- kinetics:
  - Ion reactions
  - Radical reactions

# Requirements for analytical reactions

- 1. Fast reactions během promíchání (titrace)
- 2. Unambiguous reactions without byproducts
- 3. Completness of conversion equilibrium  $\rightarrow$  products

Chemical equilibrium

Collision theory of chemical reactions

A + B  $\Rightarrow$  AB (activated complex)  $\Rightarrow$  products

 $N_A N_B$  – number of particles in a given volume Number of collisions AB is given by combinatorial number:  $(N_A + N_B)!/[2!(N_A + N_B - 2)!] - N_A!/[2!(N_A - 2)!] - N_B!/[2!(N_B - 2)!] = N_A \cdot N_B$ Similarly for aA + bB  $\Leftrightarrow A_a B_b$  the number of possible groupings reads =  $= (N_A)^a \cdot (N_B)^b/a! \cdot b!$ 

Instant reaction rate

v=k[A]<sup>a</sup> · [B]<sup>b</sup>

### Requirements for analytical reactions $aA + bB \Leftrightarrow cC + dD$

 $v=k[A]^{a} \cdot [B]^{b}$   $v'=k'[C]^{c} \cdot [D]^{d}$  K = k/k'

Theromodynamic equilibrium constant

$$K_a = \frac{a_C^c \cdot a_D^d}{a_A^a \cdot a_B^b}$$

- Standard thermodynamic quantities  $\Delta G^{\circ}$ ,  $\Delta H^{\circ}$ ,  $\Delta S^{\circ}$
- $\Box \ \Delta G^{\circ} = \Delta H^{\circ} T \ \Delta S^{\circ} = -RT \ In \ K_{a} \qquad T, \ p = const.$
- □  $\Delta$  = final initial state, R = 8,314 J K<sup>-1</sup>mol<sup>-1</sup>
- ΔG°= 5,708·103 log Ka, ΔG°≈ J mol<sup>-1</sup>
- □ Molar concentration of substance  $c_A = n_A/V$ 
  - $n_A$  number of moles, V volume

## Requirements for analytical reactions

- Activity  $a_A = [A] y_A [A] equilibrium concentration$
- y<sub>A</sub> activity coefficient, expresses diffrences in behaviour:
  - solvation, electrostatic effects between ions
- Concentration × thermodynamic constant

$$K_{a} = \frac{\left[C\right]^{c}\left[D\right]^{d}}{\left[A\right]^{a}\left[B\right]^{b}} \cdot \frac{y_{C}^{c}y_{D}^{d}}{y_{A}^{a}y_{B}^{b}} = K \cdot \frac{y_{C}^{c}y_{D}^{d}}{y_{A}^{a}y_{B}^{b}}$$

- Activity coefficients, theory Debye-Hückel:
  - Molal activity coefficients  $\gamma$
  - Molar activity coefficients y
  - Molar fraction, activity coefficients f

# Requirements for analytical reactions

- Strong electrolytes
  - Debye-Hückel:
    - log  $\gamma$  = 0.5115 ·  $z_i^2 \sqrt{(I)/[1+\sqrt{(I)}]}$  25°C,  $z_i$  ion charge, I = ½ $\Sigma c_i z_i^2$  ionic strength

valid for c< 10<sup>-3</sup> mol/l

limit D-H relation:  $-\log y_i = 0.5115 z_i^2 \sqrt{(I)}$ 

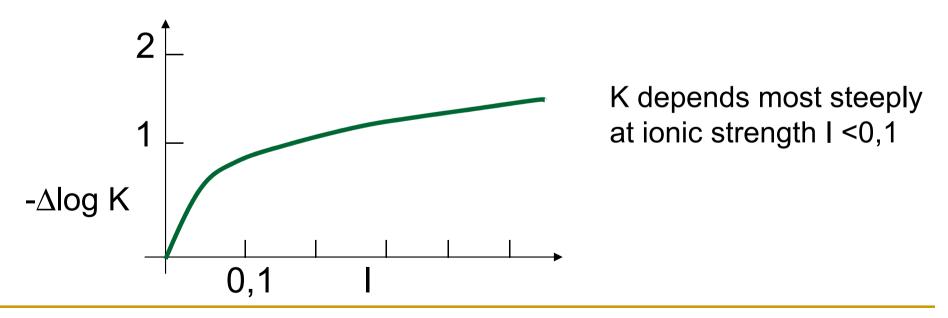

- Weak electrolytes (in the absence of strong electrolytes)
  - Activity = molar concentration, valid for molecules without charge up to c < 0,1 mol/l (non-dissociated weak electrolytes)</li>
- Nonelectrolytes (in presence of strong electrolytes)
  - For concentrations  $c_0 < 0.5$  mol/l and l < 5 je

#### $\log y_0 = k \cdot I$

□ Activity of nonelectrolytes increases in presence of ions  $\Rightarrow$  their solubility decreases (salting out of solutions)

## Thermodynamic and concentration equilibrium constants

- $K_a = \lim (\log K) \text{ for } I \rightarrow 0$
- $\log K = \log (K_a) + \Delta \log K$
- $\Delta \log K = \log K \log (K_a) = \Delta z_i^2 (\sqrt{(I)}/[1+\sqrt{(I)}] 0,3I)$
- $\Delta z_i^2$  = algebraic sum of charges,  $\Delta z_i^2$  of products >0,  $\Delta z_i^2$  of reactants < 0

## Completness of reaction from equilibrium constant

 $aA + bB \Leftrightarrow cC + dD$ 

 $c_A$ ,  $c_B$  initial concentrations of reactants, conversion to 99,90 % at equilibrium [A] = [B] = 0,001 c\_A, [C] = [D] = 0,999 c<sub>A</sub>

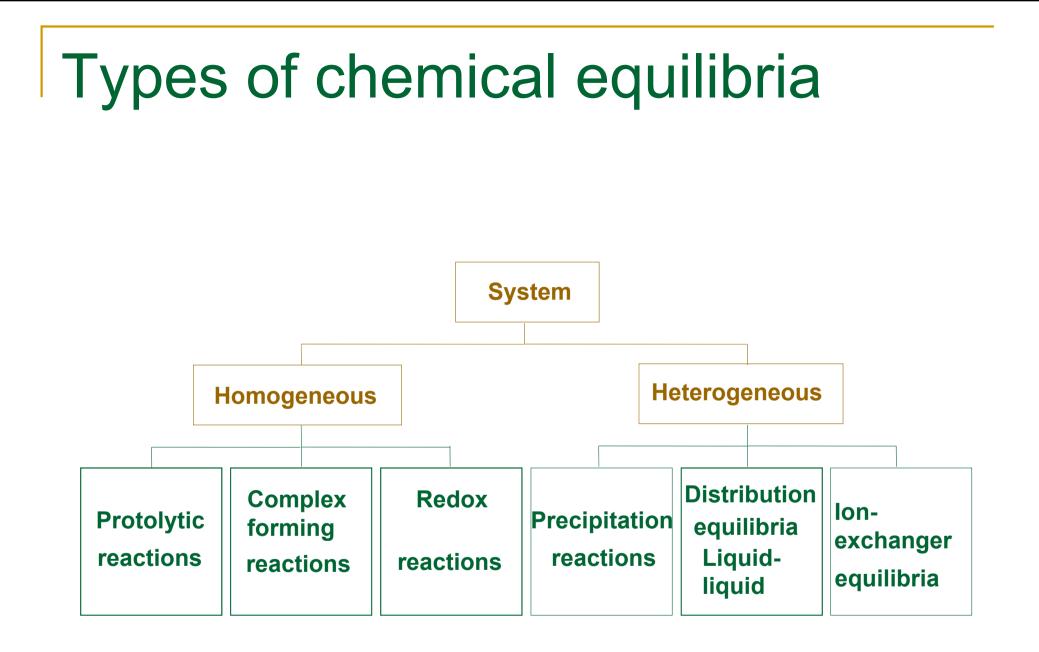

$$K = \frac{0,999^2}{0,001^2} = 9,98 \cdot 10^5 = 10^6$$

je-li K =  $10^6 \Rightarrow 99,9\%$ conversion to products K=  $x^2/(1-x)^2$ 

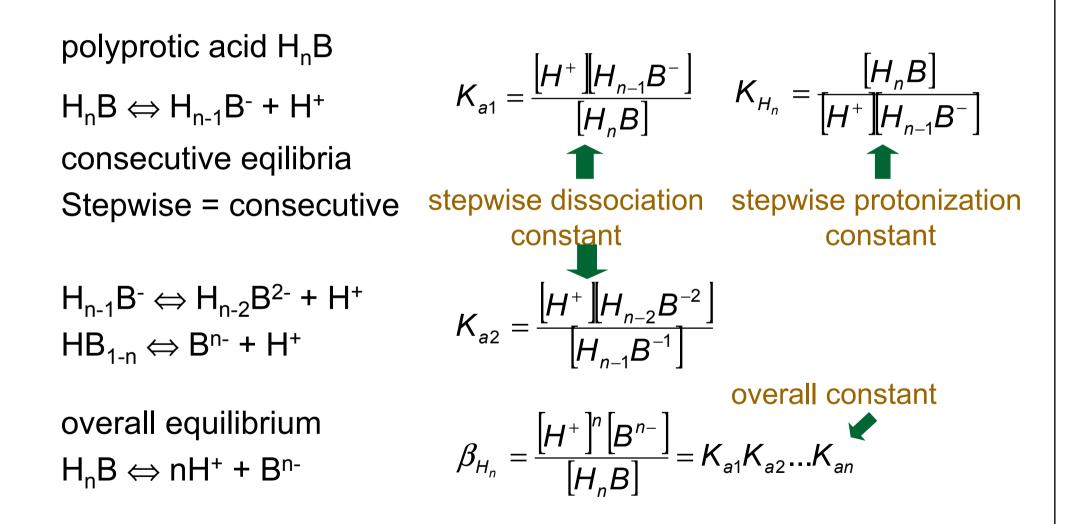

posun rovnováhy nadbytkem činidla
 (fotometrie, gravimetrie, extrakce) × rušení, vedlejší reakce

## Effect of reaction kinetics

- Halftime of reaction < 10 s, titration, redox processes at  $n_1 \neq n_2$  are slow
- Exploitation in kinetic methods determination of concentrations from time dependences
- Increase in the reaction rate: heating, transfer to reaction complex using catalyst

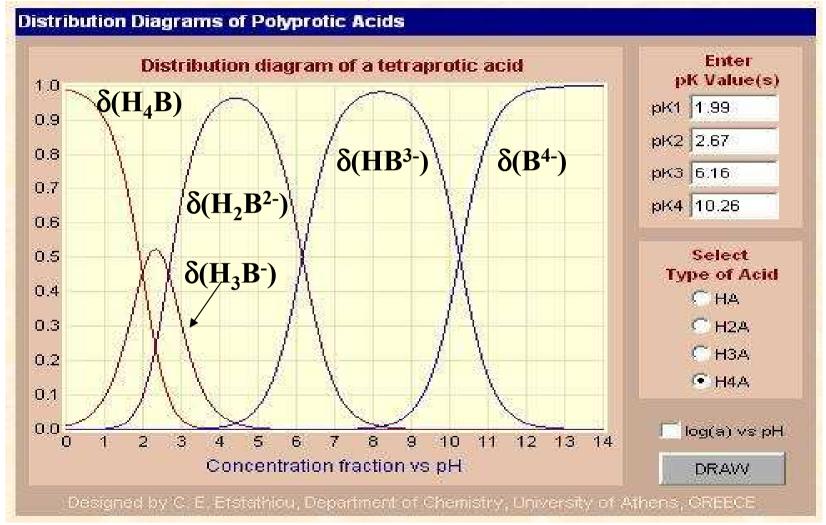

## Protolytic equilibria

## Protolytic equilibria

#### Distribution diagram of H<sub>4</sub>B acid

## Protolytic equilibria

- 2 conjugated acid-base pairs
- Acid-base equilibrium of amphiprotic solvent= autoprotolysis
   2 SH ⇔ SH<sub>2</sub><sup>+</sup>+ S<sup>-</sup> K<sub>SH</sub>= [SH<sub>2</sub><sup>+</sup>][S<sup>-</sup>]
- Protolytic equilibrium of acid
  HB + SH  $\Leftrightarrow$  SH<sub>2</sub><sup>+</sup> + B<sup>-</sup>
  [SH] >> [HB], [B<sup>-</sup>], [SH<sub>2</sub><sup>+</sup>]
- Dissociation constant of base  $NH_4OH \Leftrightarrow NH_4^+ + OH^- \qquad \longrightarrow \qquad K_b = \frac{[NH_4^+][OH^-]}{[NH_4OH]}$
- Acidic dissociation constant of base  $NH_4^+ \Leftrightarrow NH_3 + H^+$   $K_a = \frac{[NH_3][H^+]}{[NH_4^+]}$
- K<sub>a</sub>K<sub>b</sub>=K<sub>w</sub>= [H<sup>+</sup>][OH<sup>-</sup>] ion product of water (self-ionization)

#### Complex:

- □ Coordination compound– association equilibrium: m M + n L  $\Leftrightarrow$  M<sub>m</sub>L<sub>n</sub> M - centr. ion, L - ligand
- Cumulative (overall) stability (formation)
   Constant β<sub>nm</sub>
- Consecutive stability constants K:
  - $\Box \quad \mathsf{M} + \mathsf{L} \Leftrightarrow \mathsf{ML}$

$$ML + L \Leftrightarrow ML_2 \qquad K_1 = \frac{[ML]}{[M][L]} \qquad K_2 = \frac{[ML_2]}{[ML][L]}$$

- Bjerrum formation function  $\overline{n}$ :
  - Average number of particles of ligand L bound to the central ion M at the overall composition of the complex forming system

$$\beta_{nm} = \frac{[M_m L_n]}{[M]^m [L]^n}$$

Bjerrum formation function

$$\overline{n} = \frac{c_L - [L]}{c_M} = \frac{\sum_{k=1}^n k\beta_k [L]^k}{1 + \sum_{k=1}^n \beta_k [L]^k}$$

c<sub>M</sub> and c<sub>L</sub> – total (analytical) concentrations of metal (ion) and ligand [L]

$$c_{L} - [L] = [ML] + 2 [ML_{2}] + \dots + n [ML_{n}] = \beta_{1}[M][L] + 2 \beta_{2}[M][L]^{2} + \dots + n \beta_{n} [M][L]^{n} = \sum_{k=1}^{n} [M]k\beta_{k}[L]^{k} = [M]\sum_{k=1}^{n} k\beta_{k}[L]^{k}$$

 $c_M = [M] + [ML] + ... + [ML_n] = [M] + [M] \beta_1 [L] + ... + [M] \beta_n [L]^n =$ 

= [M] {1 +  $\beta_1$  [L] +...+  $\beta_n$  [L]<sup>n</sup>} =

- Distribution coefficient indicates the relative share of individual
- Distribution coefficient matrix complexes  $\delta_{k} = [ML_{k}]/c_{M}$   $\delta_{k} = \frac{\beta_{k}[L]^{k}}{1 + \sum_{k=1}^{n} \beta_{k}[L]^{k}} = \frac{\beta_{k}[L]^{k}}{\alpha_{M(L)}}$   $\alpha_{M(L)} = \text{side reaction coefficient}$

$$\overline{n} = \delta_1 + 2\delta_2 + \dots k\delta_k + \dots n\delta_n^{\mathsf{M}(\mathsf{L})} = \text{side reaction coefficient}$$
Conditional stability constant
conditioned concentration (asterisk)
$$\beta_{ML}^* = \frac{\left[ML^*\right]}{\left[M^*\right]L^*}$$

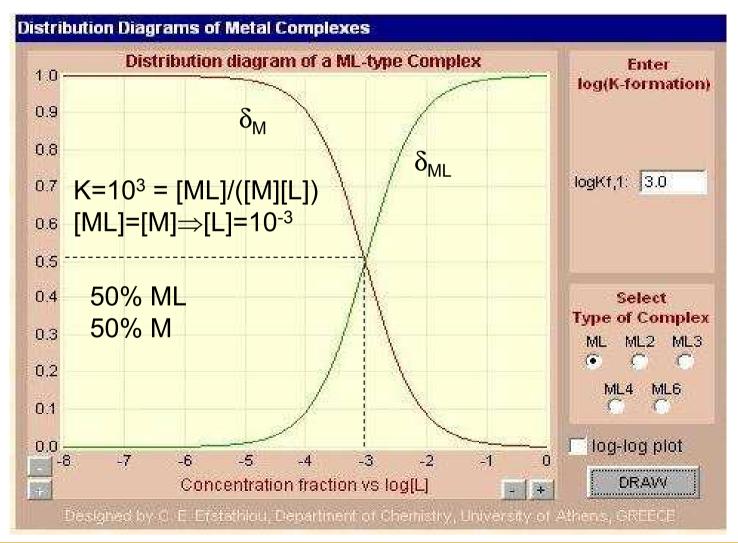

Conditional stability constant conditioned concentration (asterisk)

$$[ML^*] = [ML] + [MHL] + ... = \alpha_{ML} [ML]$$
  
$$[M^*] = c_M - [ML^*] = [M] + [MOH] + ... = \alpha_M [M]$$
  
$$[L^*] = c_L - [ML^*] = [L] + [HL] + ... = \alpha_L [L]$$

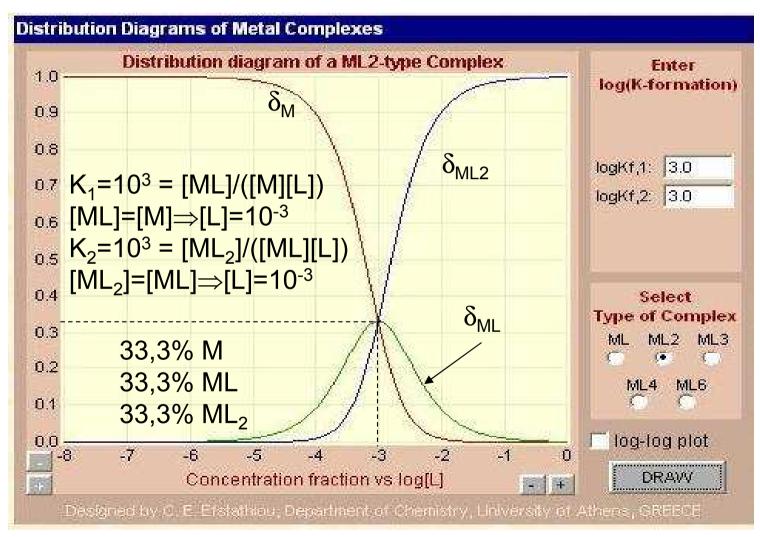

$$\beta_{ML}^{*} = \beta_{ML} \frac{\alpha_{ML}}{\alpha_{M} - \alpha_{L}}$$

 $\alpha_{MI}$  = side reaction coefficient

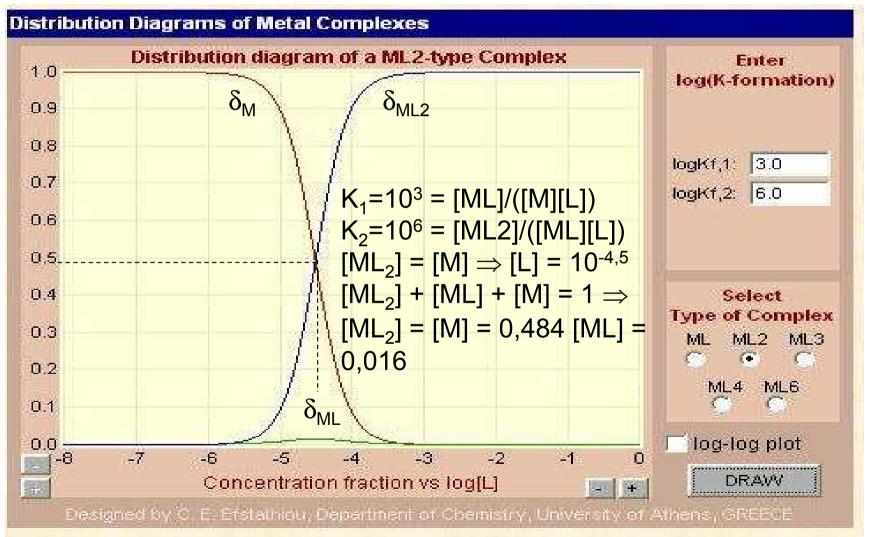

distribution diagram of complex ML (1:1), log K = 3,0

• distribution diagram of complexes ML a ML<sub>2</sub>, log  $K_1 = \log K_2 = 3,0$ 

distribution diagram of complexes ML and ML<sub>2</sub>, log  $K_1 = 3 \log K_2 = 6,0$ 

## Solubility equilibria

- $M_m N_n (s) \Leftrightarrow M_m N_n \Leftrightarrow m M^{n+} + n N^{m-}$   $I \qquad II \qquad III \qquad III$
- Strong electrolytes:
  - In polar solvent I + III
  - In non-polar solvent I + II
- Weak electrolytes: in polar solvent I + II + III
- Chemical potential

Gibbs energy Partial molar free enthalpy

$$= \left(\frac{\partial G}{\partial n_i}\right)_{T,P,n_{j\neq j}}$$

- Isothermal-isobaric process
  - $\Box \quad G = U + pV TS = H TS$

is work associated with the transfer of 1 mole of solute from the state of unit activity to activity a<sub>i</sub>

 $\mu_i$ 

## Solubility equilibria

- Equilibrium between solid phase and saturated solution  $\Delta G = 0$ □  $\mu_I = \mu_{III} = m\mu_M^0 + mRT \cdot \ln a_M + n\mu_N^0 + nRT \cdot \ln a_N$
- Activities are constant and unit in solid phase

$$\square \quad \mu_{I}^{0} = \mu_{III}^{0} + RT \cdot In a_{M}^{m} \cdot a_{N}^{n}$$

- Solubility product constant (K<sub>s</sub>)<sub>a</sub> = a<sub>M</sub><sup>m</sup> · a<sub>N</sub><sup>n</sup>, const. at const. T
- $a_M = [M^{n+}] \cdot y_M$   $a_N = [N^{m-}] \cdot y_N$   $K_s = [M^{n+}]^m [N^{m-}]^n = (K_s)_a / (y_M \cdot y_N)$  $\Rightarrow$  for a certain value of ionic strenght
- Conditional solubility product  $K_S^* = K_S \cdot (\alpha_{M(L)})^m (\alpha_{N(H)})^n$
- Electrolyte solubility: c [mol/l]
  - □ Stoichiometry of precipitate:  $n(M_mN_n) : nM : nN = 1 : m : n \Rightarrow [M^{n+}] = m \cdot c , [N^{m-}] = n \cdot c$  $\boxed{K_S}$

$$\Rightarrow C = {}^{m+n} \sqrt{\frac{\kappa_s}{m^m \cdot n^n}}$$

## Redox equilibria

- Redox processes
   – electric work is exerted × protolytic and complex forming equilibria
- Electric work is associated with transfer of n = n<sub>A</sub>n<sub>B</sub> electrons from reduced form of substance B onto oxidized form of substance A:

$$-\Delta G = n_A n_B F E^{\circ}$$

where  $n_A$ ,  $n_B$  are amounts of substances, F is Faraday constant (96 484 C mol<sup>-1</sup>) and E° is standard cell voltage

Redox pairs = partial reactions:

$$\begin{array}{ll} \mathsf{A}_{\mathsf{ox}} + \mathsf{n}_{\mathsf{A}}\mathsf{e}^{\scriptscriptstyle{-}} \Leftrightarrow \mathsf{A}_{\mathsf{red}} & \mathsf{E}_{\mathsf{A}}^{\circ} \\ \mathsf{B}_{\mathsf{ox}} + \mathsf{n}_{\mathsf{B}}\mathsf{e}^{\scriptscriptstyle{-}} \Leftrightarrow \mathsf{B}_{\mathsf{red}} & \mathsf{E}_{\mathsf{B}}^{\circ} \end{array}$$

Nernst-Peters equation:

 $E_A = E_A^{\circ} + [RT/(n_AF)]ln(a_{Aox}/a_{Ared})$ standard H-electrode, p = 101,32 kPa,  $a_{H^+} = 1$ , c = 1,18 mol/l HCl, Pt black, H<sub>2</sub> gaseous

 $2H^{+} + 2e^{-} \Leftrightarrow H_{2}(g)$ 

## Redox equilibria

•  $E_{H^+/H^2}^0 = 0$ ;  $E_A^o > 0$ ;  $A_{ox}$  is stronger oxidant than H<sup>+</sup>  $E_A^o < 0$ ;  $A_{red}$  is stroger reductant than H<sub>2</sub>

•  $\Delta G^0 = RT \ln (K_a) \Rightarrow \log (K_a) = -\Delta G^0/(2,303RT) =$ =  $n_A \cdot n_B \cdot F \cdot E^0/(2,303 RT)$ ;  $E^0 = E_A^0 - E_B^0$ : "total conversion" (99,9 %) at  $n_A = n_B$  is at  $K_a = 10^6$ 

■ T = 25 °C

# Sampling and sample preparation for analysis

- composition of the analyzed sample must correspond to the composition of the examined substances
  - Sampling of solids ČSN 650611, liquids ČSN 650512
- Sampling involves two operations
  - gross sample collection from analyzed substance
    - gross sample sample portion taken from analyzed substance; from solid material – it is processed by mechanical mixing, quartering, splitting, grinding, sieving and gradual sample reduction
  - analytical sample collection from gross sample
    - analytický vzorek must have identical composition with analyzed material

### A) Dissolution in

- 1) water
- 2) acids
- 3) hydroxides

#### "Wet" decomposition:

- □ HCI, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, HClO<sub>4</sub>, HF
- Beakers, dishes, pressurized autoclaves: glass, quartz, porcelain, PTFE
- heating: gas burner, hotplate, microwave oven

### B) Fusion

- 1) acid
- 2) alkaline

#### "Dry" decomposition:

- Sodium carbonate, potassium carbonate, borax, disulphate, hydroxides
   – conversion to salts dissoluble in acids and in H<sub>2</sub>O
- Crucibles Pt, Ni, Fe, glassy graphite
- Burner, muffle furnace

#### Dissolution

spontaneous process in which particles are released from the range of forces, which bind them in solid phase by the effect of solvation forces that stabilize the particles in solution

#### Solvent

- Liquid capable of dissolving gases, liquids or solids, without chemically reacting with them
- Most important water

- Decomposition in acids
  - □ HCI, diluted 1+1 (6 mol/I), without the effect of oxidation
    - dissolves:
      - 1) Metal with negative reduction potential
      - 2) Alloys Fe s Cr, Co, Ni, Ti
      - 3) Salts of weak acids
      - 4) Carbonate ores
      - 5) Oxidic ores (Zn, Mn, Fe)
      - 6) Hydrolytic products (BiOCI)
    - does not dissolve:
      - 1) Bauxite, corindum
      - 2) spinels  $M^{II}O \cdot M^{III}_2O_3$

- HNO<sub>3</sub>, diluted1+1 (cca 4,6 mol/l, 30%), conc. too, oxidation effects, nitrates soluble
  - dissloves:
    - 1) Most of metals with exception of Au and platinum group metals
    - 2) alloys: Bi, Cd, Cu, Pb, Fe-Mn, Fe-P
    - 3) ores: Cu, Mo, Co, Ni
  - $\blacksquare M^{||} + 2 \operatorname{NO}_{3^{-}} + 8 \operatorname{H}^{+} \Leftrightarrow 3 \operatorname{M}^{2+} + 2 \operatorname{NO} + 4 \operatorname{H}_{2}\operatorname{O}$
  - As, Sb transferred into solution  $(H_3AsO_3)$
  - Sn precipitates stannic acid:

 $Sn + 4 NO_3^- + 4 H^+ + (x-2) H_2O \Leftrightarrow SnO_2^- x H_2O + 4NO_2^-$ 

- Concentrated HNO<sub>3</sub>
  - Passivation AI, Cr, Fe
  - Oxidation of organic compounds

### □ HCI + HNO<sub>3</sub> (3+1) aqua regia

### dissolves:

- 1) PGM and Au
- 2) Ores and some silicates
- 3) phosphides, arsenides, antimonides, sulphides  $\Rightarrow$  acids: phosphoric, arsenic, chloroantimonic
- Active component Cl<sub>2</sub> a NOCI

$$HNO_{3} + 3 HCI \Rightarrow NOCI + CI_{2} + 2H_{2}O$$

$$2 NOCI \Rightarrow 2 NO + CI_{2}$$

$$2 NO + O_{2} \Rightarrow 2 NO_{2}$$

$$Hg + 2 NOCI \Rightarrow HgCI_{2} + 2 NO$$

$$Au + 3/2 CI_{2} + HCI \Rightarrow [AuCI_{4}]^{-} + H^{+}$$

# Transferring the sample into aHF conc.Solution

Decomposes all silicates:

 $SiO_2$  + 4 HF  $\Leftrightarrow$   $SiF_4$  + 2 H<sub>2</sub>O

- Rocks, ores (Nb, Ta, W), glasses, ceramics, alloys
- Used in mixture with H<sub>2</sub>SO<sub>4</sub> orHClO<sub>4</sub> (increased boiling point), H<sub>2</sub>SO<sub>4</sub> binds water and prevents thus hydrolysis, perchloric acid exhibits oxidative effects

### $\Box H_2 SO_4$

- Diluted behaves as HCI:
  - □ alone limited use, sulphates less soluble than chlorides
- Concentrated
  - Oxidative effects, diss. Sb:

2 Sb + 6  $H_2SO_4 \Rightarrow$  2 Sb<sup>3+</sup>+ 3 SO<sub>4</sub><sup>2-</sup> + 3 SO<sub>2</sub> + 6  $H_2O$ 

- $\hfill\square$  phosphides, arsenides  $\Rightarrow$  phosphoric and arsenic acids
- □ Kjeldalization mineralization of organic nitrogen containing substances

- HCIO<sub>4</sub> conc. (72%) exhibits oxidative effects at elevated temperature
  - dissolves:
    - 1) steels(Cr, Si, V, P)
    - 2) carbides
    - 3) In mixture with HF for decomposition of silicates
  - advantage: soluble salts
  - disadvantage: explosive with organic compunds
- $\square H_3PO_4$ 
  - 1) alloys
  - 2) ferrovanadium, ferrosilicium, ferrochromium, ferroboron

- Decomposition in hydroxides
  - NaOH, KOH (35%)
    - dissolves:
      - 1) Light alloys (Al, Zn, Si, Mg), resulting aluminates, zincates, silicates:

 $2 \text{ AI} + 2 \text{ OH}^{-} + 6 \text{ H}_2\text{O} \Leftrightarrow 2 [\text{AI}(\text{OH})_4]^{-} + 3 \text{ H}_2$  $\text{Mg} + 2 \text{ H}_2\text{O} \Leftrightarrow \text{Mg}(\text{OH})_2 + \text{H}_2$ 

#### Fusion

- process, where high-temperature heated material changes from solid to liquid
  - Resulting products are dissoluble in water or dissolved acids
  - According to fusion agent: alkaline and acidic fusion
    - Alkaline fusion: transfer of acidic components (silicates, sulphates) in a solution by melting, flux is anhydrous sodium carbonate or a mixture of sodium carbonate and potassium
    - Acidic fusion: conversion of base-forming oxides to soluble salts (metal oxides, etc.). Transfer into solution by fusion with potassium sulphate, or sodium tetraborate.

#### Fusion agents

- Reagents used for decomposition by fusion
- Alkaline fusion: sodium carbonate, alkaline hydroxide, mixture of sodium carbonate and sulphur; for acidic fusion: potassium disulphate, boron oxid, boric acid, sodium tetraborate

## Převádění vzorku do roztoku

### Alkaline fusion

 decomposed: quartz, glass, porcelain, enamels, cement, aluminosilicates

### $\square Na_2CO_3$

- 1) Aluminosilicates are converted into soluble alkaline aluminates and silicates
- 2) Other oxides are converted to carbonates or depolymerize and in HCI are converted into soluble chlorides

### NaOH, KOH

fusion in crucibles Ag, Ni or Fe

decomposed: ores W, Sn, Cr, Ti, Sb, Zr, corindum, bauxit, partially silicates

### □ Li<sub>2</sub>B<sub>4</sub>O<sub>7</sub>, LiBO<sub>2</sub>

1) Formation of borate glasses soluble in diluted acids –Si retained in solution

## Převádění vzorku do roztoku

### Sintration

- Reaction i solid phase at increased temperature but below the melting point of sintration reagent (Na<sub>2</sub>O<sub>2</sub>)
- Pt crucibles, sintered material soluble in water

## Převádění vzorku do roztoku

- Acidic fusion
  - $\Box \text{ KHSO}_4, \text{ K}_2\text{S}_2\text{O}_7$

 $\begin{array}{l} 2 \hspace{0.1cm} \mathsf{KHSO}_4 \Leftrightarrow \mathsf{K}_2\mathsf{S}_2\mathsf{O}_7 + \mathsf{H}_2\mathsf{O} \\ \mathsf{TiO}_2 + 2 \hspace{0.1cm} \mathsf{K}_2\mathsf{S}_2\mathsf{O}_7 \Leftrightarrow \mathsf{Ti}(\mathsf{SO}_4)_2 + 2 \hspace{0.1cm} \mathsf{K}_2\mathsf{SO}_4 \end{array}$ 

- decomposed: aluminates, spinels, ores Cu, Sb, Ni, Ti
- Leaching of sulphates Zr a Ti at cold by addition of H<sub>2</sub>SO<sub>4</sub>
- Active constituent is SO<sub>3</sub>

$$\begin{split} & \mathsf{S}_2\mathsf{O}_7^{2\text{-}} \Leftrightarrow \mathsf{SO}_4^{2\text{-}} + \mathsf{SO}_3 \\ & \mathsf{Al}_2\mathsf{O}_3 + 3 \; \mathsf{SO}_3 \Leftrightarrow 2 \; \mathsf{Al}^{3\text{+}} + 3 \; \mathsf{SO}_4^{2\text{-}} \\ & \mathsf{TiO}_2 + 2 \; \mathsf{SO}_3 \; \Leftrightarrow \mathsf{Ti}^{4\text{+}} + 2 \; \mathsf{SO}_4^{2\text{-}} \end{split}$$
