1. Horniny – náhodné ale i cílené sběry

The Stone Age marks a period of prehistory in which humans used primitive stone tools. Lasting roughly 2.5 million years, the Stone Age ended around 5,000 years ago when humans in the Near East began working with metal and making tools and weapons from bronze.

https://www.history.com/topics/pre-history/stone-age

Humans weren't the first to make or use stone tools. That honor appears to belong to the ancient species that lived on the shores of Lake Turkana, in Kenya, some 3.3 million years ago. First discovered in 2011, these more primitive tools were created some 700,000 years before the earliest members of the Homo genus emerged.

Paleolithic Art in the Roucadour cave, Themines, Quercy, Lot, France.

The paintings and engravings in the Roucadour cave, France, are attributed to the oldest phase of Paleolithic Art in Quercy, between 28,000 and 24,000 years BP.

Jadeite axes from the Neolithic Period in central Europe. Vzácnější materiál i místo výskytu – rozsáhlejší těžba na místě a obchod

Nejstarší systematická těžba

Based on archaeological records, the world's oldest mine is the Lion Caves located in Swaziland, South Africa. Once tested radiokarbon, the old mine came from 43,000 years ago. One of the interesting things about Lion Caves is that the mine is a pigment mine. Mining of red ocher, pigments by primitive people as body paint for their rituals. The amount of material moved is quite impressive. Approximately 50-100 tons are regularly mined.

Multiple-block extraction on descending platforms in the New Kingdom to Late Period part of the el-Sawayta limestone quarry near Samalut and Minya. Photo by JAMES HARRELL.

But the possibility of mining in the Nile River Valley is older. There are four old mining sites reported around the Nile, Qena and Nazlet Safaha that have existed since 50,000 years ago, while Nazlet Khater and Beit Allam, have existed since 60,000 years ago. All the old mining sites are stone quarries.

Bylo nalezeno 575 ručních seker

...Simbiro III level C, in the upper Awash valley of Ethiopia, allows us to test this assumption in its assemblage of stone tools made only with obsidian, dated to more than 1.2 million years (Myr) old. Here we first reconstruct the palaeoenvironment, showing that the landscape was seasonally flooded. Following the deposition of an accumulation of obsidian cobbles by a meandering river, hominins began to exploit these in new ways, producing large tools with sharp cutting edges. We show through statistical analysis that this was a focused activity, that very standardized handaxes were produced and that this was a stone-tool workshop....

highly organised flint mining is being studied in Belarus.

Neolithic Flint Mines at Spiennes (Mons)

Spiennes, minière du Camp-à-Cayaux © SPW

Grime's Graves: A Neolithic Flint Mine, Norfolk, UK Beginning around 5,000 years ago, and continuing for an entire millennium, Stone Age peoples mined 'floorstone' flint beneath more than 10 meters of chalk.

Grimes Graves is one of a series of mines dug in prehistoric sussex following a rich seam of flint bearing chalk. Other shafts were dug before at nearby harrow hill and a further 200 shafts were dug at cissbury.

Sklo

These two cobalt-blue glass beads, found in 3,400-year-old graves in Denmark, came from ancient Egypt, probably via extensive European trade routes, according to new research. A. MIKKELSEN, NATIONAL MUSEUM OF DENMARK https://www.sciencenews.org/article/ancient-egyptian-blue-glassbeads-reached-scandinavia

...dates from between late First Century B.C. to early First Century A.D and stands 13in (33.5cm) high, they are formed from two layers of glass – cobalt blue with a layer of white on top – which is cut down after cooling to create the cameo-style decoration

Glass as an independent object (mostly as beads) dates back to about 2500 BC. It originated perhaps in Mesopotamia and was brought later to Egypt. Vessels of glass appeared about 1450 BC, during the reign of Thutmose III, a pharaoh of the 18th dynasty of Egypt. A glass bottle bearing Thutmose's hieroglyph is in the British Museum in London. From Mesopotamia and Egypt, glassmaking using the basic soda-lime-silica composition traveled to Phoenicia, along the coast of presentday Lebanon.

The Romans and Egyptians probably used sand mixed with ground seashells as raw materials for silica and lime and hardwood ash as the source of soda. They also showed astonishing skill in the way they used metallic oxides as colorizers. Very small differences in oxide content can drastically affect the final colour of a glass; yet colours and tints were reproduced time and again with remarkable consistency. Copper was used to make green and ruby-red glass; iron produced black, brown, and green; antimony, yellow; manganese was employed to make purple and amethyst glass. An opaque white glass, made by using tin, was important in glass cameo work, of which the famous Portland vase, made in 1stcentury Rome, is an outstanding example.

Two different sources of alkali affected the composition of early glasses. On the Eastern Mediterranean littoral natron (hydrated Na2CO3) was usually the favored alkali, because it was available from northern Egypt. Further east, in Mesopotamia and Persia, the alkali was usually provided by plant ash that contained more K2O (2%-4%) and MgO (2%-6%).

The Portland Vase is a Roman cameo glass vase, which dates between 1 A.D. and 25 A.D..

Bronz - doba bronzová - zdroje

Great Orme on the north Welsh coast was an exception, becoming the first industrially worked copper mine, dominating production from 1500 to 1200 BC. Copper is mined from green malachite and it is estimated that in the Bronze Age over 40,000 tonnes of ore-bearing rock were removed from the site of the underground mine and the opencast surface mine. This could have produced around 1,700 tonnes of copper ore, enough to make 10 million bronze axes.

Timberlake offers 2100 BC as a date for the beginning of tin extraction in Cornwall - alluvial tin – casiterite (gold extraction as well!) (Timberlake 2017).

Železo - doba železná

A smelting furnace from the Late Iron Age/Middle Ages, Norway

Železná houba (současná) ze železářské pece a nálezy hotových výkovků Modern archaeological evidence identifies the start of large-scale iron production in around 1200 BC, marking the end of the Bronze Age. Between 1200 BC and 1000 BC diffusion in the understanding of iron metallurgy and the use of iron objects was fast and far-flung. Anthony Snodgrass suggests that a shortage of tin, as a part of the Bronze Age Collapse and trade disruptions in the Mediterranean around 1300 BC, forced metalworkers to seek an alternative to bronze.

The spreading of iron technology after 1200 BC

...až ocel

1751 Sheffield, ...a další pokroky v metalurgii

Výroba oceli je metalurgický postup získání oceli, technické slitiny železa s nižším obsahem uhlíku, než mají litiny, ze surového železa odstraňováním přebytečného uhlíku a dalších nežádoucích prvků, jako je fosfor a síra, a dodáním žádoucích legujících prvků, např. manganu, silikonu-křemíku a dalších: Cr, Mo, W, Ni, Co. Akashi Kaikyō Bridge – Kobe, Japan The Akashi Kaikyo Bridge – also known as the Pearl Bridge – is the longest suspension bridge in the world spanning 1991 metres in length. The central span length of the bridge is about twice as long as any other suspension bridge in the world, however, a central girder still had to be erected. The girder dives almost 60m into the ocean and can support a vertical force of 120,000 tonnes. An engineering marvel, the Akashi Kaikyō Bridge can withstand extremely high winds and even earthquakes.

Whilst terrestrial iron is naturally abundant, temperatures above 1,250 °C (2,280 °F) are required to smelt it, placing it out of reach of commonly available technology until the end of the second millennium BC. In contrast, the components of bronze -- tin with a melting point of 231.9 °C (449.4 °F) and copper with a relatively mpderate melting point of 1,085 °C (1,985 °F) -- were within the capabilities of Neolithic kilns, which date back to 6000 BC and were able to produce temperatures greater than 900 °C (1,650 °F). In addition to specially designed furnaces, ancient iron production required the development of complex procedures for the removal of impurities, the regulation of the admixture of carbon, and the invention of hotworking to achieve a useful balance of hardness and strength in steel.

The origin of hydraulic cements goes back to ancient Greece and Rome. The materials used were lime and a volcanic ash that slowly reacted with it in the presence of water to form a hard mass. This formed the cementing material of the Roman mortars and concretes of more than 2,000 years ago and of subsequent construction work in western Europe. Volcanic ash mined near what is now the city of Pozzuoli, Italy, was particularly rich in essential aluminosilicate minerals, giving rise to the classic pozzolana cement of the Roman era.

Portland cement is a successor to a hydraulic lime that was first developed by John Smeaton in 1756 when he was called in to erect the Eddystone Lighthouse off the coast of Plymouth, Devon, England. The invention of portland cement usually is attributed to Joseph Aspdin of Leeds, Yorkshire, England, who in 1824 took out a patent for a material that was produced from a synthetic mixture of limestone and clay.

Římský beton

It was previously thought that the key to Roman concrete's durability was the introduction of pozzolanic ash, a natural siliceous or siliceousaluminous material which reacts with calcium hydroxide in the presence of water at room temperature.

...A closer examination of ancient samples shows white mineral features referred to as "lime clasts," another key component in the concrete mix.

...Using high-resolution multiscale imaging and chemical mapping techniques, the researchers have determined that the white inclusions were, indeed, made out of various forms of calcium carbonate...

The Pantheon (completed around 126-128 A.D) in Rome features the world's largest unreinforced concrete dome.

IV. Průmysl 4.0 – digitalizace,...?

Industry 4.0

Industry 4.0 is known as the digitization/digitized era, where the industries are transformed with smart machines/ assets, sensors, and smart data collection processes. The IIoT is leading this whole era with other technologies like Artificial intelligence, big data, cloud computing, and CPS (Cyber-physical system). It improves automation, connectivity, and achieving higher productivity, quality, and efficiency. With this industry 4.0, the smart factories have the ability to achieve some advancements like predicting failures before it occurs (in case of any machines/assets failures) and accomplish it autonomously and also even take a decision within minutes to hours based on real-time as well as achieve competitive advantage.

Industry 4.0 is revolutionizing the way companies manufacture, improve and distribute their products. Manufacturers are integrating new technologies, including Internet of Things (IoT), cloud computing and analytics, and AI and machine learning into their production facilities and throughout their operations. This digital technologies lead to increased automation, predictive maintenance, self-optimization of process improvements and, above all, a new level of efficiencies and responsiveness to customers not previously possible. Industry 4.0 concepts and technologies can be applied across all types of industrial companies, including discrete and process manufacturing, as well as oil and gas, mining and other industrial segments.
