Start

Kohezní energie bulku

**Kohezní energie je rozdíl energie atomů vázaných v pevné látce
a energie jednotlivých atomů v plynné fázi**

$$E_c = E_{\text{tot}}(\text{A,g}) + E_{\text{tot}}(\text{B,g}) - E_{\text{tot}}(\text{AB,s}) > 0$$

Závisí na charakteru vazby:

Iontová vazba - elektrostatické síly mezi ionty, lokalizované elektrony, vysoká vazebná energie.

Kovalentní vazba - sdílení valenčních elektronů mezi sousedními atomy, orientované vazby, vysoké až střední energie vazeb.

Kovová vazba - sdílení malého množství elektronů všemi atomy krystalu, volné elektrony, nízká vazebná energie

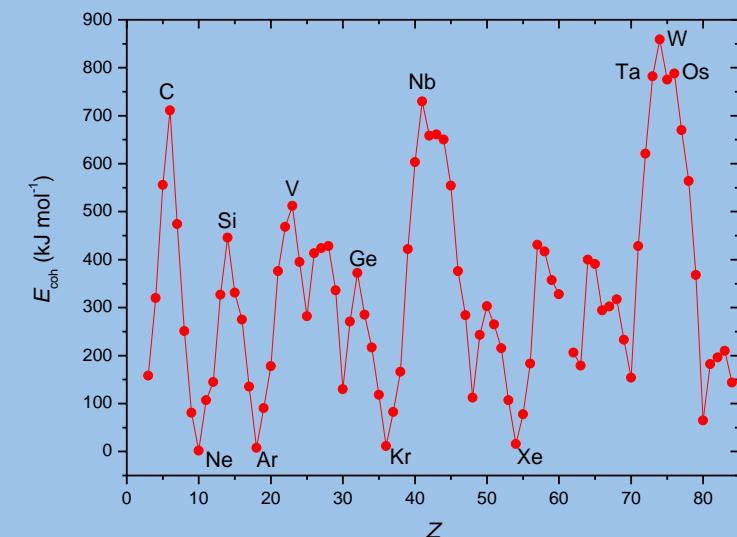

Slabé vazby - van der Waalsovy síly (dipól-ion, dipól-dipól, indukované dipoly), H-vazby

Víceatomové molekuly v plynné fázi:

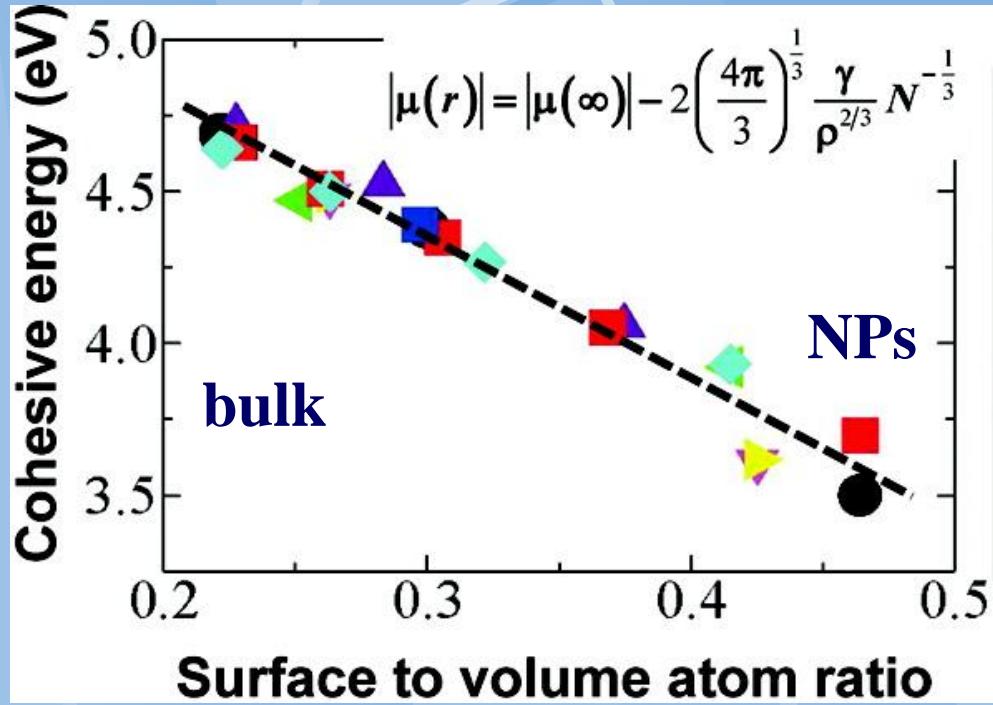

$$E_c = \frac{1}{2} E_{\text{tot}}(\text{A}_2,\text{g}) - E_{\text{tot}}(\text{A},\text{s})$$

Čisté kovy

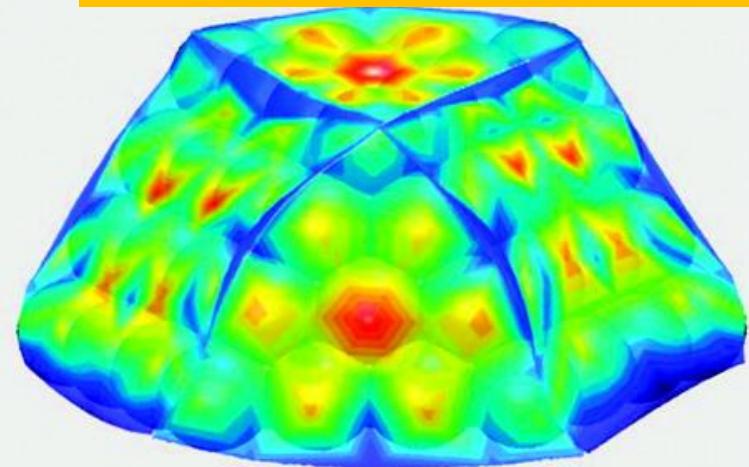

$$E_c = E_{\text{tot}}(\text{A,g}) - E_{\text{tot}}(\text{A,s})$$

Kohezivní energie NPs

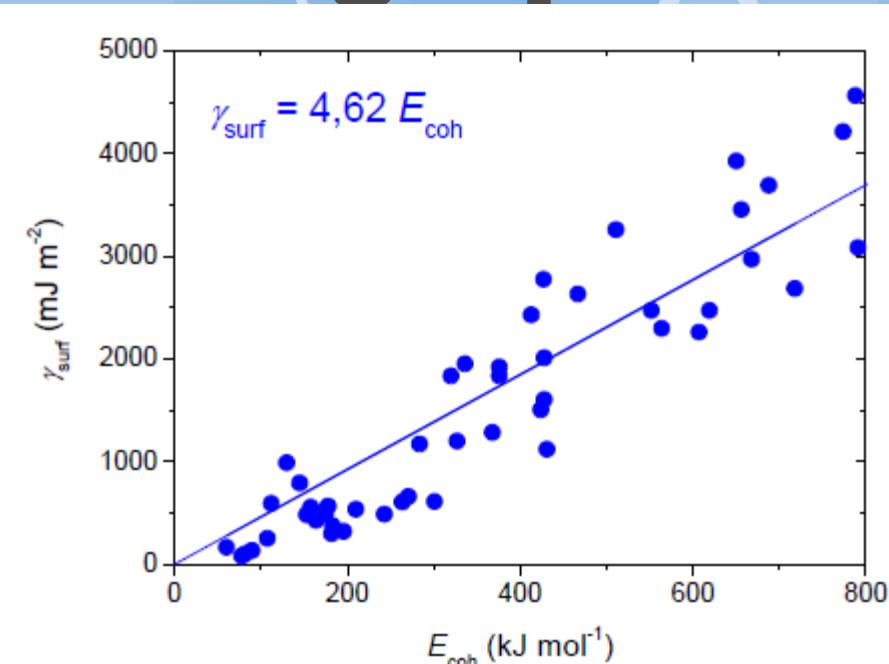

Kohezní energie není všude stejná (ab-initio výpočet):

Kohezivní energie nanočástic různých tvarů a velikosti jako funkce podílu povrchu k objemu.

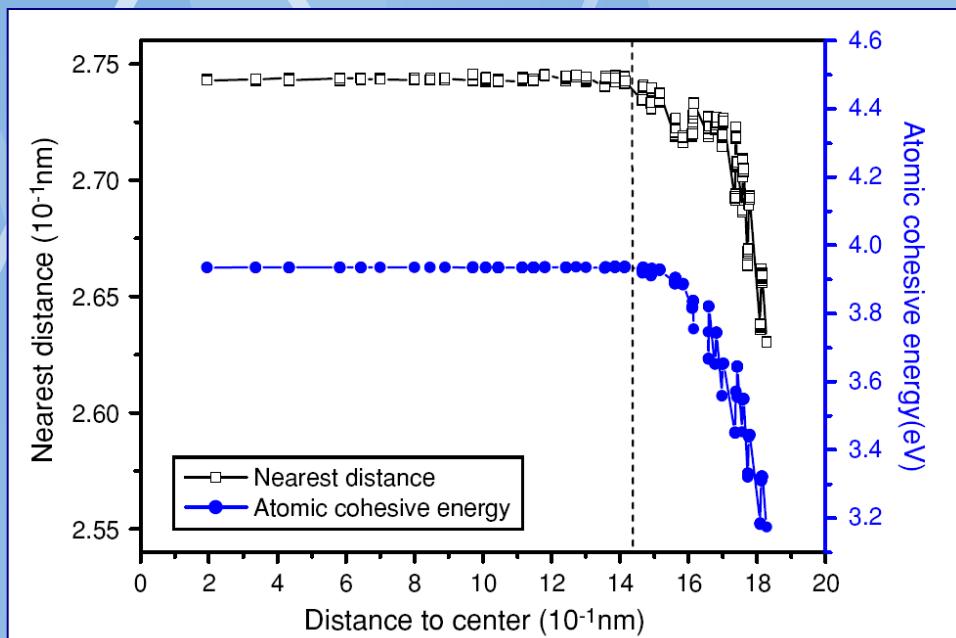

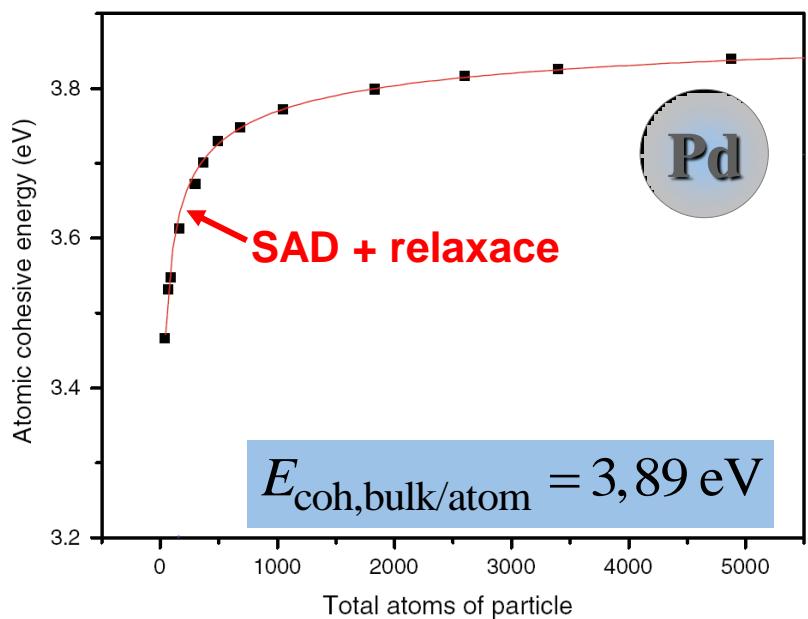

Místa náchylná k adsorpci kyslíku.

Korelace mezi povrchovou a kohezní energií pro bulk

Kohezní energie povrchu NPs

Povrchové atomy jsou vázány menším počtem kratších a pevnějších vazeb – kohezní energie $E_{\text{coh,surf/atom}} < E_{\text{c,bulk/atom}}$

Figure 2. Multi-functionalized NPs. Graphical representation of multifunctional NP for molecular imaging (functionalized with contrast agents for CT/MRI, with radiotracer for PET/SPECT), for drug delivery (functionalized with drug molecules incorporated within the core of NP or conjugated to the surface), for specific targeting (functionalized with specific ligands) and for stealth (hydrophilic surfactants). Spacer/linker molecules are also indicated

Multifunkční povrch

In the figure above, the core is based on styrene DVB. The first layer is approx. 10 nm thick, comprising EDMA and MAA. Its presence is confirmed by the before and after IR spectra, clearly showing the appearance of the carbonyl and OH stretch signals. The next layer was about 5 nm thick and composed of vinyl benzyl chloride, confirmed by the reappearance of chlorine in the elemental analysis. The final layer is about 10nm thick and composed of a polymerisable anthracene derivative. Its presence is clearly confirmed by the before and after fluorescence spectra.

a, Size-selective hydrogenation of *n*-hexene and *cis*-cyclooctene catalysed by Pt/ZIF-8 composite (3.3 nm Pt nanoparticles, Pt content 2%). Pure ZIF-8, T-Pt@ZIF-8 composite (Pt content 2%) and Pt/CNT (Pt content 5%) were used as controls. *b*, Field-dependent magnetization curve of 8 nm Fe₃O₄/ZIF-8 composite at room temperature (inset: photograph of the collection of the composite by applying a magnetic field (right) to its suspension (left)). *c*, Normalized photoluminescence spectra with excitation at 980 nm for lanthanide-doped NaYF₄ rods (50 nm × 310 nm) (dotted line) and the corresponding NaYF₄/ZIF-8 composite (solid line) in methanol (inset: photoluminescence microscope image of the NaYF₄/ZIF-8 hybrid crystals excited at 980 nm). *d*, Normalized photoluminescence spectra with excitation at 400 nm for CdTe (dotted line) and the corresponding CdTe/ZIF-8 composite in methanol (inset: photographs of the CdTe/ZIF-8 composite suspended in methanol illuminated with ambient light).
