Comparing groups Chi-square test T-test

E0420

Week 3

| Handed- ness Sex | Right-handed | Left-handed | Total | |
|------------------------|--------------|-------------|-------|--|
| Male | 43 | 9 | 52 | |
| Female | 44 | 4 | 48 | |
| Total | 87 | 13 | 100 | |

Let's analyze!

- https://stats.idre.ucla.edu/other/mult-pkg/whatstat/
- Testing associations between:
- 1 categorical independent variable (IV, predictor, exposure variable)
 - T-test can handle only 2 categories (if more, use ANOVA)
 - Chi-square is not limited by the number of categories
- 1 dependent variable (DV, outcome)
 - Categorical Chi-square test
 - Continuous T-test

Let's analyze!

- Categorical IV:
 - Gender (males vs females), type of exposure (eating fish vs not eating fish), work or school group/class (scientists vs administrators), or experimental/treatment group
- DV
 - Continuous BMI, depression score, hrs slept per night
 - Categorical presence of a diagnosis (diabetes, pregnancy, depression), success or failure
- Comparing means (T-test) or proportions (Chi-square) of a DV across 2 groups/levels of an IV
- A word about categorization of continuous IVs
 - Mean/median/tercile split
 - Change in the original information, smaller effect size, potentially spurious effects

How does Chi-square work?

- 1. Constructing contingency table (2x2 table, cross tabulation)
- = number of cases in each category
- 2. Comparing observed numbers in each category to expected numbers in each category if there is no association (= null hypothesis)
- = obtaining the χ 2 statistic
- 3. Using χ^2 distribution for specific degrees of freedom to determine how likely is the obtained χ^2 if null hypothesis is true
- = determining statistical significance (*p*-value)
- If the probability is 5% ($\alpha = .05$) or less, the $\chi 2$ is stat. sig.
- In general, large χ2 suggests rejection of null hypothesis

1. Contingency table

| | Feeling depressed | | |
|--------|-------------------|-----------|-------|
| | Yes | No | Total |
| Male | 96 (40%) | 144 (60%) | 240 |
| Female | 72 (24%) | 228 (76%) | 300 |
| Total | 168 (31%) | 372 (69%) | 540 |

Observed numbers

2. Obtaining the x2 statistic

Observed numbers

| | Feeling depressed | | |
|--------|-------------------|-----------|-------|
| | Yes | No | Total |
| Male | 96 (40%) | 144 (60%) | 240 |
| Female | 72 (24%) | 228 (76%) | 300 |
| Total | 168 (31%) | 372 (69%) | 540 |

Expected numbers

| | Feeling depressed | | |
|--------|-------------------|-----------|-------|
| | Yes | No | Total |
| Male | 75 | 165 | 240 |
| Female | 93 | 207 | 300 |
| Total | 168 (31%) | 372 (69%) | 540 |

2. Obtaining the x2 statistic

$$\chi^2 = \sum rac{\left(O_i - E_i
ight)^2}{E_i}$$

 χ^2 = chi squared

 O_i = observed value

 E_i = expected value

• In our case, χ 2 = 15.97

3. Determining statistical significance

- degrees of freedom (df) = (r-1)(c-1) where r is the number of rows and c is the number of columns
- Critical value is based on the selected alpha level and df
- In our case, $\chi 2 = 15.97$

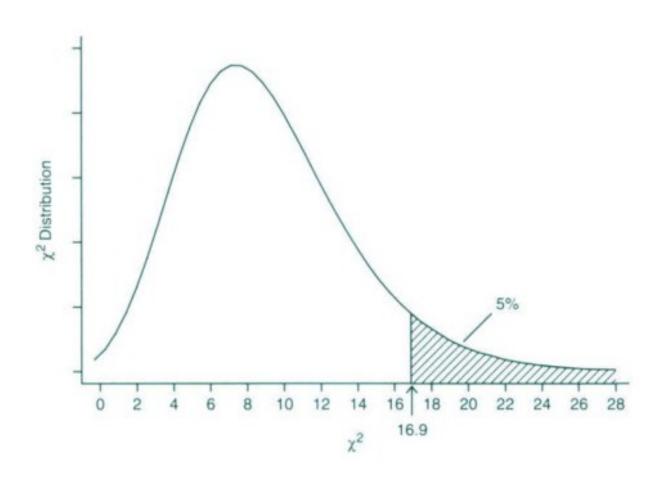

Critical values of the Chi-square distribution with *d* degrees of freedom

and a second transition of the second

| | Probability of exceeding the critical value | | | | | | | |
|----|---|--------|--------|----|--------|--------|--------|--|
| d | 0.05 | 0.01 | 0.001 | d | 0.05 | 0.01 | 0.001 | |
| 1 | 3.841 | 6.635 | 10.828 | 11 | 19.675 | 24.725 | 31.264 | |
| 2 | 5.991 | 9.210 | 13.816 | 12 | 21.026 | 26.217 | 32.910 | |
| 3 | 7.815 | 11.345 | 16.266 | 13 | 22.362 | 27.688 | 34.528 | |
| 4 | 9.488 | 13.277 | 18.467 | 14 | 23.685 | 29.141 | 36.123 | |
| 5 | 11.070 | 15.086 | 20.515 | 15 | 24.996 | 30.578 | 37.697 | |
| 6 | 12.592 | 16.812 | 22.458 | 16 | 26.296 | 32.000 | 39.252 | |
| 7 | 14.067 | 18.475 | 24.322 | 17 | 27.587 | 33.409 | 40.790 | |
| 8 | 15.507 | 20.090 | 26.125 | 18 | 28.869 | 34.805 | 42.312 | |
| 9 | 16.919 | 21.666 | 27.877 | 19 | 30.144 | 36.191 | 43.820 | |
| 10 | 18.307 | 23.209 | 29.588 | 20 | 31.410 | 37.566 | 45.315 | |

INTRODUCTION TO POPULATION GENETICS, Table D.1

Chi-square distribution

Chi-square write-up

• A chi-square test was performed to examine the association between gender and feeling depressed. The association between these variables was significant, $\chi 2$ (1, N = 540) = 15.97, p < .001. Women were more likely than men to feel depressed.

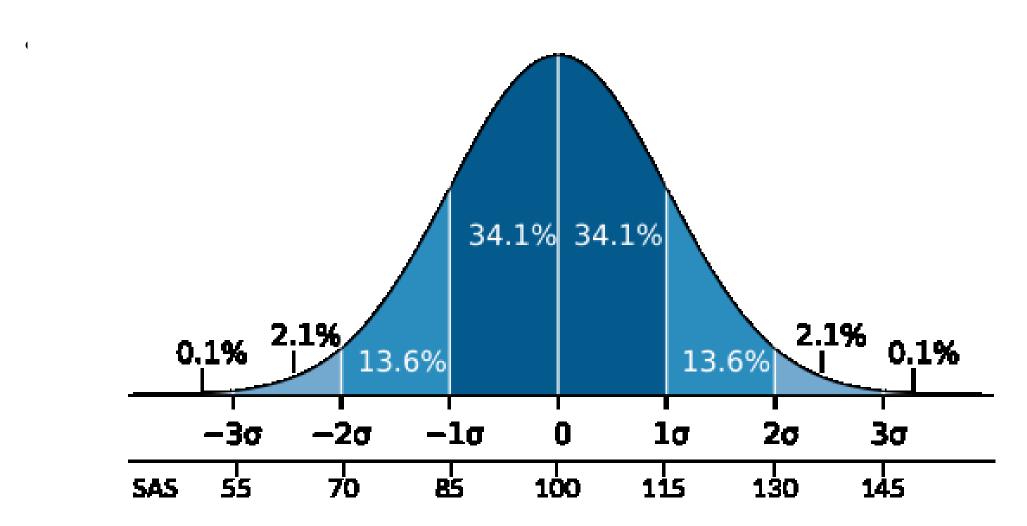

T-test use

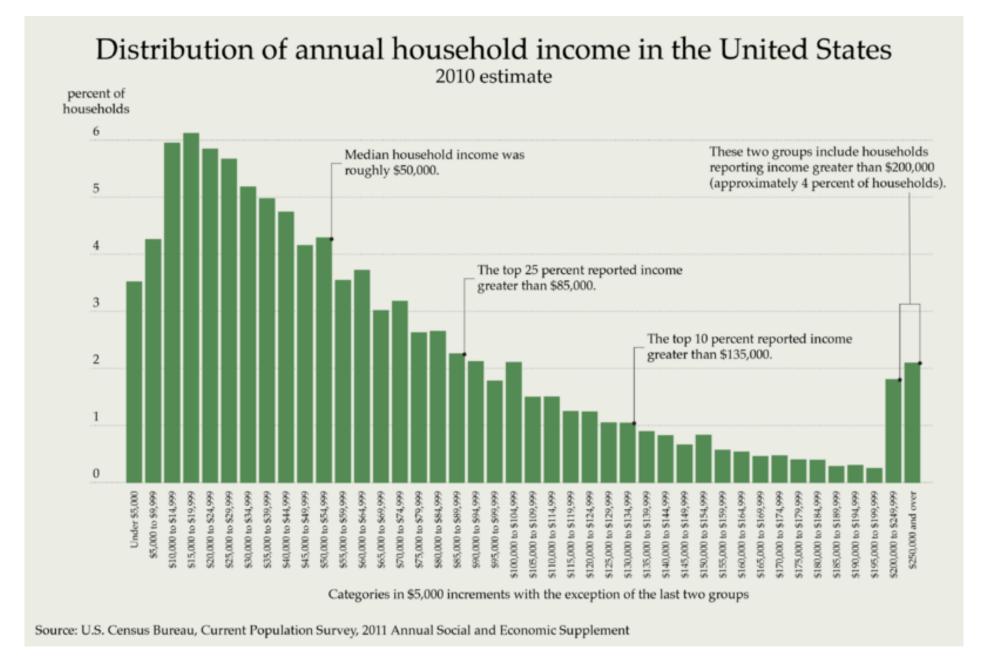

- Purpose:
 - Comparing means of a continuous DV across 2 groups (binary IV)
 - Useful when we have "natural" IV groups (e.g., experimental condition)
- Types:
 - Independent T-test
 - Paired-samples T-test

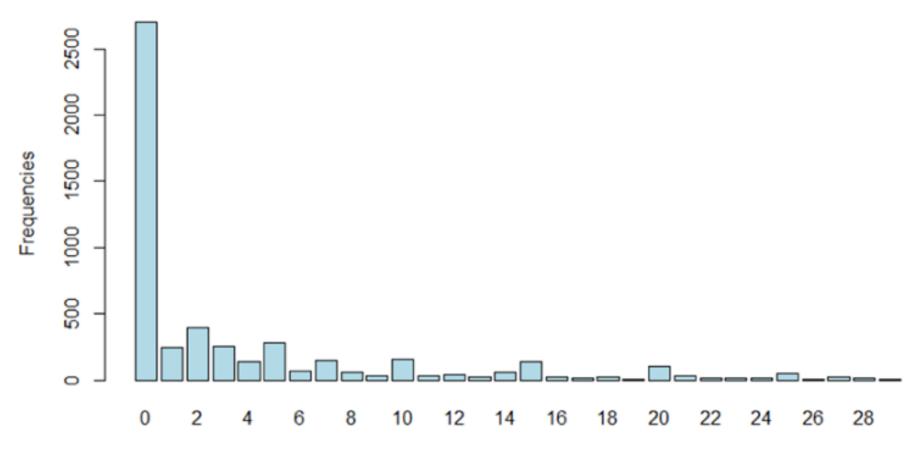

T-test assumptions

- Assumption of independence
 - Applies for independent t-test
- Assumption of normality
 - DV should be approximately normally distributed
- Assumption of homogeneity of variance
 - The two independent samples are assumed to be drawn from populations with identical population variances
 - The variances of DV should be equal in both IV groups

Normal/Gaussian distribution

Observed unhealthy days during the past 30 days

How does T-test work?

- 1. Obtaining mean and SD of the DV in each IV group
- 2. Comparing the observed differences in the group means to expected differences (= null hypothesis)
- = obtaining the *t* statistic
- 3. Using *t* distribution for specific degrees of freedom to determine how likely is the obtained *t* if null hypothesis is true
- = determining statistical significance (*p*-value)
- If the probability is 5% ($\alpha = .05$) or less, the *t* is stat. sig.
- In general, large t suggests rejection of null hypothesis

1. Obtaining means and SDs

Testing differences in depression scores on Beck Depression Inventory (BDI) between males and females

- Females
 - Mean = 9
 - SD = 2
 - N = 50
- Males
 - Mean = 6
 - SD = 3
 - N = 40

2. Obtaining the *t* statistic

Paired-samples T-test

$$t=rac{\overline{x}_{ ext{diff}}-0}{s_{\overline{x}}}$$

where

$$s_{\overline{x}} = rac{s_{ ext{diff}}}{\sqrt{n}}$$

where

 $ar{x}_{ ext{diff}}$ = Sample mean of the differences

n = Sample size (i.e., number of observations)

 $s_{\rm diff}$ = Sample standard deviation of the differences

 $\boldsymbol{s}_{\bar{\boldsymbol{x}}}$ = Estimated standard error of the mean (s/sqrt(n))

Independent T-test

Equal variance assumed

$$t=rac{\overline{x}_1-\overline{x}_2}{s_p\sqrt{rac{1}{n_1}+rac{1}{n_2}}}$$

with

$$s_p = \sqrt{rac{(n_1-1)s_1^2 + (n_2-1)s_2^2}{n_1 + n_2 - 2}}$$

Where

 $ar{m{x}}_1$ = Mean of first sample

 $ar{x}_2$ = Mean of second sample

 n_1 = Sample size (i.e., number of observations) of first sample

 n_2 = Sample size (i.e., number of observations) of second sample

 s_1 = Standard deviation of first sample

 s_2 = Standard deviation of second sample

 s_p = Pooled standard deviation

$$t=rac{\overline{x}_1-\overline{x}_2}{\sqrt{rac{s_1^2}{n_1}+rac{s_2^2}{n_2}}}$$
 Equal variance not assumed

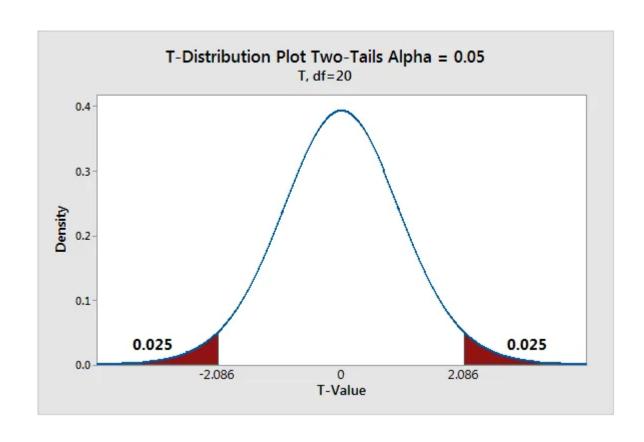

3. Determining statistical significance

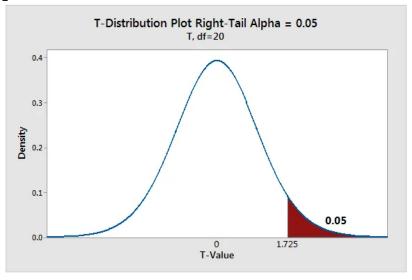

- df = n 1 for paired-samples
- df = $(n_1 1) + (n_2 1)$ for independent samples
- Critical value is based on the selected alpha level, df, and whether we are testing onetailed or two-tailed hypothesis

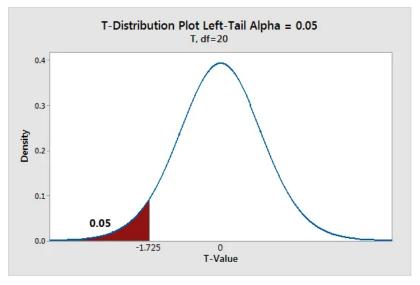

• In our case, *t* = 5.67

| | P | | | | | | | |
|-----------|-------|-------|--------|--------|--------|---------|---------|--|
| one-tail | 0.1 | 0.05 | 0.025 | 0.01 | 0.005 | 0.001 | 0.0005 | |
| two-tails | 0.2 | 0.1 | 0.05 | 0.02 | 0.01 | 0.002 | 0.001 | |
| DF | | | | | | | | |
| 1 | 3.078 | 6.314 | 12.706 | 31.821 | 63.656 | 318.289 | 636.578 | |

One-tailed or two-tailed hypothesis

T-test write-up

- The 25 participants who received the drug intervention (M = 480, SD = 34.5) compared to the 28 participants in the control group (M = 425, SD = 31) demonstrated significantly better peak flow scores, t(51) = 2.1, p = .04.
- There was a significant increase in the volume of alcohol consumed in the week after the end of semester (M = 8.7, SD = 3.1) compared to the week before the end of semester (M = 3.2, SD = 1.5), t(52) = 4.8, p < .001.
