# Practical aspects of Illumina sequencing - summary

The steps of Illumina sequencing

1. Fragment genomic DNA, e.g. with a sonicator.

2. Ligate adapters to both ends of the fragments.

3. PCR amplify the fragments with adapters

4. Spread DNA molecules across flowcells. Goal is to get exactly **one DNA molecule** per flowcell lawn of primers. This depends purely on probability, based on the concentration of DNA.

5. Use bridge PCR to amplify the single molecule on each lawn so that you can get a strong enough signal to detect. Usually this requires several hundred or low thousands of molecules.

6. Sequence by synthesis of complementary strand: reversible terminator chemistry.

A. Library Preparation

Genomic DNA

Fragmentation

Adapters

Ligation

Sequencing Library

NGS library is prepared by fragmenting a gDNA sample and ligating specialized adapters to both fragment ends.

A. Cluster Amplification

Flow Cell

Bridge Amplification Cycles

Clusters

Library is loaded into a flow cell and the fragments hybridize to the flow cell surface. Each bound fragment is amplified into a clonal cluster through bridge amplification.

C. Sequencing

Sequencing Cycles

Digital Image

Data is exported to an output file

Cluster 1 > Read 1: GAGT...
Cluster 2 > Read 2: TTGA...
Cluster 3 > Read 3: CTAG...
Cluster 4 > Read 4: ATAC...   Text File

Sequencing reagents, including fluorescently labeled nucleotides, are added and the first base is incorporated. The flow cell is imaged and the emission from each cluster is recorded. The emission wavelength and intensity are used to identify the base. This cycle is repeated "n" times to create a read length of "n" bases.

D. Alignment & Data Analysis

Reads
ATGGCATTGCAATTTGACAT
TGGCATTGCAATTTG
AGATGGTATTG
GATGGCATTGCAA
GCATTGCAATTTGAC
ATGGCATTGCAATT
AGATGGCATTGCAATTTG

Reference Genome   AGATGGTATTGCAATTTGACAT

Reads are aligned to a reference sequence with bioinformatics software. After alignment, differences between the reference genome and the newly sequenced reads can be identified.

Sources of errors: adapters

Sequencing random fragments of DNA is possible via the addition of short nucleotide sequences which allow any DNA fragment to:

- In step 2, adapters are ligated to the end of the fragments

● Bind to a flow cell for next generation sequencing

● Allow for PCR enrichment of adapter ligated DNA fragments only

● Allow for indexing or 'barcoding' of samples so multiple DNA libraries can be mixed together into 1 sequencing lane (known as multiplexing)

Spacery

Linkery

Single index — P5 · SP1 · Insert · SP2 · i7 · P7

Paired-end dual index — P5 · i5 · SP1 · Insert · SP2 · i7 · P7

Paired-end dual index with molecular barcode — P5 · i5 · SP1 · Insert · SP2 · i7 · UMI · P7

Paired-end dual index with inline UMI — P5 · i5 · SP1 · UMI · Insert · SP2 · i7 · P7

Paired-end dual index, inline UMI and barcode — P5 · i5 · SP1 · UMI · BC · Insert · SP2 · i7 · P7

P5/P7: Flow cell binding sequences (platform-specific)
SP1/2: Sequencing primer binding sites (common for all libraries)
I5/i7: Sample Indexes (specific to a particular library)
UMI: Unique molecular index (barcode tag for individual molecules)
BC: User-defined barcode (unique per sample, single cell, etc.)
Insert: Target DNA or cDNA fragment (library-specific)

Co vše se liguje

Musí být přítomny:

P5/P7 – adaptéry pro vazbu na flow cell

SP1/SP2 – vazebné místo sekvenačního primeru

Volitelné – ale často používané:

i5/i7 – Index vzorku – k rozpoznání sekvenovaných knihoven

Volitelné:

Barcode - jedinečná sekvence pro rozpoznání vzorku

UMI – Unique Molecular Identifikátor – k identifikaci technických duplikátů

Spacery - Pokud kombinujeme různé délky knihoven
Linkery - pro lepší slučování sekvencí

Indexed Sequencing Overview Guide (15057455) (ox.ac.uk)

Removal of adapters from library

- Necessary step!

- Removal of unligated adapters and adapter dimers (two adapters ligated to each other) is essential to improve data throughput and quality

- Redundant adapters often compete with library fragments for binding to a flow cell, reducing data output.

- Adapter dimers can also clonally amplify and generate sequencing "noise" that must be filtered out during data analysis.

- An excess of unligated adapters makes libraries more prone to index skipping during sequencing

Sources of errors: PCR duplicates

- In step 3 we are *intentionally* creating multiple copies of each original genomic DNA molecule so that we have enough of them.

- PCR duplicates occur when **two copies of the same original molecule get onto different primer lawns in a flowcell**.

- In consequence we read the very same sequence twice!

Higher rates of PCR duplicates e.g. 30% arise when you have too little starting material such that greater amplification of the library is needed in step 3, or when you have too great a variance in fragment size, such that smaller fragments, which are easier to PCR amplify, end up over-represented.
Clusters of identical sequences are created
Step 0 of analysis

- The identity of each base in the cluster is read from the sequence images
- One cycle -> four images!

TGCTACGAT...
TTTTTTTGT...
Flow-cell imaging

How it works

A **flow cell** contains eight lanes

Lane 1
Lane 2
·
·
·
Lane 8

Each **lane/channel** contains **three columns** of tiles

Column 1
Column 2
Column 3

Tile

Each **column** contains **100 tiles**

20K-30K Clusters
350 X 350 µm

Each tile is imaged four times per cycle – one image per base.

345,600 images for a 36-cycle run

Underclustered · Overclustered · Optimal clustering

Error source: Library concentration

- The concentrations of prepared NGS libraries can vary widely due to differences in the quantity and quality of input nucleic acid, as well as in the target enrichment method that may be used.

- **underclustering** due to a **low** library concentrations can result in reduced reads against capacity

- too many clusters can result in a low-quality score and problematic subsequent analysis - clusters are poorly distinguished by the image analysis program!

Sources of errors: sequencing by synthesis – the fluorescence

- In step 5 we amplify the signal and detect the fluorescence of each base

- The assumption is that in a cycle, every molecule on the flowcell is extended by one base

- The reality:
  - Some molecules are not extended or their base has no fluorescent dye
  - The previous fluorescent dye is not cleaved – the signal from the cluster after a few cycles is a mix of signals from previous bases
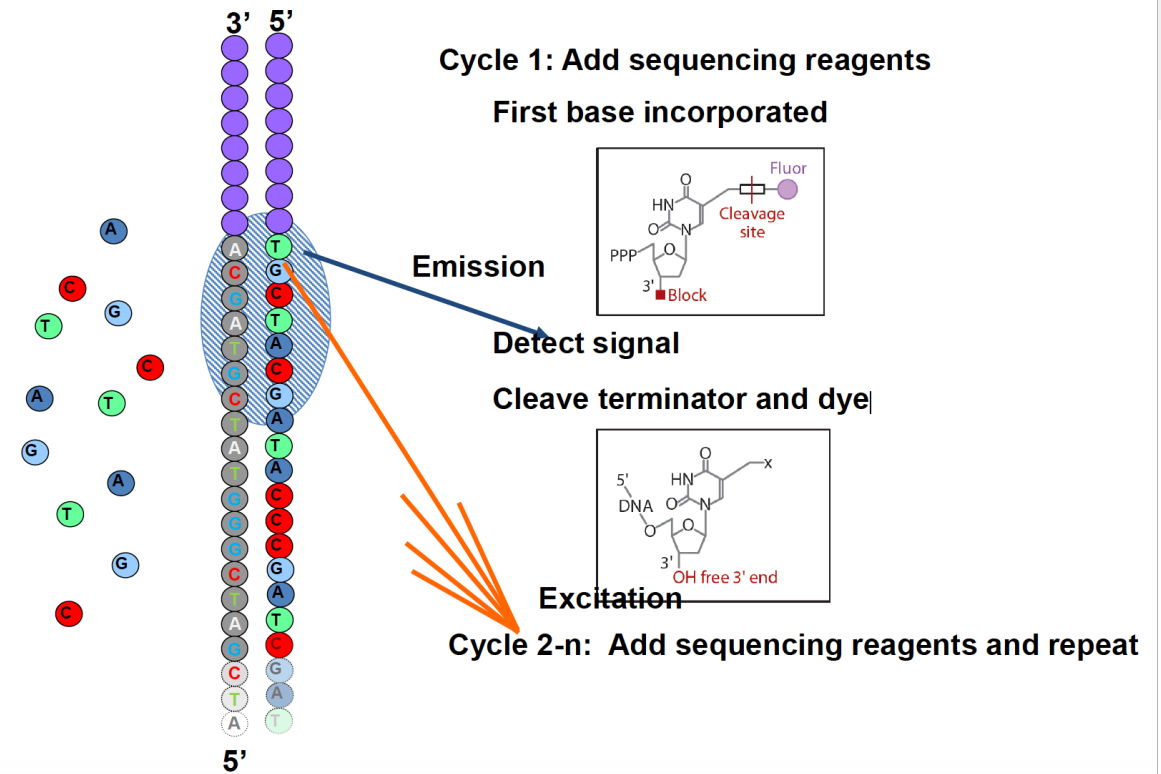

Sequencing coverage

Coverage in DNA sequencing **is the number of unique reads that include a given nucleotide** in the reconstructed sequence.

Reference genome

www.metagenomics.wiki
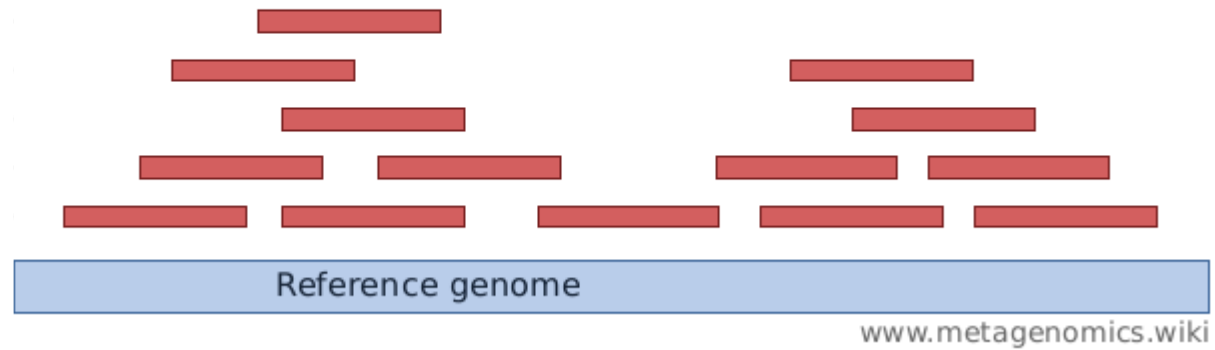

Depth of coverage
(coverage depth / mapping depth)

How strongly is the genome "covered" by sequenced fragments (short reads)?

Per-base coverage is the average number of times a base of a genome is sequenced (in other words, how many reads cover it).

Average coverage of the genome (Av)

$$Av = (NxL)/G$$

G - length of the original genome
N - number of reads
L - average read length

www.metagenomics.wiki

The coverage depth of a genome is calculated as **the number of bases of all short reads that match a genome divided by the length of this genome**. It is often expressed as 1X, 2X, 3X,... (1, 2, or, 3 times coverage).

Breadth of coverage
(covered length)

What proportion of the genome is "covered" by short reads?
Are there regions that are not covered, even not by a single read?
Breadth of coverage is the percentage of bases of a reference genome that are covered with a certain depth. For example: "90% of a genome is covered at 1X depth; and still 70% is covered at 5X depth."

Coverage recommendations

Coverage is determined based on:

Read lengths

Genome size

Application

Recommendations in the literature

Gene expression levels

Complexities of the genome, repetitive regions

**Average coverage of the genome (Av)**

$$Av = (NxL)/G$$

G - length of the original genome
N - number of reads
L - average read length

- Errors in the sequencing tool or methodology

- Analysis algorithm

Coverage recommendations / DNA

Application Type	Coverage
DNA-Seq (Re-Sequencing)	30 - 80X
DNA-Seq (De novo assembly)	100X
SNP Analysis / Rearrangement Detection	10 - 30X
Exome	100 - 200X
ChIP-Seq	10 - 40X

Average coverage of the genome (Av)

$$Av = (N \times L)/G$$

G - length of the original genome
N - number of reads
L - average read length

Coverage and Read Depth Recommendations for Next-Generation Sequencing Applications (genohub.com)

Coverage recommendations / RNA

Sample Type	Reads Needed for Differential Expression (millions)	Reads Needed for Rare Transcript or De Novo Assembly (millions)	Read Length
Small Genomes (i.e. Bacteria / Fungi)	5	30 - 65	50 SR or PE for positional info
Intermediate Genomes (i.e. Drosophila / C. Elegans)	10	70 - 130	50 – 100 SR or PE for positional info
Large Genomes (i.e. Human / Mouse)	15 - 25	100 - 200	>100 SR or PE for positional info

Different transcripts are expressed at different levels => more reads will be captured from highly expressed genes
Transcriptome complexity, alternative expression, 3' associated bias, and distribution of expression levels make coverage estimation difficult.

ATTENTION WHEN CALCULATING! We need to count mapped reads, not total reads.

Illumina	MiSeq v2 Nano	Lane	1,000,000	5

Designing Next-Generation Sequencing Runs (genohub.com)

Single or paired- end?

Single-end sequencing

- Pros: fast, cheap

- Cons: limited use

- Useage: usually sufficient for studies looking to detect counts rather than structural changes, such as RNA-Seq or ChIP-Seq
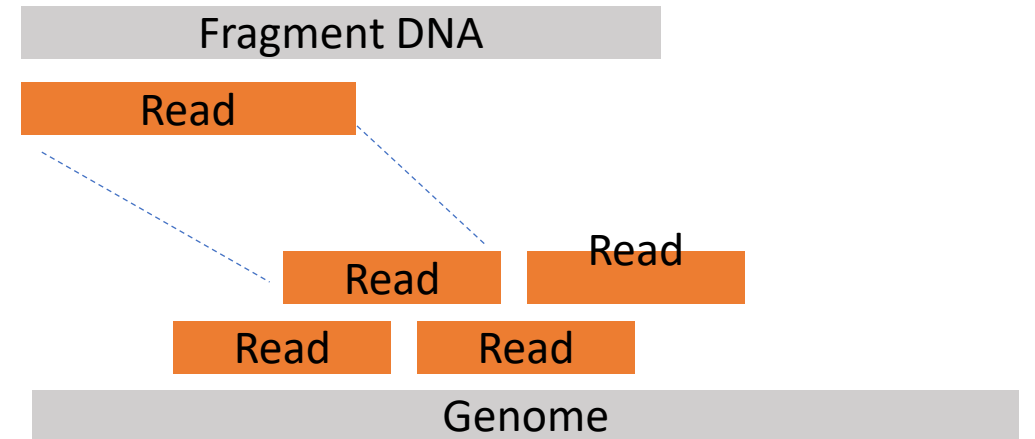

Single or paired- end?

Paired-end sequencing

- Pros:
  - greater accuracy, double the number of reads per sample in one run (higher capacity) for less than the cost of two sequencing runs

- Cons: slower, more expensive (relatively)

- Usage:
  - de novo genome assembly
  - Analysis of structural changes (deletions, insertions, inversions) and SNPs
  - A study of splicing variants
 - Epigenetic modifications (methylation)
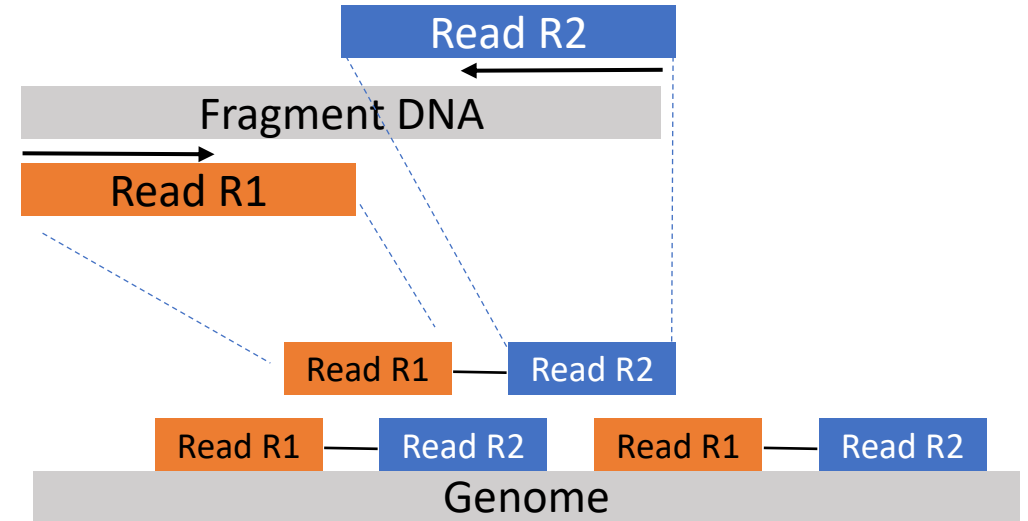

Read length

- Longer read lengths provide more precise information about the relative positions of the bases in the genome, they are more expensive than shorter ones.
- 50-75 cycles are typically sufficient for simple mapping of reads to a reference genome and quantifying experiments e.g. gene expression (RNA-Seq)
- Read lengths greater than or equal to 100 are typically chosen for genome or transcriptome studies that require greater precision
- **The exact read length depends on the length of the inserts!!!**

Read length and fragments

- The length of the fragments should roughly correspond to the length of the read (in the case of paired-end reads their sum)

- Uniformity of fragment sizes is essential because read lengths are limited

- **Significantly longer DNA inserts** => some parts of the inserts remain unsequenced.

- **Shorter than recommended** => suboptimal use of sequencing reagents and resources.

- The combination of short and long inserts => reduces sequencing efficiency and presents problems in data analysis.

Read length and fragments!

Read length is limited by the sequencing platform and reagent kit

Reagent Type		Reagent Kit Size	Maximum Number of Cycles	Additional Cycles Needed for Dual Index?
iSeq™ 100	i1 (v1 or v2)	300	322	No
MiniSeq™	Rapid Kit	100	128	Yes - 7 cycles
	High Output or Mid Output	75	92	No
		150	168	
		300	318	
MiSeq™	v2 (including Micro and Nano kits)	50	79	Yes - 7 cycles
		300	329	
		500	529	
	v3	150	179	
		600	629	
NextSeq™ 500/550	High Output or Mid Output	75	92	No
		150	168	
		300	318	
HiSeq™ 1000/1500/2000/2500	Rapid SBS v2	50	79	7 cycles required for paired-end flow cells
		200	229	
		500	529	
	TruSeq SBS v3	50	58	
		200	209	
	HiSeq SBS v4	50	79	
		250	279	

How many cycles of SBS chemistry are in my kit? (illumina.com)

Sequencing Platform	SBS Kit Version	Maximum Read Length
iSeq 100	v1	2 x 151bp
	v2	2 x 151bp
MiniSeq	MO*	2 x 151bp
	HO*	2 x 151bp
MiSeq	v2	2 x 251bp
	v3	2 x 301bp
NextSeq 500/550	MO*	2 x 151bp
	HO*	2 x 151bp
NextSeq 1000/2000	P1, P2, P3	2 x 151bp
HiSeq 1000/1500/2000/2500	HO* v3	2 x 101bp
	HO* v4	2 x 126bp
	RR** v4	2 x 251bp
HiSeq 3000/4000	N/A	2 x 151bp
