TEM

SEM – skenovací EM, TEM – transmisní/prozařovací EM

Focused Ion Beam (FIB) + SEM

Negative Stain vs. Vitreous Ice

Specimen in Stain

- High contrast image
- No special temperature control
- Essentially no radiation damage
- Particle distorted
- Image = stain "shell" around the particle
- Low resolution method: 20-15 Å
- Great choice for initial sample screening

Cryogenic Specimen

- Low contrast image
- Sample maintained at cryogenic temperature (85 K)
- High radiation damage
- Particle undistorted
- Image is of the actual particle
- Higher resolution obtained: 15-4 Å
- Best choice for reconstruction

TEM – Sample preparation

Negative staining

Pros: quick sample screening
high amplitude contrast
less prone to beam damage

Cons: limited resolution (20Å)
flattening artefacts
denaturation of proteins

Heavy metal staining

e.g. uranyl acetate

Negative staining

Sample vitrification

Cryogens	Melting point (°C)	Boiling point (°C)	Cooling rate (10^3 °C/s)	Relative cooling efficiency*
Ethane	-183	-89	-260 - -258	1.3
Liquid nitrogen	-210	-196	-272	0.1
Propane	-189	-42	-263 - -261	1.0
Freon 22	-160	-41	-267 - -265	0.7

3-4ul
0.1-1mg/ml for purified protein complexes
OD~0.5 for bacteria

Structure determination of biomolecules using TEM

(c)

Structure determination using single particle cryoEM

- 1) Sample preparation – 2) vitrification – 3) measurement – 4) particle picking – 5) 2D classification – 6) 3D model reconstruction

<https://doi.org/10.1016/j.cell.2019.04.006>

Micrographs processing

1) Denoising

- i. Just Another Noise 2 Noise Implementation (JANNI)
- ii. TOPAZ

2) Lowpass filtering

Original data* After
denoising

Input (TRPC4)

Denoised by JANNT
using the general model

*each micrograph is average of a movie of ~40..60 frames, motion corrected and dose-weighted

Particle picking

1. Initial Manual Picking (cyYOLO, Relion, Topaz, cryoSPARC ...)
 - i. Selected micrographs (10-100)
 - ii. Fully picked micrographs (80-100 % of particles present)
2. Model Training
3. Full Dataset Picking
(X00.000 – X.000.000 particles)

Particle Extraction

- i) Creates separate image for each individual picked particles
- ii) Large particles can be reduced by so called binning
=> speeds up initial calculations
- iii) Once dataset is “cleaned” and only “good” particles selected,
calculations are repeated using full-scale particles

2D Classification

- i) **.alignment** (a translation and an in-plane rotation) to map one image onto another
- ii) images have high noise relative to the signal of particles
- iii) aligning several similar images to each other then averaging them
=> image with higher signal to noise ratio
- iv) the **noise is mostly randomly distributed** and the underlying **image features constant**
- v) averaging the intensity of each pixel over several images only the constant features are reinforced.

—

2.995.892 particles picked from
13.807 micrographs using
cryoSPARC template picker

718.639 particles selected after
2D classification

3D Reconstruction

- i) Initial model
- ii) 3D model reconstruction

=> only a 3D electron density map will be provided

3D structure reconstruction is another (tedious) work:

1. rigid body docking
2. manual model building (semi-automatic) – Coot, Isolde ...

EM map

Fitting of known structures
(rigid body fitting)

Flexible fitting of
known structures

Building of
de novo models

- Many more sequences available than structures
- Many applications rely on structural information
- Structure is often more conserved than sequence (evolution preserves function)

1. Align sequence with structures

Template structure(s)
Target sequence

SRQYVDTSLVQCGAYCQA AI
GNDIAF TDRH MADDYFGDAATVQ

2. Extract spatial restraints

3. Satisfy spatial restraints

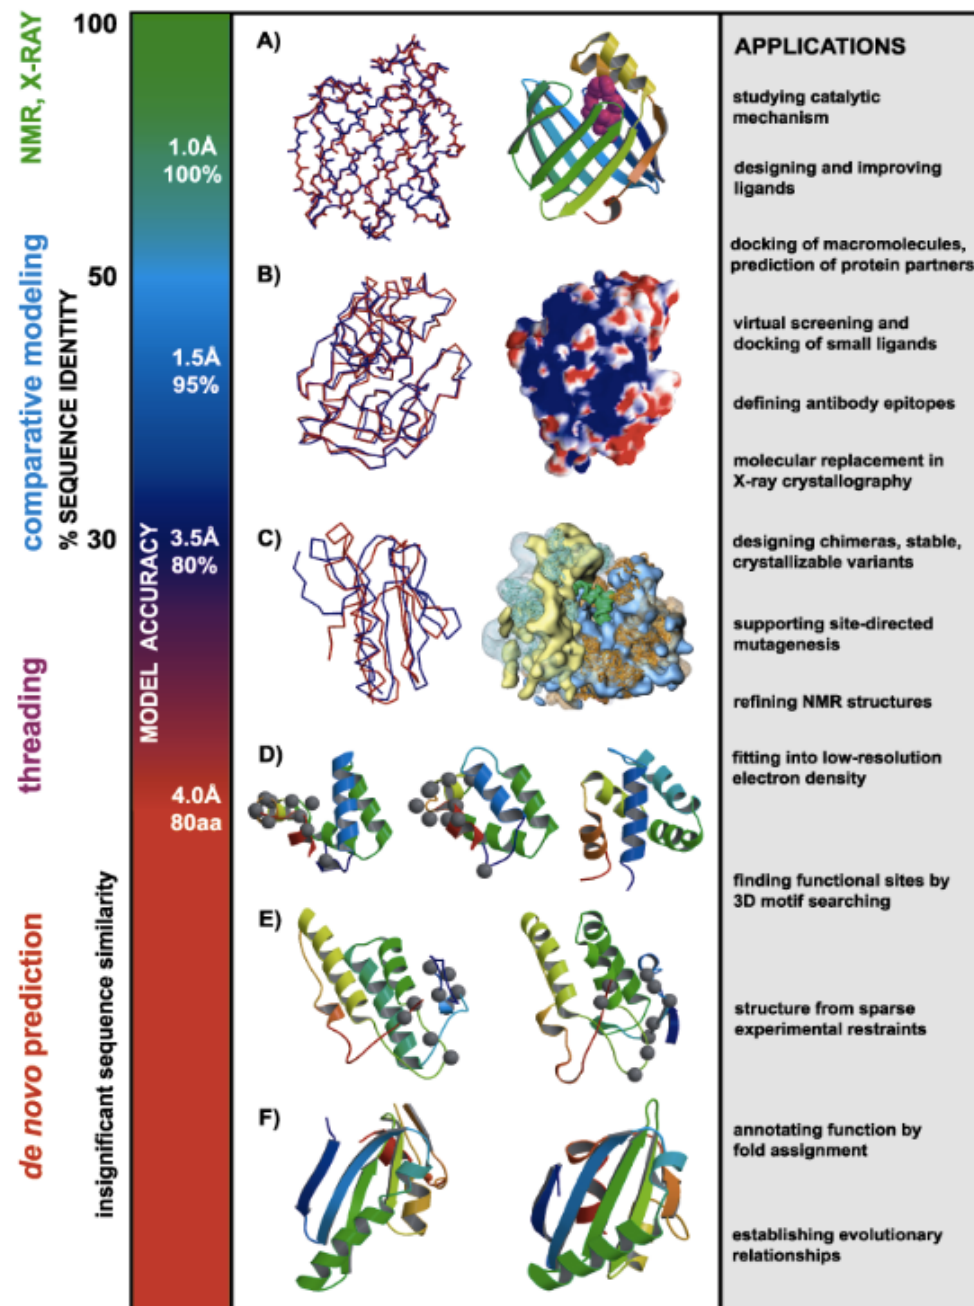

1) Assembly of rigid bodies
(core, loops, sidechains)

2) Segment matching

3) Satisfaction of spatial restraints
