(cf. the notes at the end of subsection 8.2.5, verify that the integrated function satisfies the conditions given there, and compute that thoroughly!). Hence the integral results in  $\sqrt{2\pi}$ , so the function  $f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$  is a well-defined density of a random variable.

### NORMAL DISTRIBUTION

The distribution of the random variable  $Z$  with density

$$\varphi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}$$

is called the (standard) *normal distribution*  $N(0, 1)$ . The corresponding distribution function

$$\Phi(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^z e^{-x^2/2} dx$$

cannot be expressed in terms of elementary functions.

It is called the *Gaussian function* and the graph of  $\varphi(x)$  is often called the *Gaussian curve*.

So far, the correct density which approximates the binomial distribution is not found. The diagram that compares the probability function of the binomial distribution to the Gaussian curve shows that the position of the maximum must be moved as well as an application of shrinkage or stretch to the curve horizontally. The first goal is easily reached by constant

**10.F.1.** An archer shoots five arrows at a target. Each time, the probability he hits is 0.6, and the individual results are independent. Let  $X$  be the random variable which corresponds to the number of hits. Determine its distribution and find its expected value and variance.

**Solution.** Clearly, the shots are independent experiments with the Bernoulli distribution  $A(\frac{3}{5})$ . Thus, by the definition of the binomial distribution, we have  $X \sim \text{Bi}(5, \frac{3}{5})$ . By **F**, the expected value and variance of  $\text{Bi}(n, p)$  are equal to  $np$  and  $np(1-p)$ , respectively, which gives  $E X = 3$  and  $\text{var } X = \frac{6}{5}$  for our case.  $\square$

**10.F.2.** Consider the discrete random variable  $X$  which takes on the values  $k = 0, 1, 2, 3, \dots$ , each with probability  $P(X = k) = p(1-p)^k$  (geometric distribution). Find  $E X$  (the expected number of failures before the first success) and  $\text{var } X$ .

**Solution.** Using the definition of the expected value and the formula for summing the derivative of a geometric series, we calculate

$$\begin{aligned} E X &= \sum_{k=0}^{\infty} k p (1-p)^k = p(1-p) \sum_{k=0}^{\infty} k (1-p)^{k-1} = \\ &= p(1-p) \frac{1}{p^2} = \frac{1-p}{p}. \end{aligned}$$

Similarly, using the formula for summing the second derivative of a geometric series, we compute

$$E(X^2) = \sum_{k=0}^{\infty} k^2 p (1-p)^k = \frac{(1-p)(2-p)}{p^2},$$

hence the variance is  $\text{var } X = E(X^2) - (E X)^2 = \frac{1-p}{p^2}$ .  $\square$

**10.F.3.** A random variable  $X$  is defined by its density  $f_X(x) = \frac{3}{x^4}$  for  $x \in (1, \infty)$  and  $f_X(x) = 0$  elsewhere. Find its distribution function, expected value, and variance.

**Solution.** By the definition of the distribution function, we have, for  $x \in (1, \infty)$ ,

$$F_X(x) = \int_1^x \frac{3}{t^4} dt = \left[ -\frac{1}{t^3} \right]_1^x = 1 - \frac{1}{x^3}.$$

The expected value of  $X$  is equal to

$$E X = \int_1^{\infty} \frac{3}{x^3} dx = \left[ -\frac{3}{2x^2} \right]_1^{\infty} = \frac{3}{2}$$

and the expected value of  $X^2$  is

$$E(X^2) = \int_1^{\infty} \frac{3}{x^2} dx = \left[ -\frac{3}{x} \right]_1^{\infty} = 3.$$

Therefore,  $\text{var } X = 3 - (\frac{3}{2})^2 = \frac{3}{4}$ .

shift  $\mu$  of the variable  $z$ , while scaling the difference  $x - \mu$  by coefficient  $\sigma > 0$  does the rest. Thus, there are two real parameters  $\mu$  and  $\sigma > 0$  and the density function is of the form:

$$g_{\mu, \sigma}(x) = e^{-(x-\mu)^2 / (2\sigma^2)}.$$

Simple variable substitution leads to

$$\int_{-\infty}^{\infty} e^{-(x-\mu)^2 / (2\sigma^2)} dx = \sqrt{2\pi} \sigma.$$

Thus there is an entire two-parametric class of densities

$$\varphi_{\mu, \sigma} = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

of random variables. The corresponding distributions are denoted by  $N(\mu, \sigma^2)$ .

We return to the asymptotic closeness of the normal and binomial distributions for  $n \rightarrow \infty$  after creating suitable tools. The following illustration reveals, how well this works. The discrete values correspond to  $\text{Bi}(40, 0.5)$ , while the curve depicts the density of  $N(20, 10)$ .

**10.2.22. Distributions of random vectors.** As for the scalar random variables, one defines the distribution functions and the density or the probability mass function for continuous and discrete random vectors. There are joint probability mass functions and densities.

For two discrete random variables, i.e. a discrete vector  $(X, Y)$  of random variables, define their *(joint) probability mass function*

$$f(x, y) = \begin{cases} P(X = x_i \wedge Y = y_j) & x = x_i, y = y_j \\ 0 & \text{otherwise.} \end{cases}$$

A random vector  $(X, Y)$  is called continuous, if its distribution function is defined as for continuous random variables. This means, for all  $a, b \in \mathbb{R}$ ,

$$\begin{aligned} F(a, b) &= P(X < a, Y < b) = \\ &= \int_{-\infty}^b \int_{-\infty}^a f(x, y) dx dy, \end{aligned}$$

and the function  $f(x, y)$  is called the *(joint) density* of the random vector  $(X, Y)$ .  $\square$

**10.F.4.** A random variable  $X$  is defined by its density  $f_X(x) = \cos x$  for  $x \in \langle 0, \frac{\pi}{2} \rangle$  and  $f_X(x) = 0$  elsewhere. Find its expected value, variance, and median.

**Solution.** Using the definition and integration by parts, we get

$$E X = \int_0^{\frac{\pi}{2}} x \cos x dx = [x \sin x + \cos x]_0^{\frac{\pi}{2}} = \frac{\pi}{2} - 1.$$

Using double integration by parts, we obtain

$$\begin{aligned} E(X^2) &= \int_0^{\frac{\pi}{2}} x^2 \cos x dx = \\ &= [x^2 \sin x + 2x \cos x - 2 \sin x]_0^{\frac{\pi}{2}} = \left(\frac{\pi}{2}\right)^2 - 2, \end{aligned}$$

so the variance is equal to  $\text{var } X = (\frac{\pi}{2})^2 - 2 - (\frac{\pi}{2} - 1)^2 = \pi - 3$ . By definition, the distribution function is equal to  $F_X(x) = \int_0^x \cos t dt = \sin x$ , and the median is  $F^{-1}(0.5) = \frac{\pi}{6}$ .  $\square$

**10.F.5.** A random variable  $X$  is defined by its density  $f_X(x) = \lambda e^{-\lambda x}$  for  $x \geq 0$ , and  $f_X(x) = 0$  elsewhere (the so-called exponential distribution;  $\lambda > 0$  is a fixed parameter). Find its expected value, variance, mode (the real number where the density reaches its maximum), and median.

**Solution.** Using the definition and integration by parts, we get

$$E X = \int_0^{\infty} x \lambda e^{-\lambda x} dx = \left[ -x e^{-\lambda x} - \frac{1}{\lambda} e^{-\lambda x} \right]_0^{\infty} = \frac{1}{\lambda},$$

$$\begin{aligned} E(X^2) &= \int_0^{\infty} x^2 \lambda e^{-\lambda x} dx = \\ &= \left[ -x^2 e^{-\lambda x} - 2x \frac{1}{\lambda} e^{-\lambda x} - \frac{2}{\lambda^2} e^{-\lambda x} \right]_0^{\infty} = \frac{2}{\lambda^2}, \end{aligned}$$

hence  $\text{var } X = E(X^2) - (E X)^2 = \frac{1}{\lambda^2}$ . Since  $F'_X(x) = -\lambda^2 e^{-\lambda x} < 0$ , the density keeps decreasing. Therefore, its maximum is at zero. By definition, we have

$$F(x) = \int_0^x \lambda e^{-\lambda t} dt = 1 - e^{-\lambda x},$$

so the median is equal to  $F^{-1}(0.5) = -\frac{1}{\lambda} \ln(\frac{1}{2}) = \frac{\ln 2}{\lambda}$ .  $\square$

**10.F.6.** The joint probability mass function of a discrete random vector  $(X_1, X_2)$  is defined by  $\pi(0, -1) = c$ ,  $\pi(1, 0) = \pi(1, 1) = \pi(2, 1) = 2c$ ,  $\pi(2, 0) = 3c$  and zero elsewhere. Find the parameter  $c$  and compute the covariance  $\text{cov}(X_1, X_2)$ .

**Solution.** If  $\pi$  is to be a probability mass function, then the sum of its values over the entire domain must be equal to 1, i. e.,

$$\sum_{i,j} \pi(i, j) = c + 3.2c + 3c = 10c = 1,$$

so  $c = \frac{1}{10}$ . The probability mass function  $\pi_1$  of  $X_1$  is given by the sum of the joint function over all possible values of  $X_2$ , i. e.,  $\pi_1(i) = \sum_j \pi(i, j)$ . Thus, we have  $\pi_1(0) = c$ ,  $\pi_1(1) = 4c$ ,  $\pi_1(2) = 5c$  and zero elsewhere. Similarly, for

For a general continuous random vector  $X = (X_1, \dots, X_n)$ , define

$$\begin{aligned} F(a_1, \dots, a_n) &= P(X_1 < a_1, \dots, X_n < a_n) = \\ &= \int_{-\infty}^{a_n} \dots \int_{-\infty}^{a_1} f(x_1, \dots, x_n) dx_1 \dots dx_n, \end{aligned}$$

and similarly for discrete random vectors with more components.

A random vector  $(X, Y)$  with both  $X$  and  $Y$  continuous is not always a continuous vector in the above sense. For example, taking a continuous variable  $X$ , the random vector  $(X, 2X)$  is neither continuous nor discrete, since the entire probability mass is concentrated along the line  $y = 2x$  in the plane, but not in individual points.

The *marginal distribution* for one of the variables can be obtained by summation or integration over the others.

For instance, in the case of a discrete random vector  $(X, Y)$ , the events  $(X = x_i, Y = y_j)$  for all possible values  $x_i$  and  $y_j$  with non-zero probabilities for  $X$  and  $Y$ , respectively, form an exhaustive collection of events for the vector  $(X, Y)$ . Thus

$$P(X = x_i) = \sum_{j=1}^{\infty} P(X = x_i, Y = y_j),$$

which relates the *marginal probability distribution* of the random variable  $X$  to the joint probability distribution of the random vector  $(X, Y)$ . In the case of continuous random vectors, proceed similarly using integrals instead of sums.

**10.2.23. Stochastic independence.** It is known from

subsection 10.2.3 what (in)dependence means for events. Random variables  $X_1, \dots, X_n$  are (*stochastically*) *independent* if and only if for any  $a_i \in \mathbb{R}$ , the events  $X_1 < a_1, \dots, X_n < a_n$  are independent. In view of the definition of the distribution function  $F$  of the random vector  $(X_1, \dots, X_n)$ , this is equivalent to

$$F(x_1, \dots, x_n) = F_{X_1}(x_1) \dots F_{X_n}(x_n),$$

where  $F_{X_i}$  are the distribution functions of the individual components.

It follows that the events corresponding to  $X_k \in I_k$  for arbitrarily chosen intervals  $I_k$  is also independent. The probability of  $X_1 \in [a, b)$  and simultaneously  $X_i \in (-\infty, c_i)$  for the other components is  $F(b, c_2, \dots, c_n) - F(a, c_2, \dots, c_n) = (F_{X_1}(b) - F_{X_1}(a))F_{X_2}(c_2) \dots F_{X_n}(c_n)$ , and so on. The densities and probability mass functions behave well too:

**Proposition.** For any random vector  $(X_1, \dots, X_n)$ , the following two conditions are equivalent:

- The random variables  $X_1, \dots, X_n$  are stochastically independent.
- The joint distribution function  $F$  of the random vector  $(X_1, \dots, X_n)$  is the product of the marginal distribution functions  $F_{X_i}$  of the individual components.

the probability mass function  $\pi_2$  of  $X_2$ , we get  $\pi_2(-1) = c$ ,  $\pi_2(0) = 5c$ ,  $\pi_2(1) = 4c$  and zero elsewhere. Hence,  $E X_1 = \sum_i i\pi_1(i) = 14c = 1.4$  and  $E X_2 = \sum_j j\pi_2(j) = 3c = 0.3$ . By the definition of the covariance, we have

$$\text{cov}(X_1, X_2) = \sum_{i,j} (i-1, 4)(j-0, 3)\pi(i, j) = 0.18.$$

□

**10.F.7.** In many scientific fields, the behavior of a random variable which is bounded onto an interval is modeled using the so-called beta-distribution. That is a continuous distribution is defined by its density on the interval  $[0, 1]$ :

$$f_X(x) = \frac{1}{B(\alpha, \beta)} x^{\alpha-1}(1-x)^{\beta-1},$$

where  $\alpha, \beta$  are fixed parameters, chosen suitably for description of the given random variable, and  $B(\alpha, \beta)$  is a normalizing constant, guaranteeing that the integral of  $f_X(x)$  over  $[0, 1]$  is equal to zero. Find its a) mode, b) expected value, and c) variance.

**Solution.** a) By definition, the mode is the value where  $f_X(x)$  reaches its maximum. Thus, let us look at its stationary points. We can easily calculate that the equation  $f'_X(x) = 0$  is equivalent to

$$(\alpha-1)(1-x) - x(\beta-1) = 0,$$

and this is satisfied for  $x = \frac{\alpha-1}{\alpha+\beta-2}$ . Since  $f_X(0) = f_X(1) = 0$  and the function is positive, it must be the wanted maximum.

b) By definition, we have

$$E X = \frac{1}{B(\alpha, \beta)} \int_0^1 x^\alpha(1-x)^{\beta-1} dx.$$

Integrating by parts, we get

$$E X = -\frac{1}{B(\alpha, \beta)\beta} [x^\alpha(1-x)^\beta]_0^1 + \frac{\alpha}{B(\alpha, \beta)\beta} \int_0^1 x^{\alpha-1}(1-x)^\beta dx.$$

Clearly, the first term is equal to zero. Refining the second one, we obtain

$$E X = \frac{\alpha}{B(\alpha, \beta)\beta} \int_0^1 x^{\alpha-1}(1-x)^{\beta-1} dx - \frac{\alpha}{B(\alpha, \beta)\beta} \int_0^1 x^\alpha(1-x)^{\beta-1} dx.$$

Now, the integral in the first term is, thanks to the normalization, equal to  $B(\alpha, \beta)$ , and the second integral is the expected value, too. Thus, the above equation can be written as

$$E X = \frac{\alpha}{\beta} - \frac{\alpha}{\beta} E X.$$

Hence it immediately follows that  $E X = \frac{\alpha}{\alpha+\beta}$ .

c) In order to compute the variance, we must calculate

$$E X^2 = \frac{1}{B(\alpha, \beta)} \int_0^1 x^{\alpha+1}(1-x)^{\beta-1} dx.$$

This integral can be computed similarly as in b):

$$E X^2 = \frac{\alpha+1}{B(\alpha, \beta)\beta} \int_0^1 x^\alpha(1-x)^\beta dx = \frac{\alpha+1}{\beta} E X - \frac{\alpha+1}{\beta} E X^2$$

Moreover, if all  $X_i$  are discrete random variables, then they are independent if and only if the joint probability mass function  $f$  of the random vector  $(X_1, \dots, X_n)$  is the product of the marginal probability mass functions  $f_{X_i}$  of the individual components.

Similarly, if all  $X_i$  are continuous random variables, then they are independent if and only if the joint density function  $f$  of the random vector  $(X_1, \dots, X_n)$  exists and it is the product of the marginal density functions  $f_{X_i}$  of the individual components.

In particular, any random vector with independent continuous components is again a continuous random vector.

**PROOF.** Many of the claims are already verified. The only nontrivial implication left is the one assuming the product formula for the joint distribution function and deriving the claim on the probability function or the density. The argument for  $n = 2$  is shown below, the general case is analogous.

Consider first two discrete independent random variables  $X, Y$ . Then  $f_{X,Y}(x_i, y_j) = P(X = x_i, Y = y_j) = P(X = x_i)P(Y = y_j) = f_X(x_i)f_Y(y_j)$ . The joint distribution function is

$$\begin{aligned} F_{X,Y}(x, y) &= \sum_{x_i < x} \sum_{y_j < y} f_X(x_i)f_Y(y_j) \\ &= \left( \sum_{x_i < x} f_X(x_i) \right) \left( \sum_{y_j < y} f_Y(y_j) \right), \end{aligned}$$

which is equivalent to  $f_{X,Y}(x, y) = f_X(x)f_Y(y)$ .

Similarly, assuming that the joint distribution function  $F_{X,Y}$  is the product of the distributions functions of two continuous random variables  $X, Y$ , then its mixed partial derivatives exist. Thus is set:

$$\begin{aligned} f_{X,Y}(x, y) &= \frac{\partial^2}{\partial x \partial y} F_{X,Y}(x, y) \\ &= \frac{\partial^2}{\partial x \partial y} F_X(x)F_Y(y) \\ &= f_X(x)f_Y(y), \end{aligned}$$

which is the requested joint density function for  $F_{X,Y}$ .

All the other implications are either direct consequences of the definitions or are obvious. □

**10.2.24. Example.** Consider a simple example which illustrates that it is not a good idea to view a random vector only as a pair of random variables. Consider stochastic properties of a random vector  $(X, Y)$  which has continuous uniform distribution on the unit disc in the plane  $\mathbb{R}^2$ , centered at the origin. Then, its (joint) density function is

$$f(x, y) = \begin{cases} \frac{1}{\pi} & x^2 + y^2 \leq 1 \\ 0 & \text{otherwise.} \end{cases}$$

The components  $X$  and  $Y$  of this random vector (in the usual Euclidean coordinates) cannot be independent random variables: For instance, note that the probability of  $(X, Y)$  falling outside the unit disc but inside the square with vertices at

Hence,  $E X^2 = \frac{(\alpha+1) E X}{\alpha+\beta+1}$ . Substituting the expected value, we obtain

$$\frac{\text{var } X}{(\alpha + \beta + 1)(\alpha + \beta)^2} = \frac{E X^2 - (E X)^2}{\alpha \beta} \quad \square$$

**10.F.8.** We toss three coins. Let  $X$  denote the total number of heads on the first and second coins, and  $Y$  denote the total number of heads on the second and third coins.

**Solution.** First of all, we build the table describing the joint probability mass function of the discrete random vector  $(X, Y)$ , whence we can get the probability distributions of the variables we will need:

	Y	0	1	2
X				
0		$\frac{1}{8}$	$\frac{1}{8}$	0
1		$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{8}$
2		0	$\frac{1}{8}$	$\frac{1}{8}$

The discrete variables  $X$  and  $Y$  have the same probability distribution: they take on the value 0 with probability  $1/4$ , 1 with  $1/2$ , and 2 with  $1/4$ . (Of course, we could have come to this even without the table.) The variable  $XY$  takes on the values 0, 1, 2, 4 with probabilities  $3/8, 1/4, 1/4, 1/8$ , respectively. Now, we compute the expected values of the variables  $X, X^2, Y, Y^2, XY$ :

$$\begin{aligned} E(X) &= E(Y) = 0 \cdot \frac{1}{4} + 1 \cdot \frac{1}{2} + 2 \cdot \frac{1}{4} = 1 \\ E(X^2) &= E(Y^2) = 0 \cdot \frac{1}{4} + 1 \cdot \frac{1}{2} + 4 \cdot \frac{1}{4} = \frac{3}{2} \\ E(XY) &= 0 \cdot \frac{3}{8} + 1 \cdot \frac{1}{4} + 2 \cdot \frac{1}{4} + 4 \cdot \frac{1}{8} = \frac{5}{4} \end{aligned}$$

Thus, we have

$$\begin{aligned} \sigma^2(X) &= \zeta^2(Y) = E(X^2) - [E(X)]^2 = \frac{1}{2} \\ \text{cov}(X, Y) &= E(XY) - E(X)E(Y) = \frac{1}{4} \end{aligned}$$

Altogether,

$$\rho_{X,Y} = \frac{\text{cov}(X, Y)}{\sigma(X) \cdot \sigma(Y)} = \frac{1}{2} \quad \square$$

**10.F.9.** Consider random variables  $U, V$ , defined by their joint probability mass function ( $U$  takes on 1 or 2,  $V$  takes on 1, 2 or 3):

	V		
U	1	2	3
1	0.1	0.2	0.3
2	0.2	0.1	0.1

$(\pm 1, \pm 1)$  is zero, while the marginal distribution functions are non-zero for the values  $|x| < 1$  and  $|y| < 1$ .

Expressing this random vector in polar coordinates  $(R, \Phi)$ ,

$$P(R < r_0, \Phi < \varphi_0) = \int_0^{r_0} \int_0^{\varphi_0} \frac{1}{\pi} r \, d\varphi \, dr = \frac{1}{2\pi} \varphi_0 r_0^2.$$

The joint density of the vector  $(R, \Phi)$  is thus  $f(r, \varphi) = \frac{r}{\pi}$  for  $0 < r \leq 1, 0 < \varphi \leq 2\pi$ , and it is zero otherwise. The marginal densities are

$$\begin{aligned} f_R(r) &= \int_0^{2\pi} \frac{r}{\pi} \, d\varphi = 2r, \quad \text{if } 0 < r \leq 1, \\ f_\Phi(\varphi) &= \int_0^1 \frac{r}{\pi} \, dr = \frac{1}{2\pi}, \quad \text{if } 0 < \varphi \leq 2\pi, \end{aligned}$$

and zero otherwise. Therefore, the random variables  $R$  and  $\Phi$  are independent. This is a very important feature in mathematical statistics.

**10.2.25. Functions of random variables.** In practice, random

vectors are encountered in two quite different roles. Firstly, we can observe several random variables which describe less or more related events. As an example, examine various numerical parameters connected to individual students (their results in particular courses, weight, height, age, annual income, etc.). In this case, tools are needed which allow the examination of differences or dependencies between these variables.

We can examine only one of the parameters on a large collection of objects and select only a small number  $n$  of them. This procedure is described by an  $n$ -dimensional vector  $(X_1, \dots, X_n)$  where all the random variables  $X_k$  have the same probability distribution. In this case, we are more interested in the quantities that correspond to statistical numerical characteristics discussed in the previous part of this chapter.

Both cases can be dealt with using one simple concept. Instead of the given random variable or random vector, consider functions of those.

This is a useful tool even in the case of one random variable. As an example, consider the random variable  $X$  with uniform distribution over the interval  $[1, 2] \subset \mathbb{R}$  giving the length of the side of a square, asking for the random variable  $Y = X^2$  describing the area of such a square. The problem is to see the stochastic behaviour of  $Y$  in terms of the known parameters of  $X$ .

The obvious technical condition on  $\psi$  is to guarantee that  $Y = \psi \circ X$  is again a random variable according to the definition. This means the preimage  $\psi^{-1}$  of a Borel-measurable set should be again a Borel-measurable set.

Elementary arguments reveal that  $\psi^{-1}(A \setminus B) = \psi^{-1}(A) \setminus \psi^{-1}(B)$  and  $\cup_{i \in I} \psi^{-1}(A_i) = \psi^{-1}(\cup_{i \in I} A_i)$ , for subsets  $A, B, A_i \in \mathbb{R}$ . Since each open subset in  $\mathbb{R}^n$  is a countable union of intervals, and the pre-images  $\psi^{-1}(U)$  are open for continuous functions  $\psi$  and open sets  $U$ , the continuous function  $\psi$  always satisfies the condition.

Find the marginal distributions of both variables, their expected values, variances, and correlation coefficient. ○

**10.F.10.** Find the expected value and variance of the random variable  $X^2$  provided  $X$  has uniform distribution on the interval  $\langle -1, 1 \rangle$ . ○

**10.F.11.** We roll two dice. Let  $X$  denote how many times we got an even number, and  $Y$  denote how many times we got an odd number. Find their correlation coefficient. ○

**10.F.12.** Consider random variables  $U, V$ , defined by their joint probability mass function ( $U$  takes on 1 or 2,  $V$  takes on 1, 2 or 3):

	V		
U	1	2	3
1	0.1	0.1	0.4
2	0.2	0.1	0.1

Find the marginal distributions of both variables, their expected values, variances, and correlation coefficient. ○

**G. Transformations of random variables**

Consider a continuous function of a random variable  $Y = \psi(X)$ . If the transformation  $\psi$  is increasing, then the resulting distribution function satisfies

$$F_Y(y) = P(Y \leq y) = P(\psi(X) \leq y) = P(X \leq \psi^{-1}(y)) = F_X(\psi^{-1}(y)),$$

where  $F_X$  is the distribution function of  $X$  (analogously for decreasing  $\psi$ ). Thus, the density of the transformed random variable  $Y$  satisfies

$$f_Y(y) = \frac{dF_Y(y)}{dy} = f_X(\psi^{-1}(y)) \left| \frac{d\psi^{-1}(y)}{dy} \right|.$$

Applying the rule for transformation of coordinates, we can compute the expected value of  $Y$  as

$$EY = \int_{-\infty}^{\infty} y f_Y(y) dy = \int_{-\infty}^{\infty} \psi(x) f_X(x) dx,$$

ans similarly for the variance of  $Y$ .

**10.G.1.** Consider a random variable  $X$  with density  $f(x)$ . Find the density of the random variable  $Y$  defined by

- i)  $Y = e^X, x \geq 0,$
- ii)  $Y = \sqrt{X}, x > 0,$
- iii)  $Y = \ln X, x > 0,$
- iv)  $Y = \frac{1}{X}, x > 0.$

**Solution.** We can simply apply the formula for the density of a transformed random variable, which yields a)  $f_Y(y) = f(\ln y) \frac{1}{y}$ , b)  $f_Y(y) = 2f(y^2)y$ , c)  $f_Y(y) = f(e^y)e^y$ , d)  $f_Y(y) = f(1/y) \frac{1}{y^2}$ . □

In the sequel, we restrict ourselves to this case.

FUNCTIONS OF RANDOM VARIABLES AND VECTORS

For a continuous function  $\psi : \mathbb{R} \rightarrow \mathbb{R}$  and a random variable  $X$ , there is also the random variable  $Y = \psi(X)$ .  $Y$  is said to be a *function of the random variable  $X$* .

In the case of a random vector  $(X_1, \dots, X_n)$  and a continuous function  $\psi : \mathbb{R}^n \rightarrow \mathbb{R}$ , we talk about a function  $Y = \psi(X_1, \dots, X_n)$  of the *random vector*.

It is useful to know whether independent random variables remain independent after transformations. The answer and its verification are simple:

**Proposition.** Consider two independent random variables  $X$  and  $Y$  and two functions  $g$  and  $h$  such that  $U = g(X)$ ,  $V = h(X)$  are random variables. Then  $U$  and  $V$  are independent, too.

**PROOF.** For fixed reals  $u, v$ , write

$$A_u = \{x; g(x) < u\} \quad B_v = \{y; h(y) < v\}.$$

Then the joint distribution function for the vector  $(U, V)$  is

$$\begin{aligned} F_{U,V}(u, v) &= P(U < u, V < v) = P(X \in A_u, Y \in B_v) \\ &= P(X \in A_u)P(Y \in B_v) \\ &= P(U < u)P(V < v) = F_U(u)F_V(v). \end{aligned}$$

Thus, the transformed random variables are stochastically independent, as expected. □

**10.2.26. Affine transformations and sums.** The simplest function (except constants) is an affine dependency

$$\psi(X) = a + bX$$

with constants  $a, b \in \mathbb{R}, b \neq 0$ .

If  $f_X(x)$  is the probability mass function of a random variable with discrete distribution, it is easily computed that

$$(1) \quad f_{\psi(X)}(y) = P(\psi(X) = y) = \sum_{\psi(x_i)=y} f(x_i).$$

Thus, in the case of the affine dependency  $Y = a + bX$ , the probability mass function is non-zero exactly at the points  $y_i = ax_i + b$ .

As an example of a function of a random vector  $X = (X_1, \dots, X_n)$ , consider the sum of  $n$  independent random variables with the Bernoulli distribution  $X_i \sim A(p)$ . Of course, this leads just to the binomial distribution  $\text{Bi}(n, p)$ . The above formula for  $f_{\psi(X)}(y)$  reveals the already known probability function for  $Y = X_1 + \dots + X_n$ . Only  $y \in \{0, \dots, n\}$  can be reached. Collect all the possibilities of summing  $y$  ones, when each of them appears with probability  $p^y(1-p)^{n-y}$ .

Similarly, proceed with continuous random variables. The two parameter family  $Y = \mu + \sigma Z$  is met already, where

**10.G.2.** Consider a random variable  $X$  which has uniform distribution on the interval  $(-\frac{\pi}{2}, \frac{\pi}{2})$ . Find the density of  $X$  as well as the densities of transformed variables  $Y = \sin X, Z = \tan X$ .

**Solution.** Since the length of the interval where  $X$  is non-zero is  $\pi$ , the density of  $X$  is  $f_X(x) = \frac{1}{\pi}$  for  $x \in (-\frac{\pi}{2}, \frac{\pi}{2})$  and zero elsewhere. Applying the formula for the density of a transformed random variable and the derivatives of elementary functions, we get

$$f_Y(y) = f_X(\arcsin(y)) \arcsin'(y) = \frac{1}{\pi\sqrt{1-y^2}}$$

and

$$f_Z(z) = f_X(\arctan(z)) \arctan'(z) = \frac{1}{\pi(1+z^2)}.$$

□

**10.G.3.** Consider a random variable  $X$  whose density is  $\cos x$  for  $x \in (0, \frac{\pi}{2})$  and zero elsewhere. Find the density of the random variable  $Y = X^2$  and calculate  $EY$  and  $\text{var } Y$ .

**Solution.** Applying the formula for the density of a transformed random variable, we get

$$f_Y(y) = f_X(\sqrt{y})(\sqrt{y})' = \frac{1}{2\sqrt{y}} \cos x.$$

It is simpler to compute the expected value and variance of  $Y$  directly from the density of  $X$ . We have  $EY = \int_{-\infty}^{\infty} x^2 f_X(x) dx$ . Thus,

$$EY = \int_0^{\frac{\pi}{2}} x^2 \cos x dx = [x^2 \sin x + 2x \cos x - 2 \sin x]_0^{\frac{\pi}{2}} = \frac{\pi^2 - 8}{4}.$$

The integral was computed by parts. Applying this method again, we obtain

$$E(Y^2) = \int_0^{\frac{\pi}{2}} x^4 \cos x dx = [(x^4 - 12x^2 + 24) \sin x + 4(x^3 - 6x) \cos x]_0^{\frac{\pi}{2}}.$$

Hence,  $E(Y^2) = (\frac{\pi}{2})^4 - 12(\frac{\pi}{2})^2 + 24$ , so  $\text{var } Y = \frac{\pi^4}{16} - 3\pi^2 + 24 - \frac{\pi^4 - 16\pi^2 + 64}{16} = 20 - 2\pi^2$ .

□

**10.G.4.** Let  $X$  be a random variable which takes on values 0 and 1, each with probability  $\frac{1}{2}$ . Similarly, let  $Y$  take on the values  $-1$  and 1, each with probability  $\frac{1}{2}$ . Show that the random variables  $X$  and  $Z = XY$  are uncorrelated, yet dependent. Give an example of two continuous random variables with this property.

**Solution.** First of all, we compute the expected values of our random variables:  $E X = 0 \cdot \frac{1}{2} + 1 \cdot \frac{1}{2} = \frac{1}{2}$ ,  $E Z = E(XY) = 0 \cdot \frac{1}{2} + (-1) \cdot \frac{1}{4} + 1 \cdot \frac{1}{4} = 0$ . As for the expected value of their product, we have  $E(XZ) = E(X^2 Y) = 1 \cdot \frac{1}{4} + (-1) \cdot \frac{1}{4} = 0$ . By theorem 10.2.33, the covariance is equal to  $\text{cov}(X, Z) = 0 - \frac{1}{2} \cdot 0 = 0$ . Thus, the variables  $X$  and  $Y$  are uncorrelated. At the same time, the conditional probability  $P(Z = 1 | X = 0)$  is clearly zero, i. e., we also have  $P(Z = 1, X = 0) = 0$ , while  $P(Z = 1) = \frac{1}{4}$  and  $P(X = 0) = \frac{1}{2}$ , so  $P(Z = 1) \cdot P(X = 0) = \frac{1}{8} \neq 0$ . We can

$Z \sim N(0, 1)$  in 10.2.21. This is verified easily.

$$\begin{aligned} F_Y(y) &= P(Y < y) = P(\mu + \sigma Z < y) \\ &= \Phi\left(\frac{y - \mu}{\sigma}\right) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\frac{y - \mu}{\sigma}} e^{-z^2/2} dz \\ &= \int_{-\infty}^y \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x - \mu)^2}{2\sigma^2}} dx, \end{aligned}$$

where the substitution  $x = \mu + \sigma z$  is used in the last step. This is exactly what is wanted.

More generally, the above formula (1) has the straightforward analog for the density of  $Y = \psi(X)$  for a continuous  $X$  in the case when  $\psi$  has got non-zero derivative (thus  $\psi$  is invertible).

$$(2) \quad f_Y(y) = \int_{-\infty}^y |\psi'(\psi^{-1}(y))|^{-1} f_X(\psi^{-1}(y)) dy.$$

Check the formula yourself! (Start with the case when the derivative  $\psi'$  is always positive.)

It is more complicated with more general sums of independent random variables. Consider two such continuous random variables  $X$  and  $Y$  with densities  $f_X$  and  $f_Y$ , respectively. The distribution function of the random variable  $V = X + Y$  is computed directly (exploit the independence of  $X$  and  $Y$  write the joint density of  $(X, Y)$  as product):

$$\begin{aligned} F_V(u) &= \int_{x+y < u} f_X(x) f_Y(y) dx dy = \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{u-x} f_X(x) f_Y(y) dy dx \\ &= \int_{-\infty}^u \left( \int_{-\infty}^{\infty} f_X(x) f_Y(v-x) dx \right) dv, \end{aligned}$$

where the substitution  $v = x + y$  is used together with the Fubini theorem. Thus, the joint density of the sum of two independent random variables is just the convolution of their densities

$$(3) \quad f_V = f_X * f_Y,$$

already met in subsection 7.2.2 (page 656). Similarly, there is a discrete convolution of probability mass functions in the case of discrete random variables.

In the seventh chapter, we viewed the convolution as a kind of blurry picture of one of the functions with the help of the kernel expressed by the other. This should be the right intuition for the density of the sum of independent random variables as well. Of course, this also suggests that the convolution must be symmetric in the arguments.

**10.2.27. Numerical characteristics.** When examining some values (of a measurement, for example) from the statistical point of view, important numerical characteristics like the arithmetic mean and the standard deviation are looked for. Now we introduce similar characteristics for random variables and

see that  $P(Z = 1) \cdot P(X = 0) \neq P(Z = 1, X = 0)$ , which means that  $X$  and  $Z$  are dependent.

It can be easily verified from the corresponding definitions that if  $X$  is any random variable with zero expected value, finite second moment and zero third moment, then  $X$  and  $Y = X^2$  are dependent, but uncorrelated.  $\square$

**H. Inequalities and limit theorems**

Markov’s inequality provides a rough estimate of the behavior of a non-negative random variable if we know nothing more than its expected value. In exact words, for any non-negative random variable  $X$  and any  $a > 0$ , it holds that  $P(X \geq a) \leq \frac{EX}{a}$ .

**10.H.1.** Consider a non-negative random variable  $X$  with expected value  $\mu$ . With no further information about  $X$ , bound  $P(X > 3\mu)$ . Then, compute  $P(X > 3\mu)$  if you know that  $X \sim \text{Ex}(\frac{1}{\mu})$ .

**Solution.** If the non-negative random variable  $X$  does not take zero with probability 1, then its expected value  $\mu$  is positive. Therefore, the wanted probability can be bounded using Markov’s inequality as

$$P(X \geq 3\mu) \leq \frac{\mu}{3\mu} = \frac{1}{3}.$$

If we know that  $X \sim \text{Ex}(\frac{1}{\mu})$ , then

$$P(X > 3\mu) = 1 - P(X \leq 3\mu) = 1 - F(3\mu),$$

where  $F$  is the distribution function of the exponential distribution. By definition, this is

$$F(x) = \int_0^x \frac{1}{\mu} e^{-\frac{t}{\mu}} dt = \left[-e^{-\frac{t}{\mu}}\right]_0^x = 1 - e^{-\frac{x}{\mu}}.$$

Hence,  $P(X > 3\mu) = \frac{1}{e^3}$ .  $\square$

**10.H.2.** At a particular place, the average speed of wind is 20 kilometers per hour.

- Regardless of the distribution of the speed as a random variable, bound the probability that in a given observation, the speed does not exceed 60 km/h.
- Find the interval in which the speed lies with probability at least 0.9 if you know that the standard deviation is  $\sigma = 1$  km/h.

**Solution.** Let  $X$  denote the random variable that corresponds to the speed. In the first case, we can only use Markov’s inequality, leading to

$$P(X \leq 60) = 1 - P(X \geq 60) \geq 1 - \frac{20}{60} = \frac{2}{3}.$$

In the second case, we know the variance (or standard deviation) of the speed, so we can use Chebyshev’s inequality (see 10.2.32):

$$0.9 \leq P(|X - 20| < x) = 1 - P(|X - 20| \geq x) \leq 1 - \frac{1}{x^2}.$$

Hence,  $x \geq \sqrt{10} \approx 3.2$ . Thus, the wanted interval is (16.8 km/h, 23.2 km/h).  $\square$

random vectors. The first one is an analogy of the arithmetic mean.

EXPECTED VALUE

For any random variable  $X$ , define its *expected value*  $EX$  by

$$EX = \begin{cases} \sum_i x_i f_X(x_i) & \text{for a discrete variable} \\ \int_{-\infty}^{\infty} x f_X(x) dx & \text{for a continuous variable,} \end{cases}$$

provided the sum or integral converges absolutely. If not, the random variable  $X$  is said to have no expected value.

The *expected value of a random vector* is simply the vector of expected values of the individual components.

The expected value can also be expressed directly for functions  $Y = \psi(X)$  of a random variable or vector  $X$ . Recall that we consider only those functions  $\psi$  for which  $Y$  is again a random variable.

In the discrete case, compute

$$\begin{aligned} EY &= \sum_j y_j P(Y = y_j) \\ &= \sum_j y_j \sum_{\psi(x_i)=y_j} P(X = x_j) \\ &= \sum_i \psi(x_i) P(X = x_i), \end{aligned}$$

provided the sum converges absolutely. Of course, it is not guaranteed that a function of a random variable which has expected value also has it.

Similarly, the expected value of a function of a continuous random variable is :

$$E\psi(X) = \int_{-\infty}^{\infty} \psi(x) f_X(x) dx,$$

provided the integral converges absolutely.

Note that the random variable  $Y = \psi(X)$  does not have to be continuous even if the original variable  $X$  is. Nevertheless, if  $\psi$  is a differentiable monotone function with non-zero derivative, it is an easy exercise to verify that the definition of  $E\psi(X)$  coincides with  $EY$ . We do not go into further details here.

Shortly, in the part devoted to statistics, it is shown that the expected value has a direct connection with the arithmetic mean of the corresponding vector of values.

**10.2.28. St. Petersburg paradox.** We return to the example used as motivation for the need of discrete random variables in subsection 10.2.1. Reformulate the model as potential rules for a casino. This results in a good example of a situation where the expected value of the examined random variable does not exist at all.

The gambler pays an initial amount  $C$  and then keeps tossing a coin until it comes up heads. Denoting the number of tosses he has made by  $T$ , he wins  $2^T$ . The problem is to determine a “reasonable value” for the initial amount  $C$ . If  $X$

**10.H.3.** Each yogurt of an undisclosed company contains a photo of one of 26 ice-hockey world champions. Suppose the players are distributed uniformly at random. How many yogurts must Vera buy if she wants the probability of getting at least 5 photos of Jaromír Jágr to be at least 0.95?

**Solution.** Let  $X$  denote the random variable that corresponds to the number of obtained photos of Jaromír Jágr (parametrized by the number  $n$  of yogurts bought). Clearly,  $X \sim \text{Bi}(n, \frac{1}{26})$ . We are looking for the value of  $n$  for which  $P(X \geq 5) = 0.95$ , i. e.,  $F_X(4) = P(X \leq 4) = 0.05$ . In order to find it, we use the de Moivre-Laplace theorem and approximate the binomial distribution with the normal distribution (we assume that  $n$  is large, so the approximation error will be small). By **F**, the expected value of  $X$  is  $E X = \frac{n}{26}$ , and its variance is  $\text{var } X = \frac{25n}{26^2}$ . Denoting the corresponding standardized variable by  $Z$ , we can reformulate the condition as

$$0.05 = P(X \leq 4) = P\left(Z \leq \frac{4 - \frac{n}{26}}{\frac{5\sqrt{n}}{26}}\right) = F_Z\left(\frac{104 - n}{5\sqrt{n}}\right),$$

where by the approximation assumption,  $F_Z \approx \Phi$  is the distribution function of the normal distribution  $N(0, 1)$ . Since we must have  $n > 104$ , using  $\Phi(-x) = 1 - \Phi(x)$ , the above equation gives  $n - 104 = \Phi^{-1}(0.95) \cdot 5\sqrt{n}$ . Using a table of the normal distribution or appropriate software, we can learn that  $z(0.95) = 1.65$ . Solving this quadratic equation, we get  $n \doteq 228.8$ . Thus, Vera must buy at least 229 yogurts.  $\square$

**10.H.4.** We roll a die 1200 times. Find the probability that the number of 6s lies between 150 and 250 (inclusive) using Chebyshev's inequality, and then using Moivre-Laplace theorem.

**Solution.** Let  $X$  denote the random variable which corresponds to the number of 6s. Clearly,  $X \sim \text{Bi}(1200, \frac{1}{6})$ . By **F**, we have  $E X = 1200 \cdot \frac{1}{6} = 200$  and  $\text{var } X = 200(1 - \frac{1}{6}) = \frac{500}{3}$ . The condition on the number of 6s says that  $150 \leq X \leq 250$ , which can be written as  $|X - 200| \leq 50$ . Using Chebyshev's inequality **10.2.32**, we get

$$P(|X - 200| \leq 50) = 1 - P(|X - 200| \geq 51) \geq 1 - \frac{500}{3 \cdot 51^2} \approx 0.94.$$

(2) The exact value of the wanted probability is given by the expression

$$P(150 \leq X \leq 250) = F_X(250) - F_X(150),$$

where  $F_X$  is the distribution function of the binomial distribution. By definition,

$$P(150 \leq X \leq 250) = \sum_{k=150}^{250} \binom{1200}{k} \left(\frac{1}{6}\right)^k \left(\frac{5}{6}\right)^{1200-k}.$$

This expression is hard to evaluate without a computer, so we use Moivre-Laplace theorem. Replacing  $X$  with the standardized random variable

$$Z = \frac{\sqrt{3}(X - 200)}{10\sqrt{5}},$$

is the random variable corresponding to the won amount, it seems that the correct answer is "anything below the expected value  $E X$ ".

As derived in **10.2.1**,  $P(T = k) = 2^{-k}$ , provided that the coin is fair. Sum up all the probabilities multiplied by  $2^k$ , to obtain  $\sum_1^\infty 1 = \infty$ . Therefore, the expected value does not exist. So it seems that it is advantageous for the gambler to play even if the initial amount is very high...

Simulate the game for a while, to obtain that the amount won is somewhere around  $2^4$ . The reason is that no one is able to play infinitely long, hence the extremely high amounts are not feasible enough to be won, so such amounts cannot be taken seriously. In decision theory, these cases (when the expected value does not directly correspond to the evaluated utility) are called *St. Petersburg paradox*, and much literature has been devoted to this topic.<sup>3</sup>

**10.2.29. Properties of the expected value.** In the case of simple distributions, compute the expected value directly from the definition. For instance, for the Bernoulli distribution  $A(p)$ , it is immediate that

$$E X = (1 - p) \cdot 0 + p \cdot 1 = p.$$

Similarly, compute the expected value  $np$  of the binomial distribution  $\text{Bi}(n, p)$ . This requires more thought. The result is a direct corollary of the following general theorem since  $\text{Bi}(n, p)$  is the sum of  $n$  random variables with the Bernoulli distributions  $A(p)$ .

For any random variables  $X, Y$ , real constants  $a, b$ , consider the expected values of the functions of random variables  $X + Y$  and  $a + bX$ , provided the expected values  $E X$  and  $E Y$  exist.

It follows directly from the definition that the constant random variable  $a$  has expected value  $a$ . Further,

$$E(bX) = b E X,$$

since the constant  $b$  can be factored out from the sums or integrals.

More generally, the expected value of the product of independent random variables  $X$  and  $Y$  can be computed as follows. Suppose the components of the vector  $(X, Y)$  are discrete and independent, with probability mass functions  $f_X(x_i), f_Y(y_j)$ . Then,

$$\begin{aligned} E(XY) &= \sum_i \sum_j x_i y_j f_X(x_i) f_Y(y_j) \\ &= \left(\sum_i x_i f_X(x_i)\right) \left(\sum_j y_j f_Y(y_j)\right) = E X E Y. \end{aligned}$$

Similarly, verify the equality  $E(XY) = E X E Y$  for independent continuous random variables.

<sup>3</sup>Going back to Bernoulli, 1738, the real value is given by the utility, rather than the price.

then, by 10.2.40, we have  $Z \sim N(0, 1)$ , i. e.,  $F_Z \approx \Phi$ . Thus,

$$P(150 \leq X \leq 250) = P\left(\frac{\sqrt{3}(250-200)}{10\sqrt{5}} \leq Z \leq \frac{\sqrt{3}(150-200)}{10\sqrt{5}}\right) \approx \Phi(\sqrt{15}) - \Phi(-\sqrt{15}) = 2\Phi(\sqrt{15}) - 1.$$

We learn that  $\Phi(\sqrt{15}) \approx 0.99994$ , so the wanted probability is approximately 99.988 %.  $\square$

**10.H.5.** At the Faculty of Informatics, 10 % of students have prumer less than 1.2 (let us call them successful). How many students must we meet if the probability that there are 8–12 % successful ones among them is to be at least 0.95? Solve this problem using Chebyshev’s inequality, and then using Moivre-Laplace theorem.

**Solution.** Let  $X$  denote the random variable that corresponds to the number of successful students, parametrized by the number  $n$  of students we meet. Since a randomly met student has probability 10 % of being successful, when meeting  $n$  students, we have  $X \sim \text{Bi}(n, \frac{1}{10})$ . By F, we have  $E X = 0.1n$  and  $\text{var } X = 0.09n$ . By Chebyshev’s inequality 10.2.32, the wanted probability satisfies

$$P(|X - 0.1n| \leq 0.02n) = 1 - P(|X - 0.1n| \geq 0.02n) \geq 1 - \frac{0.1 \cdot 0.9n}{(0.02n)^2} = 1 - \frac{225}{n}.$$

The inequality  $1 - \frac{225}{n} \geq 0.95$  and hence

$$P(|X - 0.1n| \leq 0.02n) \geq 0.95$$

holds for  $n \geq 4500$ . The exact value of the probability is given in terms of the distribution function  $F_X$  of the binomial distribution:

$$P(0.08n \leq X \leq 0.12n) = F_X(0.12n) - F_X(0.08n).$$

Using the de Moivre-Laplace theorem (see 10.2.40), we can approximate the standardized random variable  $Z = \frac{10X-n}{3\sqrt{n}}$  with the standard normal distribution,  $F_Z \approx \Phi$ , so

$$\begin{aligned} 0.95 &= P(0.08n \leq X \leq 0.12n) = P\left(-\frac{\sqrt{n}}{15} \leq Z \leq \frac{\sqrt{n}}{15}\right) \\ &\approx \Phi\left(\frac{\sqrt{n}}{15}\right) - \Phi\left(-\frac{\sqrt{n}}{15}\right) = \\ &= 2\Phi\left(\frac{\sqrt{n}}{15}\right) - 1. \end{aligned}$$

Hence  $\sqrt{n} = 15z(0.975)$  and we learn  $n \approx 864.4$ . Thus, we can see that it is sufficient to meet 865 students.  $\square$

**10.H.6.** The probability that a planted tree will grow is 0.8. What is the probability that out of 500 planted trees, at least 380 trees will grow?

**Solution.** The random variable  $X$  that corresponds to the number of trees that will grow has binomial distribution  $X \sim \text{Bi}(500, \frac{4}{5})$ . By F, we have  $E X = 400$  and  $\text{var } X = 80$ . The standardized random variable is  $Z = \frac{X-400}{\sqrt{80}}$ . By the de

Now compute  $E(X + Y)$  for arbitrary random variables. For discrete distributions of  $X$  and  $Y$ ,

$$\begin{aligned} E(X + Y) &= \sum_i \sum_j (x_i + y_j) P(X = x_i, Y = y_j) \\ &= \sum_i \left( x_i \sum_j P(X = x_i, Y = y_j) \right) \\ &\quad + \sum_j \left( y_j \sum_i P(X = x_i, Y = y_j) \right) \\ &= \sum_i x_i P(X = x_i) + \sum_j y_j P(Y = y_j), \end{aligned}$$

where absolute convergence of the first double sum follows from the triangle inequality and the absolute convergence of the sums that stand for the expected values of the particular random variables. Absolute convergence is used in order to interchange the sums.

Dealing with continuous variables  $X$  and  $Y$ , whose expected values exist, proceed analogously.

$$\begin{aligned} E(X + Y) &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x + y) f_{X,Y}(x, y) dx dy \\ &= \int_{-\infty}^{\infty} x \int_{-\infty}^{\infty} f_{X,Y}(x, y) dy dx + \int_{-\infty}^{\infty} y \int_{-\infty}^{\infty} f_{X,Y}(x, y) dy dx \\ &= \int_{-\infty}^{\infty} x f_X(x) dx + \int_{-\infty}^{\infty} y f_Y(y) dy = E X + E Y, \end{aligned}$$

where absolute convergence of integrals of the expected values  $E X$  and  $E Y$  is used to interchange the integrals by Fubini’s theorem.

Altogether, the expected formula:

$$E(X + Y) = E X + E Y$$

is obtained, whenever the expected values  $E X$  and  $E Y$  exist.

Straightforward application of this result leads to the following:

AFFINE NATURE OF EXPECTED VALUES

For any constants  $a, b_1, \dots, b_k$  and random variables  $X_1, \dots, X_k$ ,

$$E(a + b_1 X_1 + \dots + b_k X_k) = a + b_1 E X_1 + \dots + b_k E X_k.$$

The following theorem extends this behaviour with respect to affine transformations of random vectors, and shows that the expected value is invariant with respect to affine transformations, as is the arithmetic mean:

**Theorem.** Let  $X = (X_1, \dots, X_n)$  be a random vector with expected value  $E X$ ,  $a \in \mathbb{R}^m$ ,  $B \in \text{Mat}_{mn}(\mathbb{R})$  a matrix. Then,

$$E(a + B \cdot X) = a + B \cdot E X.$$

**PROOF.** There is almost nothing remaining to be proved. Since the expected value of a vector is defined as the vector of the expected values of the components, it suffices to restrict attention to a single item in  $E(a + B \cdot X)$ . Thus, it can be assumed that  $a$  is a scalar and  $B$  is a matrix with a single row.

Moivre-Laplace theorem, we have  $F_Z \approx \Phi$ , so

$$\begin{aligned} P(X \geq 380) &= P\left(Z \geq \frac{380 - 400}{\sqrt{80}}\right) \approx 1 - \Phi\left(-\frac{\sqrt{20}}{2}\right) = \\ &= \Phi\left(\frac{\sqrt{20}}{2}\right) \approx 0.987. \end{aligned}$$

□

**10.H.7.** Using the distribution function of the standard normal distribution, find the probability that the absolute difference between the heads and the tails in 1600 tosses of a coin is at least 82.

**Solution.** Let  $X$  denote the random variable that corresponds to the number of times the coin came up heads. Then  $X$  has binomial distribution  $Bi(1600, 1/2)$  (with expected value 800 and standard deviation 20), so for a large value of  $n = 1600$ , by the de Moivre-Laplace theorem, the distribution function of the variable  $\frac{X-800}{20}$  can be approximated with the distribution function  $\Phi$  of the standard normal distribution. Thus, the wanted probability is

$$\begin{aligned} P &= 1 - P[759 \leq X \leq 841] \\ &= 1 - P\left[-2.05 \leq \frac{X - 800}{20} \leq 2.05\right] \\ &\doteq 2\Phi(-2, 05) \doteq 0.0404. \end{aligned}$$

□

**10.H.8.** Using the distribution function of the standard normal distribution, find the probability that the absolute difference between the heads and the tails in 3600 tosses of a coin is at most 66.

**Solution.** Let  $X$  denote the random variable that corresponds to the number of times the coin came up heads. Then  $X$  has binomial distribution  $Bi(3600, 1/2)$  (with expected value 1800 and standard deviation 30), so for a large value of  $n = 3600$ , the distribution function of the variable  $\frac{X-1800}{30}$  can be approximated, by the de Moivre-Laplace theorem, with the distribution function  $\Phi$  of the standard normal distribution. Thus, the wanted probability is

$$\begin{aligned} P[1767 \leq X \leq 1833] &= P\left[-1, 1 \leq \frac{X - 1800}{30} \leq 1, 1\right] \\ &\doteq \Phi(1, 1) - \Phi(-1, 1) \doteq 0, 7498. \end{aligned}$$

□

**10.H.9.** The probability that a seed will grow is 0.9. How many seeds must we plant if we require that with probability at least 0.995, the relative number of grown items differs from 0.9 by at most 0.034.

**Solution.** The random variable  $X$  that corresponds to the number of grown seeds, out of  $n$  planted ones, has binomial distribution  $X \sim Bi(n, \frac{9}{10})$ . By F, we have  $E X = 0.9n$  and  $\text{var } X = 0.09n$ , so the standardized variable is  $Z = \frac{X-0.9n}{\sqrt{0.09n}}$ .

Then, the expected value of a finite sum of random variables is obtained, and by the above results, that exists and is given as the sum of the expected values of the individual items. This is exactly what is wanted to be proved. □

**10.2.30. Quantiles and critical values.** Introduce numerical characteristics that are analogous to those from descriptive statistics. There, the next useful characteristics are the *quantiles*, cf. 10.1.5.

Consider a random variable  $X$  whose distribution function  $F_X$  is strictly monotone. This is satisfied by any random variable whose density is nowhere equal to zero, which is the case for the normal distribution, for example. In this case, define the *quantile function*  $F_X^{-1}$  simply as the inverse function  $(F_X)^{-1} : (0, 1) \rightarrow \mathbb{R}$ . This means that the value  $y = F_X^{-1}(\alpha)$  is such that  $P(X < y) = \alpha$ . This corresponds precisely to the quantiles from descriptive statistics using relative frequencies for the probabilities.

#### QUANTILE FUNCTION

For any random variable  $X$  with distribution function  $F_X(x)$ , define its *quantile function*

$$F_X^{-1}(\alpha) = \inf\{x \in \mathbb{R}; F(x) \geq \alpha\}, \alpha \in (0, 1).$$

Clearly, this is a generalization of the previous definition in the case the distribution function is strictly monotone.

As seen in descriptive statistics, the most used quantiles are for  $\alpha = 0.5$  (the *median*),  $\alpha = 0.25$  (the *first quartile*),  $\alpha = 0.75$  (the *third quartile*). Similarly for *deciles* and *percentiles* when  $\alpha$  is equal to (integer) multiples of tenths and hundredths, respectively.

It follows directly from the definition that the quantile function for a given random variable  $X$  allows the determination of intervals into which the values of  $X$  fall with a chosen probability. For instance, the value  $F_X^{-1}(0.975)$ , approximately 1.96, corresponds to percentile 97.5 for the normal distribution  $N(0, 1)$ . This says that with the probability of 2.5%, the value of such a random variable  $Z \sim N(0, 1)$  is at least 1.96. Since the density of the variable  $Z$  is symmetric with respect to the origin, this observation can be interpreted as that there is only a 5% probability that the value of  $|Z|$  is greater 1.96.

There are similar intervals and values when discussing the reliability of estimates of characteristics of random variables.

#### CRITICAL VALUES

For a random variable  $X$  and a real number  $0 < \alpha < 1$ , define its *critical value*  $x(\alpha)$  at level  $\alpha$  as

$$P(X \geq x(\alpha)) = \alpha.$$

This means that  $x(\alpha) = F_X^{-1}(1 - \alpha)$  where  $F_X^{-1}$  is the quantile function of the random variable  $X$ .

The condition in question can be written as

$$\begin{aligned} P(|X - 0.9n| \leq 0.034n) &= P\left(|Z| \leq \frac{0.034n}{\sqrt{0.09n}}\right) = \\ &= P\left(|Z| \leq \frac{0.34}{3}\sqrt{n}\right) \geq 0.995. \end{aligned}$$

By the de Moivre-Laplace theorem, for large  $n$ , the distribution function can be approximated by the distribution function  $\Phi$  of the normal distribution. Thus,

$$\begin{aligned} P\left(|Z| \leq \frac{0.34}{3}\sqrt{n}\right) &\approx \Phi\left(\frac{0.34}{3}\sqrt{n}\right) - \Phi\left(-\frac{0.34}{3}\sqrt{n}\right) = \\ &= 2\Phi\left(\frac{0.34}{3}\sqrt{n}\right) - 1. \end{aligned}$$

Altogether, we get the condition

$$2\Phi\left(\frac{0.34}{3}\sqrt{n}\right) - 1 \geq 0.995.$$

Odtud vypočítáme  $n \geq \left(\frac{3z(0.9975)}{0.34}\right)^2 \approx 615$ . □

**10.H.10.** The service life (in hours) of a certain kind of gadget has exponential distribution with parameter  $\lambda = \frac{1}{10}$ . Using the central limit theorem, bound the probability that the total service life of 100 such gadgets lies between 900 and 1050 hours.

**Solution.** In exercise 10.F.5, we computed that the expected value and variance of a random variable  $X_i$  with exponential distribution are equal to  $E X_i = \frac{1}{\lambda}$  and  $\text{var } X_i = \frac{1}{\lambda^2}$ , respectively. Thus, the expected service life of each gadget is  $E X_i = \mu = 10$  hours, with variance  $\text{var } X_i = \sigma^2 = 100$  hours<sup>2</sup>. By the central limit theorem, the distribution of the transformed random variable  $\frac{1}{\sqrt{n}} \sum_{i=1}^n \left(\frac{X_i - \mu}{\sigma}\right) = \frac{1}{100} \sum_{i=1}^{100} X_i - 10$  approaches the standard normal distribution as  $n$  tends to infinity. Thus, the wanted probability for the service life of 100 gadgets

$$P(900 \leq \sum X_i \leq 1050) = P\left(-1 \leq \frac{1}{100} \sum_{i=1}^{100} X_i - 10 \leq 0.5\right)$$

can be approximated with the distribution function of the normal distribution:

$$P(900 \leq \sum X_i \leq 1050) \approx \Phi(0.5) - \Phi(-1) \approx 0.533.$$

□

**10.H.11.** We keep putting items into a chest. The expected mass of an item is 3 kg and the standard deviation is 0.8 kg. What is the maximum number of items that we can put into the chest so that with probability at least 99%, the total mass does not exceed one ton?

**Solution.** Let  $X_i$  denote the random variable that corresponds to the mass of the  $i$ -th item. Then, we have  $\mu = E X_i = 3$  and  $\sigma = \sqrt{\text{var } X_i} = 0.8$  (in kilograms), and we want to have

$$P\left(\sum_{i=1}^n X_i \leq 1000\right) = 0.99.$$

**10.2.31. Variance and standard deviation.** The simple numerical characteristics concerning the variability of sample values in descriptive statistics were the variance and the standard deviation. Define them similarly for random variables.

VARIANCE OF A RANDOM VARIABLE

Given a random variable  $X$  with finite expected value, its *variance* is defined as

$$\text{var } X = E((X - E X)^2),$$

provided the right-hand expected value exists. Otherwise, the variance of  $X$  does not exist.

The square root  $\sqrt{\text{var } X}$  of the variance is called the *standard deviation of the random variable*  $X$ .

Using the properties of the expected value, a simpler formula can be derived for the variance of a random variable  $X$  whose expected value exists:

$$\begin{aligned} \text{var } X &= E(X - E X)^2 = E(X^2 - 2X(E X) + (E X)^2) \\ &= E X^2 - 2(E X)^2 + (E X)^2 \\ &= E X^2 - (E X)^2. \end{aligned}$$

Consider how affine transformations change the variance of a random variable. Given real numbers  $a, b$  and a random variable  $X$  with expected value and variance, consider the random variable  $Y = a + bX$ . Compute

$$\begin{aligned} \text{var } Y &= E((a + bX) - E(a + bX))^2 = E(b(X - E X))^2 \\ &= b^2 \text{var } X. \end{aligned}$$

Thus are derived the following useful formulae:

PROPERTIES OF VARIANCE

$$\begin{aligned} (1) \quad &\text{var } X = E(X^2) - (E X)^2 \\ (2) \quad &\text{var}(a + bX) = b^2 \text{var } X \\ (3) \quad &\sqrt{\text{var}(a + bX)} = b\sqrt{\text{var } X} \end{aligned}$$

Given a random variable  $X$  with expected value and non-zero variance, define its *standardization* as the random variable

$$Z = \frac{X - E X}{\sqrt{\text{var } X}}.$$

Thus, the standardized variable is the affine transformation of the original variable whose expected value equals zero and variance equals one.

**10.2.32. Chebyshev's inequality.** A good illustration of the usefulness of variance is the Chebyshev's inequality. This connects the variance directly to the probability that the random variable assumes values that are distant from its expected value.

By the central limit theorem 10.2.40, the distribution of the random variable

$$S_n = \frac{1}{\sqrt{n}} \sum_{i=1}^n \left( \frac{X_i - 3}{0.8} \right) = \frac{1}{0.8\sqrt{n}} \sum_{i=1}^n X_i - \frac{3\sqrt{n}}{0.8}$$

can be approximated by the standard normal distribution. Thus, we get

$$P\left(\sum_{i=1}^n X_i \leq 1000\right) = P\left(S_n \leq \frac{1000}{0.8\sqrt{n}} - \frac{3\sqrt{n}}{0.8}\right) \approx \Phi\left(\frac{1000}{0.8\sqrt{n}} - \frac{3\sqrt{n}}{0.8}\right)$$

We learn that  $z(0.99) \approx 2.326$ , so the wanted  $n$  satisfies the quadratic equation

$$\frac{1000}{0.8\sqrt{n}} - \frac{3\sqrt{n}}{0.8} = 2.326,$$

whence we get  $n \approx 322$ .  $\square$

### I. Testing samples from the normal distribution

In subsection 10.3.4, we introduced the so-called two-sided interval estimate of an unknown parameter  $\mu$  of the normal distribution  $N(\mu, \sigma^2)$ . In some cases, we may be interested only in an upper or lower estimate, i.e. a statistic  $U$  or  $L$  for which  $P(\mu < U)$  or  $P(L < \mu)$ , respectively. Then, we talk about a one-sided confidence interval  $(-\infty, U)$  or  $(L, \infty)$ . The formula for these intervals can be derived similarly as for the two-sided interval. Now, we have for the random variable  $Z = \sqrt{n} \frac{\bar{X} - \mu}{\sigma} \sim N(0, 1)$  that

$$1 - \alpha = \Phi(z(1 - \alpha)) = P(Z < z(1 - \alpha)).$$

Hence it immediately follows that

$$1 - \alpha = P\left(\bar{X} - \frac{\sigma}{\sqrt{n}} z(1 - \alpha) < \mu\right),$$

so  $L = \bar{X} - \frac{\sigma}{\sqrt{n}} z(1 - \alpha)$ . Similarly, we find  $U = \bar{X} + \frac{\sigma}{\sqrt{n}} z(1 - \alpha)$ , and for a distribution with unknown variance,  $\mu \geq \bar{X} - \frac{S}{\sqrt{n}} t_{n-1}(1 - \alpha)$  and  $\mu \leq \bar{X} + \frac{S}{\sqrt{n}} t_{n-1}(1 - \alpha)$ .

If we want to estimate the variance  $\sigma^2$  of a random distribution, then we use theorem 10.3.3, similarly as when we derived it for the expected value. This time, we use the second part of the theorem, by which the random variable  $\frac{n-1}{\sigma^2} S^2$  has distribution  $\chi^2$ . Then, we can immediately see that

$$1 - \alpha = P\left(\chi_{n-1}^2(\alpha/2) \leq \frac{n-1}{\sigma^2} S^2 \leq \chi_{n-1}^2(1 - \alpha/2)\right).$$

Thus, the two-sided  $100(1 - \alpha)\%$  confidence interval for the variance is

$$\left( \frac{(n-1)S^2}{\chi_{n-1}^2(1 - \alpha/2)}, \frac{(n-1)S^2}{\chi_{n-1}^2(\alpha/2)} \right)$$

and similarly for the one-sided upper and lower estimates, we get

$$\sigma^2 \leq \frac{(n-1)S^2}{\chi_{n-1}^2(\alpha)}, \text{ resp. } \frac{(n-1)S^2}{\chi_{n-1}^2(1 - \alpha)} \leq \sigma^2.$$

### CHEBYSHEV'S INEQUALITY

**Theorem.** Consider a random variable  $X$  with finite variance, and fix an arbitrary  $\varepsilon > 0$ . Then,

$$P(|X - E X| \geq \varepsilon) \leq \frac{\text{var } X}{\varepsilon^2}.$$

**PROOF.** Suppose  $X$  is continuous. Set  $\mu = E X$  and compute, using the definition:

$$\begin{aligned} \text{var } X &= \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx \\ &= \int_{|x-\mu| \geq \varepsilon} (x - \mu)^2 f(x) dx \\ &\quad + \int_{|x-\mu| < \varepsilon} (x - \mu)^2 f(x) dx \\ &\geq \int_{|x-\mu| \geq \varepsilon} \varepsilon^2 f(x) dx = \varepsilon^2 P(|X - \mu| \geq \varepsilon). \end{aligned}$$

$\square$

The analogous proof for discrete random variables is left as an exercise for the reader.

Realizing that the variance is the square of the standard deviation  $\sigma$ , the choice  $\varepsilon = k\sigma$  yields the probability

$$P(|X - E X| \geq k\sigma) \leq \frac{1}{k^2}.$$

The Chebyshev's inequality helps understanding asymptotic descriptions of limit processes. For instance, consider the sequence of random variables  $X_1, X_2, \dots$  with probability distributions  $X_n \sim \text{Bi}(n, p)$ , with a fixed value of  $p$ ,  $0 < p < 1$ . Intuitively, it is expected that the relative frequency of success should approach the probability  $p$  as  $n$  increases, i.e., that the values of the random variables  $Y_n = \frac{1}{n} X_n$  should approach  $p$ . Clearly,

$$E Y_n = \frac{np}{n} = p, \quad \text{var } Y_n = \frac{np(1-p)}{n^2} = \frac{p(1-p)}{n}.$$

Direct application of Chebyshev's inequality yields, for any fixed  $\varepsilon > 0$ , that

$$P(|Y_n - p| \geq \varepsilon) \leq \frac{p(1-p)}{n\varepsilon^2}.$$

Hence it is clear that, for any fixed  $\varepsilon > 0$ ,

$$\lim_{n \rightarrow \infty} P\left(\left|\frac{X_n}{n} - p\right| \geq \varepsilon\right) = 0.$$

This result is known as *Bernoulli's theorem* (one of many).

This type of limit behaviour is called *convergence in probability*. Thus it is proved (as a corollary of Chebyshev's inequality) that the random variables  $Y_n$  converge in probability to the constant random variable  $p$ .

**10.I.1.** We roll a die 600 times, obtaining only 45 sixes. Is it possible to say that the die is ideal at level  $\alpha = 0.01$ ?

**Solution.** For an ideal die, the probability of rolling a six is always  $p = \frac{1}{6}$ . The number of sixes in 600 rolls is given by a random variable  $X$  with binomial distribution  $X \sim \text{Bi}(600, \frac{1}{6})$ . By 10.2.40, this distribution can be approximated by the distribution  $N(100, \frac{250}{3})$ . The measured value  $X = 45$  can be considered a random sample consisting of one item. Assuming that the variance is known and applying 10.3.4, we get that the 99% (two-sided) confidence interval for the expected value  $\mu$  equals  $(45 - \sqrt{\frac{250}{3}}z(0.995), 45 + \sqrt{\frac{250}{3}}z(0.995))$ . We learn that the quantile is approximately  $z(0.995) \approx 2.58$ , which gives the interval (21, 69). However, for an ideal die, we clearly have  $\mu = 100$ , so our die is not ideal at level  $\alpha = 0.01$ .  $\square$

**10.I.2.** Suppose the height of 10-years-old boys has normal distribution  $N(\mu, \sigma^2)$  with unknown expected value  $\mu$  and variance  $\sigma^2 = 39.112$ . Taking the height of 15 boys, we get the sample mean  $\bar{X} = 139.13$ . Find

- i) the 99% two-sided confidence interval for the parameter  $\mu$ ,
- ii) the lower estimate for  $\mu$  at significance level 95 %.

**Solution.** a) By 10.3.4, the  $100(1 - \alpha)\%$  two-sided confidence interval for the unknown expected value  $\mu$  of the normal distribution is

$$(1) \quad \mu \in \left( \bar{X} - \frac{\sigma}{\sqrt{n}}z(1 - \alpha/2), \bar{X} + \frac{\sigma}{\sqrt{n}}z(1 - \alpha/2) \right),$$

where  $\bar{X}$  is the sample mean of  $n$  items,  $\sigma^2$  is the known variance, and  $z(1 - \alpha/2)$  is the corresponding quantile. Substituting the given values  $n = 15$ ,  $\sigma \approx 6.254$  and the learned  $z(0.995) \approx 2.576$ , we get  $\frac{\sigma}{\sqrt{n}}z(\alpha/2) \approx 4.16$ , i. e.,  $\mu \in (134.97, 143.29)$ .

b) The lower estimate  $L$  for the parameter  $\mu$  at significance level 95 % is given by the expression  $L = \bar{X} - \frac{\sigma}{\sqrt{n}}z(0.95)$ . We learn that  $z(0.95) \approx 1.645$ , and direct substitution leads to  $\mu \in (136.474, \infty)$ .  $\square$

**10.I.3.** A customer tests the quality of bought products by examining 21 randomly chosen ones. He will accept the delivery if the sample standard deviation does not exceed 0.2 mm. We know that the pursued property of the products has normal distribution of the form  $N(10 \text{ mm}; 0.0734 \text{ mm}^2)$ . Using statistical tables, find the probability that the delivery will be accepted. How does the answer change if the customer, in order to save expenses, tests only 4 products?

**Solution.** The problem asks for the probability  $P(S \leq 0.2)$ . By theorem 10.3.3, when sampling  $n$  products, the random variable  $\frac{n-1}{\sigma^2}S^2$  has distribution  $\chi_{n-1}^2$ . In our case,  $n = 21$  and  $\sigma^2 = 0.0734$ , so

$$P(S \leq 0.2) = P\left(\frac{20}{0.0734}S^2 \leq \frac{20}{0.0734}0.2^2\right) = \chi_{20}^2\left(\frac{20 \cdot 0.2^2}{0.0734}\right) = bdE((X - E X)(Y - E Y)) = bd \text{cov}(X, Y).$$

**10.2.33. Covariance.** We return to random vectors. In the case of the expected value, the situation is very simple — just take the vector of expected values. When characterizing the variability, the dependencies between the individual components are also of much interest. We follow the idea from 10.1.9 again.

COVARIANCE

Given random variables  $X, Y$  whose variances exist, Define their covariance as

$$\text{cov}(X, Y) = E((X - E X)(Y - E Y))$$

The basic properties of the concept can be derived very easily:

**Theorem.** For any random variables  $X, Y, Z$  whose variances exist and real numbers  $a, b, c, d$ ,

- (1)  $\text{cov}(X, Y) = \text{cov}(Y, X)$
- (2)  $\text{cov}(X, Y) = E(XY) - (E X)(E Y)$
- (3)  $\text{cov}(X + Y, Z) = \text{cov}(X, Z) + \text{cov}(Y, Z)$
- (4)  $\text{cov}(a + bX, c + dY) = bd \text{cov}(X, Y)$
- (5)  $\text{var}(X + Y) = \text{var} X + \text{var} Y + 2 \text{cov}(X, Y)$ .

Moreover, if  $X$  and  $Y$  are independent, then  $\text{cov}(X, Y) = 0$ , and consequently

$$(6) \quad \text{var}(X + Y) = \text{var} X + \text{var} Y.$$

**PROOF.** Directly from the definition, the covariance is symmetric in the arguments. The second proposition follows immediately from the properties of the expected value:

$$\begin{aligned} \text{cov}(X, Y) &= E(X - E X)(Y - E Y) \\ &= E(XY) - (E Y)X - (E X)Y + E X E Y \\ &= E(XY) - E X E Y. \end{aligned}$$

The next proposition also follows easily if the definition is expanded and the fact that the expected value of the sum of random variables equals the sum of their expected values is used.

The next proposition can be computed directly:

$$\begin{aligned} \text{cov}(a + bX, c + dY) &= \\ &= E((a + bX - E(a + bX))(c + dY - E(c + dY))) \\ &= E((bX - bE(X))(dY - dE(Y))) \\ &= E(bd(X - E(X))(Y - E(Y))) \\ &= bdE((X - E X)(Y - E Y)) = bd \text{cov}(X, Y). \end{aligned}$$

The expression in the argument of the distribution function is approximately 10.9, and we can learn from the table of the  $\chi^2$  distribution that  $\chi_{20}^2(10.9) \approx 0.05$ . Thus, the probability that delivery will be accepted is only 5%. We could have expected the probability to be low: indeed,  $ES^2 = \sigma^2 = 0.0734 > 0.2^2$ . If the customer tests only 4 products, then the probability of acceptance is given by the expression  $\chi_3^2\left(\frac{3 \cdot 0.2^2}{0.0734}\right) \approx \chi_3^2(1.63)$ . The value of the distribution function of  $\chi^2$  in this argument cannot be found in most tables. Therefore, we estimate it using linear interpolation. For instance, if the nearest known points are  $\chi_3^2(0.58) = 0.1$  and  $\chi_3^2(6.25) = 0.9$ , then

$$\chi_3^2(1.63) \approx (1.63 - 0.58) \frac{0.9 - 0.1}{6.25 - 0.58} + 0.1 \approx 0.24.$$

Although this results is only an estimate, we can be sure that the probability of acceptance is much greater than when testing 21 products.  $\square$

**10.I.4.** From a population with distribution  $N(\mu, \sigma^2)$ , where  $\sigma^2 = 0.06$ , we have sampled the values 1.3; 1.8; 1.4; 1.2; 0.9; 1.5; 1.7. Find the two-sided 95% confidence interval for the unknown expected value.

**Solution.** We have a random sample of size  $n = 7$  from the normal distribution with known variance  $\sigma^2 = 0.06$ . The sample mean is

$$\bar{X} = \frac{1}{7}(1.3 + 1.8 + 1.4 + 1.2 + 0.9 + 1.5 + 1.7) = 1.4$$

and we can learn for the given confidence level  $\alpha = 0.05$  that  $z(1 - \alpha/2) = z(0.975) \approx 1.96$ . Substituting into (1), we immediately obtain the wanted interval (1.22, 1.58).  $\square$

**10.I.5.** Let  $X_1, \dots, X_n$  be a random sample from the distribution  $N(\mu, 0.04)$ . Find the least number of measurements that are necessary so that the length of the 95% confidence interval for  $\mu$  would not exceed 0.16.

**Solution.** Since we have a normal distribution with known variance, we know from (1) that the length of the  $(1 - \alpha)\%$  confidence interval is  $\frac{2\sigma}{\sqrt{n}}z(1 - \alpha/2)$ . Substituting the given values, we get that the number  $n$  of measurements satisfies the inequality

$$\frac{2 \cdot 0.2}{\sqrt{n}}z(0.975) \leq 0.16.$$

Since  $z(0.975) \approx 1.96$ , we obtain  $n \geq 24.01$ . Thus, at least 25 measurements are necessary.  $\square$

**10.I.6.** Consider a random variable  $X$  with distribution  $N(\mu, \sigma^2)$ , where  $\mu, \sigma^2$  are unknown. The following table shows the frequencies of individual values of this random variable:

$X_i$	8	11	12	14	15	16	17	18	20	21
$n_i$	1	2	3	4	7	5	4	3	2	1

Calculate the sample mean, sample variance, sample standard deviation, and find the 99% confidence interval for the expected value  $\mu$ .

The other propositions about the variance are quite simple corollaries:

$$\begin{aligned} \text{var}(X + Y) &= E((X + Y) - E(X + Y))^2 \\ &= E((X - EX) + (Y - EY))^2 \\ &= E(X - EX)^2 + 2E(X - EX)(Y - EY) \\ &\quad + E(Y - EY)^2 \\ &= \text{var } X + 2\text{cov}(X, Y) + \text{var } Y. \end{aligned}$$

Furthermore, if  $X$  and  $Y$  are independent, then  $E(XY) = EXEY$ , and hence that their covariance is zero.  $\square$

Directly from the definition,

$$\text{var}(X) = \text{cov}(X, X).$$

The latter theorem claims that covariance is a symmetric bilinear form on the real vector space of random variables whose variance exists. The variance is the corresponding quadratic form. The covariance can be computed from the variance of the particular random variables and of their sum, as seen in linear algebra, see the property (5).

Notice that the random variable, equal to the sum of  $n$  independent and identically distributed random variables  $Y_i$  behaves, very much differently than the multiple  $nY$ . In fact,

$$\text{var}(Y_1 + \dots + Y_n) = n \text{var } Y, \quad \text{var}(nY) = n^2 \text{var } Y.$$

**10.2.34. Correlation of random variables.** To a certain extent, covariance corresponds to dependency between the random variables. Its relative version is called the *correlation of random variables* and, similarly as for the standard deviation, the following concept is defined:

#### CORRELATION COEFFICIENT

The *correlation coefficient* of random variables  $X$  and  $Y$  whose variances are finite and non-zero is defined as

$$\rho_{X,Y} = \frac{\text{cov}(X, Y)}{\sqrt{\text{var } X} \sqrt{\text{var } Y}}.$$

As seen from theorem 10.2.33, the correlation coefficient of random variables equals the covariance of the standardized variables  $\frac{1}{\sqrt{\text{var } X}}(X - EX)$  and  $\frac{1}{\sqrt{\text{var } Y}}(Y - EY)$ .

The following equalities hold (here,  $a, b, c, d$  are real constants,  $bd \neq 0$ , and  $X, Y$  are random variables with finite non-zero variances)

$$\begin{aligned} \rho_{a+bX, c+dY} &= \text{sgn}(bd)\rho_{X,Y} \\ \rho_{X, X} &= 1. \end{aligned}$$

Moreover, if  $X$  and  $Y$  are independent, then  $\rho_{X,Y} = 0$ .

Note that if the variance of a random variable  $X$  is zero, then it assumes the value  $EX$  with probability 1. If the value of  $X$  falls into an interval  $I$  not containing  $EX$  with probability  $p \neq 0$ , then the expression  $\text{var } X = E(X - EX)^2$  is positive. Stochastically, random variables with zero variance behave as constants.

**Solution.** The sample mean is given by the expression  $\bar{X} = \sum n_i X_i / \sum n_i$ . Substituting the given values, we get  $\bar{X} = 490/32 \approx 15.3$ . By definition, the sample variance is  $S = \sum n_i (X_i - \bar{X})^2 / (\sum n_i - 1)$ . Substituting the given values, we get  $S^2 = 1943/256 \approx 7.6$ , so the sample standard deviation is  $S \approx 2.8$ . The formula for the two-sided  $(1 - \alpha)\%$  confidence interval for the expected value  $\mu$ , when the variance is unknown, was derived at the end of subsection 10.3.4:

$$\mu \in \left( \bar{X} - \frac{S}{\sqrt{n}} t_{n-1}(1 - \alpha/2), \bar{X} + \frac{S}{\sqrt{n}} t_{n-1}(1 - \alpha/2) \right).$$

Substitution yields  $\bar{X} = 15.3$ ,  $n = 32$ ,  $S \approx 2.8$ ,  $\alpha = 0.01$ , and we learn  $t_{31}(0.995) \approx 2.75$ . Thus, the 99% confidence interval is  $\mu \in (14.0, 16.7)$ .  $\square$

**10.I.7.** Using the following table of the distribution function of the normal distribution, find the probability that the absolute difference between the heads and the tails in 3600 tosses of a coin is greater than 90.

Gilbert Strang, Typset with JTBK on April 20, 2006.

**Solution.** Let  $X$  denote the random variable that corresponds to the number of heads. Then,  $X$  has binomial distribution  $Bi(3600, 1/2)$  (with expected value 1800 and standard deviation 30), so by the de Moivre-Laplace theorem, for large values of  $n$ , the distribution function of the variable  $\frac{X-1800}{30}$  can be approximated by the distribution function  $\Phi$  of the normal

If the covariance is a positive-definite symmetric bilinear form, then it would follow from the Cauchy-Schwarz inequality (see 3.4.3) that

$$(1) \quad |\rho_{X,Y}| \leq 1$$

The following theorem claims more. It shows that the full correlation or anti-correlation, i.e.  $\rho_{X,Y} = \pm 1$  of random variables  $X$  and  $Y$  says that they are bound by an affine relation  $Y = kX + c$ , where the sign of  $k$  corresponds to the sign in  $\rho_{X,Y} = \pm 1$ . On the other hand, a zero correlation coefficient says that the (potential) dependency between the variables is very far from any affine relation of the mentioned type. (Note, however, this does not mean that the variables must be independent).

For instance, consider random variables  $Z \sim N(0, 1)$  and  $Z^2$ . Then  $\text{cov}(Z, Z^2) = E Z^3 = 0$  since the density of  $Z$  is an even function. Thus the expected value of an odd power of  $Z$  is zero, if it exists.

**Theorem.** If the correlation coefficient is defined, then  $|\rho_{X,Y}| \leq 1$ . Equality holds if and only if there are constants  $k, c$  such that  $P(Y = kX + c) = 1$ .

**PROOF.** A stochastic affine relation between  $Y$  and  $X$  with nonzero coefficient at  $Y$  is sought. This is equivalent to  $Y + sX \sim D(c)$  for some fixed value of the parameter  $s$  and constant  $c$ . In such a case the variance vanishes. Thus one considers the following non-negative quadratic expression:

$$0 \leq \text{var} \left( \frac{Y - EY}{\sqrt{\text{var}Y}} + t \frac{X - EX}{\sqrt{\text{var}X}} \right) = 1 + 2t\rho_{X,Y} + t^2.$$

The right-hand quadratic expression does not have two distinct real roots; hence its discriminant cannot be positive. So  $4(\rho_{X,Y})^2 - 4 \leq 0$ . Hence the desired inequality is obtained, and also the discriminant vanishes if  $\rho_{X,Y} = \pm 1$ . For the only (double) root  $t_0$ , the corresponding random variable has zero variance; thus it assumes a fixed value with probability 1. This yields the affine relation as expected.  $\square$

**10.2.35. Covariance matrix.** The variability of a random vector must be considered. This suggests considering the covariances of all pairs of components. The following definition and theorem show that this leads to an analogy of the variance for vectors, including the behaviour of the variance under affine transformations of the random variables.

distribution. Thus, the wanted probability is

$$P = 1 - P[1755 \leq X \leq 1845] = 1 - P\left[-1.5 \leq \frac{X - 1800}{30} \leq 1.5\right] = 2\Phi(-1.5) \doteq 0.1336,$$

where the last value was learned from the table.  $\square$

**10.I.8.** The probability that a newborn baby is a boy is 0.515. Find the probability that there are at least the same number of girls as boys among ten thousand babies.

**Solution.**

$$P[X < 5000] = P\left[\underbrace{\frac{X - 5150}{\sqrt{5150 \cdot 0.485}}}_{\sim N(0,1)} < \underbrace{\frac{-150}{\sqrt{5150 \cdot 0.485}}}_{-3.001\dots}\right] \doteq 0.00135$$

$\square$

**10.I.9.** Using the distribution function of the standard normal distribution, find the probability that we get at least 3100 sixes out of 18000 rolls of a six-sided die.

**Solution.** We proceed similarly as in the exercises above.  $X$  has binomial distribution  $Bi(18000, 1/6)$ . We find the expected value  $((1/6)(18000) = 3000)$  as well as the standard deviation  $\sqrt{((1/6)(1 - 1/6)18000)} = 50$ . Therefore, the variable  $\frac{X-3000}{50}$  can be approximated with the distribution function  $\Phi$  of the standard normal distribution:

$$P[X \geq 3100] = P\left[\frac{X - 3000}{50} \geq \frac{3100 - 3000}{50}\right] = P\left[\frac{X - 3000}{50} \geq 2\right] \doteq 1 - \Phi(2) \doteq 0.0228.$$

$\square$

**10.I.10.** A public opinion agency organizes a survey of preferences of five political parties. How many randomly selected respondents must answer so that the probability that for each party, the survey result differs from the actual preference by no more than 2% is at least 0.95?

**Solution.** Let  $p_i, i = 1 \dots 5$  be the actual relative frequency of voters of the  $i$ -th political party in the population, and let  $X_i$  denote the number of voters of this party among  $n$  randomly chosen people. Note that given any five intervals, the events corresponding to  $X_i/n$  falling into the corresponding interval may be dependent. If we choose  $n$  so that for each  $i, X_i/n$  falls into the given interval with probability at least  $1 - ((1 - 0.95)/5) = 0.99$ , then the desired condition is sure to hold even in spite of the dependencies. Thus, let us look for  $n$  such that  $P[|\frac{X}{n} - p| < 0.02] \geq 0.99$ . First of all, we

COVARIANCE MATRIX

Consider a random vector  $X = (X_1, \dots, X_n)^T$  all of whose components have finite variances.

The *covariance matrix* of the random vector  $X$  is defined in terms of the expected value as (notice the vector  $X$  is viewed as a column of random variables now)

$$\text{var } X = E(X - E X)(X - E X)^T.$$

Using the definition of the expected value of a vector and expanding the matrix multiplication, it is immediate that the covariance matrix  $\text{var } X$  is the symmetric matrix

$$\begin{pmatrix} \text{var } X_1 & \text{cov}(X_1, X_2) & \cdots & \text{cov}(X_1, X_n) \\ \text{cov}(X_2, X_1) & \text{var } X_2 & \cdots & \text{cov}(X_2, X_n) \\ \vdots & \vdots & \ddots & \vdots \\ \text{cov}(X_n, X_1) & \text{cov}(X_n, X_2) & \cdots & \text{var } X_n \end{pmatrix}.$$

**Theorem.** Consider a random vector  $X = (X_1, \dots, X_n)^T$  all of whose components have finite variances. Further, consider the transformed random vector  $Y = BX + c$ , where  $B$  is an  $m$ -by- $n$  matrix of real constants and  $c \in \mathbb{R}^m$  is a vector of constants. Then,

$$\text{var}(Y) = \text{var}(BX + c) = B(\text{var } X)B^T.$$

**PROOF.** The claim follows from direct computation, using the properties of the expected value:

$$\begin{aligned} \text{var}(Y) &= E((BX + c) - E(BX + c))((BX + c) - E(BX + c))^T \\ &= E(B(X - E X))(B(X - E X))^T \\ &= B E(X - E X)(X - E X)^T B^T \\ &= B(\text{var } X)B^T. \end{aligned}$$

$\square$

The constant part of the transformation has no impact, while with respect to the linear part of the transformation, the covariance matrix behaves as the matrix of a quadratic form.

**10.2.36. Moments and moment function.** The expected value and variance reflect the square of the deviation of values of a random variable from the average. In descriptive statistics, one also examines the skewness of the data, and it is natural to examine the variability of random variables in terms of higher powers of the given random variable  $X$ .

The characteristic  $E(X^k)$  is called the *k-th moment*; the characteristic  $\mu_k = E((X - EX)^k)$  is called the *k-th central moment* of a random variable  $X$ . What also comes in handy is the *k-th absolute moment*, given by  $E|X|^k$ .

From the definition it follows that for a continuous random variable  $X$ ,

$$E X^k = \int_{-\infty}^{\infty} x^k f_X(x) dx.$$

rearrange the expression:

$$\begin{aligned}
 & P \left[ \left| \frac{X}{n} - p \right| < 0.02 \right] \\
 &= P \left[ -0.02 < \frac{X}{n} - p < 0.02 \right] = \\
 &= P \left[ -0.02 \cdot n < X - pn < 0.02 \cdot n \right] = \\
 &= P \left[ \frac{-0.02 \cdot n}{\sqrt{np(1-p)}} < \frac{X - pn}{\sqrt{np(1-p)}} < \frac{0.02 \cdot n}{\sqrt{np(1-p)}} \right] = \\
 &= \Phi \left( \frac{0.02 \cdot n}{\sqrt{np(1-p)}} \right) - \Phi \left( -\frac{0.02 \cdot n}{\sqrt{np(1-p)}} \right) = \\
 &= 2\Phi \left( \frac{0.02 \cdot n}{\sqrt{np(1-p)}} \right) - 1,
 \end{aligned}$$

where  $\Phi$  is the distribution function of the normal distribution. Thus, let us solve the inequality

$$\begin{aligned}
 2\Phi \left( \frac{0.02 \cdot n}{\sqrt{np(1-p)}} \right) - 1 &\geq 0.99 \\
 \Phi \left( \frac{0.02 \cdot n}{\sqrt{np(1-p)}} \right) &\geq 0.995
 \end{aligned}$$

Since the distribution function is increasing, the last condition is equivalent to

$$\begin{aligned}
 \frac{0.02 \cdot n}{\sqrt{np(1-p)}} &\geq \Phi^{-1}(0.995) \\
 \frac{0.02 \cdot n}{\sqrt{np(1-p)}} &\geq 2.576 \\
 \sqrt{n} &\geq 50 \cdot 2.576 \cdot \underbrace{\sqrt{p(1-p)}}_{\leq \frac{1}{2}} \implies \\
 \implies n &\geq (25 \cdot 2.276)^2 \cdot 4147
 \end{aligned}$$

Here, we used the fact that the maximum of the function  $p(1-p)$  is  $\frac{1}{4}$ , and it is reached at  $p = \frac{1}{2}$ . We can see that if e. g.  $p \doteq 0.1$ , then  $\sqrt{p(1-p)} = 0.3$  and the value of the least  $n$  is lower. This accords with our expectations: for less popular parties, it suffices to have fewer respondents (if the agency estimates the gain of such party to be around 2 % without asking anybody, then the wanted precision is almost guaranteed). □

**10.I.11. Two-choice test.** Consider random vectors  $Y_1$  and  $Y_2$  all of whose components are pairwise independent random variables with normal distribution, and suppose that the components of vector  $Y_i$  have expected value  $\mu_i$ , and the variance  $\sigma$  is the same for all the components of both vectors.

Use the general linear model to test the hypothesis whether  $\mu_1 = \mu_2$ .

**Solution.** We will proceed quite similarly as in subsection 10.3.12 of the theoretical part. This time, we can write both

Similarly, for a discrete random variable  $X$  whose probability is concentrated into points  $x_i$ ,

$$E X^k = \sum_i x_i^k f_X(x_i).$$

The next theorem shows that all the moments completely describe the distribution of the random variable, as a rule.

For the sake of computations, it is advantageous to work with a power series in which the moments appear in the coefficients. Since the coefficients of the Taylor series of a function at a given point can be obtained using differentiation, it is easy to guess the right choice of such a function:

MOMENT GENERATING FUNCTION

Given a random variable  $X$ , consider the function  $M_X(t) : \mathbb{R} \rightarrow \mathbb{R}$  defined by

$$M_X(t) = E e^{tX} = \begin{cases} \sum_i e^{tx_i} f_X(x_i) & \text{if } X \text{ is discrete} \\ \int_{-\infty}^{\infty} e^{tx} f_X(x) dx & \text{if } X \text{ is continuous.} \end{cases}$$

If this expected value exists, the *moment generating function* of the random variable  $X$  can be discussed.

It is clear that this function  $M_X(t)$  is always analytic in the case of discrete random variables with finitely many values  $x_i$ .

**Theorem.** Let  $X$  be a random variable such that its analytic moment generating function on an interval  $(-a, a)$  exists. Then,  $M_X(t)$  is given on this interval by the absolutely convergent series

$$M_X(t) = \sum_{k=0}^{\infty} \frac{t^k}{k!} E X^k.$$

If two random variables  $X$  and  $Y$  share their moment generating functions over a nontrivial interval  $(-a, a)$ , then their distribution functions coincide.

**PROOF.** The verification of the first statement is a simple exercise on the techniques of differential and integral calculus. In the case of discrete variables, there are either finite sums or absolutely and uniformly converging series. In the case of continuous variables, there are absolutely converging integrals. Thus, the limit process and the differentiation can be interchanged. Since  $\frac{d}{dt} e^{tx} = x e^{tx}$ , it is immediate that

$$\frac{d^k}{dt^k} M_X(t) = E X^k,$$

as expected.

The second claim is obvious for two discrete variables  $X$  and  $Y$  with only a finite number of values  $x_1, \dots, x_k$  for which either  $f_X(x_i) \neq 0$  or  $f_Y(x_i) \neq 0$ . Indeed, the functions  $e^{tx_i}$  are linearly independent functions and thus their coefficients in the common moment function

$$M(t) = e^{tx_1} f(x_1) + \dots + e^{tx_k} f(x_k)$$

must be the shared probability function values for both random variables  $X$  and  $Y$ .

vectors  $Y_i$  into one column, and we consider the model

$$\begin{pmatrix} Y_{11} \\ \vdots \\ Y_{1n_1} \\ Y_{21} \\ \vdots \\ Y_{2n_2} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \vdots & \vdots \\ 1 & 0 \\ 1 & 1 \\ \vdots & \vdots \\ 1 & 1 \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix} + \sigma Z.$$

We will work with arithmetic means of the individual vectors  $\bar{Y}_1$  and  $\bar{Y}_2$ . Direct application of the general formula from theory gives the estimate  $b$  in the form

$$\begin{pmatrix} b_1 \\ b_2 \end{pmatrix} = \begin{pmatrix} n_1 + n_2 & n_2 \\ n_2 & n_2 \end{pmatrix}^{-1} \begin{pmatrix} n_1 \bar{Y}_1 + n_2 \bar{Y}_2 \\ n_2 \bar{Y}_2 \end{pmatrix} = \frac{1}{n_1 n_2} \begin{pmatrix} n_2 & -n_2 \\ -n_2 & n_1 + n_2 \end{pmatrix} \begin{pmatrix} n_1 \bar{Y}_1 + n_2 \bar{Y}_2 \\ n_2 \bar{Y}_2 \end{pmatrix} = \begin{pmatrix} \bar{Y}_1 \\ \bar{Y}_2 - \bar{Y}_1 \end{pmatrix}$$

and for the matrix  $C = (X^T X)^{-1}$ , where  $X$  is the 2-column matrix with zeros and ones from our model, we have

$$C = \begin{pmatrix} \frac{1}{n_1} & -\frac{1}{n_1} \\ -\frac{1}{n_1} & \frac{1}{n_1} + \frac{1}{n_2} \end{pmatrix}.$$

Thus, we test the hypothesis  $\mu_1 = \mu_2$ , which means that we test whether  $\beta_2 = 0$ . For this, it is suitable to use the statistic

$$T = \frac{\bar{Y}_2 - \bar{Y}_1}{S} \left( \frac{n_1 n_2}{n_1 + n_2} \right)^{\frac{1}{2}},$$

where the standard deviation  $S$  is substituted as

$$S^2 = \frac{1}{n_1 + n_2 - 2} \left( \sum_{i=1}^{n_1} (Y_{1i} - \bar{Y}_1)^2 + \sum_{i=1}^{n_2} (Y_{2i} - \bar{Y}_2)^2 \right).$$

The distribution of this statistic is  $t_{n_1+n_2-2}$ , so the null hypothesis  $\mu_1 = \mu_2$  is rejected at level  $\alpha$  if we have

$$|T| \geq t_{n_1+n_2-2}(\alpha). \quad \square$$

**10.I.12.** In JZD<sup>1</sup> Tempo, the milk yield of their cows was measured during five days, the results being 15, 14, 13, 16 a 17 hectoliters. In JZD Boj, which had the same number of cows, they performed the same measurement during seven days, the results being 12, 16, 13, 15, 13, 11, 18 hectoliters.

- Find the 95% confidence interval for the milk yield of JZD Boj's cows, and the 95% confidence interval for the milk yield of JZD Tempo's cows.
- On the 5% level, test the hypothesis that both farms have cows of the same quality.

Suppose that the milk yield of the cows in each day is given by the normal distribution. Solve these problems assuming that there are no data from previous measurements, and then assuming that the previous measurements showed that the standard deviation was  $\sigma = 2$  hl.

<sup>1</sup>JZD — jednotné zemědělské družstvo — an agricultural cooperative farm, created by forced collectivization in 1950s in Czechoslovakia.

In the case of continuous variables  $X$  and  $Y$  sharing their generating function  $M(t)$ , the argument is more involved and an indication only is provided. Notice that  $M(t)$  is analytic and thus it is defined for all complex numbers  $t$ ,  $|t| < a$ .

In particular,

$$M(it) = \int_{-\infty}^{\infty} e^{itx} f(x) dx,$$

which is the inverse Fourier transform of  $f(x)$ , up to the constant multiple  $\sqrt{2\pi}$ , see 7.2.5 (on page 657). If this works for all  $t$ , then clearly  $f$  is obtained by the Fourier transform of  $(\sqrt{2\pi})^{-1} M(it)$  and thus must be the same for both  $X$  and  $Y$ . Further details, in particular covering general random variables, would need much more input from measure theory and Fourier analysis, and thus it is not provided here.  $\square$

It can be also shown that the assumptions of the theorem are true whenever both  $M_X(-a) < \infty$  and  $M_X(a) < \infty$ .

**10.2.37. Properties of moment function.** By the properties of the exponential functions, it is easy to compute the behaviour of the moment function under affine transformations and sums of independent random variables.

**Proposition.** Let  $a, b \in \mathbb{R}$  and  $X, Y$  be independent random variables with moment generating functions  $M_X(t)$  and  $M_Y(t)$ , respectively. Then, the moment generating functions of the random variables  $V = a + bX$  and  $W = X + Y$  are

$$\begin{aligned} M_{a+bX}(t) &= e^{at} M_X(bt) \\ M_{X+Y}(t) &= M_X(t) M_Y(t) \end{aligned}$$

**PROOF.** The first formula can be computed directly from the definition:

$$M_V(t) = \mathbb{E} e^{(a+bX)t} = \mathbb{E} e^{at} e^{(bt)X} = e^{at} M_X(bt).$$

As for the second formula, recall that  $e^{tX}$  and  $e^{tY}$  are independent variables. Use the fact that the expected value of the product of independent random variables equals the product of the expected values.

$$\begin{aligned} M_W(t) &= \mathbb{E} e^{t(X+Y)} = \mathbb{E} e^{tX} e^{tY} \\ &= \mathbb{E} e^{tX} \mathbb{E} e^{tY} = M_X(t) M_Y(t). \end{aligned} \quad \square$$

**10.2.38. Normal and binomial distributions.** As an illustrating example, compute the moment function of two random variables  $X \sim N(\mu, \sigma)$  and  $X \sim \text{Bi}(n, p)$ .

MOMENT GENERATING FUNCTION FOR  $N(\mu, \sigma)$

**Proposition.** If  $X \sim N(\mu, \sigma)$ , then

$$M_X(t) = e^{\mu t} e^{\frac{\sigma^2 t^2}{2}}.$$

In particular, it is an analytic function on all of  $\mathbb{R}$ .

**Solution.** First of all, let us compute the results for the known variance. In order to find the confidence interval, we use the statistic

$$U = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}},$$

which has standardized normal distribution (see 10.2.21).

Then, the confidence interval is (see 10.3.4)

$$\left( \bar{X} - \frac{\sigma}{\sqrt{n}}z(\alpha/2), \bar{X} + \frac{\sigma}{\sqrt{n}}z(\alpha/2) \right),$$

where  $\alpha = 0,05$ . Now, it suffices to substitute the specific values. For JZD Tempo, we thus get the sample mean

$$\bar{X}_1 = \frac{15 + 14 + 13 + 16 + 17}{5} = 15,$$

and using appropriate software, we can learn that  $z(0.025) = 1.96$ , which gives the interval

$$\left( 15 - \frac{2}{\sqrt{5}}1.96, 15 + \frac{2}{\sqrt{5}}1.96 \right) \doteq (13.25; 16.75).$$

For JZD Boj, we get

$$\bar{X}_2 = \frac{12 + 16 + 13 + 15 + 13 + 11 + 18}{7} = 14,$$

so the 95% confidence interval for the milk yield of their cows is

$$(12.52; 15.48).$$

If the variance of the measurements is not known, we use the so-called sample variance for the estimate. In order to find the confidence interval, we use the statistic

$$T = \frac{\bar{X} - \mu}{S\sqrt{n}},$$

which has Student's distribution with  $n - 1$  degrees of freedom (see also 10.3.4). Then, we can analogously obtain the 95% confidence interval

$$\left( \bar{X} - \frac{S}{\sqrt{n}}t_{n-1}(\alpha/2), \bar{X} + \frac{S}{\sqrt{n}}t_{n-1}(\alpha/2) \right).$$

For the values of JZD Tempo, we get the sample variance

$$S_1^2 = \frac{0^2 + (-1)^2 + (-2)^2 + 1^2 + 2^2}{4} = 2.5,$$

i. e.,  $S \doteq 1.58$ . Further, we have  $t_4(0,025) \doteq 2,78$ , so the 95% confidence interval for JZD Tempo is

$$(13.03; 16.97).$$

For JZD Boj, we get the sample variance  $S_2^2 = 6$ , so the wanted confidence interval is

$$(11.73; 16.27).$$

b) If we compare the expected values of milk yield in both farms, then this is a comparison of the expected values of two independent choices from the normal distribution. In the case of unknown variances, we further assume that the variance is the same for both farms.

**PROOF.** Suppose  $Z \sim N(0, 1)$ . Then

$$\begin{aligned} M_Z(t) &= \int_{-\infty}^{\infty} e^{tx} \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} dx \\ &= \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x^2 - 2tx + t^2 - t^2)} dx \\ &= e^{\frac{t^2}{2}} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{(x-t)^2}{2}} dx \\ &= e^{\frac{t^2}{2}}, \end{aligned}$$

where use is made of the fact that in the last-but-one expression, for every fixed  $t$ , the density of a continuous random variable is integrated; hence this integral equals one.

Substitute the formula for the moment generating function  $M_{\mu+\sigma Z}$ , to obtain for  $X \sim N(\mu, \sigma)$  that

$$M_X(t) = e^{\mu t} e^{\frac{\sigma^2 t^2}{2}},$$

again a function analytic over entire  $\mathbb{R}$ . □

In particular, the moments of  $Z$  of all orders exist. Substitute  $\frac{1}{2}t^2$  into the power series for the exponential function, and calculate them all:

$$\begin{aligned} M_Z(t) &= \sum_{k=0}^{\infty} \frac{1}{k!} \left( \frac{t^2}{2} \right)^k = \sum_{k=0}^{\infty} \frac{1}{k!2^k} t^{2k} = \\ &= 1 + 0t + \frac{1}{2}t^2 + 0t^3 + \frac{3}{4!}t^4 + \dots \end{aligned}$$

In particular, the expected value of  $Z$  is  $E Z = 0$ , and its variance is  $\text{var } Z = E Z^2 - (E Z)^2 = 1$ . Further, all moments of odd orders vanish,  $E Z^4 = 3$ , etc.

Hence the sum of independent normal distributions  $X \sim N(\mu, \sigma)$  and  $Y \sim N(\mu', \sigma')$  has again the normal distribution  $X + Y \sim N(\mu + \mu', \sigma + \sigma')$ .

Similarly, considering the discrete random variable  $X \sim \text{Bi}(n, p)$ ,

$$\begin{aligned} M_X(t) &= E e^{tX} = \sum_{k=0}^n (p e^t)^k \binom{n}{k} (1-p)^{n-k} \\ &= (p e^t + (1-p))^n = (p(e^t - 1) + 1)^n \\ &= 1 + npt + \frac{1}{2}(n(n-1)p^2 + np)t^2 + \dots \end{aligned}$$

is computed. Of course, the same can be computed even easier using the proposition 10.2.37 since  $X$  is the sum of  $n$  independent variables  $Y \sim A(p)$  with the Bernoulli distribution. Therefore,

$$E e^{tX} = (E e^{tY})^n = (p e^t + (1-p))^n.$$

Hence all the moments of the variable  $Y$  equal  $p$ . Therefore,  $E Y = p$ , while  $\text{var } Y = p(1-p)$ . From the moment function  $M_X(t)$ ,  $E X = np$  and  $\text{var } X = E X^2 - (E X)^2 = np(1-p)$ .

Thus, let us examine the hypothesis assuming the known variances  $\sigma_1^2 = \sigma_2^2 = 4$ . We use the statistic

$$\begin{aligned} U &= \frac{(\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} = \\ &= \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} \sim N(0, 1), \end{aligned}$$

where  $\mu_1$  and  $\mu_2$  are the unknown expected values of milk yield in the examined farms, and  $n_1, n_2$  are the numbers of measurements. This statistic has, as indicated, the standardized normal distribution. We reject the hypothesis at the 5% level if and only if the absolute value of the statistic  $U$  is greater than  $z_{0.025}$ , i. e., if and only if 0 does not lie in the 95% confidence interval for the difference of the expected values of milk yield in both farms. For the specific values, we get

$$U = \frac{15 - 14}{\sqrt{\frac{4}{5} + \frac{4}{7}}} \doteq 0.854.$$

Thus, we have  $|U| < z(0.025) = 1.96$ , so the hypothesis that the expected values of milk yield are the same in both farms is not rejected at the 5% level. The reached  $p$ -value of the test (see 10.3.9) is 39.4%, so we did not get much closer to rejecting the hypothesis (the probability that the value of the examined statistic is less than 0.854 provided the null hypothesis holds is 60.6%).

If we do not know the variances of the measurements but we know that they must be equal in both farms, we use the statistic

$$\begin{aligned} K &= \frac{(\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2)}{S_* \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} = \\ &= \frac{\bar{X}_1 - \bar{X}_2}{S_* \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \sim t_{n_1+n_2-2}, \end{aligned}$$

where

$$S_* = \frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2}.$$

For the specific values, we get  $K \doteq 0.796$ ,  $|K| < t_{10}(0, 025) = 2.2281$ , so again, the null hypothesis is not rejected. The reached  $p$ -value of the test is 44.6%, which is even greater than in the above test.  $\square$

**10.I.13. Analyzing the variance of a simple sort.** For  $k \geq 2$  independent samples  $Y_i$  of size  $n_i$  from normal distributions with equal variance, use a linear model to test the hypothesis that all the expected values of individual samples are equal.

**Solution.** The technique is quite similar to that of the above exercise. The hypothesis to be tested is equivalent to stating that a submodel in which all the components of the random vector  $Y$  created by joining the given  $k$  vectors  $Y_i$  have the same expected value holds.

**10.2.39. Skewness and kurtosis.** Since the third central moment is given in terms of third powers of deviations from the expected value, it expresses to a certain extent the symmetry of the random variable distributed around the expected value. In descriptive statistics, we describe this by the coefficient of skewness. For random variables, we use similarly the characteristic

$$\gamma_1 = \frac{E(X - EX)^3}{(\sqrt{\text{var } X})^3},$$

which is called the *coefficient of skewness of a random variable*  $X$ .

Another commonly used characteristic is the *kurtosis* of a random variable  $X$ , defined as

$$\gamma_2 = \frac{E(X - EX)^4}{(\text{var } X)^2} - 3.$$

The standard normal distribution has third central moment equal to zero and the fourth one equal to 3. Thus, the kurtosis is standardized so that its value for the standard normal distribution is zero. For a general distribution, the kurtosis provides comparison to the normal distribution.

In practice, there are other standardizations of skewness coefficients and kurtosis.

**10.2.40. Law of large numbers.** Now, we can consider the key tools which connect probability and statistics. We start with the generalization of Bernoulli's theorem about the binomial distribution, discussed at the end of subsection 10.2.32.

The random variables  $\frac{1}{n}X_n$ , where  $X_n \sim \text{Bi}(n, p)$ , can be viewed as the arithmetic means of  $n$  independent variables with distribution  $A(p)$ , and Bernoulli's theorem then says that these means converge to  $p$  with probability 1.

Such a proposition holds in general. Independence of the variables is not needed, only the fact that  $\text{cov}(X_i, X_j) = 0$  guarantees that the variances sum up.

THE LAW OF LARGE NUMBERS

**Proposition.** Consider a sequence of pairwise uncorrelated random variables  $X_1, X_2, \dots$  which have the same finite expected value  $E X_i = \mu$ . Moreover, assume the variances are bounded, so that  $\text{var } X_i \leq C$ , for a fixed constant  $C$ . Then for any  $\varepsilon > 0$ ,

$$\lim_{n \rightarrow \infty} P\left(\left|\frac{1}{n} \sum_{i=1}^n X_i - \mu\right| < \varepsilon\right) = 1.$$

**PROOF.** By the use Chebyshev's inequality just as at the end of subsection 10.2.32,

$$\begin{aligned} P\left(\left|\frac{1}{n} \sum_{i=1}^n X_i - \mu\right| \geq \varepsilon\right) &\leq \frac{\text{var}\left(\frac{1}{n} \sum_{i=1}^n X_i - \mu\right)}{\varepsilon^2} \\ &= \frac{\frac{1}{n^2} \sum_{i=1}^n \text{var } X_i}{\varepsilon^2} \leq \frac{C}{n\varepsilon^2}. \end{aligned}$$

Thus, the used model is of the form

$$\begin{pmatrix} Y_{11} \\ \vdots \\ Y_{1n_1} \\ Y_{21} \\ \vdots \\ Y_{k1} \\ \vdots \\ Y_{kn_k} \end{pmatrix} = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 1 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 1 \end{pmatrix} \begin{pmatrix} \mu_1 \\ \mu_2 \\ \vdots \\ \mu_k \end{pmatrix} + \sigma Z.$$

We can easily compute estimates for the expected values  $\mu_i$  using arithmetic means:

$$\bar{Y}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} Y_{ij}.$$

Hence we get the estimate  $\hat{Y}_{ij} = \bar{Y}_i$ , so the residual sum of squares is of the form

$$RSS = \sum_{i=1}^k \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2.$$

The estimate of the common expected value in the considered submodel is

$$\bar{Y} = \frac{1}{n} \sum_{i=1}^k \sum_{j=1}^{n_i} Y_{ij} = \frac{1}{n} \sum_{i=1}^k n_i \bar{Y}_i,$$

where  $n = n_1 + \cdots + n_k$ , and the residual sum of squares in this submodel is

$$RSS^0 = \sum_{i=1}^k \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y})^2.$$

In the original model, there are  $k$  independent parameters  $\mu_i$ , while in the submodel, there is a single parameter  $\mu$ , so the tested statistic is of the form

$$F = \frac{(n - k) (RSS^0 - RSS)}{(k - 1) RSS}.$$

□

### J. Linear regression

We already met the linear regression in chapter three, subsection ???. Now, we will try to apply the same principle to problems which are often studied by statisticians.

One standard application of the linear regression is “laying a line” through given data. Thus, we have a sequence of measurements for which we record the values of two variables between which we anticipate linear dependency. A classical example is the dependency of a son’s height on his father’s height.

Thus, the probability  $P$  is bounded from below by

$$P\left(\left|\frac{1}{n} \sum_{i=1}^n X_i - \mu\right| < \varepsilon\right) \geq 1 - \frac{C}{n\varepsilon^2},$$

which proves the proposition. □

Thus, existence and uniform boundedness of variances suffices for the means of pairwise uncorrelated variables  $X_i$  with zero expected value to converge (in probability) to zero.

**10.2.41. Central limit theorem.** The next goal is more ambitious. In addition to the law of large numbers, the stochastic properties of the fluctuation of the means  $\bar{X}_n = \frac{1}{n} \sum_{i=1}^n X_i$  around the expected value  $\mu$  need to be understood. We focus first on the simplest case of sequences of independent and identically distributed random variables  $X_i$ . Then formulate a more general version of the theorem and provide only comments on the proofs.

Move to a sequence of normalized random variables  $X_i$ . Assume  $E X_i = 0$  and  $\text{var } X_i = 1$ . Assume further that the moment generating function  $M_X(t)$  exists and is shared by all the variables  $X_i$ .

The arithmetic means  $\frac{1}{n} \sum_{i=1}^n X_i$  are, of course, random variables with zero expected value, yet their variances are  $\frac{n}{n^2} = \frac{1}{n}$ . Thus, it is reasonable to renormalize them to

$$S_n = \frac{1}{\sqrt{n}} \sum_{i=1}^n X_i,$$

which are again standardized random variables. Their moment generating functions are (see proposition 10.2.37)

$$M_{S_n}(t) = E e^{\frac{t}{\sqrt{n}} \sum_i X_i} = \left( M_X\left(\frac{t}{\sqrt{n}}\right) \right)^n.$$

Since it is assumed that the variables  $X_i$  are standardized,

$$M_X\left(\frac{t}{\sqrt{n}}\right) = 1 + 0 \frac{t}{\sqrt{n}} + \frac{1}{2n} \frac{t^2}{n} + o\left(\frac{t^2}{n}\right),$$

where again  $o(G(n))$  is written for expressions which, when divided by  $G(n)$ , approach zero as  $n \rightarrow \infty$ , see subsection 6.1.12.

Thus, in the limit,

$$\lim_{n \rightarrow \infty} M_{S_n}(t) = \lim_{n \rightarrow \infty} \left( 1 + \frac{t^2}{2n} + o\left(\frac{1}{n}\right) \right)^n = e^{\frac{t^2}{2}}.$$

This is just the moment generating function of the normal distribution  $Z \sim N(0, 1)$ , see the end of subsection 10.2.35. Thus, the standardized variables  $S_n$  asymptotically have the standard normal distribution.

We have thus proved a special version of the following fundamental theorem. Although the calculation is merely a manipulation of moment generating functions, many special cases were proved in different ways, providing explicit estimates for the speed of convergence, which of course is useful information in practice.

Notice that the following theorem does not require the probability distributions of the variables  $X_i$  to coincide!

**10.J.1.** Find the linear regression model for the dependence of  $Y$  on  $X$ , based on the following lists of measured data:  $X = [1, 4, 5, 7, 10]$ ,  $Y = [3, 7, 8, 12, 18]$ .

**Solution.** In order to find the parameters of the regression line, use the formulas derived in 10.3.12. Using the method of least squares, we try to minimize the distance of the vector  $b_1X + b_0$  from the vector  $Y$  with respect to the parameters  $b_1$  and  $b_0$ . This distance, as we know from chapter two, is minimal for the orthogonal projection of the vector  $Y$  onto the vector subspace generated by the vectors  $(1, \dots, 1)$  and  $(x_1, \dots, x_n)$ . For parameters  $b_0, b_1$  of the regression line  $Y = b_1X + b_0$ , we obtain

$$b_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y})}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{(1 - 5.4)(3 - 9.6) + \dots + (10 - 5.4)(18 - 9.6)}{((1 - 5.4)^2 + (4 - 5.4)^2 + (5 - 5.4)^2 + (7 - 5.4)^2 + (10 - 5.4)^2)} = 1.677.$$

Now, we can easily calculate the coefficient  $b_0$ :

$$b_0 = \bar{Y} - b_1\bar{x} = 0.5442.$$

Therefore, the wanted linear dependency is

$$Y = 1.677 \cdot X + 0.5442.$$

Note that in this model, the roles of the variables  $X$  and  $Y$  are totally equal. Using the same method, we could have obtained the dependency of  $X$  on  $Y$ :

$$X = 0.5867 \cdot Y - 0.2322. \quad \square$$

**Remark.** Think out why the linear regression model of the dependency of  $X$  on  $Y$  cannot be obtained by merely expressing  $X$  from the linear regression model of the dependency of  $Y$  on  $X$ .

**Remark.** In many real situations, the dependency of the variables is clearly given, if one of the variables is time, for example.

**10.J.2.** An orbital station has measured, at the same instant of five consecutive days, the following velocities of an unknown cosmic object (in km/s): 10, 11.4, 13.1, 15.8, and 18.7. Estimate the object's velocity on the tenth day.

**Solution.** Here, it is good to notice that the velocity does not change linearly with time (the acceleration is increasing). Thus, we can hypothesize that the object is being attracted to another one with the gravitational force. Then, its velocity would be a quadratic function of time. So let us use the method of least squares to lay a quadratic function (as precise as possible) through the measured data. The procedure is the same as if we made the linear regression of the vector  $v = (v_1, v_2, \dots, v_n)$  dependent on  $x = (x_1, \dots, x_n)$  and  $x^2 = (x_1^2, \dots, x_n^2)$ . This method is called *quadratic regression*. Thus, we are looking for a vector of parameters  $b = (b_0, b_1, b_2)$  so that the variable  $b_2x^2 + b_1x + b_0$  would

CENTRAL LIMIT THEOREM

**Theorem.** Consider a sequence of independent random variables  $X_i$  which have the same expected value  $E X_i = \mu$ , variance  $\text{var } X_i = \sigma^2 > 0$  and uniformly bounded third absolute moment  $E |X_i|^3 < C$ . Then, the distribution of the random variable

$$S_n = \frac{1}{\sqrt{n}} \sum_{i=1}^n \left( \frac{X_i - \mu}{\sigma} \right)$$

satisfies

$$\lim_{n \rightarrow \infty} P(S_n < x) = \Phi(x),$$

where  $\Phi$  is the distribution function of the standard normal distribution.

Note that the central limit theorem gives a result on asymptotic behaviour which says that the distribution functions of certain variables approach the standard normal distribution. Such behaviour is called *convergence in distribution*. This type of convergence is weaker than convergence in probability.

The assumption that all  $X_i$  are independent and identically distributed was not fully exploited in the argumentation above. Only the knowledge of  $E X_i = 0$  and  $\text{var } X_i = 1$  was used. The assumption of the uniformly bounded third absolute moments of  $X_i$  can be used to prove the existence of the moment generating functions. The estimate  $E |X_i|^3$  can then be used to complete the above proof exactly as above.

There are many more general results. We mention at least the *Lyapunov's central limit theorem* formulated as follows:

Consider a sequence of random variables  $X_i$  with finite expected values  $\mu_i$  and variances  $\sigma_i^2$ . Write

$$s_n = \sqrt{\sum_{i=1}^n \sigma_i^2}$$

and assume for some  $\delta > 0$

$$\lim_{n \rightarrow \infty} \frac{1}{s_n^{2+\delta}} \sum_{i=1}^n E |X_i - \mu_i|^{2+\delta} = 0.$$

Then  $\frac{X_i - \mu_i}{s_n}$  converges in distribution to  $Z \sim N(0, 1)$ .

The previous version of the central limit theorem is derived by choosing  $\delta = 1$ . Then  $s_n = \sigma\sqrt{n}$  and the condition of the Lyapunov's theorem reads

$$0 \leq \lim_{n \rightarrow \infty} n^{-3/2} \sigma^{-3} \sum_{i=1}^n E |X_i|^3 \leq C\sigma^{-3} \lim_{n \rightarrow \infty} n^{-3/2+1} = 0.$$

**10.2.42. De Moivre-Laplace theorem.** Historically, the first formulated special case of the central limit theorem was that of variables  $Y_n$  with binomial distribution  $\text{Bi}(n, p)$ . They can be viewed as the sum of  $n$  independent variables  $X_i$  with Bernoulli distribution  $A(p)$ ,  $0 < p < 1$ . These variables have moment generating functions and  $E |X_i|^3 = p < 1$ .

estimate  $y$ . Let us build the matrix  $X$  of the values of independent variables:

$$X = \begin{pmatrix} 1 & x_1 & x_1^2 \\ \vdots & \vdots & \vdots \\ 1 & x_n & x_n^2 \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 4 \\ 1 & 3 & 9 \\ 1 & 4 & 16 \\ 1 & 4 & 25 \end{pmatrix},$$

and the vector of parameters  $b = (b_0, b_1, b_2)$  can be computed by (1):

$$b = (X^T X)^{-1} X^T v \doteq (9.26; 0.47; 0.29).$$

Then, the wanted quadratic estimate is

$$v = 0.29x^2 + 0.47x + 9.26,$$

so the estimated velocity on the tenth day is approximately 42.96 km/s. In the model of classic linear regression, we would get

$$v = 2.18x + 7.26,$$

which yields 29.06 km/s for the tenth day. The difference between these estimates is quite large. This illustrates that analysis of the situation is a very important part of statistics.  $\square$

## K. Bayesian data analysis

**10.K.1.** Consider the Bernoulli process defined by a random variable  $X \sim \text{Bi}(n, \theta)$  with binomial distribution, and assume that the parameter  $\theta$  is a random variable with uniform distribution on the interval  $(0, 1)$ . We define the *success chance* in our process as the variable  $\gamma = \frac{\theta}{1-\theta}$ . What is the density of this variable  $\gamma$ ?

**Solution.** Intuitively, we can feel that the distribution is not uniform.

Denoting the wanted probability density by  $f(s)$ , we can use the relation between  $\theta$  and  $\gamma$  to compute  $\theta = \frac{\gamma}{1+\gamma}$ . In addition, we can immediately see that the probability density of  $\gamma$  is non-zero only for positive values of the variable. Now, we can formulate the statement as the requirement

$$(1) \quad \Theta = P(\theta < \Theta) = P(\gamma < \frac{\Gamma}{1+\Gamma}) = \int_0^\Gamma f(s) ds,$$

where  $\Gamma = \frac{\Theta}{1-\Theta}$ . However, the right-hand upper bound contains the changing limit  $\gamma$ , so we get the defining formula for  $f(s)$

$$f(s) = \left( \frac{s}{s+1} \right)' = \frac{1}{(s+1)^2}.$$

Indeed, the wanted density gives much higher probability to low values of the chance than to high ones.  $\square$

We could see in subsection 10.3.7 that when taking the Bayesian approach with binomial model of probability distribution of a random variable  $X \sim \text{Bi}(n, \theta)$ , then we are interested in its probability mass function  $f_X(k) = \binom{n}{k} \theta^k (1-\theta)^{n-k}$ . This function can be viewed as the conditional probability  $P(\theta | X = k)$  for the uniform a priori probability distribution of the variable  $\theta$  on the interval  $(0, 1)$ . Thus, it is just

Thus, the central limit theorem says in this case that the random variables

$$S_n = \frac{1}{\sqrt{n}} \sum_{i=1}^n \left( \frac{X_i - p}{\sqrt{p(1-p)}} \right) = \frac{X - np}{\sqrt{np(1-p)}}$$

behave asymptotically as the standard normal distribution.

This can be formulated: the random variable  $X \sim \text{Bi}(n, p)$  behaves as the random variable with normal distribution  $N(np, np(1-p))$  as  $n$  increases.

This behaviour is demonstrated exactly in the illustration at the end of 10.2.21.

In practice, approximation of the binomial distribution by the normal distribution is usually considered appropriate if  $np(1-p) > 9$ .

We illustrate the result with a concrete example. Suppose it is desired to know what percentage of students like a given course, with an error of at most 5%. The number of people who like the course among  $n$  randomly chosen people should behave as the random variable  $X \sim \text{Bi}(n, p)$ . Further, suppose the result is desired to be correct with confidence (i.e., probability again) to at least 90%. Thus,

$$P\left( \left| \frac{1}{n} X - p \right| < 0.05 \right) \simeq 0.9$$

is desired by choosing a high enough number  $n$  of students to ask.

Approximate

$$\begin{aligned} 0.9 &\simeq P\left( \left| \frac{1}{n} X - p \right| < 0.05 \right) \\ &= P\left( -\frac{0.05n}{\sqrt{np(1-p)}} < \frac{X - np}{\sqrt{np(1-p)}} < \frac{0.05n}{\sqrt{np(1-p)}} \right) \\ &\simeq \Phi\left( \frac{0.05n}{\sqrt{np(1-p)}} \right) - \Phi\left( -\frac{0.05n}{\sqrt{np(1-p)}} \right) \\ &= 2\Phi\left( \frac{0.05n}{\sqrt{np(1-p)}} \right) - 1, \end{aligned}$$

where the symmetry of the density function of the normal distribution is exploited. Thus,

$$\Phi\left( \frac{0.05n}{\sqrt{np(1-p)}} \right) \simeq \frac{1}{2}(1 + 0.9) = 0.95$$

is wanted. This leads to the choice (recall the definition of critical values  $z(\alpha)$  for a variable  $Z$  with standard normal distribution in subsection 10.2.30)

$$\Phi\left( \frac{0.05n}{\sqrt{np(1-p)}} \right) \simeq z(0.05) = 1.64485.$$

Since  $p(1-p)$  is at most  $\frac{1}{4}$ , the necessary number of students can be bounded by  $n > 270$ , independently of  $p$ .

the a posteriori probability distribution of  $\theta$  corresponding to the result  $X = k$  of the experiment. The following exercise concerns the general class of these probability distributions.

**10.K.2.** Find the basic characteristics of the so-called *beta-distribution*  $\text{fi}(a, b)$  with probability density of the form

$$f_Y = \begin{cases} C y^{a-1}(1-y)^{b-1} & y \in (0, 1) \\ 0 & \text{otherwise.} \end{cases}$$

**Solution.** The constant  $C$  must be chosen as the multiplicative inverse of the integral  $\int_0^1 y^{a-1}(1-y)^{b-1} dy$ , which is a function  $B(a, b)$ , known as *beta-function* in mathematical analysis and other sciences (e. g. physics). The function gamma, which generalizes the discrete values of factorial, emerges in the following calculation:

$$\begin{aligned} \Gamma(x)\Gamma(y) &= \int_0^\infty e^{-t} t^{x-1} dt \cdot \int_0^\infty e^{-s} s^{y-1} ds = \\ &= \int_0^\infty \int_0^\infty e^{-t-s} t^{x-1} s^{y-1} dt ds = \\ &\text{(substitution } t = rq, s = r(1-q)) \\ &= \int_{r=0}^\infty \int_{q=0}^1 e^{-r} (rq)^{x-1} (r(1-q))^{y-1} r dq dr = \\ &= \int_{r=0}^\infty e^{-r} r^{x+y-1} dr \cdot \int_{t=0}^1 q^{x-1} (1-q)^{y-1} dq = \\ &= \Gamma(x+y)B(x, y). \end{aligned}$$

Thus, we get the general formula

$$B(a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}$$

and it follows from properties of the gamma-function for positive integers  $a, b$  that

$$B(n-k+1, k+1) = \frac{k!(n-k)!}{(n+1)!} = \frac{1}{n+1} \binom{n}{k}^{-1}.$$

We can directly compute that the expected value of the variable  $X \sim \text{fi}(a, b)$  with beta-distribution is (applying  $\Gamma(z+1) = z\Gamma(z)$ )

$$E X = \frac{B(a+1, b)}{B(a, b)} = \frac{a}{a+b}.$$

If  $a = b$ , then the expected value and median are  $\frac{1}{2}$ .

We can also directly calculate the variance

$$\text{var } X = E(X - E X)^2 = \frac{ab}{(a+b)^2(a+b+1)}.$$

Thus, for  $a = b$ , we get  $\text{var } X = \frac{1}{8a+4}$ , which shows that the variance decreases as  $a = b$  increases. For  $a = b = 1$ , we get the ordinary uniform distribution on the interval  $(0, 1)$ .  $\square$

**10.2.43. Important distributions.** In the sequel, we return to statistics. It should be of no surprise that we work with the characteristics of random vectors similar to the sample mean and variance, as well as relative quotients of such characteristics, etc. We consider several such cases.

Consider a random variable  $Z \sim N(0, 1)$ , and compute the density  $f_Y(x)$  of the random variable  $Y = Z^2$ . Clearly,  $f_Y(x) = 0$  for  $x \leq 0$ , while for positive  $x$ ,

$$\begin{aligned} F_Y(x) &= P(Y < x) = P(-\sqrt{x} < Z < \sqrt{x}) \\ &= \int_{-\sqrt{x}}^{\sqrt{x}} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \int_0^x \frac{1}{\sqrt{2\pi}} t^{-1/2} e^{-t/2} dt. \end{aligned}$$

Differentiation leads to

$$f_Y(x) = \frac{d}{dx} F_Y(x) = \frac{1}{\sqrt{2\pi}} x^{-1/2} e^{-x/2}.$$

This distribution is called  $\chi^2$  with one degree of freedom, written  $Y \sim \chi^2$ .

We work with sums of such independent variables. All fall into a general class of distributions whose densities are of the form

$$f_X(x) = cx^{a-1} e^{-bx}$$

for  $x > 0$ , while  $f_X(x) = 0$  for non-positive  $x$ , i.e., the distribution  $\chi^2$  corresponds to the choice  $a = b = 1/2$ . This case is already thoroughly discussed as an example in subsection 10.2.20. Hence such a function is the density for the constant  $c = \frac{b^a}{\Gamma(a)}$ . Thus, it is the distribution  $\Gamma(a, b)$  with density, for positive  $x$ ,

$$f_X(x) = \frac{b^a}{\Gamma(a)} x^{a-1} e^{-bx}.$$

In general, the  $k$ -th moment of such variable  $X$  is easily computed:

$$\begin{aligned} E X^k &= \int_0^\infty x^k \frac{b^a}{\Gamma(a)} x^{a-1} e^{-bx} dx \\ &= \frac{\Gamma(a+k)}{\Gamma(a)b^k} \int_0^\infty \frac{b^{a+k}}{\Gamma(a+k)} x^{a-1+k} e^{-bx} dx \\ &= \frac{\Gamma(a+k)}{\Gamma(a)b^k}, \end{aligned}$$

since the integral of the density of  $\Gamma(a+k, b)$  in the last expression must be equal to one

In particular,  $E X = \frac{\Gamma(a+1)}{b\Gamma(a)} = \frac{a}{b}$ , while

$$\text{var } X = \frac{\Gamma(a+2)}{b^2\Gamma(a)} - \frac{a^2}{b^2} = \frac{(a+1)a - a^2}{b^2} = \frac{a}{b^2}.$$

Similarly, the moment generating function can be computed for all values  $t$ ,  $-b < t < b$

$$\begin{aligned} M_X(t) &= \int_0^\infty e^{tx} \frac{b^a}{\Gamma(a)} x^{a-1} e^{-bx} dx = \\ &= \frac{b^a}{(b-t)^a} \int_0^\infty x^k \frac{(b-t)^a}{\Gamma(a)} x^{a-1} e^{-(b-t)x} dx = \\ &= \frac{b^a}{(b-t)^a}. \end{aligned}$$

**10.K.3.** In the situation as in the problem above the previous one, assume that the success chance  $\theta$  in the Bernoulli process is a random variable with probability distribution  $\text{fi}(a, b)$ . What is the probability distribution of the variable  $\gamma = \frac{\theta}{1-\theta}$ ? In what is it special when  $a = b = p$ ?

**Solution.** We have already discussed the special case with uniform distribution  $\text{fi}(1, 1)$ . Thus, we can continue with the equality  $\|1\|$ , where we used the form of this distribution. Now the left-hand side contains, instead of  $\Theta$ , the expression

$$\frac{1}{B(a, b)} \int_0^\Theta t^{a-1} (1-t)^{b-1} dt.$$

When differentiating, we must use the rule for differentiation of integral with variable upper bound. Thus, we get for the wanted density that

$$\begin{aligned} B(a, b)f(s) &= \left(\frac{s}{s+1}\right)^{a-1} \left(1 - \frac{s}{s+1}\right)^{b-1} \frac{1}{(s+1)^2} = \\ &= \left(\frac{s^{a-1}}{s+1}\right)^{a+b}. \end{aligned}$$

The picture shows the densities for  $a = b = p = 2, 5, 15$ .

This enforces the intuition that the same and not too small values of  $a = b = p$  correspond to the most probable value  $\theta = \frac{1}{2}$ , so the density of the chance is greatest around one. The higher  $p$ , the lower the variance of this variable.  $\square$

**10.K.4.** Show that the Bernoulli experiment, described by a random variable  $X \sim \text{Bi}(n, \theta)$ , and the a priori probability of a random variable  $\theta$  with beta-distribution, the a posteriori probability also has beta-distribution with suitable parameters which depend on the experiment results. What is the a posteriori expected value of  $\theta$  (i. e., the Bayesian point estimate of this random variable)?

**Solution.** As justified in subsection 10.3.7 of the theoretic part, the a posteriori probability density is, up to an appropriate constant, given as the product of the a priori probability density

$$g(\theta) = \frac{1}{B(a, b)} \theta^{a-1} (1-\theta)^{b-1}$$

and the probability of the examined variable  $X$  provided the value of  $\theta$  occurred. Thus, assuming  $k$  successes in the

Thus, for the sum of independent variables  $Y = X_1 + \dots + X_n$  with distributions  $X_i \sim \Gamma(a_i, b)$ , the moment generating function (for values  $|t| < b$ ) is obtained

$$M_Y(t) = \left(\frac{b}{b-t}\right)^{a_1+\dots+a_n},$$

that is,  $Y \sim \Gamma(a_1 + \dots + a_n, b)$ . It is essential that all of the gamma distributions share the same value of  $b$ .

As an immediate corollary, the density of the variable  $Y = Z_1^2 + \dots + Z_n^2$  is obtained, where  $Z_i \sim N(0, 1)$ . As just shown, this is the gamma distribution  $Y \sim \Gamma(n/2, 1/2)$ ; hence its density is

$$f_Y(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}.$$

This special case of a gamma distribution is called  $\chi^2$  with  $n$  degrees of freedom. Usually, it is denoted by  $Y \sim \chi_n^2$ .

**10.2.44. The F-distribution.** In statistics, it is often wanted

to compare two sample variances, so we need to consider variables which are given as a quotient

$$U = \frac{X/k}{Y/m},$$

where  $X \sim \chi_k^2$  and  $Y \sim \chi_m^2$ .

Suppose  $f_X(x)$  and  $f_Y(y)$  are the densities of independent random variables  $X$  and  $Y$ . Suppose  $f_Y$  is non-zero only for positive values of  $x$ . Compute the distribution function of the random variable  $U = cX/Y$ , where  $c > 0$  is an arbitrary constant. By Fubini's theorem, the order of integration can be interchanged with respect to the individual variables.

$$\begin{aligned} F_U(u) &= P(X < (u/c)Y) = \int_0^\infty \int_{-\infty}^{uy/c} f_X(x) f_Y(y) dx dy \\ &= \int_0^\infty \left( \int_{-\infty}^u \frac{y}{c} f_X(ty/c) f_Y(y) dt \right) dy \\ &= \int_{-\infty}^u \left( \frac{1}{c} \int_0^\infty y f_X(ty/c) f_Y(y) dy \right) dt. \end{aligned}$$

This expression for  $F_U(u)$  shows that the density  $f_U$  of the random variable  $U$  equals

$$f_U(u) = \frac{1}{c} \int_0^\infty y f_X(uy/c) f_Y(y) dy.$$

Substitute the densities of the corresponding special gamma distributions for  $X \sim \chi_k^2$  and  $Y \sim \chi_m^2$ . Set  $c = m/k$ . The random variable  $U = \frac{X/k}{Y/m}$  has density  $f_U(u)$  equal to

$$\frac{(k/m)^{k/2}}{2^{(k+m)/2} \Gamma(k/2) \Gamma(m/2)} \int_0^\infty y^{(k+m)/2-1} e^{-y(1+ku/m)/2} dy.$$

The integrand in the latter integral is, up to the right constant multiple, the density of the distribution of a random variable  $Y \sim \Gamma((k+m)/2, (1+ku/m)/2)$ . Hence the multiple can be rescaled (notice  $u$  is constant there) in order to get

Bernoulli experiment, we get the a posteriori density (the sign used instead of equality denotes “proportional”)

$$\begin{aligned} g(\theta|X = k) &\propto P(X = k|\theta)g(\theta) \propto \\ &\propto \theta^k(1 - \theta)^{n-k}\theta^{a-1}(1 - \theta)^{b-1} = \\ &= \theta^{a+k-1}(1 - \theta)^{b+n-k-1}. \end{aligned}$$

Thus, we have indeed obtained the density (up to a constant, which we need not evaluate) of the a posteriori distribution for  $\theta$  with distribution  $B(a + k, b + n - k)$ .

Its a posteriori expected value is

$$\hat{\theta} = \frac{a + k}{a + b + n}.$$

For  $n$  and  $k$  approaching infinity so that  $k/n \rightarrow p$ , our a posteriori estimate also satisfies  $\hat{\theta} \rightarrow p$ . Thus, we can see that for large values of  $n$  and  $k$ , the observed fraction of successful experiments outweighs the a priori assumption. On the other hand, for small values, the a priori assumption is very important.  $\square$

**10.K.5.** We have data about accident rates for  $N = 20$  drivers in the last  $n = 10$  years (the  $k$ -th item corresponds to the number of years when the  $k$ -th driver had an accident):

$$0, 0, 2, 0, 0, 2, 2, 0, 6, 4, 3, 1, 1, 1, 0, 0, 5, 1, 1, 0.$$

We assume that the probabilities  $p_j$ ,  $j = 1, \dots, N$ , that the  $j$ -th driver has an accident in a given year are constants.

For each driver, estimate the probability that s/he has an accident in the following year (in order to determine the individual insurance fee, for instance). <sup>2</sup>

**Solution.** We introduce random variables  $X_{ij}$  with value 0 if the  $i$ -th driver has no accident in the  $j$ -th year, and 1 otherwise. The individual years are considered to be independent. Thus, we can assume that the random variables  $S_j = \sum_{i=1}^n X_{ji}$  that correspond to the number of accidents in all the  $n = 10$  years have distribution  $\text{Bi}(n, p_j)$ .

Of course, we could estimate the probabilities for all drivers altogether, i. e., using the arithmetic mean

$$\hat{p} = \frac{1}{N} \sum_{j=1}^n S_j \frac{1}{n} = \frac{1}{20} \frac{29}{10} = 0.145.$$

However, consider the homogeneity of the distribution of the variables  $X_j$ , they can hardly be accounted equal, so such estimate would be misleading.

On the other hand, the opposite extreme, i. e., a totally independent and individual estimate

$$\hat{p}_j = \frac{1}{n} S_j$$

is also inappropriate, since we surely do not want to set zero insurance fee until the first accident happens.

The realistic method is to use the same assumption for the a priori distribution of the probabilities  $p_j$  of accident

<sup>2</sup>This problem is taken from the contribution M. Friesl, Bayesovské odhady v některých modelech, published in: Analýza dat 2004/II (K. Kupka, ed.), Trilobyte Statistical Software, Pardubice, 2005, pp. 21-33.

the integral to evaluate to one. The density  $f_U(u)$  is then expressed as

$$\frac{\Gamma((k + m)/2)}{\Gamma(k/2)\Gamma(m/2)} \left(\frac{k}{m}\right)^{k/2} u^{k/2-1} \left(1 + \frac{k}{m}u\right)^{-(k+m)/2}.$$

This distribution is called the *Fisher-Snedecor distribution with  $k$  and  $m$  degrees of freedom*, or *F-distribution* in short.

**10.2.45. The t-distribution.** One encounters another useful distribution when examining the quotient of variables  $Z \sim N(0, 1)$  and  $\sqrt{X/n}$ . Here  $X \sim \chi_n^2$ . (We are interested in the quotient of  $Z$  and the standard deviation of some sample).

Compute first the distribution function of  $Y = \sqrt{X}$  (note that  $X$ , and hence  $Y$  as well, take only positive values with non-zero probability)

$$\begin{aligned} F_Y(y) &= P(\sqrt{X} < y) = P(X < y^2) \\ &= \int_0^{y^2} \frac{1}{2^{n/2}\Gamma(n/2)} x^{n/2-1} e^{-x/2} dx \\ &= \int_0^y \frac{1}{2^{n/2-1}\Gamma(n/2)} t^{n-1} e^{-t^2/2} dt. \end{aligned}$$

Hence the density of the random variable  $Y$  is

$$f_Y(y) = \frac{1}{2^{n/2-1}\Gamma(n/2)} y^{n-1} e^{-y^2/2}.$$

The same method can be used as in the previous subsection with the random variable  $U = cZ/Y$ , setting  $c = \sqrt{n}$ ,  $Y = \sqrt{X}$ . This leads to the random variable

$$T = \frac{Z}{\sqrt{X/n}}.$$

Similar computation as the one above yields that the density  $f_T$  satisfies

$$f_T(t) = \frac{\Gamma((n + 1)/2)}{\Gamma(n/2)\sqrt{n\pi}} \left(1 + \frac{t^2}{n}\right)^{-(n+1)/2}.$$

This is called the *Student's t-distribution with  $n$  degrees of freedom*.

**10.2.46. Multidimensional normal distribution.** Consider

a random vector  $Z = (Z_1, \dots, Z_n)$  with independent components  $Z_i \sim N(0, 1)$ . Then its covariance matrix is equal to the unit matrix, i.e.,  $\text{var } Z = \mathbb{I}_n$ .

Random vectors are often encountered which are an affine transformation  $U = a + BZ$  of such a vector  $Z$ , where  $a$  is an arbitrary constant vector in  $\mathbb{R}^m$  and  $B$  is an  $m$ -by- $n$  constant matrix.

As derived in theorems 10.2.29 and 10.2.35, these random vectors have expected value  $E U = a$  and covariance matrix  $\text{var } U = V = B B^T$  (since the covariance matrix of  $Z$  is the identity matrix). Therefore, this covariance matrix is always positive-semidefinite.

The random vector  $U$  is said to have *multivariate normal distribution*  $N_m(a, V)$ .

rates of individual drivers. In practice, one often uses a model with the Poisson distribution  $\text{Po}(\lambda_j)$  for the  $j$ -th driver, with further assumptions about the distribution of the parameter  $\lambda$  among the drivers. We can also assume quite well (and simply) that the distribution is  $p_j \sim \text{fi}(a, b)$  with suitable parameters  $a, b$  which should reflect the cumulated results of all drivers. Thus, let us go this way.

We know from the above exercise that the a posteriori probability distribution will be  $(p_j | S_j = k) = \text{fi}(a + k, b + n - k)$ , so the corresponding expected value will be

$$\hat{p}_j^b = \frac{a + k}{a + b + n}.$$

Let us compare this estimate to the common estimate  $\hat{p}$  mentioned above and the individual estimate  $\hat{p}_j$ . We introduce the values  $p_0 = \frac{a}{a+b}$ , i. e., the expected value of the a priori common distribution for all drivers, and  $n_0 = a + b$ . We get

$$\hat{p}_j^b = \frac{(a+b)a}{(a+b+n)(a+b)} + \frac{nk}{(a+b+n)n} = \frac{n_0}{n_0+n} p_0 + \frac{n}{n_0+n} \hat{p}_j$$

which is a linear combination of the expected value  $p_0$  and the individual estimate  $\hat{p}_j$ .

Thus, it only remains to reasonably estimate the unknown parameters  $a, b$ . We know that

$$\begin{aligned} \mathbb{E} X_{ji} &= \mathbb{E} \mathbb{E}(X_{ji} | p) = \mathbb{E} p = p_0 \\ \frac{\mathbb{E} \text{var}(X_{ji} | p)}{\text{var} \mathbb{E}(X_{ji} | p)} &= \frac{\mathbb{E}(p(1-p))}{\text{var} p} = a + b = n_0 \end{aligned}$$

and the left-hand variables can be estimated directly.

$$\begin{aligned} \mathbb{E} X_{ij} &= \mathbb{E} \mathbb{E}(X_{ji} | p) \simeq \frac{1}{N} \sum_{j=1}^N \hat{p}_j \\ \mathbb{E} \text{var}(X_{ji} | p) &\simeq \frac{1}{N} \sum_{j=1}^N \left( \frac{n}{n-1} \hat{p}_j (1 - \hat{p}_j) \right) \\ \text{var} \mathbb{E}(X_{ji} | p) &\simeq s_{\hat{p}_j}^2 - \frac{1}{nN} \sum_{j=1}^N \left( \frac{n}{n-1} \hat{p}_j (1 - \hat{p}_j) \right), \end{aligned}$$

where  $s_{\hat{p}_j}^2$  denotes the sample variance between individual estimates (you can verify that the subtraction of the right-most expression guarantees that the last estimate is unbiased).

Since for the mentioned data, we get  $n_0 \simeq 3.8643$  and  $p_0 \simeq 0.1450$ , the Bayesian estimate of the individual probability of accidents is

$$\hat{p}_j^b = 0.154 \cdot 0.145 + 0.846 \cdot \hat{p}_j.$$

Thus, it is a combination of the confidence estimate  $\hat{p} = 0.145$  of the collective probability  $p_0$  with the individual (frequentist) estimate  $\hat{p}_j$ , which is measured from a small number  $n = 10$  of observations of one driver.  $\square$

For any multivariate normal distribution  $N_m(a, V)$ , consider again the affine transformation

$$W = c + DU$$

with a vector of constants  $c \in \mathbb{R}^k$  and an arbitrary  $k$ -by- $m$  constant matrix  $D$ . Direct calculation leads to

$$W = c + D(a + BZ) = (c + Da) + (DB)Z,$$

which is a random vector  $W \sim N_k(c + Da, DBB^T D^T)$ . Thus, the covariance matrix of the multivariate normal distribution behaves as a quadratic form with respect to affine transformations.

This straightforward idea shows that any linear combination of components of a random vector with the multivariate normal distribution is a random variable with the normal distribution. Similarly, any vector obtained by choosing only some of the components of the vector  $U$  is again a random vector with the multivariate normal distribution.

Note that when the random vector  $Z \sim N_n(0, \mathbb{I}_n)$  is transformed with an orthogonal matrix  $Q^T$ , then the joint distribution function of the random vector  $U = Q^T Z$  can be computed directly. If the transformation in coordinates as  $t = Q^T z$  is written, then its inverse is  $z = Qt$ , and the Jacobian of this transformation is equal to one. Hence (note that  $\sum_i z_i^2 = \sum_i t_i^2$ ). As in chapter 3, write  $z < u$  if all components satisfy  $z_i < u_i$ )

$$\begin{aligned} F_U(u) &= P(U_i < u_i, i = 1, \dots, n) = \\ &= \int \dots \int_{Q^T z < u} (2\pi)^{-n/2} e^{-\sum z_i^2/2} dz_1 \dots dz_n \\ &= \int \dots \int_{t < u} (2\pi)^{-n/2} e^{-\sum t_i^2/2} dt_1 \dots dt_n \\ &= \left( \int_{-\infty}^{u_1} (2\pi)^{-1/2} e^{-t_1^2/2} dt_1 \right) \dots \\ &\quad \dots \left( \int_{-\infty}^{u_n} (2\pi)^{-1/2} e^{-t_n^2/2} dt_n \right) \\ &= F_{U_1}(u_1) \dots F_{U_n}(u_n) \end{aligned}$$

Hence it directly follows that all components of the random vector  $U$  are again independent, and  $U \sim N_n(0, \mathbb{I}_n)$ .

### 3. Mathematical statistics

The data processing in mathematical statistics is based on quite sophisticated mathematics, but the actual methods are also very much dependent on the inputs from the diverse application fields.

Here we restrict attention to a few modest notes about statistical methods. We suggest curious readers to look for more detailed literature (which would reflect the field of application as well).

**L. Processing of multidimensional data**

Sometimes, we need to process multidimensional data: for each of  $n$  objects, we determine  $p$  characteristics. For instance, we can examine marks of several students in various subjects.

**10.L.1.** In his attempts, J.G.Mendel examined 10 plants of pea, and each was examined for the number of yellow and green seeds. The results of the experiment are summarized in the following table:

plant number	1	2	3	4	5	6	7	8	9	10
yellow seeds	25	32	14	70	24	20	32	44	50	44
green seeds	11	7	5	27	13	6	13	9	14	19
total seeds	36	39	19	97	37	26	45	53	64	63

It follows from the genetic models that the probability of occurrence of the yellow seed should be 0.75 (and 0.25 for green seed). At the asymptotic significance level 0.05, test the hypothesis that the results of Mendel’s experiments are in accordance with the model.

**Solution.** We test the hypothesis with the *Pearson’s chi-squared test*. We use the statistic

$$K = \sum_{j=1}^r \frac{(n_j - np_j)^2}{np_j},$$

where  $r$  is the number of sorting intervals (measurements; we have  $r = 10$ ),  $n_j$  is the actually measured frequency in the chosen sorting interval (we will count the number of yellow seeds),  $p_j$  is the expected frequency (by the assumed distribution), in our case,  $p_j = 0.75$ ,  $j = 1, \dots, 10$ . If the results of the experiment were really distributed as assumed in our model, we would have  $K \approx \chi^2(r - 1 - p)$ , where  $p$  is the number of estimated parameters in the assumed probability distribution. In our case, it is especially simple, since our model does not have any unknown parameters, so we have  $p = 0$  (the parameters may occur if, e. g., we assume that the probability distribution in our experiment is normal but with unknown variance and expected value; then we would have  $p = 2$ ). Thus,  $K \approx \chi^2(9)$ . The statistic is recommended to be used if the expected frequency of the characteristic in each of the sorting intervals is at least 5.

Let us write the data into a table:

$j$	$n_j$	$p_j$	$np_j$	$\frac{(n_j - np_j)^2}{np_j}$
1	25	0.75	27	0.148148
2	32	0.75	29, 25	0.258547
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
10	44	0.75	46.5	0.134409

The value of the statistic  $K$  for the given data is

$$K = 0.148148 + 0.258547 + \dots + 0.134409 = 1.797495.$$

**10.3.1. Introductory ideas.** In the descriptive statistics at the beginning of this chapter, we tried to equip the data sets with some characteristics which would carry essential information such as the sample mean, variance, etc.

Mathematical statistics works with some sample of a given data set, trying to describe to what extent the obtained statistics are relevant, or to find or improve an appropriate theoretical model for the behaviour of the entire data set, based on the collected data. The model is then used to either accept/reject a hypothesis about the data set, or to estimate the probability of an event that might happen in the future.

Consider an easy example: construct a wooden coin with heads and tails. Toss it  $n$  times, noting that it comes up heads  $k \leq n$  times. From this experiment, attempt to deduce the probability that the coin comes up heads in both of two more tosses.

There are two fundamental approaches to this problem. The first one is the classical statistics (or *frequentist statistics*). Build on the assumption that the individual tosses are independent and have the same probability of coming up heads, which is given by an objectively existing parameter  $\theta = p$  (unknown to us so far). Thus, the individual tosses are considered to be the realization of a random variable  $X$  with Bernoulli distribution. The probability of getting  $k$  heads out of  $n$  tosses is given by the binomial distribution, and it is expected that the “best possible” estimate for the parameter  $p$  is the ratio  $\theta = k/n$ . Usually the confidence of such an estimate is also wanted. This can be obtained from knowledge of the total number  $n$  of tosses and the asymptotic behaviour of the model as  $n$  increases. For instance, if the coin comes up heads 8 times out of 10, With a certain (mathematically estimated) confidence, it can be stated that the probability of the coin coming up heads in both of the subsequent tosses is  $0.8^2 = 0.64$ , a number much more than half.

The other possibility is quite different. Consider the parameter  $\theta$  to be a random variable from some chosen family of distributions, the collected data to be constants, and then try to deduce how to adjust the probability distribution of this random variable  $\theta$ . For example, suppose a (perhaps fair) coin is created, i.e. the expected value is (close to) 0.5, but the precision of the production ensures this only up to some small  $\varepsilon > 0$ . The experiment of tossing the coin  $n$  times allows the adjustment of the distribution within the preferred class. Thus, we build on some assumptions about the distribution and adjust the prior distribution in view of the experiment. This approach is called *Bayesian statistics*.

The first approach is based on the purely mathematical abstraction that probabilities are given by the frequencies of event occurrences in data samples which are so large that they can be approximated with infinite models. The central limit theorem can be used to estimate their confidence. From the statistical point of view, the probability is an idealization of the relative frequencies of the cases when an examined result

This value is less than  $\chi_{0.95}^2(9) = 16.9$ , so we do not reject the null hypothesis at level 0.05 (i. e., we do not refute the known genetic model).

□

occurs in many repeated experiments. This seeming advantage/rigor can become a disadvantage as soon as we are interested in the confidence of the data themselves and the suitability of the chosen experiment. The same problem occurs if we want to use frequentist statistics to estimate the probability of one or more outcomes of an experiment that is executed only once.

On the other hand, Bayesian statistics is an example of applying mathematics to “common sense” when we want to adjust our belief in light of new information.

It is interesting that, from the historical point of view, the first approach was the Bayesian one (for instance, Laplace and more as early as in the 18th century), which succumbed to frequentist statistics in the 20th century. In recent decades, Bayesian statistics has been returning, together with further new approaches.

**10.3.2. Random sample of a population.** Describe the first

approach of the above subsection. Thus, assume that there is a (huge) basic statistical set of  $N$  units, which is called the *population*, and each of the units has a numerical characteristic, i.e., there is a set of values  $(x_1, \dots, x_N)$ . From this set there is only a *sample* with values  $(X_1, \dots, X_n)$ .

In order to avoid the discussion of the actual size of the basic statistical set of  $N$  units, assume that the items of the sample are selected one by one and every item is always put back into the population. In addition, assume that every item has the same probability  $1/N$  of being chosen. This is a *random sample*.

The way of realizing the random sample can be viewed as working with a vector  $(X_1, \dots, X_n)$  of independent, identically distributed random variables. In particular, they have the same distribution function  $F_X(x)$  and moments

$$E X_i = \mu, \quad \text{var } X_i = \sigma^2.$$

The next step must be a derivation of the characteristics of the sample mean  $\bar{X}$  and the *sample variance*

$$S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2.$$

The following theorem explains why the coefficient  $\frac{1}{n-1}$  is selected instead of  $\frac{1}{n}$ , which is the case with  $s^2$  in subsection 10.1.6.

**Theorem.** *The sample mean  $\bar{X}$  computed from a random sample of size  $n$  whose distribution has finite expected value  $\mu$  and finite variance  $\sigma^2$  satisfies*

$$E \bar{X} = \mu, \quad \text{var } \bar{X} = \frac{1}{n} \sigma^2.$$

*The sample variance  $S^2$  satisfies*

$$E S^2 = \sigma^2.$$

**PROOF.** As derived in subsection 10.2.29,

$$E \bar{X} = \frac{1}{n} E \sum_{i=1}^n X_i = \frac{1}{n} n \mu = \mu.$$

Since the variables  $X_i$  are independent, additivity of variance can be used (derived in subsection 10.2.33). The variance behaves as a quadratic form with respect to multiplication by a scalar. Hence

$$\text{var } \bar{X} = \frac{1}{n^2} \text{var} \sum_{i=1}^n X_i = \frac{1}{n^2} n \sigma^2 = \frac{1}{n} \sigma^2.$$

The formula

$$\sum_{i=1}^n (X_i - \mu)^2 = \sum_{i=1}^n (X_i - \bar{X})^2 + n(\bar{X} - \mu)^2$$

can be verified simply by expanding the multiplications. Thus:

$$\begin{aligned} \text{E } s^2 &= \frac{1}{n} \text{E} \sum_{i=1}^n (X_i - \mu)^2 - \frac{n}{n} (\bar{X} - \mu)^2 = \\ &= \frac{1}{n} \sum_{i=1}^n \text{var } X_i - \text{var } \bar{X} = \\ &= \left(1 - \frac{1}{n}\right) \sigma^2. \end{aligned}$$

That is why the variance  $s^2$  is multiplied by the coefficient  $\frac{n}{n-1}$ , which leads just to the sample variance  $S^2$  and its expected value  $\sigma$ . Of course, this multiplication makes sense only if  $n \neq 1$ .  $\square$

### 10.3.3. Random sample of the normal distribution. In

practice, it is necessary to know not only the numerical characteristics of the sample mean and the variance, but also their total probability distributions. Of course, it can be derived only if the particular probability distribution of  $X_i$  is known. As a useful illustration, calculate the result for a random sample of the normal distribution.

It is already verified, as an example on properties of moment generating functions in 10.2.37, that the sum of random variables with the normal distribution results again in the normal distribution. Hence the sample mean must also have the normal distribution, and since both its expected value and variance are known,  $\bar{X} \sim N(\mu, \frac{1}{n} \sigma^2)$ .

The probability distribution of the sample variance is more complicated. Here, apply the ideas about multivariate normal distributions from subsection 10.2.37. Consider a vector  $Z$  of standardized normal variables

$$Z_i = \frac{X_i - \mu}{\sigma}.$$

The same property holds for the vector  $U = Q^T Z$  with any orthogonal matrix  $Q$ . In addition,  $\sum_i U_i^2 = \sum_i X_i^2$ . Choose the matrix  $Q$  so that the first component  $U_1$  equals the sample mean  $\bar{Z}$ , up to a multiple. This means that the first column of  $Q$  is chosen as  $(\sqrt{n})^{-1}(1, \dots, 1)$ . Then  $U_1^2 = n\bar{Z}^2$ , so we

can compute:

$$\begin{aligned}\sum_{i=1}^n U_i^2 &= \sum_{i=1}^n Z_i^2 = \sum_{i=1}^n (Z_i - \bar{Z})^2 + n\bar{Z}^2 \\ \sum_{i=2}^n U_i^2 &= \sum_{i=1}^n (Z_i - \bar{Z})^2 = \frac{1}{\sigma^2} \sum_{i=1}^n (X_i - \bar{X})^2.\end{aligned}$$

Therefore, a multiple of the sample variance  $\frac{n-1}{\sigma^2}S^2$  is the sum of  $n-1$  squares of standardized normal variables, so the following theorem is proved:

**Theorem.** *Let  $(X_1, \dots, X_n)$  be a random sample from the  $N(\mu, \sigma^2)$  distribution. Then,  $\bar{X}$  and  $S^2$  are independent variables, and*

$$\bar{X} \sim N\left(\mu, \frac{1}{n}\sigma^2\right), \quad \frac{n-1}{\sigma^2}S^2 \sim \chi_{n-1}^2.$$

Hence, it immediately follows that the standardized sample mean

$$T = \sqrt{n} \frac{\bar{X} - \mu}{S}$$

has Student's t-distribution with  $n-1$  degrees of freedom.

**10.3.4. Point and interval estimates.** Now, we have every-

thing needed to estimate the parameter values in the context of frequentist statistics. Here is a simple example. Suppose there are 500 students enrolled in a course, each of which has a certain degree of satisfaction with the course, expressed as an integer in the range 1 through 10. It may be assumed that the satisfactions  $X_i$  of the students are approximated by a random variable with distribution  $N(\mu, \sigma^2)$ . Further, suppose a detailed earlier survey showed that  $\mu = 6$ ,  $\sigma = 2$ .

In the current semester, 15 students are asked about their opinion about the course, as rumor has it that the evaluation of the new lecturer might be quite different. The results show that 2 students vote 3, 3 vote 4, 3 vote 5, 5 vote 6, and 2 vote 7. Altogether, the sample mean is  $\bar{X} = 5.133$  and the sample variance is  $S^2 = 1.695$ .

By assumptions,  $\bar{X} \sim N(\mu, \sigma^2/n)$ , so  $Z = \sqrt{n} \frac{\bar{X} - \mu}{\sigma} \sim N(0, 1)$ . In order to express the confidence of the estimate, compute the interval which contains the estimated parameter with an a priori fixed probability  $100(1-\alpha)\%$ . We talk about a confidence level  $\alpha$ ,  $0 < \alpha < 1$ . Consider  $\mu$  to be the unknown parameter, while the variance can be assumed (be it correct or not) to remain unchanged. It follows that

$$\begin{aligned}1 - \alpha &= P(|Z| < z(\alpha/2)) = P\left(\left|\sqrt{n} \frac{\bar{X} - \mu}{\sigma}\right| < z(\alpha/2)\right) \\ &= P\left(\bar{X} - \frac{\sigma}{\sqrt{n}}z(\alpha/2) < \mu < \bar{X} + \frac{\sigma}{\sqrt{n}}z(\alpha/2)\right),\end{aligned}$$

where  $z(\alpha/2)$  means the critical value, cf. 10.2.30. Thus, an interval is found whose endpoints are random variables and which contains the estimated parameter  $\mu$  with an a priori fixed probability. The middle point of this interval is called the *point estimate* for parameter  $\mu$ ; the whole interval is called the *interval estimate*. We can also say that at the confidence

level  $\alpha$ , the estimated parameter  $\mu$  is or is not different from another value  $\mu_0$ . Suppose for instance, the data and levels are  $\alpha = 0.05$  and  $\alpha = 0.1$ . Respectively we obtain the intervals

$$\mu \in (4.121, 6.145), \quad \mu \in (4.284, 5.983).$$

Considering the confidence level of 5%, we cannot affirm that the opinion of students are worse compared to the previous year because the mentioned interval also contains the value  $\mu_0 = 6$ . We can conclude this if we take the confidence level of 10% since the value  $\mu_0 = 6$  no more lies in the corresponding interval.

On the other hand, if it is assumed that the other (worse) lecturer causes the variance of the answers to change as well (for instance, the students might agree more on the bad assessment), we proceed differently. Instead of the standardized variable  $Z$ , deal in a similar way with the variable

$$T = \sqrt{n} \frac{\bar{X} - \mu}{S}.$$

As seen, this random variable has probability distribution  $T \sim t_{n-1}$ , where  $n = 15$  in this case. This leads to the interval estimate

$$\bar{X} - \frac{S}{\sqrt{n}} t_{n-1}(\alpha/2) < \mu < \bar{X} + \frac{S}{\sqrt{n}} t_{n-1}(\alpha/2).$$

Substitute the data at levels  $\alpha = 0.05$  and  $\alpha = 0.03$  respectively, to obtain

$$\mu \in (4.412, 5.854), \quad \mu \in (4.321, 5.945).$$

Therefore, at the confidence level of 3%, the opinion seems to have become worse. This corresponds to our intuition that the sample deviation  $S = 1.302$ , which is significantly smaller than  $\sigma = 2$  from the previous case, should be essential for our thinking.

**10.3.5. Likelihood of estimates.** From the mathematical

point of view, interval and point estimates are simple and easy to understand. It is much worse with their practical interpretation because it is problematic to verify all assumptions about randomness of the sample. With more complicated cases, we consider problems with the “likelihood” of our estimates.

As mathematicians, we can avoid the practical problem by defining the missing concept. In general, one works with a random sample of size  $n$ . Implicitly it is assumed that there are independent random variables  $X_i$  with the same probability distribution which depends on an unknown parameter  $\theta$  (a vector in general).

We are trying to find a *sample statistic*  $T$ , i.e., a function of the random variables  $X_1, X_2, \dots$  which, in a mathematical sense, estimates the actual value of the parameter  $\theta$ .  $T$  is said to be an *unbiased estimator* of  $\theta$  if and only if  $E T = \theta$ . The expected value  $E(T - \theta)$  is called the *bias of estimator*  $T$ .

The asymptotic behaviour of the estimator, that is, what it does as  $n$  goes to infinity is often of interest.  $T = T(n)$  is

said to be a *consistent estimator* of the parameter  $\theta$  if and only if  $T(n)$  converges in probability to  $\theta$ , i.e., for every  $\varepsilon > 0$ ,

$$\lim_{n \rightarrow \infty} P(|T(n) - \theta| < \varepsilon) = 1.$$

The Chebyshev's inequality immediately yields

$$P(|T(n) - \mathbb{E}T(n)| < \varepsilon) \geq 1 - \frac{\text{var } T(n)}{\varepsilon^2}.$$

Assuming  $\lim_{n \rightarrow \infty} \mathbb{E}T(n) = \theta$ , then, for sufficiently large values of  $n$ ,

$$P(|T(n) - \theta| < 2\varepsilon) \geq P(|T(n) - \mathbb{E}T(n)| < \varepsilon) \geq 1 - \frac{\text{var } T(n)}{\varepsilon^2}.$$

A useful proposition is thus proved :

**Theorem.** Assume that  $\lim_{n \rightarrow \infty} \mathbb{E}T(n) = \theta$  and  $\lim_{n \rightarrow \infty} \text{var } T(n) = 0$ . Then,  $T(n)$  is a consistent estimator of  $\theta$ .

As a simple example, we can illustrate this theorem on variance:

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^2 = \frac{n-1}{n} S^2.$$

Since it is known from subsection 10.3.2 that  $S^2$  is an unbiased estimator, it follows that  $\hat{\sigma}^2$  is not. However,  $\lim_{n \rightarrow \infty} \hat{\sigma}^2 = \sigma^2$ , and it can be calculated that

$$\lim_{n \rightarrow \infty} \text{var } \hat{\sigma}^2 = \lim_{n \rightarrow \infty} \text{var } S^2 = \lim_{n \rightarrow \infty} \frac{2\sigma}{n-1} = 0.$$

Therefore, the statistic  $s^2$  is a consistent estimator of the variance.

It is apparent that there may be more unbiased estimators for a given parameter. For instance, it is already shown that the arithmetic mean  $\bar{X}$  is an unbiased estimator of the expected value  $\theta$  of random variables  $X_i$ . The value  $X_1$  is, of course, an unbiased estimator of  $\theta$  as well. We wish to find the best estimator  $T$  in the class of considered statistics, which are unbiased or consistent. Consider as best the one whose variance is as small as possible. Recall that the variance of a vector statistic  $T$  is given by the corresponding covariance matrix, which is, in case of independent components, a diagonal matrix with the individual variances of the components on the diagonal. We have already defined inequalities between positive-definite matrices.

**10.3.6. Maximum likelihood.** Assume that the density function of the components of the sample is given by a function  $f(x, \theta)$  which depends on an unknown parameter  $\theta$  (a vector in general). By the assumed independence, the joint density of the vector  $(X_1, \dots, X_n)$  is equal to the product:

$$f(x_1, \dots, x_n, \theta) = f(x_1, \theta) \cdots f(x_n, \theta),$$

which is called the *likelihood function*.

We are interested in the value  $\hat{\theta}$  which maximizes the likelihood function on the set of all admissible values of the parameter. In the discrete case, this means choosing the parameter for which the obtained sample has the greatest probability.

Usually, it is more efficient to work with the *log-likelihood function*

$$\ell(x_1, \dots, x_n, \theta) = \ln f(x_1, \dots, x_n, \theta) = \sum_{i=1}^n \ln f(x_i, \theta).$$

Since the  $\ln$  function is strictly increasing, maximization of the log-likelihood function is equivalent to maximization of the original likelihood function. If, for some input, it happens that  $f(x_1, \dots, x_n, \theta) = 0$ , set  $\ell(x_1, \dots, x_n, \theta) = -\infty$ .

In the case of discrete random variables, use the same definition with probability mass function instead of the density, i.e.,

$$\ell(x_1, \dots, x_n, \theta) = \sum_{i=1}^n \ln(P(X_i = x_i|\theta)).$$

We can illustrate the principle on a random sample from the normal distribution  $N(\mu, \sigma^2)$  with size  $n$ . The unknown parameters are  $\mu$  or  $\sigma$ , or both. The considered density is

$$f(x, \mu, \sigma) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$

Take logarithms of both sides, to obtain

$$\ell(x, \mu, \sigma) = -n\frac{1}{2} \ln(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \mu)^2.$$

The maximum can be found using differentiation (note that  $\sigma^2$  is treated as a symbol for a variable):

$$\begin{aligned} \frac{\partial \ell}{\partial \mu} &= -\frac{1}{2\sigma^2} \sum_{i=1}^n (-2)(x_i - \mu) = \frac{1}{\sigma^2} \left( -n\mu + \sum_{i=1}^n x_i \right) \\ \frac{\partial \ell}{\partial \sigma^2} &= -\frac{n}{2\sigma^2} + \frac{1}{2(\sigma^2)^2} \sum_{i=1}^n (x_i - \mu)^2 = \\ &= \frac{1}{2(\sigma^2)^2} \left( -n\sigma^2 + \sum_{i=1}^n (x_i - \mu)^2 \right). \end{aligned}$$

Thus, the only critical points are given by  $\hat{\mu} = \bar{X}$  and  $\hat{\sigma}^2 = s^2$ . Substitute these values into the matrix of second derivatives, to obtain the Hessian of  $\ell$ :

$$\begin{pmatrix} -\frac{n}{\hat{\sigma}^2} & 0 \\ 0 & -\frac{n}{2(\hat{\sigma}^2)^2} \end{pmatrix}.$$

Finally, this is the required maximum, and since there is only one critical point, it must be the global maximum (think about the details of this argument!).

Thus it is verified that the expected value and the variance are the most likely estimates for  $\mu$  and  $\sigma$ , as already used.

### 10.3.7. Bayesian estimates.

We return to the example from subsection 10.3.4, now from the point of view of Bayesian statistics. This totally reverses the approach: the collected data  $X_1, \dots, X_{15}$  (i.e., the points which express how much each student is satisfied, using the scale 1 through 10) are treated as constants. On the other hand, the estimated parameter  $\mu$  (the expected value of the points of satisfaction), is viewed as the random variable

whose distribution we wish to estimate. Let us look at the general principle first (and come back to this example soon).

For this purpose, let us interpret Bayes' formula for conditional probability on the level of probability mass functions or probability densities, in the following way: If a vector  $(X, \Theta)$  has joint density  $f(x, \theta)$ , then the conditional probability of a component  $\Theta$ , given by  $X = x$ , is defined as the density

$$g(\theta|x) = \frac{f(x|\theta)g(\theta)}{f(x)},$$

where  $f(x)$  and  $g(\theta)$  are the marginal probability densities. (In the above example,  $x$  is 15-dimensional vector coming from the multidimensional normal distribution while  $\theta = \mu$  is scalar.)

Thus, given the *a priori* probability density  $g(\theta)$  of the estimated parameter  $\theta$  and the probability density  $f(x|\theta)$  (in the above example,  $\theta = \mu$  is the expected value parameter of the distribution), the formula to compute the *a posteriori* probability density  $g(\theta|x)$  can be used, based on the collected data. Indeed, we do not need to know  $f(x)$  for the following reason: we have to view  $f(x)$  as a constant independent of  $\theta$  and thus the proper density is obtained from  $f(x|\theta)g(\theta)$  by multiplying with a uniquely given constant in the end. Thus, during the computation, it is sufficient to be precise "up to a constant multiple". For this purpose, use the notation  $Q \propto R$ , meaning that there is a constant  $C$  such that the expressions  $Q$  and  $R$  satisfy  $Q = CR$ .

We shall illustrate this procedure on a more explicit example. In order to be as close as possible to the ideas from subsection 10.3.4, work with normal distributions  $N(\mu, \sigma^2)$ . Suppose that the satisfaction of individual students in particular lectures is a random variable  $X \sim N(\theta, \sigma^2)$ , while the parameter  $\theta$  reached by the particular lecturers is a random variable  $\theta \sim N(a, b)$ .

Compute, (up to a constant multiple, ignoring all multiplicative components which do not include any  $\theta$ ),

$$\begin{aligned} g(\theta|x) &\propto f(x|\theta)g(\theta) \propto \exp\left(-\frac{(x-\theta)^2}{2\sigma^2} - \frac{(\theta-a)^2}{2b^2}\right) \\ &\propto \exp\left(-\frac{1}{2}\left(\theta^2\left(\frac{1}{\sigma^2} + \frac{1}{b^2}\right) - 2\theta\left(\frac{x}{\sigma^2} + \frac{a}{b^2}\right)\right)\right) \\ &\propto \exp\left(-\frac{1}{2}\left(\theta - \frac{b^2x + \sigma^2a}{\sigma^2b^2 + b^2 + \sigma^2}\right)^2 \left(\frac{b^2\sigma^2}{b^2 + \sigma^2}\right)^{-1}\right). \end{aligned}$$

This proves already that the distribution for  $\theta$  is

$$\theta \sim N\left(\frac{b^2}{b^2 + \sigma^2}x + \frac{\sigma^2}{b^2 + \sigma^2}a, \frac{b^2\sigma^2}{b^2 + \sigma^2}\right).$$

This result can be interpreted so that if the parameters  $a, b, \sigma$  are known from long-run evaluation of surveys and the opinion of another student is learned, then the *a priori* opinion about the parameters for an individual lecture can be adjusted.

In the resulting estimate, the expected value is given by the weighted average of the found value  $x$  and the *a priori* assumed expected value  $a$ , in dependence on the standard deviations  $\sigma$  and  $b$ .

**10.3.8. Interpretation in Bayesian statistics.** We follow the ideas from the previous subsection, compared to the frequentist interpretation from 10.3.4. It may seem odd that a single query can influence an opinion so much.

For  $\sigma \rightarrow 0$ , the relevance of a single opinion is still increasing, and this corresponds to a 100% relevance of  $x$  in the case  $\sigma = 0$ . This is in accordance with the interpretation that Bayesian statistics is the probability extension of the standard discrete mathematical logic. If the variance  $\sigma$  is close to zero, then it is almost certain that the opinion of any student precisely describes the opinion of the whole population.

In subsection 10.3.4, we worked with the sample mean  $\bar{X}$  of the collected data. This can be used in the previous calculation, since the mean also has a normal distribution, too. The expected value is the same, and the only difference is that  $\sigma^2/n$  is substituted instead of  $\sigma^2$ . To facilitate the notation, define the constant

$$c_n = \frac{nb^2}{nb^2 + \sigma^2}.$$

The a posteriori estimate for  $\theta$  based on the found sample mean  $\bar{X}$  has the distribution with parameters

$$\theta \sim N(c_n \bar{X} + (1 - c_n)a, c_n \sigma^2/n).$$

As could be expected, for increasing  $n$ , the expected value of the distribution for  $\theta$  approaches the sample mean, and its variance approaches zero. In other words, the higher the value of  $n$ , the closer is the point estimate from the frequentist point of view.

A contribution of the Bayesian approach is that if the estimated distribution is used, questions of the kind: “What is the probability that the new lecturer is worse than the old one?” can be answered. Use the same data as in 10.3.4 and supplement the necessary a priori data. Assume that the lecturers are assessed quite well (otherwise, they would probably not be teaching at the university at all). For concreteness, select the a priori distribution with parameters  $a = 7.5$ ,  $b = 2.5$ , and the standard deviation with  $\sigma = 2$ . Continue with  $n = 15$  and the sample mean of 5.133. Substitute this data, to get the a posteriori estimate for the distribution

$$\theta \sim N(5.230, 0.256).$$

We are interested in  $P(\theta < 6)$ . This is computed by evaluating the distribution function of the corresponding normal distribution for the input value 6 (Excel is capable of this, too). The answer is approximately 93.6 %. This is similar to the material in subsection 10.3.4, where the known variance is assumed constant.

Note the influence of the a priori assumption about the distribution of the parameter  $\theta$  for all lecturers. To a certain extent, this reflects a faith that the lecturers are rather good. If a statistician has a reason for assuming that the actual expected value  $a$  for a specific lecturer is shifted, say  $a = 6$  as in the survey about the previous lecturer, (this can be caused,

for example, by the fact that the lecture is hard and unpopular), then the probability of his actual parameter being less than 6 would be approximately 95.0 %. (If the expected value is considered to be significantly worse only when below 5.5, then the value would be only approximately 75 %). When substituting  $a = 5$ , the value is already 96.8 %. The variance  $b^2$  is also important. For instance, the a priori estimate  $a = 6$ ,  $b = 3.5$  leads to probability 95.2 %.

In the above discussion, another very important point is touched on – *sensitivity analysis*. It would seem desirable that a small change of the a priori assumption has only a small effect on the a posteriori result. It appears that this is so in this example; however, we omit further discussion here.

The same model with exponential distributions is used in practice when judging the relevance of the output of an IQ test of an individual person. It can also be used for another similar exam where it is expected that the normal distribution approximates well the probability distribution of the results. In both cases, there is an a priori assumption to which group he/she should belong. Other good examples (with different distributions) are practical problems from insurance industry, where it is purposeful to estimate the parameters so that both the effects of the experiment upon an individual item and the altogether expectations over the population are included.

**10.3.9. Notes on hypothesis testing.** We return to deciding whether a given event does or does not occur in the context of frequentist statistics. We build on the approach from interval estimates, as presented above.

Thus, consider a random vector  $X = (X_1, \dots, X_n)$  (the result of a random sample), whose joint distribution function is  $F_X(x)$ . A *hypothesis* is an arbitrary statement about the distribution which is determined by this distribution function. Usually, one formulates two hypothesis, denoted  $H_0$  and  $H_A$ . The former is traditionally called *null hypothesis*, and the latter is called *alternative hypothesis*. The result of the test is then a decision based on a concrete realization of the random vector  $X$  (a *test*) whether the hypothesis  $H_0$  is to be rejected or not in favor of the hypothesis  $H_A$ .

During this process, two types of errors may occur. *Type I error* occurs when  $H_0$  is rejected even though it is true. *Type II error* occurs when  $H_0$  is not rejected although it is false. The decision procedure of a frequentist statistician consists of selecting the *critical region*  $W$ , i.e., the set of test results when the hypothesis is rejected. The size of the critical region is chosen so that a true hypothesis is rejected with probability not greater than  $\alpha$ . This means that a fixed bound for the probability of the type I error is required: the *significance level*  $\alpha$ . The most common choices are  $\alpha = 0.05$  or  $\alpha = 0.01$ . It is also useful in practice to determine the least possible significance level  $p$  for which the hypothesis is rejected; the *p-value* of the test.

It remains to find a reasonable procedure for choosing the critical range. This should hopefully be done so that the

type II error occurs as rarely as possible. Usually, it is convenient to consider the likelihood function  $f(x, \theta)$ , defined for a random vector  $X$  in subsection 10.3.6. For the sake of simplicity, assume there is a one-dimensional parameter  $\theta$ , and formulate the null hypothesis as  $X$  being given by the function  $f(x, \theta_0)$ , while the alternative hypothesis is given by the distribution  $f(x, \theta_1)$  for fixed distinct values  $\theta_0$  and  $\theta_1$ . Ideas about rejecting or accepting the hypotheses suggest that when substituting the values of a specific test into the likelihood function, the hypothesis can be accepted if  $f(x, \theta_0)$  is much greater than  $f(x, \theta_1)$ .

This suggests considering, for each constant  $c > 0$ , the critical range

$$W_c = \{x; f(x, \theta_1) \geq cf(x, \theta_0)\}.$$

Having chosen the significance level, choose  $c$  so that

$$\int_{W_c} f(x, \theta_0) = \alpha.$$

This guarantees that for the test result  $x \in W_c$ , when  $H_0$  is valid, the type I error occurs with at most the prescribed probability. This can also be guaranteed by other critical ranges  $W$  which also satisfy

$$\int_W f(x, \theta_0) = \alpha.$$

On the other hand, type II errors are also of interest. That is, it is desired to maximize the probability of  $H_A$  over the critical range. Thus, consider the difference

$$D = \int_{W_c} f(x, \theta_1) - \int_W f(x, \theta_1)$$

for arbitrary  $W$  as above. The regions over which integration is carried out, can be divided into the common part  $W \cap W_c$  and the remaining set differences. The contributions of the common part are subtracted, and there remains

$$D = \int_{W_c \setminus W} f(x, \theta_1) - \int_{W \setminus W_c} f(x, \theta_1).$$

Using the definition of the critical range  $W_c$ , (again, put back the same integrals over the common part)

$$\begin{aligned} D &\geq c \int_{W_c \setminus W} f(x, \theta_0) - c \int_{W \setminus W_c} f(x, \theta_0) = \\ &= c \int_{W_c} f(x, \theta_0) - c \int_W f(x, \theta_0) = c\alpha - c\alpha = 0. \end{aligned}$$

Thus is proved an important statement, the *Neyman–Pearson lemma*:

**Proposition.** *Under the above assumptions,  $W_c$  is the optimal critical range which minimizes occurrence of the type II error at a given significance level.*

**10.3.10. Example.** The interval estimate, as illustrated on an example in subsection 10.3.4, is a special case of hypothesis testing, when  $H_0$  had the form “the expected value of the satisfaction with the course remained  $\mu_0$ ”, while  $H_A$  says that it is equal to a different value  $\mu_1$ . The general procedure mentioned above leads in this case to the critical range given by

$$|Z| = \left| \frac{\bar{X} - \mu_0}{\sigma} \sqrt{n} \right| \geq z(\alpha/2).$$

Note that in the definition of the critical range, the actual value  $\mu_1$  is not essential. In the context of classical probability, the decision at a given level  $\alpha$  whether or not there is a change to the expected value  $\mu$  is thus formalized.

To test only whether the satisfaction is decreased, assume beforehand that  $\mu_1 < \mu_0$ . We analyze this case thoroughly: The critical range from the Neyman–Pearson lemma is determined by the inequality

$$\frac{f(x, \mu_1, \sigma^2)}{f(x, \mu_0, \sigma^2)} = e^{-\frac{1}{2\sigma^2} \sum_{i=1}^n ((x_i - \mu_1)^2 - (x_i - \mu_0)^2)} \geq c.$$

Take logarithms and rearrange to obtain

$$2\bar{x}(\mu_1 - \mu_0) - (\mu_1^2 - \mu_0^2) \geq \frac{2\sigma^2}{n} \ln c.$$

Since  $\mu_1 < \mu_0$ , it follows that

$$\bar{x} \leq \frac{\mu_1 + \mu_0}{2} + \frac{\sigma^2}{n(\mu_1 - \mu_0)} \ln c = y.$$

For a given level  $\alpha$ , the constant  $c$ , and thereby the decisive parameter  $y$ , are determined so that, under the assumption that  $H_0$  is true,

$$\alpha = P(\bar{X} \leq y) = P\left(\frac{\bar{X} - \mu_0}{\sigma} \sqrt{n} \leq \frac{y - \mu_0}{\sigma} \sqrt{n}\right).$$

By assuming that  $H_0$  is true,

$$Z = \frac{\bar{X} - \mu_0}{\sigma} \sqrt{n} \sim N(0, 1),$$

so the requirement means choosing  $Z \leq -z(\alpha)$ , which determines uniquely the optimal  $W_c$ .

Note that this critical region is independent of the chosen value  $\mu_1$ , and the actual value for  $y$  did not have to be expressed at all. It was only essential to assume that  $\mu_1 < \mu_0$ .

In the illustrative example from subsection 10.3.4,  $H_0 : \mu = 6$ , and the alternative hypothesis is  $H_A : \mu < 6$ . The variance is  $\sigma^2 = 4$ . The test with  $n = 15$  yielded  $\bar{x} = 5.133$ . Substitute this, to get the value  $z = \frac{5.133 - 6}{2} \sqrt{15} = -1.678$ , while  $-z(0.05) = -1.645$ .

Therefore, if we are testing whether the new teacher is even worth than the previous one, we reject the hypothesis at the level of 5 %, deducing that the students’ opinions are really worse.

If, for the critical range, the union of the critical ranges for the cases  $\mu_1 < \mu_0$  and  $\mu_1 > \mu_0$  are chosen, the same results as for the interval estimate are obtained, as mentioned above.

We remark that in the Bayesian approach, it is also possible to accept or reject hypotheses in a direct connection to the a posteriori probability of events, as was, to certain extent, indicated in subsection 10.3.8 where our specific example is interpreted.

**10.3.11. Linear models.** As is usual in the analysis of mathematical problems, either we deal with linear dependencies and objects, or we discuss their linearizations. In statistics, many methods belong to the linear models, too. We consider a quite general scheme of this type.

Consider a random vector  $Y = (Y_1, \dots, Y_n)^T$  and suppose

$$Y = X \cdot \beta + \sigma Z,$$

where  $X = (x_{ij})$  is a constant real-valued matrix with  $n$  rows and  $k < n$  columns, whose rank is  $k$ ,  $\beta$  is an unknown constant vector of  $k$  parameters of the model,  $Z$  is a random vector whose  $n$  components have distribution  $N(0, 1)$ , and  $\sigma > 0$  is an unknown positive parameter of the model. This is a *linear model* with full rank.

In practice, the variables  $x_{ij}$  are often known. The problem is to estimate or predict the value of  $Y$ . For instance,  $x_{ij}$  can express the grade in maths of the  $i$ -th student in the  $j$ -th semester ( $j = 1, 2, 3$ ), and we want to know how this student will fare in the fourth semester. For this purpose, the vector  $\beta$  needs to be known. This can be estimated using complete observations, that is, from the knowledge of  $Y$  (from the results of past years, for example).

In order to estimate the vector  $\beta$ , the *least squares method* can often be used. This means looking for the estimate  $b \in \mathbb{R}^k$  for which the vector  $\hat{Y} = Xb$  minimizes the squared length of the vector  $Y - X\beta$ .

This is a simple problem from linear algebra, looking for the orthogonal projection of the vector  $Y$  onto the subspace  $\text{span } X \subset \mathbb{R}^n$  generated by the columns of the matrix  $X$ . This is minimizing the function

$$\|Y - X\beta\|^2 = \sum_{i=1}^n \left( Y_i - \sum_{j=1}^k x_{ij} \beta_j \right)^2.$$

Choose an arbitrary orthonormal basis of the vector subspace  $\text{span } X$  and write it into columns of the matrix  $P$ . For any choice of basis, the orthogonal projection is realized as multiplication by the matrix  $PP^T$ . In the subspace  $\text{span } X$ , the mapping given by this matrix is the identity. That is,

$$\hat{Y} = PP^T Y = PP^T (X\beta + \sigma Z) = X\beta + \sigma PP^T Z.$$

The matrix  $PP^T$  is positive-semidefinite. Extend the basis consisting of the columns of  $P$  to an orthonormal basis of the whole space  $\mathbb{R}^n$ . In other words, create a matrix  $Q = (P \ R)$  by writing the newly added basis vectors into the matrix  $R$  with  $n - k$  columns and  $n$  rows. Denote by  $V = P^T Z$  and  $U = R^T Z$  the random vectors with  $k$  and  $n - k$  components, respectively. They are orthogonal, and their sum in  $\mathbb{R}^n$  is the vector  $(V^T \ U^T)^T = Q^T Z$ .

Clearly (see subsection 10.2.46), both vectors  $V$  and  $U$  have multivariate normal distribution with zero expected value and identity covariance matrix. The random vector  $Y$  is decomposed to the sum of a constant vector  $X\beta$  and two orthogonal projections

$$Y = X\beta + \sigma PV + \sigma RU,$$

and the desired orthogonal projection is the sum of the first and second summands. In subsection 10.2.46, the distribution of such random vectors is also derived.

The size of  $\|Y - \hat{Y}\|^2$  is called the *residual sum of squares*, sometimes denoted by *RSS*. Also, the *residual variance* is defined as

$$S^2 = \frac{\|Y - Xb\|^2}{n - k}.$$

Recall that  $\hat{Y} = Xb$  and that  $X^T X$  is invertible as the full rank of  $X$  is assumed. Thus  $b = (X^T X)^{-1} X^T \hat{Y}$  can be computed. At the same time,  $X^T (Y - \hat{Y}) = \sigma X^T (RU) = 0$ , since the columns of  $X$  and  $R$  are mutually orthogonal. Therefore,

$$(1) \quad b = (X^T X)^{-1} X^T Y.$$

The chosen matrix  $P$  can be used with advantage. Since its columns generate the same subspace as the columns of  $X$ , there is a square matrix  $T$  such that  $X = PT$  (its columns are the coefficients of linear combinations which are expressed by the columns of  $X$  in the basis of  $P$ ). Substitute (using the fact that  $P^T P$  is the identity matrix and  $T$  is invertible):

$$\begin{aligned} b &= (T^T P^T P T)^{-1} T^T P^T Y = \\ &= T^{-1} (T^T)^{-1} T^T P^T (PT\beta + \sigma Z) = \\ &= \beta + \sigma T^{-1} V. \end{aligned}$$

Thus is proved the main properties of the linear model:

**Theorem.** Consider a linear model  $Y = X\beta + \sigma Z$ .

(1) For the estimate of  $\hat{Y}$ ,

$$\hat{Y} = X\beta + \sigma PV, \quad \hat{Y} \sim N(X\beta, \sigma^2 P P^T).$$

(2) The residual sum of squares and the normed square of the residue size have distributions:

$$Y - \hat{Y} \sim N(0, \sigma^2 R R^T), \quad \|Y - \hat{Y}\|^2 / \sigma^2 \sim \chi_{n-k}^2.$$

(3) The random variable  $b = \beta + \sigma T^{-1} V$  has distribution

$$b \sim N(\beta, \sigma^2 (X^T X)^{-1}).$$

(4) The residual variance satisfies  $(n - k)S^2 / \sigma^2 \sim \chi_{n-k}^2$ .

(5) The expected value of the residual variance is  $E S^2 = \sigma^2$ .

(6) The variables  $b$  and  $S^2$  are independent.

**PROOF.** Both the shape and distribution of  $\hat{Y}$  are determined. It is clear that  $Y - \hat{Y} = \sigma RU$ , which verifies the second proposition. Further,

$$\|Y - \hat{Y}\|^2 / \sigma^2 = \|RU\|^2 = \|U\|^2,$$

where the last equality follows from the fact that in the construction,  $U$  is the vector of coordinates of the projection  $Z$  onto the complement of  $\text{span } X$ , and  $RU$  is this projection. The size of a vector is exactly the sum of squares of its coordinates in any orthonormal basis.

Therefore, the random vector  $\|Y - \hat{Y}\|^2/\sigma^2$  is the sum of  $(n-k)$  squares of random variables with distribution  $N(0, 1)$ , so it is the distribution  $\chi_{n-k}^2$ , which proves the rest of (2).

The next proposition follows directly from the definitions and calculations. It suffices to estimate the covariance matrix for  $b$ . From the general properties, it should be the matrix  $T^{-1}(T^T)^{-1}$ . This is the same as  $(X^T X)^{-1} = ((PT)^T(PT))^{-1}$ .

The proposition (4) is a reformulation of the information in (2). The next proposition follows from the fact that the expected value of the  $\chi^2$  distribution equals the number of degrees of freedom.

Finally, independence of the variables  $b$  and  $S$  is a consequence of the fact that the former variable is a function of the vector  $V$ , while the latter one is a function of the vector  $U$ . These vectors are independent since they are two complementary parts from an orthogonal transformation of the vector  $Z$ .  $\square$

In practice, the hypothesis whether fewer parameters are sufficient to estimate the expected value is sometimes tested. A random vector  $Y$  is said to satisfy a *submodel* if and only if both  $Y = X\beta + \sigma Z$  and

$$Y = X^0 \beta^0 + \sigma Z,$$

where  $X^0$  has only  $q < k$  columns. It is assumed that the columns of  $X^0$  generate a subspace in  $\text{span } X$ , i.e., all are linear combinations of the columns of  $X$ .

Repeat the above construction, choosing the matrix  $P$  so that the first  $q$  vectors of  $P$  generate  $\text{span } X^0$ . The matrix  $P$  is then of the form  $(P^0 P^1)$ , and the vector  $V$  decomposes similarly:

$$V = \begin{pmatrix} V^0 \\ V^1 \end{pmatrix} = \begin{pmatrix} (P^0)^T Z \\ (P^1)^T Z \end{pmatrix}.$$

This yields a finer decomposition of the vectors and their sizes and the corresponding residues:

$$\hat{Y}^0 = P^0(P^0)^T Y = X^0 \beta^0 + \sigma P^0 V^0$$

$$Y - \hat{Y}^0 = \sigma P^1 V^1 + \sigma R U$$

$$\|Y - \hat{Y}^0\|^2 = \sigma^2 \|V^1\|^2 + \sigma^2 \|U\|^2$$

$$(\text{RSS}^0 - \text{RSS})/\sigma^2 = \|V^1\|^2.$$

Therefore, the normed difference of the residues has distribution  $\chi_{k-q}^2$ . It follows immediately that the statistic  $F$  given as the relative difference of the residues has Fisher-Snedecor distribution:

$$F = \frac{(\text{RSS}^0 - \text{RSS})/(k-q)}{\text{RSS}/(n-k)} \sim F_{k-q, n-k}.$$

In practice, the parameter  $\sigma$  is seldom known, and so the estimate  $S^2$  is used. Instead of the individual components  $b_j \sim N(\beta_j, \sigma^2 c_{jj})$  of the random vector  $b$ , where  $c_{jj}$  are the diagonal entries of the matrix  $C = (X^T X)^{-1}$ , work with the statistics

$$T_j = \frac{b_j - \beta_j}{S\sqrt{c_{jj}}} \sim t_{n-k}.$$

Of course, these variables need not be independent.

If the full rank of the matrix  $X$  is not assumed, a pseudoinverse matrix can be used instead of  $C = (X^T X)^{-1}$ .

**10.3.12. Examples of tests.** As an illustration, we mention some examples of application of linear models in the simplest types of tests. The most trivial case is when there is only one sample. Here the test is whether or not the only parameter  $\beta$  equals a given value  $\beta_0$ .

For this case, choose the matrix  $X$  as a single column consisting of ones. Then, the expression

$$Y = X\beta + \sigma Z$$

indicates that the individual components in  $Y$  are independent variables  $Y_i \sim N(\beta, \sigma^2)$ . It is a random sample of size  $n$  from the normal distribution. In general, the estimate

$$b = (X^T X)^{-1} X^T Y = \frac{1}{n} \sum_{i=1}^n Y_i = \bar{Y}$$

$$S^2 = \frac{1}{n-1} \|Y - X\bar{Y}\|^2 = \frac{1}{n-1} \sum_{i=1}^n (Y_i - \bar{Y})^2,$$

which respectively is exactly the sample mean and variance used before.

In this context, the statistic

$$T = \frac{\bar{Y} - \beta_0}{S} \sqrt{n}$$

may also be of interest.

Testing the hypothesis  $\beta = \beta_0$  is called the *one-sample t-test*. The hypothesis is rejected at level  $\alpha$  if  $|T| \geq t_{n-1}(\alpha)$ .

There is another simple application of the general model, which is called the *paired t-test*. It is appropriate for cases when pairs of random vectors  $W_1 = (W_{i1})$  and  $W_2 = (W_{i2})$  are tested. The differences  $Y_i = W_{i1} - W_{i2}$  of their components have distribution  $N(\beta, \sigma^2)$ . In addition, the variables  $Y_i$  need to be independent (which does not mean that the individual pairs  $W_{i1}$  and  $W_{i2}$  have to be independent!). In the context of our illustrative example from 10.3.4, we can imagine the assessment of two lecturers by the same student.

Test the hypothesis that for every  $i$ ,  $E W_{i1} = E W_{i2}$ . Thus, use the statistic

$$T = \frac{\bar{W}_1 - \bar{W}_2}{S} \sqrt{n}.$$

Finally, we consider an example with more parameters. It is a classical case of the *regression line*.

Assume that the variables  $Y_i, i = 1, \dots, n$  have distribution  $N(\beta_0 + \beta_1 x_i, \sigma^2)$ , where  $x_i$  are given constant. Examine the best approximation

$$Y_i = b_0 + b_1 x_i,$$

and the matrix  $X$  of the corresponding linear model is

$$X^T = \begin{pmatrix} 1 & 1 & \dots & 1 \\ x_1 & x_2 & \dots & x_n \end{pmatrix}.$$

Substitute into general formulae, and compute the estimate

$$\begin{aligned} \begin{pmatrix} b_0 \\ b_1 \end{pmatrix} &= \begin{pmatrix} n & n\bar{x} \\ n\bar{x} & \sum_{i=1}^n x_i^2 \end{pmatrix}^{-1} \begin{pmatrix} n\bar{Y} \\ \sum_{i=1}^n x_i Y_i \end{pmatrix} = \\ &= \begin{pmatrix} \sum_{i=1}^n (x_i - \bar{x})^2 \\ \frac{1}{n} \sum_{i=1}^n x_i^2 & -\bar{x} \\ -\bar{x} & 1 \end{pmatrix}^{-1} \begin{pmatrix} n\bar{Y} \\ \sum_{i=1}^n x_i Y_i \end{pmatrix}. \end{aligned}$$

It follows that

$$b_1 = \frac{\sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y})}{\sum_{i=1}^n (x_i - \bar{x})^2}.$$

Finally, compute  $b_0 = \bar{Y} - b_1 \bar{x}$ . From the calculations,

$$\text{var } b_1 = \sigma^2 / \sum_{i=1}^n (x_i - \bar{x})^2.$$

In order to test the hypothesis whether the expected value of a variable  $Y$  does not depend on  $x$ , that is, whether or not  $H_0$  is of the form  $\beta_1 = 0$ , use the statistic

$$T = \frac{b_1}{S} \left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{1/2} \sim t_{n-2}.$$

The statistical analysis of multiple regression is similar. There are several sets of values  $x_{ij}$  to evaluate the statistical relevance of the approximation

$$Y_i = b_0 + b_1 x_{1i} + \dots + b_k x_{ki}.$$

The individual statistics  $T_j$  allow for a t-test of dependence of the regression on the individual parameters. Software packages often provide a parameter which expresses how well the values  $Y_i$  are approximated. It is called the coefficient of determination:

$$R^2 = 1 - \frac{\text{RSS}}{\sum_{i=1}^n (Y_i - \bar{Y})^2}.$$

**10.3.13.** In practice, problems are often met where the distributions of the statistical data sets are either completely unknown or errors are assumed in the model, together with deviations with non-zero expected value and a non-normal distribution. In these cases, application of classical frequentist statistics is very hard or even totally impossible.

There are approaches which work directly with the sample set. Then derive statistics of point or interval estimates or probability calculations about the above, including the evaluation of standard errors.

One of the pioneering articles of this topic is the brief work of Bradley Efron of Stanford University, published in

1981: *Nonparametric estimates of standard error: The jackknife, the bootstrap and other methods*<sup>4</sup>. The keywords of this article are: Balanced repeated replications; Bootstrap; Delta method; Half-sampling; Jackknife; Infinitesimal jackknife; Influence function.

The procedure used in the *bootstrap* method uses software resources, created from a given data sample, and new data samples of the same size (with replacement). The desired statistics (sample mean, variance, etc.) is then examined for each of them. After a great number of executions of this procedure, a data sample is obtained which is considered a relevant approximation of the probability distribution of the examined statistic. The characteristics of this data set is considered a good approximation of the characteristics of the examined statistics for point or interval estimates, analysis of variance, etc. There is not enough space for a more detailed analysis of these techniques, which is the foundations of non-parametric methods in contemporary software statistical tools.

## Number theory

*God created the integers, all else is the work of man.*  
*Leopold Kronecker*

### A. Basic properties of divisibility

Let us recall the basic properties of divisibility, whose proof follows directly from the definition: the integer 0 is divisible by every integer; the only integer that is divisible by 0 is 0; every integer  $a$  satisfies  $a \mid a$ ; every triple of integers  $a, b, c$  satisfies the following four implications:

$$\begin{aligned} a \mid b \wedge b \mid c &\implies a \mid c, \\ a \mid b \wedge a \mid c &\implies (a \mid b + c) \wedge (a \mid b - c), \\ c \neq 0 &\implies (a \mid b \iff ac \mid bc), \\ a \mid b \wedge (b > 0) &\implies a \leq b. \end{aligned}$$

The mere knowledge of these basic rules allows us to solve many problems.

**11.A.1.** Determine the natural numbers  $n$  for which the integer  $n^3 + 1$  is divisible by the integer  $n - 1$ .

**Solution.** We have  $n^3 - 1 = (n - 1)(n^2 + n + 1)$ , so the integer  $n^3 - 1$  is divisible by the integer  $n - 1$  for any  $n$ . If  $n - 1$  is to divide  $n^3 + 1$  as well, it must also divide the difference  $(n^3 + 1) - (n^3 - 1) = 2$  (see the second property of divisibility). Since  $n \in \mathbb{N}$ , we have  $n - 1 \geq 0$ . Now,  $n - 1 \mid 2$  implies that  $n - 1 = 1$  or  $n - 1 = 2$ , whence  $n = 2$

In this chapter, we will deal with problems concerning integers, which include mainly divisibility and solving equations whose domain will be the set of integers (or natural numbers). Notice that in this chapter, unlike in the other parts of this book, we will not consider zero to be a natural number, as is usual in this field of mathematics. Although the natural numbers and the integers are, from a certain point of view, the simplest mathematical structure, examination of their properties yielded a good deal of tough problems for generations of mathematicians. These are often problems which can be formulated quite easily, yet many of them remain unsolved so far. Let us mention some of the most popular of them:

- *twin primes* – the problem is to decide whether there are infinitely many primes  $p$  such that  $p + 2$  is also a prime,<sup>1</sup>
- *Sophie Germain primes* – the problem is to decide whether there are infinitely many primes  $p$  such that  $2p + 1$  is also a prime,
- *existence of an odd perfect integer* – i.e., the sum of whose divisors equals twice the integer, e.g., 6 or 28,
- *Goldbach's conjecture* – the problem is to decide whether every even integer greater than 2 can be expressed as the sum of two primes.

A jewel among the problems of number theory is the *Fermat's Last Theorem* – the problem is to decide whether there are natural numbers  $n, x, y, z$  such that  $n > 2$  and  $x^n + y^n = z^n$ ; Pierre de Fermat formulated this problem as early as in 1637; much effort of many generations was put to this question, and it was solved (using results of various fields of mathematics) by Andrew Wiles in 1995.

### 1. Fundamental concepts

**11.1.1. Divisibility.** Recall that we say that an integer  $a$  divides an integer  $b$  (or that  $b$  is *divisible* by  $a$ , also that  $b$  is a *multiple* of  $a$ ) if and only if there exists an integer  $c$  satisfying  $a \cdot c = b$ . We write this as  $a \mid b$ . The concept of divisibility can be considered much more generally, as we shall see in 12.3.5.

<sup>1</sup>In 2013, Yitang Zhang published a proof of a promising proposition: for some  $n < 7 \cdot 10^7$ , there are infinitely many pairs of primes which differ by  $n$ . See Y. Zhang, *Bounded gaps between primes*, *Annals of Mathematics*, 2013. Although the bound was improved to  $N = 246$  already one year later by James Maynard and Terence Tao, the problem is still open.

or  $n = 3$ . The wanted property is thus possessed only by the natural numbers 2 and 3.  $\square$

**11.A.2.** Prove that for any  $a \in \mathbb{Z}$ , the following holds:

- i)  $a^2$  leaves remainder 0 or 1 when divided by 4;
- ii)  $a^2$  leaves remainder 0, 1, or 4 when divided by 8;
- iii)  $a^4$  leaves remainder 0 or 1 when divided by 16.

**Solution.**

- It follows from the Euclidean division theorem that every integer  $a$  can be written uniquely in either the form  $a = 2k$  or  $a = 2k + 1$ . Squaring this leads to  $a^2 = 4k^2$  or  $a^2 = 4(k^2 + k) + 1$ , which is what we wanted to prove.
- Making use of the above result, we immediately obtain the statement for the (even) integers of the form  $a = 2k$ . Back then, we arrived at  $a^2 = 4k(k + 1) + 1$  for odd integers  $a$ ; we get the proposition easily if we realize that  $k(k + 1)$  is surely even.
- Again, we utilize the result of the previous parts, i.e.  $a^2 = 4\ell$  or  $a^2 = 8\ell + 1$ . Squaring these equalities once again, we get  $a^4 = (a^2)^2 = 16\ell^2$  for  $a$  even, and  $a^4 = (a^2)^2 = (8\ell + 1)^2 = 64\ell^2 + 16\ell + 1 = 16(4\ell^2 + \ell) + 1$  for  $a$  odd.  $\square$

**11.A.3.** Prove that if integers  $a, b \in \mathbb{Z}$  leave remainder 1 when divided by an  $m \in \mathbb{N}$ , then so does their product  $ab$ .

**Solution.** By the Euclidean division theorem, there are  $s, t \in \mathbb{Z}$  such that  $a = sm + 1, b = tm + 1$ . Multiplying these equalities leads to the expression

$$ab = (sm + 1)(tm + 1) = (stm + s + t)m + 1,$$

where  $stm + s + t$  is the quotient, so the remainder of  $ab$  when divided by  $m$  is equal to 1.  $\square$

*It follows from the Euclidean division theorem that the greatest common divisor  $(a, b)$  of any pair of integers  $a, b$  exists, is unique, and can be computed efficiently by the Euclidean algorithm. At the same time, the coefficients in Bézout's identity, i.e., integers  $k, l$  such that  $ka + lb = (a, b)$ , can be determined this way. It can also be easily proved straight from the properties of divisibility that integer linear combinations of integers  $a, b$  are exactly the multiples of their greatest common divisor.*

**11.A.4.** Find the greatest common divisor of the integers  $a = 10175, b = 2277$  and determine the corresponding coefficients in Bézout's identity.

**Solution.** We will invoke the Euclidean algorithm:

$$\begin{aligned} 10175 &= 4 \cdot 2277 + 1067, \\ 2277 &= 2 \cdot 1067 + 143, \\ 1067 &= 7 \cdot 143 + 66, \\ 143 &= 2 \cdot 66 + 11, \\ 66 &= 6 \cdot 11 + 0. \end{aligned}$$

We will often take advantage of one of the most important properties of the integers, the unique *Euclidean division* (i.e., division with remainder).

UNIQUE DIVISION WITH REMAINDER

**Theorem.** For any integers  $a \in \mathbb{Z}, m \in \mathbb{N}$ , there exists a unique pair of integers  $q \in \mathbb{Z}, r \in \{0, 1, \dots, m - 1\}$  satisfying  $a = qm + r$ .

**PROOF.** First, we will prove the existence of the integers  $q, r$ . Let us fix a natural number  $m$  and prove the statement for any  $a \in \mathbb{Z}$ . Assume first that  $a$  is non-negative and prove the existence of the integers  $q, r$  by induction on  $a$ :

If  $0 \leq a < m$ , we can choose  $q = 0, r = a$ , and the equality  $a = qm + r$  holds trivially.

Next, suppose that  $a \geq m$  and the existence of the integers  $q, r$  has been proved for all  $a' \in \{0, 1, 2, \dots, a - 1\}$ . In particular, for  $a' = a - m \geq 0$ , there are  $q', r'$  such that  $a' = q'm + r'$  and  $r' \in \{0, 1, \dots, m - 1\}$ .

Therefore, if we select  $q = q' + 1, r = r'$ , we obtain  $a = a' + m = (q' + 1)m + r' = qm + r$ , which is what we wanted to prove.

Now, if  $a$  is negative, then we have proved that for the positive integer  $-a$ , there are  $q' \in \mathbb{Z}, r' \in \{0, 1, \dots, m - 1\}$  such that  $-a = q'm + r'$ . If  $r' = 0$ , we set  $r = 0, q = -q'$ ; otherwise (i.e.,  $r' > 0$ ), we put  $r = m - r', q = -q' - 1$ .

In either case, we get  $a = q \cdot m + r$ . Therefore, the integers  $q, r$  with the wanted properties exist for every  $a \in \mathbb{Z}, m \in \mathbb{N}$ .

Finally, we will prove the uniqueness. Suppose that there are integers  $q_1, q_2 \in \mathbb{Z}$  and  $r_1, r_2 \in \{0, 1, \dots, m - 1\}$  which satisfy  $a = q_1m + r_1 = q_2m + r_2$ . Simple rearrangement yields  $r_1 - r_2 = (q_2 - q_1)m$ , so  $m \mid r_1 - r_2$ . However, we have  $0 \leq r_1 < m$  and  $0 \leq r_2 < m$ , whence it follows that  $-m < r_1 - r_2 < m$ .

Therefore,  $r_1 - r_2 = 0$ , and  $(q_2 - q_1)m = 0$ , hence  $q_1 = q_2, r_1 = r_2$ .  $\square$

The integers  $q$  and  $r$  from the theorem are respectively called the *quotient* and *remainder* of the division of  $a$  by  $m$  with remainder. The choice of this terminology seems more intuitive if we rearrange the equality  $a = mq + r$  into the form

$$\frac{a}{m} = q + \frac{r}{m}, \quad \text{where } 0 \leq \frac{r}{m} < 1.$$

**11.1.2. Greatest common divisor.** One of the most needed tools of computational number theory is the algorithm for computing the greatest common divisor. Since it is a relatively fast procedure, as we are going to show, it is used very often in modern algorithms as well.

$$\begin{aligned} 2^7 - 1 &= k(2^{49} - 1) + \ell(2^{35} - 1): \\ 2^7 - 1 &= (2^{35} - 1) - (2^{21} + 2^7)(2^{14} - 1) \\ &= (2^{35} - 1) - (2^{21} + 2^7)((2^{49} - 1) - 2^{14}(2^{35} - 1)) \\ &= (2^{35} + 2^{21} + 1)(2^{35} - 1) - (2^{21} + 2^7)(2^{49} - 1). \end{aligned}$$

Therefore,  $k = -(2^{21} + 2^7)$ ,  $\ell = 2^{35} + 2^{21} + 1$ . Let us bear in mind that these coefficients are never determined uniquely.  $\square$

**11.A.7.** Now, let us try to generalize the result of the previous exercise, i.e., prove that it holds for any  $a, m, n \in \mathbb{N}$ ,  $a \neq 1$ , that  $(a^m - 1, a^n - 1) = a^{(m,n)} - 1$ .

**Solution.** This statement follows easily from the fact that any pair of natural numbers  $k, \ell$  satisfies  $a^k - 1 \mid a^\ell - 1$  if and only if  $k \mid \ell$ . This can be proved by dividing the integer  $\ell$  by the integer  $k$  with remainder, i.e., we set  $\ell = kq + r$ , where  $q, r \in \mathbb{N}_0, r < k$ , and consider that

$$a^{kq+r} - 1 = (a^k - 1)(a^{k(q-1)+r} + a^{k(q-2)+r} + \dots + a^r) + a^r - 1$$

is the division of the integer  $a^{kq+r} - 1$  by the integer  $a^k - 1$  with remainder (apparently, we have  $a^r - 1 < a^k - 1$ ). Hence we can easily see that the remainder  $r$  is zero if and only if the remainder  $a^r - 1$  is zero, which is what we wanted to prove.  $\square$

**11.A.8.** Prove that for all  $n \in \mathbb{N}$ ,  $25 \mid 4^{2n+1} - 10n - 4$ .

**Solution.** This statement can be proved in several ways (the easiest one is in terms of congruences, which will be introduced a bit later). Here, we will prove it by induction and then as a consequence of the binomial theorem.

The proposition is clearly true for  $n = 0$  (even though the problem does not ask about the situation for  $n = 0$ , we can surely prove the desired property for the set  $n \in \mathbb{N}_0$ , thereby simplifying the first step of the induction). As for the second step: assuming  $25 \mid 4^{2n-1} - 10(n-1) - 4$ , then we also have  $25 \mid 16(4^{2n-1} - 10(n-1) - 4) = 4^{2n+1} - 10n - 4 - 150n + 100$ , whence it easily follows that the desired proposition  $25 \mid 4^{2n+1} - 10n - 4$  holds.

The second proof uses the binomial theorem. By that,

$$(5 - 1)^{2n+1} = \sum_{k=0}^{2n+1} \binom{2n+1}{k} 5^{2n+1-k} (-1)^k,$$

where all of the terms of the sum, except the last two, are apparently multiples of 25, i.e., the only part of the sum which is not divisible by 25 is  $\binom{2n+1}{2n} 5^1 (-1)^{2n} + 5^0 (-1)^{2n+1}$ . In other words,  $4^{2n+1}$  leaves the same remainder when divided by 25 as the integer  $10n + 4$ , which is equivalent to what we were to prove.  $\square$

## B. Prime numbers

*Euclid's theorem 11.2.1 is a fundamental property of primes as it can be seen in the following example.*

On the other hand, any common divisor of the given integers  $a_1, a_2$  divides the integer  $a_3 = a_1 - q_1 a_2$  as well, hence it also divides  $a_4 = a_2 - q_2 a_3, a_5, \dots$ , and especially  $a_{k-1} = a_{k-3} - q_{k-3} a_{k-2}$ . We have thus proved that  $a_{k-1}$  is the greatest common divisor of the integers  $a_1, a_2$ .  $\square$

It follows from the previous statement and the fact that  $(a, b) = (a, -b) = (-a, b) = (-a, -b)$  holds for any  $a, b \in \mathbb{Z}$ , that every pair of integers has a greatest common divisor.

**11.1.3. Bézout's theorem.** The Euclidean algorithm provides another interesting statement, which is often used.

**Theorem (Bézout).** For every pair of integers  $a, b$ , there exist integers  $k, l$  such that  $(a, b) = ka + lb$ .

**PROOF.** Surely it suffices to prove the theorem for  $a, b \in \mathbb{N}$ . Let us notice that if it is possible to express integers  $r, s$  in the form  $r = r_1 a + r_2 b, s = s_1 a + s_2 b$ , where  $r_1, r_2, s_1, s_2 \in \mathbb{Z}$ , then we can also express

$$r + s = (r_1 + s_1)a + (r_2 + s_2)b$$

in this way as well as

$$c \cdot r = (c \cdot r_1)a + (c \cdot r_2)b$$

for any  $c \in \mathbb{Z}$ , and thus also any integer linear combination of the numbers  $r$  and  $s$  arising in the process of Euclidean algorithm. It follows from the Euclidean algorithm (for  $a_1 = a, a_2 = b$ ) that we can also thus express  $a_3 = a_1 - q_1 a_2, a_4 = a_2 - q_2 a_3, \dots$ , hence the integer  $a_{k-1} = a_{k-3} - q_{k-3} a_{k-2}$ , too, which is  $(a_1, a_2)$ .

Let us emphasize that the wanted numbers  $k, l$  are *not* determined uniquely.  $\square$

The Euclidean algorithm and Bézout's identity are the fundamental results of elementary number theory and form one of the pillars of the algorithms used in algebra and number theory.

**11.1.4. Least common multiple.** We have ignored the properties of the least common multiple so far. However, we will see that thanks to the following proposition, they can be derived from the properties of the greatest common divisor.

**Lemma.** For every pair of integers  $a, b$ , their least common multiple  $[a, b]$  exists and it holds that  $(a, b) \cdot [a, b] = |a \cdot b|$ .

**PROOF.** The statement is trivially true if either of the integers  $a, b$  is zero. Furthermore, we can assume that both these (non-zero from now on) integers are positive since their signs do not take any effect in the formula in question. We are going to show that  $q = a \cdot b / (a, b)$  is the least common multiple of the integers  $a, b$ , which will finish the proof.

Since  $(a, b)$  is a common divisor of  $a, b$ , both  $a/(a, b)$  and  $b/(a, b)$  are integers, hence

$$q = \frac{ab}{(a, b)} = \frac{a}{(a, b)} \cdot b = \frac{b}{(a, b)} \cdot a$$

is a common multiple of  $a, b$ . By Bézout's identity, there are integers  $k, l$  such that  $(a, b) = ka + lb$ . Let us suppose

**11.B.1.**

- i) Prove that if natural numbers  $m, n$  are coprime, then so are

$$m^2 + mn + n^2 \quad \text{and} \quad m^2 - mn + n^2.$$

- ii) Prove that if odd natural numbers  $m, n$  are coprime, then so are

$$m + 2n \quad \text{and} \quad m^2 + 4n^2.$$

**Solution.**

- i) To reach a contradiction, suppose that there is a prime  $p$  which divides both of the integers  $m^2 + mn + n^2$  and  $m^2 - mn + n^2$ . Then, it divides their difference  $2mn$  as well, whence  $p = 2$  or  $p$  divides one of the integers  $m, n$ . If  $p = 2$ , then  $m^2 + mn + n^2$  is even, so the integers  $m$  and  $n$  must be even as well, which contradicts that they are coprime. If  $p$  divides  $m$  as well as  $m^2 + mn + n^2$ , then it also divides  $n^2$ , whence, by Euclid's theorem (11.2.1), it divides  $n$  as well. However, this also contradicts that  $m, n$  are coprime. The case of  $p \mid n$  is analogous.
- ii) Just like in the above exercise, let us suppose that there is a prime  $p$  which divides  $m + 2n$  as well as  $m^2 + 4n^2$ . Then, it must also divide  $(m^2 + 4n^2) - (m + 2n)(m - 2n) = 8n^2$ , and since  $p \neq 2$  (if  $m + 2n$  were even, then so would  $m$  be), we necessarily have  $p \mid n$ . However, since  $p$  divides  $m + 2n$  as well, we get  $p \mid m$ , which is a contradiction.

**11.B.2.** Prove that any  $n \in \mathbb{N}, n > 1$ , is prime iff  $n$  is not divisible by any prime  $p \leq \sqrt{n}$ .

**Solution.** For  $n$  composite we have  $n = ab$  with appropriate  $a, b > 1$ . If we admitted  $a, b > \sqrt{n}$  then we would have  $n = ab > \sqrt{n} \cdot \sqrt{n} = n$ . Therefore  $n$  has a divisor (and thus also a prime divisor) not greater than  $\sqrt{n}$ .  $\square$

The theoretical part contains Euclid's proof of the infinitude of primes and deals in detail with the distribution of primes in the set of natural numbers (in some cases, however, we were forced to leave the mentioned theorems unproved). Now, we will give several exercises on this topic.

**11.B.3.** For any natural number  $n \geq 3$ , there is at least one prime between the integers  $n$  and  $n!$ .

**Solution.** Let  $p$  denote an arbitrary prime dividing the integer  $n! - 1$  (by the Fundamental theorem of arithmetic (11.2.2), there is such a prime since  $n! - 1 > 1$ ). If we had  $p \leq n$ , then  $p$  would have to divide  $n!$  as well, so it could not divide  $n! - 1$ . Therefore,  $n < p$ . Since  $p \mid (n! - 1)$ , we have  $p \leq n! - 1$ , hence  $p < n!$ . Our prime  $p$  thus satisfies the conditions of the problem.  $\square$

The result of this exercise also implies the infinitude of primes (it suffices to consider the sequence  $a_0 = 3, a_{n+1} = a_n!$  for  $n \in \mathbb{N}$ ). However, this statement is very weak (compared to reality) since the constructed sequence contains only a "tiny" subset of the primes.

On the other hand, we are able to construct an arbitrarily long sequence of consecutive composite numbers, as shown by the following exercise.

that  $n \in \mathbb{Z}$  is an arbitrary common multiple of the integers  $a, b$ . We want to show that it is divisible by  $q$ . We thus have  $n/a, n/b \in \mathbb{Z}$ , hence the number

$$\frac{n}{b} \cdot k + \frac{n}{a} \cdot l = \frac{n(ka + lb)}{ab} = \frac{n(a, b)}{ab} = \frac{n}{q}$$

is an integer as well. However, this means that  $q \mid n$ , which is what we wanted to prove.  $\square$

**11.1.5. Coprime integers.** Analogously to the case of two integers, we can also define the greatest common divisor and least common multiple of more than two integers, and it can be easily proved that

$$(a_1, \dots, a_n) = ((a_1, \dots, a_{n-1}), a_n),$$

$$[a_1, \dots, a_n] = [[a_1, \dots, a_{n-1}], a_n].$$

Integers  $a_1, a_2, \dots, a_n \in \mathbb{Z}$  are said to be *coprime* (also relatively prime) if and only if  $(a_1, a_2, \dots, a_n) = 1$ . They are said to be *pairwise coprime* (pairwise relatively prime) if and only if we have  $(a_i, a_j) = 1$  for every pair of indices  $i, j$  satisfying  $1 \leq i < j \leq n$ .

**Remark.** Let us realize that the concepts *coprime* and *pairwise coprime* are different. For example, we have  $(6, 10, 15) = 1$ ; however, any two of the three integers 6, 10, 15 are not coprime.

**Lemma.** For any natural numbers  $a, b, c$  we have

- (1)  $(ac, bc) = (a, b) \cdot c$ ;
- (2) if  $a \mid bc$  and  $(a, b) = 1$ , then  $a \mid c$ ;
- (3)  $d = (a, b)$  if and only if there are  $k, l \in \mathbb{N}$  such that  $a = dk, b = dl$ , and  $(k, l) = 1$ .

**PROOF.** (1) Since  $(a, b)$  is a common divisor of the integers  $a, b$ ,  $(a, b) \cdot c$  is a common divisor of the integers  $ac, bc$ , hence  $(a, b) \cdot c \mid (ac, bc)$ . From Bézout's identity, we obtain  $k, l \in \mathbb{Z}$  such that  $(a, b) = ka + lb$ . Since  $(ac, bc)$  is a common divisor of the integers  $ac, bc$ , it divides the integer  $kac + lbc = (a, b) \cdot c$  as well. We have thus proved that  $(a, b) \cdot c$  and  $(ac, bc)$  are natural numbers which divide each other, hence they are equal.

(2) Let us suppose that  $(a, b) = 1$  and  $a \mid bc$ . From Bézout's identity again, we get  $k, l \in \mathbb{Z}$  such that  $ka + lb = 1$ , whence it follows that  $c = c(ka + lb) = kca + lbc$ . Since  $a \mid bc$ , it follows that  $c$  as well is a multiple of  $a$ .

(3) Let  $d = (a, b)$ , then there are  $q_1, q_2 \in \mathbb{N}$  such that  $a = dq_1, b = dq_2$ . Then, by part (1), we have  $d = (a, b) = (dq_1, dq_2) = d \cdot (q_1, q_2)$ , so  $(q_1, q_2) = 1$ . On the other hand, if  $a = dq_1, b = dq_2$ , and  $(q_1, q_2) = 1$ , then  $(a, b) = (dq_1, dq_2) = d(q_1, q_2) = d \cdot 1 = d$  (again invoking part (1) of this lemma).  $\square$

**2. Primes**

The concept of a prime is one of the most important in elementary number theory. Its importance is given mainly by the unique factorization theorem, which is a strong as well as efficient tool for solving miscellaneous problems from number theory.

**11.B.4.** Prove that for any natural number  $n$ , there exist  $n$  consecutive natural numbers none of which is prime.

**Solution.** Let us examine the integers  $(n + 1)! + 2$ ,  $(n + 1)! + 3, \dots, (n + 1)! + (n + 1)$ . For any  $k \in \{2, 3, \dots, n+1\}$ , we have  $k \mid (n+1)!$ , so  $k \mid (n+1)!+k$  as well, thus  $(n + 1)! + k$  cannot be a prime. Therefore, there are no primes among these  $n$  natural numbers.  $\square$

**Practical notes.** As we will show, it is very complicated to decide for certain whether a given large integer is a prime (on the other hand, for most composite numbers, it is really easy to prove that they are indeed composite – see part 11.6.4). Nevertheless, Indian mathematicians<sup>1</sup> managed to prove in 2002 that there is an algorithm running in polynomial time with respect to the input (i.e., the number of digits of the integer in question) which decides whether the integer is a prime.

We are unable to produce such an algorithm for prime factorization (and it is widely believed that it is impossible although no one has been able to prove this so far). The fastest generally applicable factorization algorithm, the so-called *general number field sieve*, runs in sub-exponential time  $O\left(e^{1.9(\log N)^{1/3}(\log \log N)^{2/3}}\right)$ .

In 1994, Peter Shor invented an algorithm which factors an integer  $N$  in cubic time (i.e., runs it  $O(\log^3 N)$ ) on a quantum computer. However, this algorithm requires computers with sufficient number of quantum bits. We can see how difficult this is from the fact that in 2001, IBM managed to use a quantum computer to factor the integer 15, and in 2012, another record was achieved by factoring the integer 143 (in fact using other approach, so-called adiabatic quantum computation).

We can find more evidence about the difficulty of this problem in the call made in 1991 by RSA Security.<sup>2</sup> If anyone manages to factor the integers labeled by the number of digits they have as RSA-100, ..., RSA-704, RSA-768, ..., RSA-2048, they could receive respectively 1,000, ..., 30,000, 50,000, ..., 200,000 dollars (the integer RSA-100 was factored by Arjen Lenstra that very year; the integer RSA-704 was factored in 2012; many others have not been factored yet).

*Thanks to the unique factorization theorem, we are able to (provided we know this factorization) easily answer the following questions concerning the number or sum of the divisors of a given integer. Just that easily, we can get the (intuitively well-known) procedure of computation of the greatest common divisor of two integers from their prime factorizations.*

<sup>1</sup>M. Agrawal, N. Kayal, N. Saxena. *PRIMES is in P*. Annals of Mathematics 160 (2): 781–793. 2004.

## PRIME NUMBERS

Every natural number  $n \geq 2$  has at least two positive divisors: 1 and itself. If there are no other divisors, it is called a *prime* (number). Otherwise (i.e., if there exist other divisors), we talk about a *composite* (number).

In the subsequent paragraphs, we will usually denote primes by the letter  $p$ . The first few primes are 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, ... (in particular, the number 1 is considered to be neither prime nor composite as it is a unit in the ring of the integers). As we will prove shortly, there are infinitely many primes. However, we have rather limited computational resources when it comes to determining whether a given number is prime: The number  $2^{82\,589\,933} - 1$ , which is the greatest known prime as of 2018, has only 24 862 048 digits, so its decimal representation would fit into many a prehistoric data storage device. Printing it as a book would, however, (assuming 60 rows on a page and 80 digits in a row) take 5 180 pages.

Now, let us introduce a theorem which gives a necessary and sufficient condition for being prime and is thus a fundamental ingredient for the proof of the unique factorization theorem.

**11.2.1. Theorem** (Euclid’s on primes). *An integer  $p \geq 2$  is a prime if and only if the following holds: for every pair of integers  $a, b$ ,  $p \mid ab$  implies that either  $p \mid a$  or  $p \mid b$  (or both).*

**PROOF.** “ $\implies$ ” Suppose that  $p$  is a prime and  $p \mid ab$ , where  $a, b \in \mathbb{Z}$ . Since  $(p, a)$  is a positive divisor of  $p$ , we have either  $(p, a) = p$  or  $(p, a) = 1$ . In the former case, we get  $p \mid a$ ; in the latter,  $p \mid b$  by part (2) of the previous lemma.

“ $\impliedby$ ” If  $p$  is not a prime, it has a positive divisor distinct from both 1 and  $p$ . Let us denote it by  $a$ . However, then we have  $b = \frac{p}{a} \in \mathbb{N}$  and  $p = ab$ , hence  $1 < a < p$ ,  $1 < b < p$ . We have thus found integers  $a, b$  such that  $p \mid ab$ , while  $p$  divides neither  $a$  nor  $b$ .  $\square$

**11.2.2. Fundamental theorem of arithmetic.** In arithmetic operations, we much rely on expressing the numbers (or more complicated objects) as products of simpler ones. The prime property distinguishes the simplest ones and we call them *irreducible*. We shall see in 12.3.5 how to define divisibility in an arbitrary integral domain (i.e., rings without divisors of zero). In some integral domains (e.g.  $\mathbb{Q}$ ), there are no elements with the prime property.

Other integral domains have such elements, yet they do not satisfy the unique factorization theorem. It is quite similar with the generalization of aforementioned Euclid’s theorem on primes – the elements which satisfy  $p \mid ab \implies (p \mid a \text{ or } p \mid b)$  are always irreducible, but the contrary is not generally true. Let us mention at least one example of an ambiguous

**11.B.5. Number of divisors and sum of divisors.** Prove the following formulae: Every integer  $a = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$  has got exactly

$$\tau(a) = (\alpha_1 + 1)(\alpha_2 + 1) \cdots (\alpha_k + 1)$$

positive divisors, which sum up to

$$\sigma(a) = \frac{p_1^{\alpha_1+1} - 1}{p_1 - 1} \cdots \frac{p_k^{\alpha_k+1} - 1}{p_k - 1}.$$

Moreover, let  $p_1, \dots, p_k$  be pairwise distinct primes and  $\alpha_1, \dots, \alpha_k, \beta_1, \dots, \beta_k$  be non-negative integers. Denoting  $\gamma_i = \min\{\alpha_i, \beta_i\}$ ,  $\delta_i = \max\{\alpha_i, \beta_i\}$  for every  $i = 1, 2, \dots, k$ , then we have

$$(p_1^{\alpha_1} \cdots p_k^{\alpha_k}, p_1^{\beta_1} \cdots p_k^{\beta_k}) = p_1^{\gamma_1} \cdots p_k^{\gamma_k},$$

$$[p_1^{\alpha_1} \cdots p_k^{\alpha_k}, p_1^{\beta_1} \cdots p_k^{\beta_k}] = p_1^{\delta_1} \cdots p_k^{\delta_k}.$$

**Solution.** Every positive divisor of the integer  $a = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$  is of the form  $p_1^{\beta_1} \cdots p_k^{\beta_k}$ , where  $\beta_1, \dots, \beta_k \in \mathbb{N}_0$  and  $\beta_1 \leq \alpha_1, \beta_2 \leq \alpha_2, \dots, \beta_k \leq \alpha_k$ .

The justification of all of the claims is now a simple consequence of this explicit factorization description of the the divisors. To find the number of positive divisors, we employ elementary combinatorics (the product rule) to get  $\tau(a) = (\alpha_1 + 1)(\alpha_2 + 1) \cdots (\alpha_k + 1)$ .

Next, we can see that the formula for the sum of the divisors holds if we rewrite it in the form

$$(1 + p_1 + \cdots + p_1^{\alpha_1}) \cdots (1 + p_k + \cdots + p_k^{\alpha_k}),$$

realizing that every pair of parentheses contains the sum of a finite geometric series. The other statements follow directly from the definition.  $\square$

*The sum of all positive divisors of an integer is connected to the so-called perfect numbers. We say that an integer  $a$  is perfect if and only if  $\sigma(a) = 2a$ , i.e., if and only if the sum of all positive divisors of  $a$ , excluding  $a$  itself, equals  $a$ .*

*Perfect numbers include, for instance,  $6 = 1 + 2 + 3$ ,  $28 = 1 + 2 + 4 + 7 + 14$ ,  $496$ , and  $8128$  (this exhausts all perfect numbers less than 10 000).*

*It can be shown that even perfect numbers are in a tight relation with the so-called Mersenne primes since the following holds:*

**11.B.6.** Show that a natural number  $a$  is an even perfect number if and only if it is of the form  $a = 2^{q-1}(2^q - 1)$ , where  $2^q - 1$  is a prime.

**Solution.** If  $a = 2^{q-1}(2^q - 1)$ , where  $p = 2^q - 1$  is a prime, then the previous statement yields

$$\sigma(a) = \frac{2^q - 1}{2 - 1} \cdot (p + 1) = (2^q - 1) \cdot 2^q = 2a.$$

Such an integer  $a$  is thus a perfect number.

For the opposite direction, consider any even perfect number  $a$ , and let us write

$$a = 2^k \cdot m, \text{ where } m, k \in \mathbb{N} \text{ and } 2 \nmid m.$$

factorization – in  $\mathbb{Z}[\sqrt{-5}]$ , we have:<sup>3</sup>

$$6 = 2 \cdot 3 = (1 + \sqrt{-5}) \cdot (1 - \sqrt{-5}).$$

However, it needs a longer discussion to verify that all of the mentioned factors are really irreducible in  $\mathbb{Z}[\sqrt{-5}]$ .

FUNDAMENTAL THEOREM OF ARITHMETIC

**Theorem.** Every natural number  $n$  can be expressed as the product of primes, and this expression is unique up to the order of the factors. (If  $n$  is a prime, then it is the “product” of a single prime  $n$ ; if  $n = 1$ , it is the empty product (the product of the empty set of primes)<sup>4</sup>)

**PROOF.** First, we prove by complete induction on  $n$  that every natural number  $n$  can be expressed as a product of primes. We have already discussed the validity of this statement for  $n = 1$ .

Now, let us suppose that  $n \geq 2$  and we have already proved that all natural numbers less than  $n$  can be factored to primes. If  $n$  is a prime, the statement is clearly true. If  $n$  is not a prime, then it has a divisor  $d$ ,  $1 < d < n$ . Denoting  $e = n/d$ , we also have  $1 < e < n$ . From the induction hypothesis, we get that both  $d$  and  $e$  can be expressed as products of primes, so their product  $d \cdot e = n$  can also be expressed in this way.

To prove uniqueness, let us have an equality of products  $n = p_1 \cdot p_2 \cdots p_s = q_1 \cdot q_2 \cdots q_t$ , where  $p_i, q_j$  are primes for all  $i \in \{1, \dots, s\}, j \in \{1, \dots, t\}$ . We will prove by induction on  $s$  that  $s = t$  and  $p_1 = q_1, \dots, p_s = q_s$ .

If  $s = 1$ , then  $p_1 = q_1 \cdots q_t$  is a prime. If we had  $t > 1$ , the integer  $p_1$  would have a divisor  $q_1$  such that  $1 < q_1 < p_1$  (since  $q_2 q_3 \cdots q_t > 1$ ), which is impossible. Therefore, we must have  $t = 1$  and  $p_1 = q_1$ .

Now, let us suppose that  $s \geq 2$  and the proposition holds for  $s - 1$ . It follows from the equality  $p_1 \cdot p_2 \cdots p_s = q_1 \cdot q_2 \cdots q_t$  that  $p_s$  divides the product  $q_1 \cdots q_t$ , which is, by Euclid’s theorem, possible only if  $p_s$  divides some  $q_j$  (and after relabeling we may assume  $j = t$ ). Since  $q_j$  is a prime, it follows that  $p_s = q_t$ . Dividing both sides of the original equality by this integer, we obtain  $p_1 \cdot p_2 \cdots p_{s-1} = q_1 \cdot q_2 \cdots q_{t-1}$ , and from the induction hypothesis, we get  $s - 1 = t - 1$ ,  $p_1 = q_1, \dots, p_{s-1} = q_{s-1}$ . Altogether, we have  $s = t$  and  $p_1 = q_1, \dots, p_{s-1} = q_{s-1}, p_s = q_s$ . This proves the uniqueness, and thus the entire theorem as well.  $\square$

**11.2.3. Prime distribution.** Don Zagier wrote: *There are two facts about the distribution of prime numbers. The first is that, [they are] the most arbitrary and ornery objects studied by mathematicians: they grow like weeds among the natural numbers, seeming to obey no other law than that of chance, and nobody can predict where the next one will sprout. The second fact*

<sup>3</sup>The symbol  $\mathbb{Z}[\sqrt{-5}]$  denotes the integers extended by a root of the equation  $x^2 = -5$ , which is defined similarly as we obtained the complex numbers by adjoining the number  $\sqrt{-1}$  to the reals.

Since the function  $\sigma$  is multiplicative (see 11.3.2), we have  $\sigma(a) = \sigma(2^k) \cdot \sigma(m) = (2^{k+1} - 1) \cdot \sigma(m)$ . However, it follows from  $a$  being perfect that  $\sigma(a) = 2a = 2^{k+1} \cdot m$ , whence

$$2^{k+1} \cdot m = (2^{k+1} - 1) \cdot \sigma(m).$$

Since  $2^{k+1} - 1$  is odd, we must have  $2^{k+1} - 1 \mid m$ , so we can lay  $m = (2^{k+1} - 1) \cdot n$  for an appropriate  $n \in \mathbb{N}$ . Rearranging leads to  $2^{k+1} \cdot n = \sigma(m)$ . Both  $m$  and  $n$  divide  $m$  (and since  $\frac{m}{n} = 2^{k+1} - 1 > 1$ , these integers are different), hence

$$2^{k+1} \cdot n = \sigma(m) \geq m + n = 2^{k+1} \cdot n,$$

and so  $\sigma(m) = m + n$ . However, this means that  $m$  is a prime with the sole divisors  $m$  and  $n = 1$ , whence  $a = 2^k \cdot (2^{k+1} - 1)$ , where  $2^{k+1} - 1 = m$  is a prime.  $\square$

**Remark.** On the other hand, people have been unsuccessful in describing odd perfect numbers; we even do not know whether there exists an odd perfect number.

Mersenne primes are those of the form  $2^k - 1$ . It should not go unnoticed that Mersenne primes are easily recognizable among all primes – for Mersenne numbers (excluding the primality requirement), there is a simple and fast procedure how to verify that they are primes. It is thus not by chance that the largest known primes are usually of the form  $2^k - 1$ .

Later, we will show how to efficiently verify whether a given Mersenne number is prime (see the Lucas-Lehmer test in part 11.6.9).

Although it may seem a weird and practically useless business to look for primes as great as possible, it pushes the borders of our cognition of mathematics forward and refines the used methods (as well as hardware). Moreover, the discoverers often benefit from this (Electronic Frontier Foundation issued EFF Cooperative Computing Awards for finding a prime having at least  $10^6$ ,  $10^7$ ,  $10^8$ , and  $10^9$  digits – rewards of 50 and 100 dollars, respectively, for the first and second categories were paid in 2000 and 2009, respectively, to the GIMPS project in both cases. Apparently, it will take a while before the other prizes are awarded.)

### C. Congruences

In this paragraph, we will see in practice how wielding basic operations with congruences can improve the expressing of our reasonings about various problems: We would be able to solve them without congruences, using only the basic properties of divisibility. However, with the help of congruences, our considerations will often be much shorter and clearer.

**11.C.1.** Show that, For any  $a, b \in \mathbb{Z}$ ,  $m \in \mathbb{N}$ , the following conditions are equivalent:

- i)  $a \equiv b \pmod{m}$ ,
- ii)  $a = b + mt$  for an appropriate  $t \in \mathbb{Z}$ ,
- iii)  $m \mid a - b$ .

is even more astonishing, for it states just the opposite: that the prime numbers exhibit stunning regularity, that there are laws governing their behavior, and that they obey these laws with almost military precision.

In the next paragraphs, we will discuss the following questions:

*Are there infinitely many primes?*

*Are there infinitely many primes in every (or at least one) arithmetic sequence?*

*How are the primes distributed among the natural numbers?*

The first question has got an easy answer and the fundamental theorem was known to Euclid already around 300 BC:

**Theorem (Euclid).** *There are infinitely many primes among the natural numbers.*

**PROOF.** Suppose that there are only finitely many, and let them be denoted by  $p_1, p_2, \dots, p_n$ . Set  $N = p_1 \cdot p_2 \cdot \dots \cdot p_n + 1$ . This integer, being greater than 1, is either a prime or it is divisible by a prime different from  $p_1, \dots, p_n$  (since the primes  $p_1, \dots, p_n$  divide the integer  $N - 1$ ), which is a contradiction.  $\square$

**11.2.4.** Next, we will mention a rather strong statement, whose proof is very laborious (that is why we do not present it), yet it can be done by elementary means<sup>5</sup>.

**Theorem (Chebyshev’s, Bertrand’s postulate).** *For every integer  $n > 1$ , there is at least one prime  $p$  satisfying  $n < p < 2n$ .*

**11.2.5.** Primes are distributed quite uniformly in the sense that in any “reasonable” arithmetic sequence (i.e. such that its terms are coprime), there are infinitely many of them.

For instance, considering the remainders upon division by 4, there are infinitely many primes with remainder 1 as well as infinitely many primes with remainder 3 (of course, there is no prime with remainder 0 and only one prime with remainder 2). The situation is analogous for remainders upon division by other integers, as explained by the following theorem, whose proof is very difficult.

**Theorem (Dirichlet’s on primes).** *If  $a, m$  are coprime natural numbers, there are infinitely many primes  $k$  such that  $mk + a$  is a prime. In other words, there are infinitely many primes among the integers  $1 \cdot m + a, 2 \cdot m + a, 3 \cdot m + a, \dots$*

We can at least mention a proof of a special case of this theorem, which is a modification of Euler’s proof of the infinitude of primes.

**Proposition.** *There are infinitely many primes of the form  $4k + 3$ , where  $k \in \mathbb{N}_0$ .*

<sup>5</sup>See Wikipedia, *Proof of Bertrand’s postulate*, [http://en.wikipedia.org/wiki/Proof\\_of\\_Bertrand’s\\_postulate](http://en.wikipedia.org/wiki/Proof_of_Bertrand’s_postulate) (as of July 29, 2017) or see M. Aigner, G. Ziegler, *Proofs from THE BOOK*, Springer, 2009.

**Solution.** (1)  $\implies$  (3) If  $a = q_1m + r$ ,  $b = q_2m + r$ , then  $a - b = (q_1 - q_2)m$ .

(3)  $\implies$  (2) If  $m \mid a - b$ , then there is a  $t \in \mathbb{Z}$  such that  $m \cdot t = a - b$ , i.e.,  $a = b + mt$ .

(2)  $\implies$  (1) If  $a = b + mt$ , then, expressing  $b = mq + r$ , it follows that  $a = m(q + t) + r$ . Therefore,  $a$  and  $b$  share the same remainder  $r$  upon division by  $m$ , i.e.,  $a \equiv b \pmod{m}$ .  $\square$

**11.C.2.** Prove fundamental properties of congruences stated in 11.3.1.

**Solution.**

i) If  $a \equiv b \pmod{m}$  and  $c \equiv d \pmod{m}$ , by the previous lemma, there are integers  $s, t$  such that  $a = b + ms$ ,  $c = d + mt$ . However, then we have  $a + c = b + d + m(s + t)$ , and, by the lemma again,  $a + c \equiv b + d \pmod{m}$ .

Adding a congruence  $a \equiv b \pmod{m}$  to  $mk \equiv 0 \pmod{m}$ , which is clearly valid, leads to  $a + mk \equiv b \pmod{m}$ .

ii) If  $a \equiv b \pmod{m}$  and  $c \equiv d \pmod{m}$ , there are integers  $s, t$  such that  $a = b + ms$ ,  $c = d + mt$ . Then,

$$ac = (b + ms)(d + mt) = bd + m(bt + ds + mst),$$

whence we get  $ac \equiv bd \pmod{m}$ .

iii) Let  $a \equiv b \pmod{m}$  and  $n$  be a natural number. Since

$$a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + \dots + b^{n-1}),$$

it follows that  $a^n \equiv b^n \pmod{m}$  as well.

iv) Suppose that  $a \equiv b \pmod{m}$ ,  $a = a_1 \cdot d$ ,  $b = b_1 \cdot d$ , and  $(m, d) = 1$ . By the lemma, the difference  $a - b = (a_1 - b_1) \cdot d$  is divisible by the integer  $m$ , and since  $(m, d) = 1$ , the integer  $a_1 - b_1$  is also divisible by  $m$  (by lemma 11.1.5). Hence it follows that  $a_1 \equiv b_1 \pmod{m}$ . Further, if  $ad \equiv bd \pmod{md}$ , i.e.,  $md \mid ad - bd$ , we get directly from the definition of divisibility that  $m \mid a - b$ .

v) If  $a \equiv b \pmod{m}$ , then  $a - b$  is a multiple of  $m$ , and hence a multiple of any divisor  $d$  of  $m$ , so  $a \equiv b \pmod{d}$ .

vi) Suppose that  $a \equiv b \pmod{m}$ ,  $b = b_1d$ ,  $m = m_1d$ . Then there is an integer  $t$  such that  $a = b + mt = b_1d + m_1dt = (b_1 + m_1t)d$ , hence  $d \mid a$ .

vii) If  $a \equiv b \pmod{m_1}$ ,  $a \equiv b \pmod{m_2}, \dots, a \equiv b \pmod{m_k}$ , then the difference  $a - b$  is a common multiple of the integers  $m_1, m_2, \dots, m_k$ , and so it is divisible by their least common multiple  $[m_1, m_2, \dots, m_k]$  whence it follows that  $a \equiv b \pmod{[m_1, \dots, m_k]}$ .

**Remark.** We have already used some properties of congruences without explicitly mentioning it – now, the result of the exercise 11.A.3 can be reformulated as “if  $a \equiv 1 \pmod{m}$ ,  $b \equiv 1 \pmod{m}$ , then also  $ab \equiv 1 \pmod{m}$ ”, which is a special case of item (2) of the previous theorem.

It is not by chance because any statement which uses congruences can be reformulated in terms of divisibility. The usefulness of congruences thus lies not in the strength to solve more problems than without them, but rather in being a very

**PROOF.** Suppose the contrary, i.e., there are only finitely many primes of this form, and let them be denoted by  $p_1 = 3, p_2 = 7, p_3 = 11, \dots, p_n$ . Further, let us set  $N = 4p_2 \cdot p_3 \cdot \dots \cdot p_n + 3$ . Factoring  $N$ , the product must contain (according to the result of exercise 11.A.3) at least one prime  $p$  of the form  $4k + 3$ . If not,  $N$  would be a product of only primes of the form  $4k + 1$ , so  $N$  as well would give remainder 1 upon division by 4, which is not true. However, none of the primes  $p_1, p_2, \dots, p_n$  can play the role of the mentioned  $p$  since if we had  $p_i \mid N$  for some  $i \in \{2, \dots, n\}$ , then we would get  $p_i \mid 3$ . Similarly,  $3 \nmid N$ , and we thus get a contradiction with the assumption of finitely many primes of the given form.  $\square$

An analogous elementary proof can be used for primes of the form  $3k + 2$  or  $6k + 5$ ; however, it will not work for primes of the form  $3k + 1$  or  $4k + 1$  (think this out well!). We will be able to remedy this in the latter case in part 11.4.11 about quadratic congruences).

**11.2.6.** From the propositions mentioned in this chapter, one can roughly imagine how “dense” the primes appear among the natural numbers. It is more accurately described (although “only” asymptotically) by the following, very important theorem, which was proved independently by J. Hadamard and Ch. J. de la Vallée-Poussin in 1896 (but we shall not go into the proof here).

**Theorem (Prime Number Theorem).** Let  $\pi(x)$  denote the number of primes less than or equal to a number  $x \in \mathbb{R}$ . Then

$$\pi(x) \sim \frac{x}{\ln x},$$

i.e., the quotient of the functions  $\pi(x)$  and  $x / \ln x$  approaches 1 for  $x \rightarrow \infty$ .

The following table illustrates how good the asymptotic estimate  $\pi(x) \sim x / \ln(x)$  is in several concrete instances in reality:

$x$	$\pi(x)$	$x / \ln(x)$	relative error
100	25	21.71	0.13
1000	168	144.76	0.13
10000	1229	1085.73	0.11
100000	9592	8685.88	0.09
500000	41538	38102.89	0.08

The density of primes among the natural numbers is also partially described by the following result by Euler. Let us remind the formula  $\sum_{n \in \mathbb{N}} \frac{1}{n^2} = \frac{\pi^2}{6}$  (see 7.1.10) which indicates that in view of the next proposition the primes are distributed more “densely” in  $\mathbb{N}$  than squares.

**Proposition.** Let  $P$  denote the set of all primes, then

$$\sum_{p \in P} \frac{1}{p} = \infty.$$

convenient way of writing which simplifies both expressions and reasonings.

**11.C.3.**

- i) Find the remainder of the integer  $7^{30}$  when divided by 50.
- ii) Find the last two digits of the decimal representation of the integer  $7^{30}$ .

**Solution.**

- i) Since  $7^2 = 49 \equiv -1 \pmod{50}$ , using the properties of congruences, which are mentioned above,  $7^{30} \equiv (-1)^{15} = -1 \pmod{50}$ , so the remainder of  $7^{30}$  upon division by 50 is 49.
- ii) Our task is actually to determine the remainder of  $7^{30}$  upon division by 100. We know from the above that the integer  $7^{30}$  leaves remainder 49 when divided by 50, so the last two digits are either 49 or 99. In particular, we already know that  $7^{30} \equiv -1 \pmod{25}$ , and we can easily calculate that  $7^{30} \equiv (-1)^{30} = 1 \pmod{4}$ . Since  $(4, 25) = 1$ , the wanted pair of digits is 49 (it leaves the desired remainder upon division by both 25 and 4).  $\square$

We now show how helpful the notion of congruence can be in solving problems similar to one already solved in 11.A.8 (where the induction and binomial theorem were used).

**11.C.4.** Prove that for any  $n \in \mathbb{N}$ , the integer  $37^{n+2} + 16^{n+1} + 23^n$  is divisible by 7.

**Solution.** We have  $37 \equiv 16 \equiv 23 \equiv 2 \pmod{7}$ , so by the basic properties of congruences,

$$\begin{aligned} 37^{n+2} + 16^{n+1} + 23^n &\equiv 2^{n+2} + 2^{n+1} + 2^n \\ &= 2^n(4+2+1) \equiv 0 \pmod{7}. \quad \square \end{aligned}$$

**11.C.5.** Prove that the integer  $n = (835^5 + 6)^{18} - 1$  is divisible by 112.

**Solution.** We factor  $112 = 7 \cdot 16$ . Since  $(7, 16) = 1$ , it suffices to show that  $7 \mid n$  and  $16 \mid n$ . We have  $835 \equiv 2 \pmod{7}$ , so

$$\begin{aligned} n &\equiv (2^5 + 6)^{18} - 1 = 38^{18} - 1 \equiv 3^{18} - 1 \\ &= 27^6 - 1 \equiv (-1)^6 - 1 = 0 \pmod{7}, \end{aligned}$$

hence  $7 \mid n$ . Similarly,  $835 \equiv 3 \pmod{16}$ , so

$$\begin{aligned} n &\equiv (3^5 + 6)^{18} - 1 = (3 \cdot 81 + 6)^{18} - 1 \equiv (3 \cdot 1 + 6)^{18} - 1 \\ &= 9^{18} - 1 = 81^9 - 1 \equiv 1^9 - 1 = 0 \pmod{16}, \end{aligned}$$

hence  $16 \mid n$ . Altogether,  $112 \mid n$ , which was to be proved.  $\square$

**11.C.6.** Prove that the following relations hold for prime  $p$ :

- i) If  $k \in \{1, \dots, p-1\}$ , then  $p \mid \binom{p}{k}$ .
- ii) If  $a, b \in \mathbb{Z}$ , then  $a^p + b^p \equiv (a+b)^p \pmod{p}$ .

**Solution.**

**PROOF.** Let  $n$  be an arbitrary natural number and  $p_1, \dots, p_{\pi(n)}$  all primes less than or equal to  $n$ . Let us set

$$\lambda(n) = \prod_{i=1}^{\pi(n)} \left(1 - \frac{1}{p_i}\right)^{-1}.$$

The particular factors can be perceived as sums of geometric series, hence

$$\lambda(n) = \prod_{i=1}^{\pi(n)} \left(\sum_{\alpha_i=0}^{\infty} \frac{1}{p_i^{\alpha_i}}\right) = \sum \frac{1}{p_1^{\alpha_1} \cdots p_{\pi(n)}^{\alpha_{\pi(n)}}},$$

where we sum over all  $\pi(n)$ -tuples of non-negative integers  $(\alpha_1, \dots, \alpha_{\pi(n)})$ . Since every integer not exceeding  $n$  factors to only primes in the set  $\{p_1, \dots, p_{\pi(n)}\}$ , all of them are included in this sum. Therefore,  $\lambda(n) > 1 + \frac{1}{2} + \dots + \frac{1}{n}$ , and since the harmonic series is divergent (see 5.D.1), we also have  $\lim_{n \rightarrow \infty} \lambda(n) = \infty$ .

Taking into account the expansion of the function  $\ln(1+x)$  to a power series (see 6.D.47), we further get

$$\begin{aligned} \ln \lambda(n) &= - \sum_{i=1}^{\pi(n)} \ln \left(1 - \frac{1}{p_i}\right) = \sum_{i=1}^{\pi(n)} \sum_{m=1}^{\infty} (mp_i^m)^{-1} = \\ &= p_1^{-1} + \dots + p_{\pi(n)}^{-1} + \sum_{i=1}^{\pi(n)} \sum_{m=2}^{\infty} (mp_i^m)^{-1}. \end{aligned}$$

Since the inner sum can be bound from above by

$$\begin{aligned} \sum_{m=2}^{\infty} (mp_i^m)^{-1} &< \sum_{m=2}^{\infty} p_i^{-m} = \\ &= p_i^{-2} (1 - p_i^{-1})^{-1} \leq 2p_i^{-2}, \end{aligned}$$

the divergent sequence  $\ln \lambda(n) < \sum_{i=1}^{\pi(n)} p_i^{-1} + 2 \sum_{i=1}^{\pi(n)} p_i^{-2}$  can also be bounded from above. The second sum apparently converges (since the series  $\sum_{n=1}^{\infty} n^{-2}$  does), so the first sum  $\sum_{i=1}^{\pi(n)} p_i^{-1}$  must diverge, which is what we wanted to prove.  $\square$

**3. Congruences and basic theorems**

This concept was introduced by C. F. Gauss in 1801 in his book *Disquisitiones Arithmeticae*. Although being a simple one, its contribution to number theory is mainly in making some reasonings (even quite complicated ones) be written much more compactly and transparently.

CONGRUENCE

If integers  $a, b$  give the same remainder  $r$  (where  $0 \leq r < m$ ) when divided by a natural number  $m$ , we say that they are *congruent modulo  $m$*  and write it as

$$a \equiv b \pmod{m}.$$

In the other case, we say that the integers  $a, b$  are not congruent modulo  $m$ , writing

$$a \not\equiv b \pmod{m}.$$

i) Since the binomial coefficient satisfies

$$\binom{p}{k} = \frac{p(p-1)\cdots(p-k+1)}{k!},$$

which is an integer, we hence know that  $k!$  divides the product  $p(p-1)\cdots(p-k+1)$ . However, since the integer  $k!$  is coprime to the prime  $p$ , we thus get that  $k! \mid (p-1)\cdots(p-k+1)$ , whence it follows that  $p \mid \binom{p}{k}$ .

ii) The binomial theorem implies that

$$(a+b)^p = a^p + \binom{p}{1}a^{p-1}b + \cdots + \binom{p}{p-1}ab^{p-1} + b^p.$$

Thanks to the previous item, we have  $\binom{p}{k} \equiv 0 \pmod{p}$  for any  $k \in \{1, \dots, p-1\}$ , whence the statement follows easily.  $\square$

**11.C.7.** Prove that for any natural numbers  $m, n$  and any integers  $a, b$  such that  $a \equiv b \pmod{m^n}$ , it is true that

$$a^m \equiv b^m \pmod{m^{n+1}}.$$

**Solution.** Since clearly  $m \mid m^n$ , we get that the congruence  $a \equiv b \pmod{m}$  holds, invoking property (5) of 11.3.1. Therefore, considering the algebraic identity

$$a^m - b^m = (a-b)(a^{m-1} + a^{m-2}b + \cdots + ab^{m-2} + b^{m-1}),$$

all the summands in the second pair of parentheses are congruent to  $a^{m-1}$  modulo  $m$ , so

$$a^{m-1} + a^{m-2}b + \cdots + b^{m-1} \equiv m \cdot a^{m-1} \equiv 0 \pmod{m}.$$

Since  $m^n$  divides  $a-b$ , and the sum  $a^{m-1} + a^{m-2}b + \cdots + b^{m-1}$  is divisible by  $m$ , we get that  $m^{n+1}$  must divide their product, which means that  $a^m \equiv b^m \pmod{m^{n+1}}$ .  $\square$

**11.C.8.** Using the result of the previous exercise (see also 11.A.2), prove that:

- i) integers  $a$  which are not divisible by 3 satisfy  $a^3 \equiv \pm 1 \pmod{9}$ ,
- ii) odd integers  $a$  satisfy  $a^4 \equiv 1 \pmod{16}$ .

**Solution.**

- i) Cubing the congruence  $a \equiv \pm 1 \pmod{3}$  (and, again, raising the exponent of the modulus), we get  $a^3 \equiv \pm 1 \pmod{3^2}$ .
- ii) This statement was proved already in the third part of exercise 11.A.2. Now, we will present another proof. Thanks to part (ii) of the mentioned exercise, we know that every odd integer  $a$  satisfies  $a^2 \equiv 1 \pmod{2^3}$ . Squaring this (and recalling the above exercise) leads to  $a^4 \equiv 1^2 \pmod{2^4}$ .

**11.C.9. Divisibility rules.** We can surely recall the basic rules of divisibility (at least by the numbers 2, 3, 4, 5, 6, 9 or 10) in terms of the decimal representation of a given integer. However, how can these rules be proved and can they be extended to other divisors as well?

We already know that we can restrict ourselves to divisibility by powers of primes (for instance, divisibility by 6 can be tested using divisibility by 2 and 3).

Whenever it is apparent that we are working with congruence relations, we usually omit the symbol  $\pmod{m}$ , or write just  $a \equiv b \pmod{m}$ .

**11.3.1. Fundamental properties.** It follows directly from the definition that the congruence modulo  $m$  is an *equivalence* relation.

Now, we will state further properties of congruences which are proven in detail in the practical column, see 11.C.2.

PROPERTIES OF CONGRUENCES

- (1) Congruences with respect to the same modulus can be added. An arbitrary multiple of the modulus can be added to either side.
- (2) Congruences with respect to the same modulus can be multiplied.
- (3) Both sides of a congruence can be raised to the power of the same natural number.
- (4) Both sides of a congruence can be divided by their common divisor provided it is coprime to the modulus. Both sides of a congruence together with the modulus can be divided by a positive divisor common to all three of them.
- (5) If a congruence is valid with respect to a modulus  $m$ , it is also valid with respect to any modulus  $d$  which divides  $m$ .
- (6) If either side of a congruence and the modulus are divisible by an integer, then this integer must divide the other side of the congruence as well.
- (7) If a congruence is valid with respect to moduli  $m_1, \dots, m_k$ , it is also valid with respect to their least common multiple  $[m_1, \dots, m_k]$ .

**Remark.** We have already used some properties of congruences without explicitly mentioning it – now, the result of the exercise 11.A.3 can be reformulated as “if  $a \equiv 1 \pmod{m}$ ,  $b \equiv 1 \pmod{m}$ , then also  $ab \equiv 1 \pmod{m}$ ”, which is a special case of the property (2) above.

It is not by chance because any statement which uses congruences can be reformulated in terms of divisibility. The usefulness of congruences thus lies not in the strength to solve more problems than without them, but rather in being a very convenient way of writing, which simplifies both expressions and reasonings.

**11.3.2. Arithmetic functions.** By arithmetic function we mean any function whose domain is the set of natural numbers. Good examples are the number of divisors  $\tau(a)$  or their sum  $\sigma(a)$ , computed in 11.B.5. A prominent example is the following function counting the coprime numbers less than given  $a$ :

The rule for divisibility by 9 says that a given integer is divisible by 9 if and only if its digit sum is. We will prove this as a consequence of a much stronger statement: It holds that every integer is congruent to its digit sum modulo 9 (in particular, it is congruent to zero if and only if its digit sum is). And this is trivial to prove: The digit sum of an integer  $n = a_k 10^k + a_{k-1} 10^{k-1} + \dots + a_1 10 + a_0$  is equal to  $S(n) = a_k + a_{k-1} + \dots + a_0$ , and since  $10^\ell \equiv 1^\ell = 1 \pmod{9}$  for any  $\ell \in \mathbb{N}_0$ , we get

$$n = a_k 10^k + \dots + a_0 \equiv a_k + \dots + a_0 = S(n) \pmod{9}.$$

This derivation is valid also if we replace 9 with 3.

The rule for divisibility by 11, which we have not mentioned yet, works similarly. Here, we have  $10^\ell \equiv (-1)^\ell \pmod{11}$ , so we get

$$\begin{aligned} n &= a_k 10^k + \dots + a_0 \equiv a_k (-1)^k + \dots + a_1 (-1) + a_0 \\ &\equiv (a_0 + a_2 + \dots) - (a_1 + a_3 + \dots) \pmod{11}. \end{aligned}$$

Therefore, an integer is divisible by 11 if and only if the difference of the sum of the digits at even places and the sum of the digits at odd places is.

There is a nice trick for the divisors 7 and 13: We have  $1001 = 7 \cdot 11 \cdot 13$ ; an integer  $n = 1000a + b$  thus satisfies  $n \equiv -a + b \pmod{m}$ , where  $m$  is any of the numbers 7, 11, 13. Therefore, 2015 is divisible by 13 since  $015 - 2 = 13$ . Similarly, 2016 is divisible by 7 as  $016 - 2 = 14$  is a multiple of 7. We could justify that 2013 is a multiple of 11 in the same way, but the aforementioned criterion  $11 \mid (3 + 0) - (1 + 2)$  is maybe more smart.

**Using divisibility for error detection.** Let us note that divisibility by eleven is often used for making decimal codes which allow us to detect a single-digit error. If we make such a mistake when copying an integer which is divisible by eleven, then the resulting integer is surely not (see the aforementioned criterion of divisibility by eleven). More details can be found in chapter 12.5.1 about coding. For instance, the national identification numbers in the Czech Republic and Slovakia contain a check digit which completes the code into an integer divisible by eleven.

Similarly, the numbers of bank accounts managed by Czech banks must comply with a similar (only a bit more complicated) procedure. Both the transformed 6-digit prefix  $a_5 a_4 a_3 a_2 a_1 a_0$  and the 10-digit account number  $b_9 b_8 b_7 b_6 b_5 b_4 b_3 b_2 b_1 b_0$  must satisfy the following condition on divisibility by eleven (here, we mention only the one for the number without the prefix):

$$\begin{aligned} 0 &\equiv b_9 2^9 + b_8 2^8 + b_7 2^7 + \dots + b_3 2^3 + b_2 2^2 + b_1 2^1 + b_0 2^0 \\ &\equiv -5b_9 + 3b_8 - 4b_7 - 2b_6 - b_5 \\ &\quad + 5b_4 - 3b_3 + 4b_2 + 2b_1 + b_0 \pmod{11}. \end{aligned}$$

This condition can be shortly described so that the account number, perceived as being in binary (though with usage of decimal digits) is to be divisible by eleven.

EULER'S TOTIENT FUNCTION  $\varphi$

For a natural number, we define the value of Euler's totient function  $\varphi$  as

$$\varphi(n) = |\{a \in \mathbb{N} \mid 0 < a \leq n, (a, n) = 1\}|.$$

For example,  $\varphi(1) = 1, \varphi(5) = 4, \varphi(6) = 2$ . If  $p$  is a prime, then clearly  $\varphi(p) = p - 1$  (all natural numbers less than  $p$  are coprime to it).

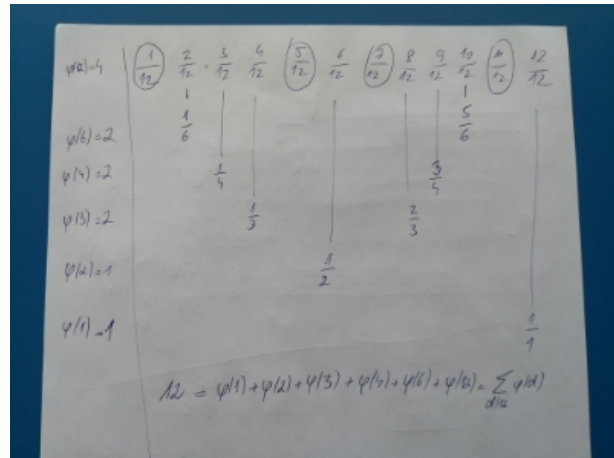

We are going to prove several important properties of the function  $\varphi$ . Let us start with a quite simple observation:

**Lemma.** Let  $n \in \mathbb{N}$ . Then,  $\sum_{d|n} \varphi(d) = n$ .

PROOF. Let us consider the  $n$  fractions

$$\frac{1}{n}, \frac{2}{n}, \frac{3}{n}, \dots, \frac{n-1}{n}, \frac{n}{n}.$$

Reducing them to lowest terms and grouping them together by the denominators, we get just the statement in question (see the picture illustrating the case  $n = 12$ ).  $\square$

**11.3.3.** Soon we shall recognize, that knowing the values of the Euler's totient function may be extremely useful. The following explicit formula is crucial. We might prove it by the inclusion-exclusion principle, determining the number of integers not coprime to  $n$  in a given interval. Here we shall employ a more conceptual approach which is of great interest by itself, and thus, the proof is postponed to 11.3.8 below.

**Theorem.** Let  $n \in \mathbb{N}$  factor to primes as  $n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$ . Then,

$$\varphi(n) = n \cdot \left(1 - \frac{1}{p_1}\right) \dots \left(1 - \frac{1}{p_k}\right).$$

**11.3.4. Multiplicative functions.** Dealing with arithmetic functions, we introduce the concept of "multiplicativity" which concerns only the coprime arguments:

**Definition.** A multiplicative function on the natural numbers is such an arithmetic function which, for all pairs of coprime natural numbers  $a, b$ , satisfies

$$f(a \cdot b) = f(a) \cdot f(b).$$

**11.C.10.** Verify that the account number of the Masaryk university, 85636621, is built correctly.

**Solution.** We will test the condition of divisibility by eleven:  
 $-5b_9 + 3b_8 - 4b_7 - 2b_6 - b_5 + 5b_4 - 3b_3 + 4b_2 + 2b_1 + b_0$   
 $\equiv -4 \cdot 8 - 2 \cdot 5 - 1 \cdot 6 + 5 \cdot 3 - 3 \cdot 6 + 4 \cdot 6 + 2 \cdot 2 + 1 \cdot 1$   
 $\equiv 0 \pmod{11}.$   $\square$

**Euler's totient function.** The totient function  $\varphi$  assigns to a natural number  $m$  the number of natural numbers which are less than or equal to  $m$  and coprime to  $m$ , which can be written as  $\varphi(m) = |\{a \in \mathbb{N} \mid 0 < a \leq m, (a, m) = 1\}|$ .

However, to be able to evaluate it efficiently, one needs to know the factorization of the input integer  $m$  to primes. In such a case, for  $m = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ , we have

$$\varphi(m) = (p_1 - 1)p_1^{\alpha_1 - 1} \cdots (p_k - 1)p_k^{\alpha_k - 1}.$$

In particular, we know that  $\varphi(p^\alpha) = (p - 1) \cdot p^{\alpha - 1}$  and that  $\varphi(m \cdot n) = \varphi(m) \cdot \varphi(n)$  holds whenever  $m, n$  are coprime.

**11.C.11.** Calculate  $\varphi(72)$ .

**Solution.**  $72 = 2^3 \cdot 3^2 \implies \varphi(72) = 72 \cdot (1 - \frac{1}{2}) \cdot (1 - \frac{1}{3}) = 24$ , alternatively  $\varphi(72) = \varphi(8) \cdot \varphi(9) = 4 \cdot 6 = 24$ .  $\square$

**11.C.12.**

- i) Determine all natural numbers  $n$  for which  $\varphi(n)$  is odd.
- ii) Prove that  $\forall n \in \mathbb{N} : \varphi(4n + 2) = \varphi(2n + 1)$ .

**Solution.**

- i) We clearly have  $\varphi(1) = \varphi(2) = 1$ . Every integer  $n \geq 3$  is either divisible by an odd prime  $p$  (then,  $\varphi(n)$  is divisible  $p - 1$ , which is an even integer) or  $n$  is a (higher-than-first) power of two (and then,  $\varphi(2^\alpha) = 2^{\alpha - 1}$  is even as well). Altogether, we have found out that  $\varphi(n)$  is odd only for  $n = 1, 2$ .
- ii) The integer  $2n + 1$  is odd, so  $(2, 2n + 1) = 1$ , and hence  $\varphi(4n + 2) = \varphi(2 \cdot (2n + 1)) = \varphi(2) \cdot \varphi(2n + 1) = \varphi(2n + 1)$ .  $\square$

**11.C.13.** Find all natural numbers  $m$  for which:

- i)  $\varphi(m) = 30$ ,
- ii)  $\varphi(m) = 34$ ,
- iii)  $\varphi(m) = 20$ ,
- iv)  $\varphi(m) = \frac{m}{3}$ .

**Solution.** In all of the above cases, we are looking for the fibers of a given integer  $a$  in the form  $m = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ , and we proceed as follows:

- Since  $\varphi(m) = (p_1 - 1)p_1^{\alpha_1 - 1} \cdots (p_k - 1)p_k^{\alpha_k - 1} = a$ , every prime  $p$  which divides  $m$  must satisfy

$$p - 1 \mid a.$$

- Similarly, every prime  $p$  whose higher power divides  $m$  must divide  $a$ . More exactly, we must even have  $p^{\alpha - 1} \mid a$ .

Clearly, the multiplicative functions include, for instance, the number of divisors  $\tau(n)$ , or their sum  $\sigma(n)$ , cf. 11.B.5.

It follows directly from Theorem 11.3.3 that the Euler's totient function is a multiplicative arithmetic function, too:

**Corollary.** Let  $a, b \in \mathbb{N}$ ,  $(a, b) = 1$ . Then

$$\varphi(a \cdot b) = \varphi(a) \cdot \varphi(b).$$

**Remark.** The multiplicativity of  $\varphi$  can also be derived directly from the knowledge that

$$(n, ab) = 1 \iff (n, a) = 1 \wedge (n, b) = 1.$$

Then the easy fact about the totient function on powers of primes

$$\varphi(p^\alpha) = p^\alpha - p^{\alpha - 1} = (p - 1) \cdot p^{\alpha - 1},$$

leads to the formula for the computation of  $\varphi$  in yet another alternative way.

**11.3.5. Möbius function.** Let us start our detour leading to the proof of Theorem 11.3.3. At the same time, the introduced convolution and inversion formulae should provide a glance into a very important conceptual direction.

**Definition.** Let a natural number  $n$  be factored to distinct primes:  $n = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ . The value of the *Möbius function*  $\mu(n)$  is defined to be 0 if  $\alpha_i > 1$  for some  $i$  (i.e., if  $n$  is divisible by a square), and  $(-1)^k$  otherwise. Further, we define  $\mu(1) = 1$  (in accordance with the convention that 1 factors to the product of zero primes).

For instance,  $\mu(4) = \mu(2^2) = 0$ ,  $\mu(6) = \mu(2 \cdot 3) = (-1)^2 = 1$ ,  $\mu(2) = \mu(3) = -1$ . By the very definition,  $\mu$  is a multiplicative function, too.

In the next paragraphs, we prove several important properties of the Möbius function, especially the so-called *Möbius inversion formula*. Let us start with a simple observation:

**Lemma.** For all  $n \in \mathbb{N} \setminus \{1\}$ , it holds that  $\sum_{d \mid n} \mu(d) = 0$ .

**PROOF.** Writing  $n$  as  $n = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ , then all divisors  $d$  of  $n$  are of the form  $d = p_1^{\beta_1} \cdots p_k^{\beta_k}$ , where  $0 \leq \beta_i \leq \alpha_i$  for all  $i \in \{1, \dots, k\}$ . Therefore,

$$\begin{aligned} \sum_{d \mid n} \mu(d) &= \sum_{\substack{(\beta_1, \dots, \beta_k) \in (\mathbb{N} \cup \{0\})^k \\ 0 \leq \beta_i \leq \alpha_i}} \mu(p_1^{\beta_1} \cdots p_k^{\beta_k}) \\ &= \sum_{(\beta_1, \dots, \beta_k) \in \{0, 1\}^k} \mu(p_1^{\beta_1} \cdots p_k^{\beta_k}) \\ &= \binom{k}{0} + \binom{k}{1} \cdot (-1) + \binom{k}{2} \cdot (-1)^2 + \cdots + \binom{k}{k} \cdot (-1)^k \\ &= (1 + (-1))^k = 0. \end{aligned}$$

In the third equality, we used a combinatorial reasoning – the summand  $\binom{k}{\ell} (-1)^\ell$  gives the contribution of the divisors  $d = p_1^{\beta_1} \cdots p_k^{\beta_k}$  with the property that exactly  $\ell$  of the exponents  $\beta_1, \dots, \beta_k$  are equal to one; there are  $\binom{k}{\ell}$  of them, and each satisfies that  $\mu(p_1^{\beta_1} \cdots p_k^{\beta_k}) = (-1)^\ell$ .  $\square$

- This procedure results in a finite set of candidates for  $m$ , which can be eliminated in a convenient way, sometimes also using the fact that any prime dividing  $a$  must occur in the factorization of  $\varphi(m)$  as a divisor of some  $p - 1$  or in a prime power  $p^{\alpha-1}$ .

Now, let us solve problems i)-iii):

- i) Every prime  $p$  from the factorization of  $m$  must satisfy  $p - 1 \mid 30$ , so  $p - 1 \in \{1, 2, 3, 5, 6, 10, 15, 30\}$ , which is satisfied by primes  $p \in \{2, 3, 7, 11, 31\}$ , and only 2 and 3 of them can divide  $m$  in higher power than the first. Therefore,

$$m = 2^\alpha 3^\beta 7^\gamma 11^\delta 31^\varepsilon,$$

where  $\alpha, \beta \in \{0, 1, 2\}, \gamma, \delta, \varepsilon \in \{0, 1\}$ . The analysis of the possibilities can be further simplified if we realize that  $\varphi(3) = 2, \varphi(3^2) = \varphi(7) = 6, \varphi(11) = 10$  are all integers which divide 30 into an odd integer greater than 1. Therefore, if we had, for instance,  $m = 7 \cdot m_1$ , where  $7 \nmid m_1$ , then we would also have  $\varphi(m_1) = 5$ , which is impossible, as we know from the previous exercise.

We thus get  $\beta = \gamma = \delta = 0$  and  $m = 2^\alpha \cdot 31^\varepsilon$ , whence we can easily obtain the solution  $m \in \{31, 62\}$ .

- ii) Similarly to above, only primes  $p \in \{2, 3\}$  can divide  $m$ , and the prime 3 can divide  $m$  only in the first power. However, since  $\frac{34}{\varphi(3)} = 17$ , the prime 3 cannot divide  $m$  at all. The remaining possibility,  $m = 2^\alpha$ , leads to  $34 = 2^{\alpha-1}$ , which is also impossible. Therefore, there is no such number  $m$ .
- iii) Now, every prime  $p$  dividing  $m$  must satisfy  $p - 1 \mid 20$ , so  $p - 1 \in \{1, 2, 4, 5, 10, 20\}$ , which is satisfied by primes  $p \in \{2, 3, 5, 11\}$ , and only 2 and 5 of those can divide  $m$  in higher power. We thus have

$$m = 2^\alpha 3^\beta 5^\gamma 11^\delta,$$

where  $\alpha \in \{0, 1, 2, 3\}, \gamma \in \{0, 1, 2\}, \beta, \delta \in \{0, 1\}$ .

First, consider  $\delta = 1$ . Then,  $\varphi(2^\alpha 3^\beta 5^\gamma) = 2$ , whence we easily get that  $\gamma = 0$  and  $(\alpha, \beta) \in \{(2, 0), (1, 1), (0, 1)\}$ , which gives three solutions:  $m \in \{44, 66, 33\}$ .

Further, let us have  $\delta = 0$ . If  $\gamma = 2$ , then  $\varphi(2^\alpha 3^\beta) = 1$ , whence  $(\alpha, \beta) \in \{(1, 0), (0, 0)\}$ . We thus obtain two more solutions:  $m \in \{50, 25\}$ .

If  $\gamma = 1$ , then we get  $\frac{20}{\varphi(5)} = 5$ , similarly to the above item. This is an odd integer, so we get no solutions in this case. This is also the case for  $\gamma = 0$  since the equation  $\varphi(2^\alpha) = 20$  has no solution, either.

Altogether, there are five satisfactory values  $m \in \{25, 33, 44, 50, 66\}$ .

- iv) This problem is of a different kind than the previous ones, so we must approach otherwise. The relation  $\varphi(m) = \frac{m}{3}$  implies that  $m$  must be a multiple of three (since the left-hand side of the equation is an integer). We will thus be looking for the solution in the form  $m = 3^\alpha \cdot n$ , where  $3 \nmid n, \alpha \geq 1$ . Then,  $\varphi(m) = 2 \cdot 3^{\alpha-1} \cdot \varphi(n) = \frac{m}{3} =$

**11.3.6. Dirichlet convolution.** There is another concept which is tightly connected to the Möbius function, the so-called Dirichlet product (also Dirichlet convolution).

**Definition.** Let  $f, g$  be arithmetic functions. Its *Dirichlet product* is defined as follows:

$$(f \circ g)(n) = \sum_{d \mid n} f(d) \cdot g\left(\frac{n}{d}\right) = \sum_{d_1 d_2 = n} f(d_1) \cdot g(d_2).$$

The next observation is nearly obvious:

**Lemma.** *The Dirichlet product is associative.*

PROOF.

$$((f \circ g) \circ h)(n) = \sum_{d_1 d_2 d_3 = n} f(d_1) g(d_2) h(d_3) = (f \circ (g \circ h))(n)$$

□

**11.3.7. Möbius inversion formula.** Let us define two useful functions  $i$  and  $I$  by  $i(1) = 1, i(n) = 0$  for all  $n > 1$  and  $I(n) = 1$  for all  $n \in \mathbb{N}$ . Then, every arithmetic function  $f$  satisfies:

$$f \circ i = i \circ f = f$$

$$(I \circ f)(n) = (f \circ I)(n) = \sum_{d \mid n} f(d).$$

Further, notice the Möbius function commutes with  $I$  and the result for all  $n > 1$  is  $i$  (the statement is clear for  $n = 1$  and we use the above Lemma 11.3.5):

$$(I \circ \mu)(n) = \sum_{d \mid n} I(d) \mu\left(\frac{n}{d}\right) = \sum_{d \mid n} I\left(\frac{n}{d}\right) \mu(d) =$$

$$= \sum_{d \mid n} \mu(d) = 0$$

**Theorem (Möbius inversion formula).** *Let an arithmetic function  $F$  be defined in terms of an arithmetic function  $f$  by  $F(n) = \sum_{d \mid n} f(d)$ . Then,  $f$  can be expressed as*

$$f(n) = \sum_{d \mid n} \mu\left(\frac{n}{d}\right) \cdot F(d).$$

PROOF. The relation  $F(n) = \sum_{d \mid n} f(d)$  can be rewritten as  $F = f \circ I$ . Therefore,  $F \circ \mu = (f \circ I) \circ \mu = f \circ (I \circ \mu) = f \circ i = f$ , which is the statement of the theorem. □

**11.3.8. Proof of the Theorem 11.3.3.** Invoking the Lemma 11.3.2 and the Möbius inversion formula, we get

$$\varphi(n) = \sum_{d \mid n} \mu(d) \frac{n}{d}$$

$$= n - \frac{n}{p_1} - \dots - \frac{n}{p_k} + \dots + (-1)^k \frac{n}{p_1 \cdots p_k}$$

$$= n \cdot \left(1 - \frac{1}{p_1}\right) \cdots \left(1 - \frac{1}{p_k}\right)$$

and the explicit formula for  $\varphi(n)$  has been proved.

ABBBB, AABBB, AAABB, AAAAB, ABABB, AABAB. □

**11.C.16.**

- i) Determine the remainder of the integer  $2^{50} + 3^{50} + 4^{50}$  when divided by 17.
- ii) Determine the remainder of the integer  $2^{181} + 3^{181} + 5^{181}$  when divided by 37.

**Solution.**

- i) By Fermat's theorem, we have  $2^{16} \equiv 3^{16} \equiv 4^{16} \equiv 1 \pmod{17}$ . Since  $50 \equiv 2 \pmod{16}$ , we get  $2^{50} + 3^{50} + 4^{50} \equiv 2^2 + 3^2 + 4^2 \equiv 12 \pmod{17}$ .
- ii) Similarly  $2^{36} \equiv 3^{36} \equiv 5^{36} \equiv 1 \pmod{37}$ , and hence  $2^{181} + 3^{181} + 5^{181} \equiv 2 + 3 + 5 \equiv 10 \pmod{37}$ . □

**Euler's theorem and orders of integers modulo  $m$ .** Thanks to Euler's theorem, it is guaranteed that every integer  $a$  which is coprime to  $m$  has an order, i.e. the least natural number  $n$  such that  $a^n \equiv 1 \pmod{m}$ . The most interesting ones are those integers  $a$  whose order equals  $\varphi(m)$ ; they are called the primitive roots modulo  $m$ .

**11.C.17.** Determine the order of 2 modulo 7.

**Solution.** The order of 2 modulo 7 is equal to 3 as  $2^1 = 2 \not\equiv 1 \pmod{7}$ ,  $2^2 = 4 \not\equiv 1 \pmod{7}$ ,  $2^3 = 8 \equiv 1 \pmod{7}$ . □

**11.C.18.** Determine the last two digits of the number  $7^{2019}$ .

**Solution.** We can easily see that the order of 7 modulo 100 is equal to 4 – by simple calculations, we have  $7^2 = 49$  and  $49^2 = (50 - 1)^2 = 50^2 - 2 \cdot 50 + 1 \equiv 1 \pmod{100}$ . Therefore, it suffices to determine the remainder  $r$  of the integer 2019 when divided by 4, since  $7^{2019} \equiv 7^r \pmod{100}$ . Apparently, we have  $r = 3$ , so the wanted last two digits are the same as those of  $7 \cdot 49$ , i.e. 43. □

Now, we mention several statements about the properties of the order of an integer modulo  $m$ .

**11.C.19.** Let  $m \in \mathbb{N}$ ,  $a, b \in \mathbb{Z}$ ,  $(a, m) = (b, m) = 1$ . Prove that if  $a \equiv b \pmod{m}$ , then the integers  $a, b$  share the same order modulo  $m$ .

**Solution.** Raising the congruence  $a \equiv b \pmod{m}$  to the  $n$ -th power leads to  $a^n \equiv b^n \pmod{m}$ , so  $a^n \equiv 1 \pmod{m} \iff b^n \equiv 1 \pmod{m}$ . □

**11.C.20.** Let  $m \in \mathbb{N}$ ,  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ . If the order of  $a$  modulo  $m$  is  $r \cdot s$ , (where  $r, s \in \mathbb{N}$ ), prove that the order of the integer  $a^r$  modulo  $m$  is  $s$ .

**Solution.** Since none of the integers  $a, a^2, a^3, \dots, a^{rs-1}$  is congruent to 1 modulo  $m$ , nor is any of the integers  $a^r, a^{2r}, a^{3r}, \dots, a^{(s-1)r}$ . On the other hand, we have  $(a^r)^s \equiv 1 \pmod{m}$ , so the order of  $a^r$  modulo  $m$  equals  $s$ . □

This formula can be generalized in many ways – especially in cases where the functions  $F$  and  $f$  map natural numbers into an abelian group  $(G, \cdot)$ . In this case, the formula (considering the operation in  $G$  to be multiplicative) gets the form

$$f(n) = \sum_{d|n} F(d) \mu\left(\frac{n}{d}\right).$$

Now, we will demonstrate the use of the Möbius inversion formula on a more complex example from the theory of finite fields. Let us consider a  $p$ -element field  $\mathbb{F}_p$  (i.e., the ring of residue classes modulo a prime  $p$ ) and examine the number  $N_d$  of monic irreducible polynomials of a given degree  $d$  over this field. Let  $S_d(x)$  denote the product of all such polynomials. Now, we borrow a (not very hard) theorem from the theory of finite fields which states that for all  $n \in \mathbb{N}$ , we have

$$x^{p^n} - x = \prod_{d|n} S_d(x).$$

Confronting the degrees of the polynomial on both sides yields

$$p^n = \sum_{d|n} dN_d,$$

whence we get, by applying the standard Möbius inversion formula, that

$$N_n = \frac{1}{n} \sum_{d|n} \mu\left(\frac{n}{d}\right) p^d.$$

In particular, we can see that for any  $n \in \mathbb{N}$ , it holds that  $N_n = \frac{1}{n} (p^n - \dots + \mu(n)p) \neq 0$  since the expression in the parentheses is a sum of distinct powers of  $p$  multiplied by coefficients  $\pm 1$ , so it cannot be equal to 0. Therefore, there exist irreducible polynomials over  $\mathbb{F}_p$  of an arbitrary degree  $n$ , so there are finite fields  $\mathbb{F}_{p^n}$  (having  $p^n$  elements) for any prime  $p$  and natural number  $n$  (in the theory of field extensions, such a field is constructed as the quotient ring  $\mathbb{F}_p[x]/(f)$  of the ring of polynomials over  $\mathbb{F}_p$  modulo the ideal generated by an irreducible polynomial  $f \in \mathbb{F}_p[x]$  of degree  $n$ , whose existence has just been proved).

**11.3.10. Example.** By the formula we have proved, the number of (monic) irreducible polynomials over  $\mathbb{F}_2$  of degree 5 is equal to

$$N_5 = \frac{1}{5} \sum_{d|5} \mu\left(\frac{5}{d}\right) 2^d = \frac{1}{5} (\mu(1) \cdot 2^5 + \mu(5) \cdot 2) = 6.$$

The number of monic irreducible polynomials over  $\mathbb{F}_3$  of degree four is then

$$N_4 = \frac{1}{4} \sum_{d|4} \mu\left(\frac{4}{d}\right) 3^d = \frac{1}{4} (\mu(1) \cdot 3^4 + \mu(2) \cdot 3^2 + \mu(4) \cdot 3^1) = \frac{1}{4} (81 - 9) = 18.$$

**11.3.11.** The next two theorems belong to the most important results of elementary number theory, and they will often be applied in further theoretical as well as practical problems.

**11.C.21.** Show that the contrary of the previous statement need not be true in general.

**Solution.** Indeed, even if the order of an integer  $a^r$  modulo  $m$  is  $s$ , the order of  $a$  modulo  $m$  may not be  $r \cdot s$ . For instance, for  $m = 13$  and the integers  $a = 3$ ,  $b = -4$ , we have  $a^2 = 9$ ,  $a^3 = 27 \equiv 1 \pmod{13}$ , so the order of  $a$  modulo 13 is 3. Similarly,  $b^2 = 16 \not\equiv 1 \pmod{13}$ ,  $b^3 = -64 \equiv 1 \pmod{13}$ , so the order of  $b$  modulo 13 is 3, too. On the other hand,  $b^2 = (-4)^2 = 16 \equiv 3 = a \pmod{13}$  has the same order (3) as  $a$ , yet the integer  $b$  does not have order  $2 \cdot 3$ .  $\square$

**11.C.22.** Determine the last digit of the numbers

- i)  $3^{5^{7^9}}$ ,
- ii)  $37^{37^{37}}$ ,
- iii)  $12^{13^{14}}$ .

**11.C.23.** It holds for all odd  $n \in \mathbb{N}$  that  $n \mid 2^{n!} - 1$ . Prove this!  $\circ$

**11.C.24.**

- i) Determine the last digit of the number  $7^{9^{5^{7^3}}}$ .
- ii) Determine the remainder of the number  $15^{14^{13}}$  when divided by 11.  $\circ$

**Solution.**

- i) The order of 7 modulo 100 is equal to 4 by exercise 11.C.18, so it suffices to find the remainder of the (extremely large) exponent upon division by 4. Since  $9 \equiv 1 \pmod{4}$ , the entire exponent leaves remainder 1 as well. Therefore, the wanted digit is  $7^1 = 7$ .
- ii) The order of  $15 \equiv 4 \pmod{11}$  is 5 (which can be found by direct computation or from the fact that 2 is a primitive root modulo 11 (see also 11.C.28); then, theorem 11.3.14 yields that the order of  $4 = 2^2$  is  $\frac{10}{(10,2)} = 5$ ). It is thus sufficient to determine the remainder of the exponent modulo 5. We have

$$14^{13} \equiv (-1)^{13} = -1 \equiv 4 \pmod{5},$$

so the wanted remainder is  $4^4 = 2^8 = 256 \equiv 6 - 5 + 2 = 3 \pmod{11}$ . Alternatively, we could have finished the calculation as follows:  $4^4 \equiv 4^{-1} \equiv 3 \pmod{11}$ .

**11.C.25.** Determine the last two digits of the decimal expansion of the number  $14^{14^{14}}$ .

**Solution.** We are interested in the remainder of the number  $a = 14^{14^{14}}$  upon division by 100. However, since  $(14, 100) > 1$ , we cannot consider the order of 14 modulo 100. Instead, we can factor the modulus to coprime integers:  $100 = 4 \cdot 25$ . Apparently,  $4 \mid a$ , so it remains to find the remainder of  $a$  modulo 25. By Euler's theorem, we have

$$14^{\varphi(25)} = 14^{20} \equiv 1 \pmod{25},$$

so we are interested in the remainder of  $14^{14}$  upon division by  $20 = 4 \cdot 5$ . Again, we clearly have  $4 \mid 14^{14}$ , and further  $14^{14} \equiv (-1)^{14} = 1 \pmod{5}$ , so

$$14^{14} \equiv 16 \pmod{20}.$$

Altogether,

$$14^{14^{14}} \equiv 14^{16} = 2^{16} \cdot 7^{16} \pmod{25}.$$

FERMAT'S LITTLE THEOREM

**Theorem.** Let  $a$  be an integer and  $p$  a prime,  $p \nmid a$ . Then,

$$a^{p-1} \equiv 1 \pmod{p}.$$

**PROOF.** The statement will follow as a simple consequence of Euler's theorem (and together with this one, it is a consequence of more general Lagrange's theorem 12.4.10). However, it can be proved directly (by mathematical induction or a combinatorial means, as mentioned in exercise 11.C.15).  $\square$

Sometimes, Fermat's little theorem is presented in the following form, which is apparently equivalent to the original statement.

**Corollary.** Let  $a$  be an integer and  $p$  a prime. Then,

$$a^p \equiv a \pmod{p}.$$

**11.3.12. Euler's theorem.** We are coming to a theorem which has got immediate striking applications in cryptography (we shall come to this point in cf. 11.6.18). Before formulating and proving Euler's theorem, we introduce a few useful concepts.

RESIDUE SYSTEMS

A *complete residue system* modulo  $m$  is an arbitrary  $m$ -tuple of integers which are pairwise incongruent modulo  $m$  (the most commonly used  $m$ -tuple is  $0, 1, \dots, m-1$  or, for odd  $m$ , its "symmetric" variation  $-\frac{m-1}{2}, \dots, -1, 0, 1, \dots, \frac{m-1}{2}$ ).

A *reduced residue system* modulo  $m$  is an arbitrary  $\varphi(m)$ -tuple of integers which are pairwise incongruent modulo  $m$  and coprime to  $m$ .

**Lemma.** Let  $x_1, x_2, \dots, x_{\varphi(m)}$  form a reduced residue system modulo  $m$ . If  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ , then the integers  $a \cdot x_1, \dots, a \cdot x_{\varphi(m)}$  also form a reduced residue system modulo  $m$ .

**PROOF.** Since  $(a, m) = 1$  and  $(x_i, m) = 1$ , we have  $(a \cdot x_i, m) = 1$ . Further, if we had  $a \cdot x_i \equiv a \cdot x_j \pmod{m}$  for some distinct indices  $i, j$ , dividing both sides of the congruence by the integer  $a$  (which is coprime to  $m$ ) would lead to  $x_i \equiv x_j \pmod{m}$ , meaning that the original  $\varphi(m)$ -tuple was not a reduced residue system, either.  $\square$

EULER'S THEOREM

**Theorem.** Let  $a \in \mathbb{Z}$ ,  $m \in \mathbb{N}$ ,  $(a, m) = 1$ . Then,

$$a^{\varphi(m)} \equiv 1 \pmod{m}.$$

**PROOF.** Let  $x_1, x_2, \dots, x_{\varphi(m)}$  be an arbitrary reduced residue system modulo  $m$ . By the previous lemma,  $a \cdot x_1, \dots, a \cdot x_{\varphi(m)}$  is also a reduced residue system modulo  $m$ .

We can simplify the computation to come a lot if we realize that

$$7^2 \equiv -1 \pmod{25}, \text{ and } 2^5 \equiv 7 \pmod{25}.$$

Then,

$$\begin{aligned} 14^{14^{14}} &\equiv 2^{16} \cdot 7^{16} \equiv (2^5)^3 \cdot 2 \cdot 7^{16} \equiv 7^3 \cdot 2 \cdot 7^{16} \\ &\equiv 2 \cdot 7^{19} \equiv 2 \cdot (-1)^9 \cdot 7 = 11 \pmod{25}. \end{aligned}$$

We are thus looking for a non-negative integer which is less than 100, is a multiple of 4, and leaves remainder 11 when divided 25 – the only such number is clearly 36.  $\square$

**11.C.26.** Determine the last three digits of the number  $12^{10^{11}}$ .  $\circ$

**11.C.27.** Find all natural numbers  $n$  for which the integer  $5^n - 4^n - 3^n$  is divisible by eleven.

**Solution.** The orders of all of the numbers 3, 4, and 5 are equal to five, so it suffices to examine  $n \in \{0, 1, 2, 3, 4\}$ . It can be seen from the following table

$n$	0	1	2	3	4
$5^n \pmod{11}$	1	5	3	4	9
$4^n \pmod{11}$	1	4	5	9	3
$3^n \pmod{11}$	1	3	9	5	4

that only the case  $n \equiv 2 \pmod{5}$  yields  $3 - 5 - 9 \equiv 0 \pmod{11}$ .

The problem is thus satisfied by exactly those natural numbers  $n$  which satisfy  $n \equiv 2 \pmod{5}$ .  $\square$

**11.C.28. Primitive roots.** Show that there are no primitive roots modulo 8, and find any primitive root modulo 11.

**Solution.** Apparently, even integers cannot be primitive roots modulo 8, so it remains to examine odd ones. We can easily calculate that  $3^2 \equiv 5^2 \equiv 7^2 \equiv 1 \pmod{8}$ , but  $\varphi(8) = 4 > 2$ . Now, we will verify that 2 is a primitive root modulo 11. The order of 2 divides  $\varphi(11) = 10$ , so it suffices to show that  $2^2 \not\equiv 1 \pmod{11}$  and  $2^5 = 32 \equiv -1 \not\equiv 1 \pmod{11}$ . Therefore, the order of 2 modulo 11 is indeed 10.  $\square$

**11.C.29.** We will now determine (with the help of propositions proving Theorem 11.3.16) primitive roots modulo 41,  $41^2$ , and  $2 \cdot 41^2$ .

**Solution.** Since  $\varphi(41) = 40 = 2^3 \cdot 5$ , it holds that an integer  $g$  coprime to 41 is a primitive root modulo 41 if and only if

$$g^{20} \not\equiv 1 \pmod{41} \wedge g^8 \not\equiv 1 \pmod{41}.$$

Therefore, for every  $i \in \{1, 2, \dots, \varphi(m)\}$ , there is a unique  $j \in \{1, 2, \dots, \varphi(m)\}$  such that  $a \cdot x_i \equiv x_j \pmod{m}$ . Multiplying these congruences leads to  $(a \cdot x_1) \cdot (a \cdot x_2) \cdots (a \cdot x_{\varphi(m)}) \equiv x_1 \cdot x_2 \cdots x_{\varphi(m)} \pmod{m}$ , which can be rearranged to

$$a^{\varphi(m)} \cdot x_1 \cdot x_2 \cdots x_{\varphi(m)} \equiv x_1 \cdot x_2 \cdots x_{\varphi(m)} \pmod{m}.$$

Dividing this by the integer  $x_1 \cdot x_2 \cdots x_{\varphi(m)}$  already gives the wanted statement.  $\square$

**Remark.** As we have already mentioned, Euler's theorem is a consequence of Lagrange's theorem (see 12.4.10) applied to the group  $(\mathbb{Z}_m^\times, \cdot)$ . This proof of Euler's theorem utilized the fact that multiplying by an integer  $a$  which is coprime to  $m$  is, in algebraic words, an automorphism of the group  $(\mathbb{Z}_m^\times, \cdot)$ .

**11.3.13.** There is an important concept which is tightly connected to Euler's totient function and Euler's theorem: the so-called *order of an integer modulo  $m$*  – once again, it is nothing else than the order of the corresponding element in the group of invertible residue classes modulo  $m$ :

ORDER OF AN INTEGER

Let  $a \in \mathbb{Z}$ ,  $m \in \mathbb{N}$ , where  $(a, m) = 1$ . The *order of  $a$  modulo  $m$*  is the least natural number  $n$  satisfying

$$a^n \equiv 1 \pmod{m}.$$

It follows from Euler's theorem that the order of an integer is well-defined – the order of any integer coprime to the modulus is surely not greater than  $\varphi(m)$ . As we will see later, the integers whose order is exactly  $\varphi(m)$  are of great interest – they are called *primitive roots* modulo  $m$  and they play an important role in solving binomial congruences, among others. This concept is just another name for a generator of the group  $(\mathbb{Z}_m^\times, \cdot)$ .

Some of the very basic results of the order are demonstrated in 11.C.19, and complete description of the dependency of the order upon the exponent is given by the subsequent two theorems.

**Theorem.** Let  $m \in \mathbb{N}$ ,  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ . Let  $r$  denote the order of  $a$  modulo  $m$ . Then, for any  $t, s \in \mathbb{N}_0$ , we have

$$a^t \equiv a^s \pmod{m} \iff t \equiv s \pmod{r}.$$

**PROOF.** Without loss of generality, we can assume that  $t \geq s$ . Dividing the integer  $t - s$  by  $r$  with remainder, we get  $t - s = q \cdot r + z$ , where  $q, z \in \mathbb{N}_0, 0 \leq z < r$ .

“ $\Leftarrow$ ” Since  $t \equiv s \pmod{r}$ , we have  $z = 0$ , hence  $a^{t-s} = a^{qr} = (a^r)^q \equiv 1^q \pmod{m}$ . Multiplying both sides of the congruence by the integer  $a^s$  leads to the wanted statement.

“ $\Rightarrow$ ” It follows from  $a^t \equiv a^s \pmod{m}$  that  $a^s \cdot a^{qr+z} \equiv a^s \pmod{m}$ . Since  $a^r \equiv 1 \pmod{m}$ , we also have  $a^{qr+z} \equiv a^z \pmod{m}$ . Altogether, after dividing both sides of the first congruence by the integer  $a^s$  (which is coprime to the modulus), we get  $a^z \equiv 1 \pmod{m}$ . Since

Now, we will go through the potential primitive roots in ascending order:

$$g = 2 : \quad 2^8 = 2^5 \cdot 2^3 \equiv -9 \cdot 8 \equiv 10 \pmod{41},$$

$$2^{20} = (2^5)^4 \equiv (-9)^4 = 81^2 \equiv (-1)^2$$

$$\equiv 1 \pmod{41},$$

$$g = 3 : \quad 3^8 = (3^4)^2 \equiv (-1)^2 = 1 \pmod{41},$$

$g = 4$  : the order of 4 = 2<sup>2</sup> always divides the order 2,

$$g = 5 : \quad 5^8 = (5^2)^4 \equiv (-2^4)^4 = 2^{16} = (2^8)^2$$

$$\equiv 10^2 \equiv 18 \pmod{41},$$

$$5^{20} = (5^2)^{10} \equiv (-2^4)^{10} = 2^{40} = (2^{20})^2$$

$$\equiv 1 \pmod{41},$$

$$g = 6 : \quad 6^8 = 2^8 \cdot 3^8 \equiv 10 \cdot 1 = 10 \pmod{41},$$

$$6^{20} = 2^{20} \cdot 3^{20} \equiv 2^{20} \cdot (3^8)^2 \cdot 3^4$$

$$\equiv 1 \cdot 1 \cdot (-1) = -1 \pmod{41}.$$

We have thus proved that 6 is the least positive primitive root modulo 41 (if we were interested in other primitive roots modulo 41 as well, we would get them as the powers of 6 with exponent taking on values from the range 1 to 40 which are coprime to 40. There are exactly  $\varphi(40) = \varphi(2^3 \cdot 5) = 16$  of them, and the resulting remainders modulo 41 are  $\pm 6, \pm 7, \pm 11, \pm 12, \pm 13, \pm 15, \pm 17, \pm 19$ ).

Now, if we prove that  $6^{40} \not\equiv 1 \pmod{41^2}$ , we will know that 6 is a primitive root modulo any power of 41 (if we had “bad luck” and found out that  $6^{40} \equiv 1 \pmod{41^2}$ , then a primitive root modulo  $41^2$  would be  $47 = 6 + 41$ ). To avoid manipulating huge numbers when verifying the condition, we will use several tricks (the so-called residue number system).

First of all, we calculate the remainder of  $6^8$  upon division by  $41^2$ ; this problem can be further reduced to computing the remainders of the integers  $2^8$  and  $3^8$ :

$$2^8 = 256 = 6 \cdot 41 + 10 \pmod{41^2},$$

$$3^8 = (3^4)^2 = (2 \cdot 41 - 1)^2 \equiv -4 \cdot 41 + 1 \pmod{41^2}.$$

Then,

$$6^8 = 2^8 \cdot 3^8 \equiv (6 \cdot 41 + 10)(-4 \cdot 41 + 1)$$

$$\equiv -34 \cdot 41 + 10 \equiv 7 \cdot 41 + 10 \pmod{41^2}$$

and

$$6^{40} = (6^8)^5 \equiv (7 \cdot 41 + 10)^5 \equiv (10^5 + 5 \cdot 7 \cdot 41 \cdot 10^4)$$

$$= 10^4(10 + 35 \cdot 41) \equiv (-2 \cdot 41 - 4)(-6 \cdot 41 + 10)$$

$$\equiv (4 \cdot 41 - 40) = 124 \not\equiv 1 \pmod{41^2}.$$

In the calculation, we made use of the fact that  $10^4 = 6 \cdot 41^2 - 86$ , i.e.,  $10^4 \equiv -2 \cdot 41 - 4 \pmod{41^2}$ .

Therefore, 6 is a primitive root modulo  $41^2$ , and since it is an even integer, we can see that  $1687 = 6 + 41^2$  is a primitive root modulo  $2 \cdot 41^2$  (while the least positive primitive root modulo  $2 \cdot 41^2$  is the integer 7).  $\square$

$z < r$ , it follows from the definition of the order that  $z = 0$ , hence  $r \mid t - s$ .  $\square$

The above theorem and Euler’s theorem apparently lead to the following corollary (whose second part is only a reformulation of Lagrange’s theorem 12.4.10 for our situation):

**Corollary.** Let  $m \in \mathbb{N}$ ,  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ , and  $r$  be the order of  $a$  modulo  $m$ .

(1) For any  $n \in \mathbb{N} \cup \{0\}$ , it holds that

$$a^n \equiv 1 \pmod{m} \iff r \mid n.$$

(2)  $r \mid \varphi(m)$

**11.3.14.** The following theorem is a generalization of the result in 11.C.20.

**Theorem.** Let  $m, n \in \mathbb{N}$ ,  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ . If the order of  $a$  modulo  $m$  is  $r$ , then the order of  $a^n$  modulo  $m$  is  $\frac{r}{(r,n)}$ .

**PROOF.** Since  $\frac{r \cdot n}{(r,n)} = [r, n]$ , which is clearly a multiple of  $r$ , we have

$$(a^n)^{\frac{r}{(r,n)}} = a^{[r,n]} \equiv 1 \pmod{m}$$

(the last statement follows from the above corollary, because  $r \mid [r, n]$ ). On the other hand, if  $k \in \mathbb{N}$  is such that  $(a^n)^k = a^{n \cdot k} \equiv 1 \pmod{m}$ , we get  $r \mid n \cdot k$  (since  $r$  is the order of  $a$ ). Further, we know that  $\frac{r}{(n,r)} \mid \frac{n}{(n,r)} \cdot k$ , whence (thanks to  $\frac{r}{(n,r)}$  and  $\frac{n}{(n,r)}$  being coprime)  $\frac{r}{(n,r)} \mid k$ . Therefore,  $\frac{r}{(n,r)}$  is the order of the integer  $a^n$  modulo  $m$ .  $\square$

The last statement of this series connects the orders of two integers to the order of their product:

**Lemma.** Let  $m \in \mathbb{N}$ ,  $a, b \in \mathbb{Z}$ ,  $(a, m) = (b, m) = 1$ . If  $a$  has order  $r$  and  $b$  has order  $s$  modulo  $m$ , where  $(r, s) = 1$ , then the integer  $a \cdot b$  has order  $r \cdot s$  modulo  $m$ .

**PROOF.** Let  $\delta$  denote the order of  $a \cdot b$ . Then,  $(ab)^\delta \equiv 1 \pmod{m}$ . Raising both sides of this congruence to the  $r$ -th power leads to  $a^{r\delta} b^{r\delta} \equiv 1 \pmod{m}$ . Since  $r$  is the order of  $a$ , we have  $a^r \equiv 1 \pmod{m}$ , i.e.,  $b^{r\delta} \equiv 1 \pmod{m}$ , and so  $s \mid r\delta$ . From  $r$  being coprime to  $s$ , we get  $s \mid \delta$ . Analogously, we can get  $r \mid \delta$ , so (again utilizing that  $r, s$  are coprime)  $r \cdot s \mid \delta$ . On the other hand, we clearly have  $(ab)^{rs} \equiv 1 \pmod{m}$ , hence  $\delta \mid rs$ . Altogether,  $\delta = rs$ .  $\square$

**11.3.15. Primitive roots.** Among the integers coprime to a modulus  $m$  (i.e., the elements of a reduced residue system modulo  $m$ ), the most important ones are those whose order is equal to  $\varphi(m)$ .

Step-by-step exponentiation of such a number yields all possible elements of a reduced residue system (or integers congruent to them). Therefore, in various problems, we can work with powers of a given integer instead of considering random elements of a reduced residue system modulo  $m$ , and this is often much simpler (see, for instance, the proof of the theorem 11.4.10 about binomial coefficients).

**D. Solving congruences**

**Linear congruences.** The following exercise illustrates that the procedure we mentioned in the proof of theorem 11.4.3 about solvability of linear congruences (which invokes Euler’s theorem) is usually not the most efficient one – we can utilize both Bézout’s theorem and equivalent modifications of the given congruence.

**11.D.1.** Solve the congruence

$$39x \equiv 41 \pmod{47}.$$

**Solution.**

- i) First, we use Euler’s theorem. Since  $(39, 47) = 1$ , we have

$$39^{\varphi(47)} = 39^{46} \equiv 1 \pmod{47},$$

i.e.,

$$\underbrace{39^{45} \cdot 39}_{39^{46} \equiv 1} x \equiv 39^{45} \cdot 41 \pmod{47},$$

whence it already follows that

$$x \equiv 39^{45} \cdot 41 \pmod{47}.$$

To complete the solution, it remains to calculate the remainder of  $39^{45} \cdot 41$  when divided by 47, which is left as an exercise to the kind reader, leading to the result  $x \equiv 36 \pmod{47}$ .

- ii) Another option is to make use of Bézout’s theorem. The Euclidean algorithm applied to the pair  $(39, 47)$  yields

$$\begin{aligned} 47 &= 1 \cdot 39 + 8, \\ 39 &= 4 \cdot 8 + 7, \\ 8 &= 1 \cdot 7 + 1. \end{aligned}$$

In the other direction, this leads to

$$\begin{aligned} 1 &= 8 - 7 = 8 - (39 - 4 \cdot 8) = 5 \cdot 8 - 39 \\ &= 5 \cdot (47 - 39) - 39 = 5 \cdot 47 - 6 \cdot 39. \end{aligned}$$

Considering this equality modulo 47 and remembering that we are solving the equation  $41 \equiv x \cdot 39$ , we obtain

$$\begin{aligned} 1 &\equiv -6 \cdot 39 && \pmod{47}, && / \cdot 41 \\ 41 &\equiv \underbrace{41 \cdot (-6)} \cdot 39 && \pmod{47}, \\ x &\equiv 41 \cdot (-6) && \pmod{47}, \\ x &\equiv -246 && \pmod{47}, \\ x &\equiv 36 && \pmod{47}. \end{aligned}$$

Let us notice that this procedure is usually used in the corresponding software tools – it is efficient and can be easily made into an algorithm. It was also important that 41 (the number we multiplied the congruence with) and the modulus 47 are coprime.

PRIMITIVE ROOT

Let  $m \in \mathbb{N}$ . An integer  $g$ ,  $(g, m) = 1$ , is said to be a *primitive root modulo  $m$*  if and only if its order modulo  $m$  equals  $\varphi(m)$ .

**Lemma.** *If  $g$  is a primitive root modulo  $m$ , then for every integer  $a$  such that  $(a, m) = 1$ , there is a unique  $x_a \in \mathbb{Z}$ ,  $0 \leq x_a < \varphi(m)$  with the property that  $g^{x_a} \equiv a \pmod{m}$ .*

The mapping  $a \mapsto x_a$  is called the *discrete logarithm* or *index* of the integer  $a$  (with respect to a given modulus  $m$  and a fixed primitive root  $g$ ), and it is a bijection between the sets  $\{a \in \mathbb{Z}; (a, m) = 1, 0 < a < m\}$  and  $\{x \in \mathbb{Z}; 0 \leq x < \varphi(m)\}$ .

**PROOF.** Suppose that it holds for  $x, y \in \mathbb{Z}$ ,  $0 \leq x, y < \varphi(m)$  that  $g^x \equiv g^y \pmod{m}$ . From the properties of the order, we get  $x \equiv y \pmod{\varphi(m)}$ , i.e.,  $x = y$ , so the mapping is injective. Since it is a mapping between two finite sets which have the same number of elements, it must be surjective as well.  $\square$

If there are primitive roots at all for a natural number  $m$ , then there are exactly  $\varphi(\varphi(m))$  of them among the integers  $1, 2, \dots, m$ : If  $g$  is a primitive root and  $a \in \{1, 2, \dots, \varphi(m)\}$  arbitrary, then the order of  $g^a$  is  $\frac{\varphi(m)}{(a, \varphi(m))}$  (by theorem 11.3.14), which is equal to  $\varphi(m)$  if and only if  $(a, \varphi(m)) = 1$ , and there are exactly  $\varphi(\varphi(m))$  such integers in the set  $\{1, 2, \dots, \varphi(m)\}$ .

Now, we are about to show that primitive roots exist for a sufficient amount of moduli  $m$ .

**11.3.16. Theorem** (Existence of primitive roots). *Let  $m \in \mathbb{N}$ ,  $m > 1$ . The modulus  $m$  has primitive roots if and only if at least one of the following conditions holds:*

- $m = 2$  or  $m = 4$ ,
- $m$  is a power of an odd prime,
- $m$  is twice a power of an odd prime.

The proof of this theorem will be done in several steps. We can easily see that 1 is a primitive root modulo 2 and 3 is a primitive root modulo 4. Further, we will show that primitive roots exist modulo any odd prime (in algebraic words, this is another proof of the fact that the group  $(\mathbb{Z}_m^\times, \cdot)$  of invertible residue classes modulo a prime  $m$  is cyclic; see also 12.4.8).

**Proposition.** *Let  $p$  be an odd prime. Then there are primitive roots modulo  $p$ .*

**PROOF.** Let  $r_1, r_2, \dots, r_{p-1}$  be the orders of the integers  $1, 2, \dots, p - 1$  modulo  $p$ . Let  $\delta = [r_1, r_2, \dots, r_{p-1}]$  be the least common multiple of these orders. We will show that there is an integer of order  $\delta$  among  $1, 2, \dots, p - 1$  and that  $\delta = p - 1$ .

Let  $\delta = q_1^{\alpha_1} \cdots q_k^{\alpha_k}$  be the factorization of  $\delta$  to primes. For every  $s \in \{1, \dots, k\}$ , there is a  $c \in \{1, \dots, p - 1\}$  such that  $q_s^{\alpha_s} \mid r_c$  (otherwise, there would be a common multiple

iii) Concerning paper-and-pencil calculations, the most efficient procedure (yet one not easily generalizable into an algorithm) is to gradually modify the congruence so that the set of solutions remains unchanged:

$$\begin{aligned} 39x &\equiv 41 && (\text{mod } 47), \\ -8x &\equiv -6 && (\text{mod } 47), && / : -2 \\ 4x &\equiv 3 && (\text{mod } 47), \\ 4x &\equiv -44 && (\text{mod } 47), && / : 4 \\ x &\equiv -11 && (\text{mod } 47), \\ x &\equiv 36 && (\text{mod } 47). \end{aligned}$$

□

**Systems of congruences.** In order to solve system of (not only linear) congruences, we will often utilize the Chinese remainder theorem, which guarantees uniqueness of the solution provided the moduli of the particular congruences are pairwise coprime.

**11.D.2.** Solve the system

$$\begin{aligned} x &\equiv 7 \pmod{27}, \\ x &\equiv -3 \pmod{11}. \end{aligned}$$

**Solution.** As  $(27, 11) = 1$ , we are guaranteed by the Chinese remainder theorem that the solution is unique modulo  $27 \cdot 11 = 297$ . There are two major possible approaches to finding the solution.

(a) Using the Euclidean algorithm, we can find the coefficients in Bézout's identity:  $1 = 5 \cdot 11 - 2 \cdot 27$ . Hence,  $[11]_{27}^{-1} = [5]_{27}$  and  $[27]_{11}^{-1} = [-2]_{11}$ . Therefore, the solution is  $x \equiv 7 \cdot 11 \cdot 5 - 3 \cdot 27 \cdot (-2) = 547 \equiv 250 \pmod{297}$ .

(b) Using step-by-step substitution, we get  $x = 11t - 3$  from the second congruence. Substituting this into the first one leads to  $11t \equiv 10 \pmod{27}$ . Multiplying this by 5 yields  $55t \equiv 50$ , i.e.,  $t \equiv -4 \pmod{27}$ . Altogether,  $x = 11 \cdot 27 \cdot s - 4 \cdot 11 - 3 = 297s - 47$  for  $s \in \mathbb{Z}$ , i.e.,  $x \equiv -47 \pmod{297}$ . □

**11.D.3.** Solve the following system of congruences:

$$\begin{aligned} x &\equiv 1 \pmod{10}, \\ x &\equiv 5 \pmod{18}, \\ x &\equiv -4 \pmod{25}. \end{aligned}$$

**Solution.** The integers  $x$  which satisfy the first congruence are those of the form  $x = 1 + 10t$ , where  $t \in \mathbb{Z}$  may be arbitrary. We will substitute this expression into the second congruence and then solve it (as a congruence in variable  $t$ ):

$$\begin{aligned} 1 + 10t &\equiv 5 \pmod{18}, \\ 10t &\equiv 4 \pmod{18}, \\ 5t &\equiv 2 \pmod{9}, \\ 5t &\equiv 20 \pmod{9}, \\ t &\equiv 4 \pmod{9}, \end{aligned}$$

of the integers  $r_1, r_2, \dots, r_{p-1}$  less than  $\delta$ ). Therefore, there exists an integer  $b$  such that  $r_c = b \cdot q_s^{\alpha_s}$ . Since  $c$  has order  $r_c$ , the order of the integer  $g_s := c^b$  is equal to  $q_s^{\alpha_s}$  (by the theorem 11.3.14 on orders of powers).

Reasoning analogously for any  $s \in \{1, \dots, k\}$ , we get integers  $g_1, \dots, g_k$ , and we can set  $g := g_1 \cdots g_k$ . From the properties of the order of a product, we get that the order of  $g$  is equal to the product of the orders of the integers  $g_1, \dots, g_k$ , i.e. to  $q_1^{\alpha_1} \cdots q_k^{\alpha_k} = \delta$ .

Now, we prove that  $\delta = p - 1$ . Since the orders of the integers  $1, 2, \dots, p - 1$  divide  $\delta$ , we get the congruence  $x^\delta \equiv 1 \pmod{p}$  for any  $x \in \{1, 2, \dots, p - 1\}$ . By theorem 11.4.8, there are at most  $\delta$  solutions to a congruence of degree  $\delta$  modulo a prime  $p$  (in algebraic words, we are actually looking for roots of a polynomial over a field, and there cannot be more of them than the degree of the polynomial, as we will see in part 12.3.4). On the other hand, we have already shown that this congruence has  $p - 1$  solutions, so necessarily  $\delta \geq p - 1$ . Still,  $\delta$  is (being the order of  $g$ ) a divisor of  $p - 1$ , whence we finally get the wanted equality  $\delta = p - 1$ . □

**11.3.17.** Next, we show that there are primitive roots modulo powers of odd primes. First, we prove two helpful lemmas and then comes the proposition.

**Lemma.** Let  $p$  be an odd prime,  $\ell \geq 2$  arbitrary. Then, it holds for any  $a \in \mathbb{Z}$  that

$$(1 + ap)^{p^{\ell-2}} \equiv 1 + ap^{\ell-1} \pmod{p^\ell}.$$

**PROOF.** This will follow easily from the binomial theorem using mathematical induction on  $\ell$ .

I. The statement is clearly true for  $\ell = 2$ .

II. Let the statement be true for  $\ell$ , and let us prove it for  $\ell + 1$ . Invoking exercise 11.C.7 and raising the statement for  $\ell$  to the  $p$ -th power, we obtain

$$(1 + ap)^{p^{\ell-1}} \equiv (1 + ap^{\ell-1})^p \pmod{p^{\ell+1}}.$$

It follows from the binomial theorem that

$$(1 + ap^{\ell-1})^p = 1 + p \cdot a \cdot p^{\ell-1} + \sum_{k=2}^p \binom{p}{k} a^k p^{(\ell-1)k}$$

and since we have  $p \mid \binom{p}{k}$  for  $1 < k < p$  (by exercise 11.C.6), it suffices to show that  $p^{\ell+1} \mid p^{1+(\ell-1)k}$ , which is equivalent to  $1 \leq (k - 1)(\ell - 1)$ . Thanks to the assumption  $\ell \geq 2$ , we get that  $p^{\ell+1} \mid p^{(\ell-1)p}$  for  $k = p$  as well. □

**Lemma.** Let  $p$  be an odd prime,  $\ell \geq 2$  arbitrary. Then, it holds for any integer  $a$  satisfying  $p \nmid a$  that the order of  $1 + ap$  modulo  $p^\ell$  equals  $p^{\ell-1}$ .

**PROOF.** By the previous lemma, we have

$$(1 + ap)^{p^{\ell-1}} \equiv 1 + ap^\ell \pmod{p^{\ell+1}},$$

and considering this congruence modulo  $p^\ell$ , we get  $(1 + ap)^{p^{\ell-1}} \equiv 1 \pmod{p^\ell}$ . At the same time, it follows directly from the previous lemma and  $p$  not being a divisor of  $a$  that

or  $t = 4 + 9s$ , where  $s \in \mathbb{Z}$  is arbitrary. The first two congruences are thus satisfied by exactly those integers  $x$  which are of the form  $x = 1 + 10t = 1 + 10(4 + 9s) = 41 + 90s$ .

Once again, this can be substituted into the third congruence and then solved:

$$\begin{aligned} 41 + 90s &\equiv -4 \pmod{25}, \\ 90s &\equiv 5 \pmod{25}, \\ 18s &\equiv 1 \pmod{5}, \\ 3s &\equiv 6 \pmod{5}, \\ s &\equiv 2 \pmod{5}, \end{aligned}$$

or  $s = 2 + 5r$ , where  $r \in \mathbb{Z}$ . Altogether,  $x = 41 + 90s = 41 + 90(2 + 5r) = 221 + 450r$ .

Therefore, the system is satisfied by those integers  $x$  with  $x \equiv 221 \pmod{450}$ .  $\square$

**11.D.4.** A group of thirteen pirates managed to steal a chest full of gold coins (there were around two thousand of them). The pirates tried to divide them evenly among themselves, but ten coins were left over. They started to fight for the remaining coins, and one of the pirates was deadly stabbed during the combat. So, they tried to divide the coins evenly once again, and now three coins were left. Another pirate died in a subsequent battle for the three coins. The remaining pirates tried to divide the coins evenly for the third time, now successfully. How many coins were there in the chest?

**Solution.** The problem leads to the following system of congruences:

$$\begin{aligned} x &\equiv 10 \pmod{13}, \\ x &\equiv 3 \pmod{12}, \\ x &\equiv 0 \pmod{11}. \end{aligned}$$

Its solution is  $x \equiv 231 \pmod{11 \cdot 12 \cdot 13}$ . Since the number  $x$  of coins is to be around 2000 and  $x \equiv 231 \pmod{1716}$ , we can easily settle that there were exactly  $231 + 1716 = 1947$  coins.  $\square$

**11.D.5.** When gymnasts made groups of eight people, three were left over. When they formed circles, each consisting of seventeen people, seven remained; and when they grouped into pyramids (each of them contains  $21 = 4^2 + 2^2 + 1$  gymnasts), two of them were incomplete (missing a person “on the top”). How many gymnasts were there, provided there were at least 2000 and at most 4000?

**Solution.** We solve the following system of linear congruences in the standard way:

$$\begin{aligned} c &\equiv 3 \pmod{8}, \\ c &\equiv 7 \pmod{17}, \\ c &\equiv -2 \pmod{21}, \end{aligned}$$

$(1 + ap)^{p^{\ell-2}} \not\equiv 1 \pmod{p^\ell}$ , which gives the wanted proposition.  $\square$

**Proposition.** Let  $p$  be an odd prime. Then, for every  $\ell \in \mathbb{N}$ , there is a primitive root modulo  $p^\ell$ .

**PROOF.** Let  $g$  be a primitive root modulo  $p$ . We will show that if  $g^{p-1} \not\equiv 1 \pmod{p^2}$ , then  $g$  is a primitive root even modulo  $p^\ell$  for any  $\ell \in \mathbb{N}$ . (If we had  $g^{p-1} \equiv 1 \pmod{p^2}$ , then  $(g + p)^{p-1} \equiv 1 + (p-1)g^{p-2}p \not\equiv 1 \pmod{p^2}$ , so we could choose  $g + p$  for the original primitive root instead of the congruent integer  $g$ .)

Let  $g$  satisfy  $g^{p-1} \not\equiv 1 \pmod{p^2}$ . Then, there is an  $a \in \mathbb{Z}$ ,  $p \nmid a$  such that  $g^{p-1} = 1 + p \cdot a$ . We will show that the order of  $g$  modulo  $p^\ell$  is  $\varphi(p^\ell) = (p-1)p^{\ell-1}$ . Let  $n$  be the least natural number which satisfies  $g^n \equiv 1 \pmod{p^\ell}$ . By the previous lemma, the order of  $g^{p-1} = 1 + p \cdot a$  modulo  $p^\ell$  is  $p^{\ell-1}$ . However, then it follows from the corollary of 11.3.13 that

$$(g^{p-1})^n = (g^n)^{p-1} \equiv 1 \pmod{p^\ell} \implies p^{\ell-1} \mid n.$$

At the same time, the congruence  $g^n \equiv 1 \pmod{p}$  implies that  $p-1 \mid n$ . From  $p-1$  and  $p^{\ell-1}$  being coprime, we get that  $(p-1)p^{\ell-1} \mid n$ . Therefore,  $n = \varphi(p^\ell)$ , and  $g$  is thus a primitive root modulo  $p^\ell$ .  $\square$

**11.3.18.** Our next task is to deal with the existing primitive roots in form of multiples of two.

**Proposition.** Let  $p$  be an odd prime and  $g$  a primitive root modulo  $p^\ell$  for  $\ell \in \mathbb{N}$ . Then the odd one of the integers  $g, g+p^\ell$  is a primitive root modulo  $2p^\ell$ .

**PROOF.** Let  $c$  be an odd natural number. Then, for every  $n \in \mathbb{N}$ , we have  $c^n \equiv 1 \pmod{p^\ell}$  if and only if  $c^n \equiv 1 \pmod{2p^\ell}$ . Since  $\varphi(2p^\ell) = \varphi(p^\ell)$ , every odd primitive root modulo  $p^\ell$  is also a primitive root modulo  $2p^\ell$ .  $\square$

The subsequent proposition describes the case of powers of two. We will use similar helping lemmas as in the case of odd primes.

**Lemma.** Let  $\ell \in \mathbb{N}$ ,  $\ell \geq 3$ . Then  $5^{2^{\ell-3}} \equiv 1 + 2^{\ell-1} \pmod{2^\ell}$ .

**PROOF.** Similarly as above for  $2 \nmid p$ .  $\square$

**Lemma.** Let  $\ell \in \mathbb{N}$ ,  $\ell \geq 3$ . Then the order of the integer 5 modulo  $2^\ell$  is  $2^{\ell-2}$ .

**PROOF.** Easily from the above lemma.  $\square$

**Proposition.** Let  $\ell \in \mathbb{N}$ . There are primitive roots modulo  $2^\ell$  if and only if  $\ell \leq 2$ .

**PROOF.** Let  $\ell \geq 3$ . Then the set

$$S = \{(-1)^a \cdot 5^b; a \in \{0, 1\}, 0 \leq b < 2^{\ell-2}; b \in \mathbb{Z}\}$$

forms a reduce residue system modulo  $2^\ell$ : it has  $\varphi(2^\ell)$  elements, and it can be easily verified that they are pairwise incongruent modulo  $2^\ell$ .

leading to the solution  $c \equiv 1027 \pmod{2856}$ , which, together with the additional information, implies that there were exactly 3883 gymnasts.  $\square$

**11.D.6.** Find which of the following (systems of) linear congruences has a solution.

- i)  $x \equiv 1 \pmod{3}$ ,  
 $x \equiv -1 \pmod{9}$ ;
- ii)  $8x \equiv 1 \pmod{12345678910111213}$ ;
- iii)  $x \equiv 3 \pmod{29}$ ,  
 $x \equiv 5 \pmod{47}$ .  $\circ$

The Chinese remainder theorem can also be used “in the opposite direction”, i.e. to simplify a linear congruence provided we are able to express the modulus as a product of pairwise coprime factors.

**11.D.7.** Solve the congruence  $23\,941x \equiv 915 \pmod{3564}$ .

**Solution.** Let us factor  $3564 = 2^2 \cdot 3^4 \cdot 11$ . Since none of the integers 2, 3, 11 divides 23 941, we have  $(23\,941, 3564) = 1$ , so the congruence has a solution. Since  $\varphi(3564) = 2 \cdot (3^3 \cdot 2) \cdot 10 = 1080$ , the solution is of the form  $x \equiv 915 \cdot 23\,941^{1079} \pmod{3564}$ . However, it would take much effort to simplify the right-hand integer to a more explicit form. Therefore, we will try to solve the congruence in a different way – we will build an equivalent system of congruences which are easier to solve than the original one.

We know that an integer  $x$  is a solution of the given congruence if and only if it is a solution of the system

$$\begin{aligned} 23941x &\equiv 915 \pmod{2^2}, \\ 23941x &\equiv 915 \pmod{3^4}, \\ 23941x &\equiv 915 \pmod{11}. \end{aligned}$$

Solving these congruences separately, we get the following, equivalent system:

$$\begin{aligned} x &\equiv 3 \pmod{4}, \\ x &\equiv -3 \pmod{81}, \\ x &\equiv -4 \pmod{11}. \end{aligned}$$

Now, the procedure for finding a solution of a system of congruences yields  $x \equiv -1137 \pmod{3564}$ , which is the solution of the original congruence as well.  $\square$

**11.D.8.** Solve the congruence  $3446x \equiv 8642 \pmod{208}$ .  $\circ$

**11.D.9.** Prove that the sequence  $(2^n - 3)_{n=1}^\infty$  contains infinitely many multiples of 5 as well as infinitely many multiples of 13, yet there is no multiple of 65 in it.  $\circ$

**Residue number system.** When calculating with large integers, it is often more advantageous to work not with their decimal or binary expansions, but rather with their representation in a so-called *residue number system*, which allows for easy parallelization of computations with large integers. Such a system is given by a  $k$ -tuple of (usually pairwise coprime) moduli, and each integer which

At the same time (utilizing the previous lemma), the order of every element of  $S$  apparently divides  $2^{\ell-2}$ . Therefore, this reduced system cannot (and nor can any other) contain an element of order  $\varphi(2^\ell) = 2^{\ell-1}$ .  $\square$

**11.3.19.** The last piece to the jigsaw puzzle of propositions which collectively prove theorem 11.3.16 is the statement about non-existence of primitive roots for composite numbers which are neither a power of prime nor twice such.

**Proposition.** Let  $m \in \mathbb{N}$  be divisible by at least two primes, and let it not be twice a power of an odd prime. Then, there are no primitive roots modulo  $m$ .

**PROOF.** Let  $m$  factor to primes as  $2^\alpha p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ , where  $\alpha \in \mathbb{N}_0, \alpha_i \in \mathbb{N}, 2 \nmid p_i$ , and  $k \geq 2$  or both  $k \geq 1$  and  $\alpha \geq 2$ . Denoting  $\delta = [\varphi(2^\alpha), \varphi(p_1^{\alpha_1}), \dots, \varphi(p_1^{\alpha_1})]$ , we can easily see that  $\delta < \varphi(2^\alpha) \cdot \varphi(p_1^{\alpha_1}) \cdots \varphi(p_1^{\alpha_1}) = \varphi(m)$  and that for any  $a \in \mathbb{Z}, (a, m) = 1$ , we have  $a^\delta \equiv 1 \pmod{m}$ . Therefore, there are no primitive roots modulo  $m$ .  $\square$

**11.3.20.** In general, it is computationally very hard to find a primitive root for a given modulus. The following theorem describes a necessary and sufficient condition for the examined integer to be a primitive root.

**Theorem.** Let  $m$  be such an integer that there are primitive roots modulo  $m$ . Let us write  $\varphi(m) = q_1^{\alpha_1} \cdots q_k^{\alpha_k}$ , where  $q_1, \dots, q_k$  are primes and  $\alpha_1, \dots, \alpha_k \in \mathbb{N}$ . Then, for every  $g \in \mathbb{Z}, (g, m) = 1$ , it holds that  $g$  is a primitive root modulo  $m$ , if and only if neither of the following congruences holds:

$$g^{\frac{\varphi(m)}{q_1}} \equiv 1 \pmod{m}, \dots, g^{\frac{\varphi(m)}{q_k}} \equiv 1 \pmod{m}.$$

**PROOF.** If either of the congruences were true, it would mean that the order of  $g$  is less than  $\varphi(m)$ .

On the other hand, if  $g$  fails to be a primitive root, then there is a  $d \in \mathbb{N}, d \mid \varphi(m)$ , where  $d < \varphi(m)$  and  $g^d \equiv 1 \pmod{m}$ . If  $u = \frac{\varphi(m)}{d} > 1$ , then there must be an  $i \in \{1, \dots, k\}$  such that  $q_i \mid u$ . However, then we get

$$g^{\frac{\varphi(m)}{q_i}} = g^{d \cdot \frac{u}{q_i}} \equiv 1 \pmod{m}.$$

$\square$

#### 4. Solving congruences and systems of them

This part will be devoted to the analog to solving equations in a numerical domain. We will actually be solving equations (and systems of equations) in the ring of residue classes  $(\mathbb{Z}_m, +, \cdot)$ ; we will, however, talk about solving congruences modulo  $m$  and write it in the more transparent way as usual.

is less than their product is then uniquely representable as a  $k$ -tuple of remainders (whose values do not exceed the moduli).

**11.D.10.** The quintuple of moduli 3, 5, 7, 11, 13 can serve to uniquely represent integers which are less than their product (i.e. less than 15015) and to perform standard arithmetic operations efficiently (and in a distributed manner if desired). Now, we will determine the representation of the integers 1234 and 5678 in this residue number system and we will determine their sum and product.

**Solution.** Calculating the remainders of the given integers upon division by the particular moduli, we get their RNS representations, which can be written as the tuples (1, 4, 2, 2, 12) and (2, 3, 1, 2, 10).

The sum is computed componentwise (reducing the results modulo the appropriate number), leading to the tuple (0, 2, 3, 4, 9). Using the Chinese remainder theorem, this tuple can then be transformed back to the integer 6912. The product is computed analogously, yielding the corresponding tuple (2, 2, 2, 4, 3), which can be transformed back to 9662 (by the Chinese remainder theorem again). This is indeed congruent to  $1234 \cdot 5678$  modulo 15015.  $\square$

**11.D.11.** In practice, the residue number system is often a triple  $2^n - 1, 2^n, 2^n + 1$  (why are these integers always coprime?), which can uniquely cover integers of  $3n$  bits at the utmost.

Consider the case  $n = 3$  and determine the representation of the integer 118 in this residue number system.

**Solution.** We can directly calculate that  $118 \equiv 6 \pmod{7}$ ,  $118 \equiv 6 \pmod{8}$ , and  $118 \equiv 1 \pmod{9}$ . The wanted representation is thus given by the triple (6, 6, 1).

In practice, however, it is very important that the RNS representation can be efficiently transformed to binary and vice versa. In our concrete case, the remainder of  $118 = (1110110)_2$  when divided by  $2^3$  can be found easily – it is the last three bits  $(110)_2 = 6$ . Computing the remainder upon division by  $2^3 + 1 = 9$  or  $2^3 - 1 = 7$  is not any more complicated. We can see (splitting the examined integer into three groups of  $n$  bits each) that

$$(1110110)_2 \equiv (001)_2 + (110)_2 + (110)_2 \equiv 6 \pmod{2^3 - 1},$$

$$(1110110)_2 \equiv (001)_2 - (110)_2 + (110)_2 \equiv 1 \pmod{2^3 + 1}.$$

A thoughtful reader has surely noticed the similarity with the criteria for divisibility by 9 and 11, which were discussed in paragraph 11.C.9.  $\square$

**11.D.12. Higher-order congruences.** Using the procedure of theorem 11.4.6, solve the congruence

$$x^4 + 7x + 4 \equiv 0 \pmod{27}.$$

**Solution.** First, we will solve this congruence modulo 3 (by substitution, for instance) – we can easily find that the solution

CONGRUENCE IN ONE VARIABLE

Let  $m \in \mathbb{N}$ ,  $f(x), g(x) \in \mathbb{Z}[x]$ . The notation

$$f(x) \equiv g(x) \pmod{m}$$

is called a *congruence in variable  $x$* , and it is understood to be the problem of finding the *set of solutions*, i.e., the set of all such integers  $c$  for which  $f(c) \equiv g(c) \pmod{m}$ .

Two congruences (in one variable) are called *equivalent* if and only if they have the same set of solutions.

The mentioned congruence is equivalent to the congruence

$$f(x) - g(x) \equiv 0 \pmod{m}.$$

The only method which always leads to a solution is trying out all possible values (however, this would, of course, often take too much time). This procedure is formalized by the following proposition.

**11.4.1. Proposition.** Let  $m \in \mathbb{N}$ ,  $f(x) \in \mathbb{Z}[x]$ . Then, it holds for every  $a, b \in \mathbb{Z}$  that

$$a \equiv b \pmod{m} \implies f(a) \equiv f(b) \pmod{m}.$$

**PROOF.** Let  $f(x) = c_n x^n + c_{n-1} x^{n-1} + \dots + c_1 x + c_0$ , where  $c_0, c_1, \dots, c_n \in \mathbb{Z}$ . Since  $a \equiv b \pmod{m}$ ,  $c_i a^i \equiv c_i b^i \pmod{m}$  holds for every  $i = 0, 1, \dots, n$ . Adding up these congruences for  $i = 0, 1, 2, \dots, n$  leads to

$$c_n a^n + \dots + c_1 a + c_0 \equiv c_n b^n + \dots + c_1 b + c_0 \pmod{m},$$

i.e.,  $f(a) \equiv f(b) \pmod{m}$ .  $\square$

**Corollary.** The set of solutions of an arbitrary congruence modulo  $m$  is a union of residue classes modulo  $m$ .

**Definition.** The number of solutions of a congruence in one variable modulo  $m$  is the number of residue classes modulo  $m$  containing the solutions of the congruence.

**Example.** The concept *number of solutions of a congruence*, which we have just defined, is a bit counterintuitive in that it depends on the modulus of the congruence. Therefore, equivalent congruences (sharing the same integers as solutions) can have different numbers of solutions.

- (1) The congruence  $2x \equiv 3 \pmod{3}$  has exactly one solution (modulo 3).
- (2) The congruence  $10x \equiv 15 \pmod{15}$  has five solutions (modulo 15).
- (3) The congruences from (1) and (2) are equivalent.

**11.4.2. Linear congruence in one variable.** Just like in the case of ordinary equations, the easiest congruences are the linear ones, for which we are able not only to decide whether they have a solution, but to efficiently find it (provided they have some). The procedure is described by the following theorem and its proof.

**11.4.3. Theorem.** Let  $m \in \mathbb{N}$ ,  $a, b \in \mathbb{Z}$ , and  $d = (a, m)$ . Then the congruence (in variable  $x$ )

$$ax \equiv b \pmod{m}$$

is  $x \equiv 1 \pmod{3}$ . Now, writing the solution in the form  $x = 1 + 3t$ , where  $t \in \mathbb{Z}$ , we will solve the congruence modulo 9:

$$\begin{aligned} x^4 + 7x + 4 &\equiv 0 \pmod{9}, \\ (1 + 3t)^4 + 7(1 + 3t) + 4 &\equiv 0 \pmod{9}, \\ 1 + 4 \cdot 3t + 7 + 7 \cdot 3t + 4 &\equiv 0 \pmod{9}, \\ 33t &\equiv -12 \pmod{9}, \\ 11t &\equiv -4 \pmod{3}, \\ t &\equiv 1 \pmod{3}. \end{aligned}$$

Writing  $t = 1 + 3s$ , where  $s \in \mathbb{Z}$ , we get  $x = 4 + 9s$ , and substituting this leads to

$$\begin{aligned} (4 + 9s)^4 + 7(4 + 9s) + 4 &\equiv 0 \pmod{27}, \\ 4^4 + 4 \cdot 4^3 \cdot 9s + 28 + 63s + 4 &\equiv 0 \pmod{27}, \\ 256 \cdot 9s + 63s &\equiv -288 \pmod{27}, \\ 256s + 7s &\equiv -32 \pmod{3}, \\ 2s &\equiv 1 \pmod{3}, \\ s &\equiv 2 \pmod{3}. \end{aligned}$$

Altogether, we get the solution in the form  $x = 4 + 9s = 4 + 9(2 + 3r) = 22 + 27r$ , where  $r \in \mathbb{Z}$ , i.e.,  $x \equiv 22 \pmod{27}$ .  $\square$

**11.D.13.** Knowing a primitive root modulo 41 from exercise 11.C.29, solve the congruence

$$7x^{17} \equiv 11 \pmod{41}.$$

**Solution.** Multiplying the congruence by 6, we get an equivalent congruence  $42x^{17} \equiv 66$ , i.e.,  $x^{17} \equiv 25 \pmod{41}$ . Since 6 is a primitive root modulo 41, the substitution  $x = 6^t$  leads to the congruence  $6^{17t} \equiv 25 \equiv 6^4 \pmod{41}$ , which is equivalent to  $17t \equiv 4 \pmod{40}$ , and this holds if and only if  $t \equiv 12 \pmod{40}$ . Therefore, the congruence is satisfied by exactly those integers  $x$  with  $x \equiv 6^{12} \equiv 4 \pmod{41}$ .  $\square$

**11.D.14.** Solve the congruence  $x^5 + 1 \equiv 0 \pmod{11}$ .

**Solution.** Since  $(5, \varphi(11)) = 5$  and

$$(-1)^{\frac{\varphi(11)}{5}} \equiv 1 \pmod{11},$$

the congruence

$$x^5 \equiv -1 \pmod{11}$$

has five solutions. There are several possibilities how to find them. We can either try all (ten) candidates or transform the problem to a linear congruence using the primitive-root trick. Since  $2^{10/2} \equiv -1 \not\equiv 1 \pmod{11}$  and  $2^{10/5} \equiv 4 \not\equiv 1 \pmod{11}$ , 2 is a primitive root modulo 11 (see also exercise 11.C.28), and the substitution  $x \equiv 2^y$  then transforms the congruence to

$$2^{5y} \equiv 2^5 \pmod{11},$$

has a solution if and only if  $d \mid b$ .

If  $d \mid b$ , then this congruence has exactly  $d$  solutions (modulo  $m$ ).

**PROOF.** First, we prove that the mentioned condition is necessary. If an integer  $c$  is a solution of this congruence, then we must have  $m \mid a \cdot c - b$ . Since  $d = (a, m)$ , we get  $d \mid m$  and  $d \mid a \cdot c - b$ , so  $d \mid a \cdot c - (a \cdot c - b) = b$ .

Now, we will prove that if  $d \mid b$ , then the given congruence has exactly  $d$  solutions modulo  $m$ . Let  $a_1, b_1 \in \mathbb{Z}$  and  $m_1 \in \mathbb{N}$  so that  $a = d \cdot a_1$ ,  $b = d \cdot b_1$ , and  $m = d \cdot m_1$ . The congruence we are trying to solve is thus equivalent to the congruence

$$a_1 \cdot x \equiv b_1 \pmod{m_1},$$

where  $(a_1, m_1) = 1$ . This congruence can be multiplied by the integer  $a_1^{\varphi(m_1)-1}$ , which, by Euler's theorem, leads to

$$x \equiv b_1 \cdot a_1^{\varphi(m_1)-1} \pmod{m_1}.$$

This congruence has a unique solution modulo  $m_1$ , thus it has  $d = m/m_1$  solutions modulo  $m$ .  $\square$

Using the theorem about solutions of linear congruences, we can, among others, prove Wilson's theorem – an important theorem which gives a necessary (and sufficient) condition for an integer to be a prime. Such conditions are extremely useful in computational number theory, where one needs to efficiently determine whether a given large integer is a prime. Unfortunately, it is not known now how fast modular factorial of a large integer can be computed. That is why Wilson's theorem is not used for this purpose in practice.

**Theorem (Wilson).** A natural number  $n > 1$  is a prime if and only if

$$(n - 1)! \equiv -1 \pmod{n}.$$

**PROOF.** First, we prove that every composite number  $n > 4$  satisfies  $n \mid (n - 1)!$ , i.e.,  $(n - 1)! \equiv 0 \pmod{n}$ . Let  $1 < d < n$  be a non-trivial divisor of  $n$ . If  $d \neq n/d$ , then the inequality  $1 < d, n/d \leq n - 1$  implies what we need:  $n = d \cdot n/d \mid (n - 1)!$ . If  $d = n/d$ , i.e.,  $n = d^2$ , then we have  $d > 2$  (since  $n > 4$ ) and  $n \mid (d \cdot 2d) \mid (n - 1)!$ . For  $n = 4$ , we easily get  $(4 - 1)! \equiv 2 \not\equiv -1 \pmod{4}$ .

Now, let  $p$  be a prime. The integers in the set  $\{2, 3, \dots, p - 2\}$  can be grouped by pairs of those mutually inverse modulo  $p$ , i.e., pairs of integers whose product is congruent to 1. By the previous theorem, for every integer  $a$  of this set, there is a unique solution of the congruence  $a \cdot x \equiv 1 \pmod{p}$ . Since  $a \neq 0, 1, p - 1$ , it is apparent that the solution  $c$  of the congruence also satisfies  $c \not\equiv 0, 1, -1 \pmod{p}$ . The integer  $a$  cannot be paired with itself, either: If so, i.e.,  $a \cdot a \equiv 1 \pmod{p}$ , we would (thanks to  $p \mid a^2 - 1 = (a + 1)(a - 1)$ ) get the congruence  $a \equiv \pm 1 \pmod{p}$ . The product of the integers of the mentioned set thus consists of products of  $(p - 3)/2$  pairs (whose product is always congruent to 1 modulo  $p$ ). Therefore, we have

$$(p - 1)! \equiv 1^{(p-3)/2} \cdot (p - 1) \equiv -1 \pmod{p}. \quad \square$$

which is equivalent to the linear congruence

$$\begin{aligned} 5y &\equiv 5 \pmod{10}, \\ y &\equiv 1 \pmod{2}. \end{aligned}$$

This congruence is satisfied by  $y \in \{-3, -1, 1, 3, 5\}$ ; the original congruence is thus (substituting  $x \equiv 2^y \pmod{11}$ ) satisfied by  $x \in \{-1, 2, -3, -4, -5\}$ .  $\square$

**11.D.15.** Solve the congruence  $x^3 - 3x + 5 \equiv 0 \pmod{105}$ .  $\circ$

**11.D.16.** Determine the number of solutions of the congruence

$$x^5 \equiv 534 \pmod{23^2}.$$

**Solution.** The given congruence is equivalent to  $x^5 \equiv 5 \pmod{23^2}$ , and since we have  $(5, \varphi(23)) = 1$ , it follows from the theorem on solvability of binomial congruences that the congruence has a unique solution if considered modulo 23. Furthermore, this solution is surely not a multiple of 23. Therefore, considering the polynomial whose roots we are looking for, its derivative  $(x^5 - 5)' = 5x^4$  does not evaluate to a multiple of 23 at the wanted solution, either. Invoking Hensel's lemma, we can summarize that the original congruence has a unique solution (without having to describe it explicitly).  $\square$

**11.D.17.** Give an example of a polynomial congruence whose degree is less than the number of its solutions.

**Solution.** Taking into account theorem 11.4.8, we must use either a modulus which is composite or a polynomial all of whose coefficients will be multiples of the modulus.

As an example of a congruence of the first kind, we can put

$$x^2 \equiv 1 \pmod{8},$$

which is a quadratic congruence with four solutions 1, 3, 5, 7.

The case if a prime modulus can be exemplified by the quadratic congruence  $10x^2 - 15 \equiv 0 \pmod{5}$ , which has five solutions.  $\square$

**11.D.18. Other types of congruences.** Prove that for any natural number  $n$ , the integer

$$111 + 2^{2^{2n-1}}$$

is divisible by 127.

**Solution.** We are to prove that the congruence

$$2^{2^{2n-1}} \equiv -111 \pmod{127}$$

is satisfied for every  $n \in \mathbb{N}$ . This congruence is equivalent to

$$2^{2^{2n-1}} \equiv 2^2 \pmod{127}.$$

Since  $2^7 = 128 \equiv 1 \pmod{127}$ , the order of 2 modulo 127 equals 7, so the congruence to be proved is (by 11.3.13) equivalent to

$$2^{2^{2n-1}} \equiv 2^2 \pmod{7}.$$

**11.4.4. Systems of linear congruences.** Having a system of linear congruences in the same variable, we can decide whether each of them is solvable by the previous theorem. If at least one of the congruences does not have a solution, nor does the whole system. On the other hand, if each of the congruences is solvable, we can rearrange it into the form  $x \equiv c_i \pmod{m_i}$ .

We thus get a system of congruences

$$\begin{aligned} x &\equiv c_1 \pmod{m_1}, \\ &\vdots \\ x &\equiv c_k \pmod{m_k}. \end{aligned}$$

Apparently, it suffices to solve the case  $k = 2$  since the solutions of a system of more congruences can be obtained by repeatedly applying the procedure for a system of two congruences.

**Proposition.** Let  $c_1, c_2$  be integers and  $m_1, m_2$  be natural numbers. Let us denote  $d = (m_1, m_2)$ . The system of two congruences

$$\begin{aligned} x &\equiv c_1 \pmod{m_1}, \\ x &\equiv c_2 \pmod{m_2} \end{aligned}$$

has no solution if  $c_1 \not\equiv c_2 \pmod{d}$ . On the other hand, if  $c_1 \equiv c_2 \pmod{d}$ , then there is an integer  $c$  such that  $x \in \mathbb{Z}$  satisfies the system if and only if it satisfies the congruence

$$x \equiv c \pmod{[m_1, m_2]}.$$

**PROOF.** If the given system is to have a solution  $x \in \mathbb{Z}$ , we must have  $x \equiv c_1 \pmod{d}$ ,  $x \equiv c_2 \pmod{d}$ , and thus  $c_1 \equiv c_2 \pmod{d}$  as well. Hence it follows that the system cannot have a solution when  $c_1 \not\equiv c_2 \pmod{d}$ .

From now on, suppose that  $c_1 \equiv c_2 \pmod{d}$ . The first congruence of the system is satisfied by those integers  $x$  which are of the form  $x = c_1 + tm_1$ , where  $t \in \mathbb{Z}$  is arbitrary. Such an integer  $x$  satisfies the second congruence of the system if and only if  $c_1 + tm_1 \equiv c_2 \pmod{m_2}$ , i.e.,  $tm_1 \equiv c_2 - c_1 \pmod{m_2}$ . By the theorem about solutions of linear congruences, this congruence (in variable  $t$ ) is solvable since  $d = (m_1, m_2)$  divides  $c_2 - c_1$ , and  $t$  satisfies this congruence if and only if

$$t \equiv \frac{c_2 - c_1}{d} \cdot \left(\frac{m_1}{d}\right)^{\varphi\left(\frac{m_2}{d}\right)-1} \pmod{\frac{m_2}{d}},$$

i.e., if and only if

$$\begin{aligned} x &= c_1 + tm_1 = c_1 + (c_2 - c_1) \cdot \left(\frac{m_1}{d}\right)^{\varphi\left(\frac{m_2}{d}\right)} + r \frac{m_1 m_2}{d} \\ &= c + r \cdot [m_1, m_2], \text{ where } r \in \mathbb{Z} \text{ is arbitrary and} \end{aligned}$$

$c = c_1 + (c_2 - c_1) \cdot (m_1/d)^{\varphi(m_2/d)}$ , as  $m_1 m_2$  equals  $d \cdot [m_1, m_2]$ . We have thus found such an integer  $c$  that every  $x \in \mathbb{Z}$  satisfies the system if and only if  $x \equiv c \pmod{[m_1, m_2]}$ , as wanted.  $\square$

Similarly, the order of 2 modulo 7 is 3, which leads to the (again equivalent) congruence

$$\begin{aligned} 2^{2n-1} &\equiv 2 \pmod{3}, \\ (-1)^{2n-1} &\equiv -1 \pmod{3}, \end{aligned}$$

and this is apparently true (we could also have proceed likewise – the order of 2 modulo 3 is 2, and so on). This proves the statement.  $\square$

**11.D.19.** Determine which natural numbers  $n$  satisfy that the integer  $n \cdot 2^n + 1$  is divisible by seven.

**Solution.** We are looking for the solution of the congruence

$$n \cdot 2^n \equiv -1 \pmod{7}.$$

We should be aware of the fact that we cannot use the theorem 11.4.1 since  $n \cdot 2^n$  is not a polynomial in variable  $n$ , so it is not guaranteed (and it is even not true) that the expression will yield the same remainder modulo 7 when evaluated at integers which are congruent modulo 7.

On the other hand, we can notice that the order of 2 modulo 7 is equal to 3, so we can split the problem into three cases according to the remainder of  $n$  when divided by 3.

For  $n \equiv 0 \pmod{3}$ , we have  $2^n \equiv 1 \pmod{7}$ , so the congruence in question is equivalent to  $n \equiv -1 \pmod{7}$ . Combining the conditions  $n \equiv 0 \pmod{3}$  and  $n \equiv -1 \pmod{7}$  in the Chinese remainder theorem leads to the solution  $n \equiv 6 \pmod{21}$ .

Now, for  $n \equiv 1 \pmod{3}$ , we have  $2^n \equiv 2 \pmod{7}$ , so the examined congruence is of the form  $2n \equiv -1 \pmod{7}$ , which is equivalent to  $n \equiv 3 \pmod{7}$ . The conditions  $n \equiv 1 \pmod{3}$  and  $n \equiv 3 \pmod{7}$  are satisfied iff  $n \equiv 10 \pmod{21}$ .

Finally, for  $n \equiv 2 \pmod{3}$ , we have  $2^n \equiv 4 \pmod{7}$ , and the solution of the congruence  $4n \equiv -1 \pmod{7}$  is  $n \equiv 5 \pmod{7}$ . Altogether,  $n \equiv 5 \pmod{21}$ .

The problem is satisfied by exactly those natural numbers  $n$  with  $n \equiv 5, 6, 10 \pmod{21}$ .  $\square$

**11.D.20.** Prove that for any natural number  $n$ , the integer  $2n^4 + n^3 + 50$  is divisible by 6 if and only if the integer  $2 \cdot 4^n + 3^n + 50$  is divisible by 13.

**Solution.** The expression  $f(n) = 2n^4 + n^3 + 50$  is a polynomial in variable  $n$ , so in this case, we can make use of theorem 11.4.1, i.e., it suffices to go through all possible remainders modulo 6. Since the order of 4 modulo 13 is equal to 6 and the order of 3 modulo 13 equals 3, it is enough (by 11.3.13) to examine the remainder of  $n$  upon division by 6 in the latter case as well.

In the former case, we calculate

$n$	0	1	2	3	4	5
$f(n) \pmod{6}$	2	5	0	5	2	3

We can notice that the proof of this theorem is constructive, i.e., it yields a formula for finding the integer  $c$ . This theorem thus gives us a procedure how to catch the condition that an integer  $x$  satisfies a given system by a single congruence. This new congruence is then of the same form as the original one. Therefore, we can apply this procedure to a system of more congruences – first, we create a single congruence from the first and second congruences of the system (satisfied by exactly those integers  $x$  which satisfy the original two); then, we create another congruence from the new one and the third one of the original system, and so on. Each step reduces the number of congruences by one; after a finite number of steps, we thus arrive at a single congruence which describes all solutions of the given system.

It follows from the procedure we have just mentioned (supposing the condition from below holds) that a system of congruences always has a solution, and this is unique.

**Theorem (Chinese remainder theorem).** Let  $m_1, \dots, m_k \in \mathbb{N}$  be pairwise coprime,  $a_1, \dots, a_k \in \mathbb{Z}$ . Then, the system

$$\begin{aligned} x &\equiv a_1 \pmod{m_1}, \\ &\vdots \\ x &\equiv a_k \pmod{m_k} \end{aligned}$$

has a unique solution modulo  $m_1 \cdot m_2 \cdot \dots \cdot m_k$ .

**Remark.** The unusual name of this theorem comes from Chinese mathematician Sun Tzu of the 4th century. In his text, he asked for an integer which leaves remainder 2 when divided by 3, leaves remainder 3 when divided by 5, and again remainder 2 when divided by 7.

The answer is rumored to be hidden in the following song:

孫子歌 Sunzi Ge

三人同行七十里  
五樹梅花廿一枝  
七子團圓正月半  
一百零五轉回起

**PROOF.** It is a simple consequence of the previous proposition about the form of the solution of a system of two congruences. However, as we show here, this result can also be proved directly. Let us denote  $M := m_1 m_2 \cdot \dots \cdot m_r$  and  $n_i = M/m_i$  for every  $i$ ,  $1 \leq i \leq r$ . Then, for any  $i$ ,  $m_i$  is coprime to  $n_i$ , so there is an integer  $b_i \in \{1, \dots, m_i - 1\}$  such that  $b_i n_i \equiv 1 \pmod{m_i}$ . Note that  $b_i n_i$  is divisible by all the numbers  $m_j$ ,  $1 \leq j \leq r$ ,  $i \neq j$ . Therefore, the wanted solution of the system is the integer

$$x = a_1 b_1 n_1 + a_2 b_2 n_2 + \dots + a_r b_r n_r.$$

$\square$

Therefore, the congruence  $f(n) \equiv 0 \pmod{6}$  is satisfied by exactly those natural numbers  $n$  which satisfy  $n \equiv 2 \pmod{6}$ .

In the latter case, we gradually compute that

$n$	0	1	2	3	4	5
$4^n \pmod{13}$	1	4	3	-1	-4	-3
$3^n \pmod{13}$	1	3	9	1	3	9
$2 \cdot 4^n + 3^n - 2 \pmod{13}$	1	9	0	-3	-7	1

Just like in the former case, the congruence  $2 \cdot 4^n + 3^n + 50 \equiv 0 \pmod{13}$  is satisfied if and only if  $n \equiv 2 \pmod{6}$ .  $\square$

**11.D.21.** Solve the congruence

$$x^2 \equiv 18 \pmod{63}.$$

**Solution.** Since  $(18, 63) = 9$ , it must be that  $9 \mid x^2$ , i.e.,  $3 \mid x$ . Setting  $x = 3x_1$ ,  $x_1 \in \mathbb{Z}$ , we get an equivalent congruence  $x_1^2 \equiv 2 \pmod{7}$ , which already satisfies that the modulus is coprime to the integer on the right-hand side. It follows from theorem 11.4.8 that this congruence has at most 2 solutions, and those are clearly  $x_1 \equiv \pm 3 \pmod{7}$ , i.e.,  $x_1 \equiv \pm 3, \pm 10, \pm 17, \pm 24, \pm 31, \pm 38, \pm 45, \pm 52, \pm 59 \pmod{63}$ . The solution of the original congruence is thus  $x \equiv 3x_1 \pmod{63}$ , i.e.,  $x \equiv \pm 9, \pm 12, \pm 30 \pmod{63}$ .  $\square$

**11.D.22.** Solve the congruence

$$x^3 \equiv 3 \pmod{18}.$$

**Solution.** Since  $(3, 18) = 3$ , we must have  $3 \mid x$ . Making the substitution  $x = 3 \cdot x_1$ , similarly to the above exercise, we get the congruence

$$27x_1^3 \equiv 3 \pmod{18},$$

which has no solution since  $(27, 18) \nmid 3$ .  $\square$

**Quadratic congruences.** In the theoretical column we state that any quadratic congruence can be transformed to the (possibly system of congruences of) binomial form  $x^2 \equiv a \pmod{p}$ , and then we can decide about the solvability using the Legendre symbol. Let us illustrate it on several examples.

**11.D.23.** Determine the number of solutions of the congruence  $13x^2 + 7x + 1 \equiv 0 \pmod{37}$ .

**Solution.** First, we need to normalize the polynomial on the left-hand side, i.e. we have to find the inverse of 13 modulo 37. Using the Euclidean algorithm we find that the inverse is 20, and after multiplication of both sides of the congruence by it and reducing modulo 37 we obtain the congruence  $x^2 + 29x + 20 \equiv 0 \pmod{37}$ . Now we complete the square (an odd coefficient 29 does not cause any trouble as it can be replaced by  $-8$ ) and we obtain  $(x - 4)^2 + 4 \equiv 0 \pmod{37}$ . After substitution of  $y$  for  $x - 4$  we finally obtain the congruence in a binomial form

$$y^2 \equiv -4 \pmod{37}.$$

Let us emphasize that this is quite a strong theorem (which is actually valid in much more general algebraic structures), which allows us to guarantee that for any remainders with respect to given (pairwise coprime) moduli, there exists an integer with the given remainders.

**11.4.5. Higher-order congruences.** Now, let us get back to the more general case of congruences.

$$f(x) \equiv 0 \pmod{m},$$

where  $f(x)$  is a polynomial with integer coefficients and  $m \in \mathbb{N}$ . So far, we have only one method at our disposal, which is tedious, yet universal – to try all possible remainders modulo  $m$ . When solving such a congruence, it is sufficient to find out for which integers  $a$ ,  $0 \leq a < m$ , it holds that  $f(a) \equiv 0 \pmod{m}$ . The disadvantage of this method is its complexity, which increases as  $m$  does. If  $m$  is composite, i.e.,  $m = p_1^{\alpha_1} \dots p_k^{\alpha_k}$ , where  $p_1, \dots, p_k$  are distinct primes, and  $k > 1$ , we can replace the original congruence by the system of congruences

$$f(x) \equiv 0 \pmod{p_1^{\alpha_1}},$$

$\vdots$

$$f(x) \equiv 0 \pmod{p_k^{\alpha_k}},$$

which has the same set of solutions. However, we can solve the congruences separately. The advantage of this method is in that the moduli of the congruences of the system are less than the modulus of the original congruence.

**Example.** Consider the congruence

$$x^3 - 2x + 11 \equiv 0 \pmod{105}.$$

If we were to try out all possibilities, we would have to compute the value of  $f(x) = x^3 - 2x + 11$  for the 105 values  $f(0), f(1), \dots, f(104)$ . Therefore, we better factor  $105 = 3 \cdot 5 \cdot 7$  and solve the congruences  $f(x) \equiv 0$  for moduli 3, 5, and 7. We evaluate the polynomial  $f(x)$  in convenient integers:

$x$	-3	-2	-1	0	1	2	3
$f(x)$	-10	7	12	11	10	15	32

The congruence  $f(x) \equiv 0 \pmod{3}$  thus has solution  $x \equiv -1 \pmod{3}$  (only the first one of the integers 12, 11, 10 is a multiple of 3); the congruence  $f(x) \equiv 0 \pmod{5}$  has solutions  $x \equiv 1$  and  $x \equiv 2 \pmod{5}$ ; finally, the solution of the congruence  $f(x) \equiv 0 \pmod{7}$  is  $x \equiv -2 \pmod{7}$ .

It remains to solve two systems of congruences:

$$\begin{array}{ll} x \equiv -1 \pmod{3}, & x \equiv -1 \pmod{3}, \\ x \equiv 1 \pmod{5}, & \text{and } x \equiv 2 \pmod{5}, \\ x \equiv -2 \pmod{7} & x \equiv -2 \pmod{7}. \end{array}$$

Solving these systems, we can find out that the solutions of the given congruence  $f(x) \equiv 0 \pmod{105}$  are exactly those integers  $x$  which satisfy  $x \equiv 26 \pmod{105}$  or  $x \equiv 47 \pmod{105}$ .

The fact that this congruence is solvable can be established either using theorem 11.4.10, or with use of the Legendre symbol. The former approach leads to the calculation  $d = (2, \varphi(37)) = 2$ , and

$$(-4)^{\frac{36}{2}} \equiv 1 \pmod{37},$$

while the latter one gives

$$\left(\frac{-4}{37}\right) = \left(\frac{-1}{37}\right) \cdot \left(\frac{2}{37}\right)^2 = 1$$

by the corollary after theorem 11.4.13 (as  $37 \equiv 1 \pmod{4}$ ). In any way we have obtained that the given congruence has  $d = 2$  solutions.  $\square$

**11.D.24.** Solve the congruence  $6x^2 + x - 1 \equiv 0 \pmod{29}$ .

**Solution.** Although we have not presented any special method for finding solutions of quadratic congruence yet (apart from the general method for binomial congruences or going through the complete residue system) we will see that in some case the set of solutions can be easily established. Let us first proceed in the usual way: multiplying the congruence by 5 (it is the inverse of 6 modulo 29) we obtain  $x^2 + 5x - 5 \equiv 0 \pmod{29}$ , and after completing the square we have

$$(x - 12)^2 \equiv 4 \pmod{29}.$$

We immediately see that this congruence is solvable with the pair of solutions  $x - 12 \equiv \pm 2 \pmod{29}$ , and thus  $x \equiv 10, 14 \pmod{29}$ .

We could have also seen almost immediately that the given polynomial can be factored as  $6x^2 + x - 1 = (3x - 1)(2x + 1)$ , and thus the prime modulus 29 has to divide either  $3x - 1$  or  $2x + 1$ . The obtained linear congruences  $3x \equiv 1 \pmod{29}$  and  $2x \equiv -1 \pmod{29}$  easily yield the same solutions  $x \equiv 10 \pmod{29}$  and  $x \equiv 14 \pmod{29}$  as above.  $\square$

**11.D.25.** Find all integers which satisfy the congruence

$$x^2 \equiv 7 \pmod{43}.$$

**Solution.** The Legendre symbol evaluates to

$$\left(\frac{7}{43}\right) = -\left(\frac{43}{7}\right) = -\left(\frac{1}{7}\right) = -1.$$

Hence it follows that 7 is a quadratic nonresidue modulo 43, so there is no solution of the given congruence.  $\square$

**11.D.26.** Find all integers  $a$  for which the congruence

$$x^2 \equiv a \pmod{43}$$

is solvable.

**Solution.** This exercise is a follow-up to the above one, from which we can see that the integer 7 does not meet the requirement. We can test all the remainders modulo 43 in the same way, but there is a simpler method. The congruence is surely solvable if  $a$  is a multiple of 43 (then, it has a unique solution);

It is not always possible to replace the congruence with a system of congruences modulo primes, as in the above example: if the original modulus is a multiple of a higher power of a prime, then we cannot “get rid” of this power. However, even such a congruence modulo a power of prime need not be solved by examining all possibilities. There is a more efficient tool, which is described by the following theorem.

**11.4.6. Theorem (Hensel’s lemma).** *Let  $p$  be a prime,  $f(x) \in \mathbb{Z}[x]$ ,  $a \in \mathbb{Z}$  such that  $p \mid f(a), p \nmid f'(a)$ . Then, for every  $n \in \mathbb{N}$ , the system*

$$\begin{aligned} x &\equiv a \pmod{p}, \\ f(x) &\equiv 0 \pmod{p^n} \end{aligned}$$

*has a unique solution modulo  $p^n$ .*

**PROOF.** We will proceed by induction on  $n$ . In the case of  $n = 1$ , the congruence  $f(x) \equiv 0 \pmod{p^1}$  is only another formulation of the assumption that the integer  $a$  satisfies  $p \mid f(a)$ . Further, let  $n > 1$  and suppose the proposition is true for  $n - 1$ . If  $x$  satisfies the system for  $n$ , then it does so for  $n - 1$  as well. Denoting one of the solutions of the system for  $n - 1$  as  $c_{n-1}$ , we can look for the solution of the system for  $n$  in the form

$$x = c_{n-1} + k \cdot p^{n-1}, \quad \text{where } k \in \mathbb{Z}.$$

We need to find out for which  $k$  we have  $f(c_{n-1} + k \cdot p^{n-1}) \equiv 0 \pmod{p^n}$ . We know that  $p^{n-1} \mid f(c_{n-1} + k \cdot p^{n-1})$ . Now, we use the binomial theorem for  $f(x) = a_m x^m + \dots + a_1 x + a_0$ , where  $a_0, \dots, a_m \in \mathbb{Z}$ . We have

$$(c_{n-1} + k \cdot p^{n-1})^i \equiv c_{n-1}^i + i \cdot c_{n-1}^{i-1} \cdot k p^{n-1} \pmod{p^n},$$

hence

$$f(c_{n-1} + k \cdot p^{n-1}) \equiv f(c_{n-1}) + k \cdot p^{n-1} f'(c_{n-1}).$$

Therefore,

$$f(c_{n-1} + k \cdot p^{n-1}) \equiv 0 \pmod{p^n} \iff$$

$$\iff 0 \equiv \frac{f(c_{n-1})}{p^{n-1}} + k \cdot f'(c_{n-1}) \pmod{p}.$$

Since  $c_{n-1} \equiv a \pmod{p}$ , we get  $f'(c_{n-1}) \equiv f'(a) \not\equiv 0 \pmod{p}$ , so  $(f'(c_{n-1}), p) = 1$ . By the theorem about the solutions of linear congruences, we can hence see that there is (modulo  $p$ ) a unique solution  $k$  of this congruence, and since  $c_{n-1}$  was, by the induction hypothesis, the only solution modulo  $p^{n-1}$ , the integer  $c_{n-1} + k \cdot p^{n-1}$  is the only solution of the given system modulo  $p^n$ .  $\square$

**Example.** Consider the congruence

$$3x^2 + 4 \equiv 0 \pmod{49}.$$

The congruence can be equivalently transformed (by solving the linear congruence  $3y \equiv 1 \pmod{49}$  and multiplying both sides of the congruence by the integer  $y \equiv 33$ ) to the form  $x^2 \equiv 15 \pmod{7^2}$ . Then, we proceed as in the constructive proof of Hensel’s lemma.

and if not, it must be a quadratic residue modulo 43. The quadratic residues can be most simply enumerated by calculating the squares of all elements of a reduced residue system modulo 43.

The quadratic residues are thus the integers congruent to  $(\pm 1)^2, (\pm 2)^2, (\pm 3)^2, \dots, (\pm 21)^2$  modulo 43, so the problem is satisfied by exactly those integers  $a$  which are congruent to any one of 1, 4, 6, 9, 10, 11, 13, 14, 15, 16, 17, 21, 23, 24, 25, 31, 35, 36, 38, 40, 41.  $\square$

Using law of quadratic reciprocity 11.4.13 we can calculate the value  $(a/p)$  for any integer  $a$  and an odd prime  $p$ . Moreover, evaluation of the Legendre symbol is fast enough even for high arguments, therefore using it is favourable to verifying criteria of the theorem 11.4.10.

**11.D.27.** Here, we recall the statement of the Law in the slightly modified way which is more suitable for direct calculations.

- i)  $-1$  is a quadratic residue for primes  $p$  which satisfy  $p \equiv 1 \pmod{4}$  and it is a quadratic nonresidue for primes  $p$  satisfying  $p \equiv 3 \pmod{4}$ .
- ii)  $2$  is a quadratic residue for primes  $p$  which satisfy  $p \equiv \pm 1 \pmod{8}$  and it is a quadratic nonresidue for primes  $p$  satisfying  $p \equiv \pm 3 \pmod{8}$ .
- iii) If  $p \equiv 1 \pmod{4}$  or  $q \equiv 1 \pmod{4}$ , then  $(p/q) = (q/p)$ ; for other odd  $p, q$ , we have  $(p/q) = -(q/p)$ .

**Solution.** We simply apply law of quadratic reciprocity in the appropriate cases.

- i) The integer  $\frac{p-1}{2}$  is even iff  $4 \mid p - 1$ .
- ii) We need to know for which odd primes  $p$  the exponent is  $\frac{p^2-1}{8}$  is even. Odd primes are congruent to  $\pm 1$  or  $\pm 3$  modulo 8, so we have (by 11.C.7) that either  $p^2 \equiv 1 \pmod{16}$  or  $p^2 \equiv 9 \pmod{16}$ .  $\square$
- iii) This is clear from the law of quadratic reciprocity.

**11.D.28.** Derive by straight calculation from Gauss's lemma 11.4.14 once again the so-called supplementary laws of quadratic reciprocity:

$$\left(\frac{-1}{p}\right) = (-1)^{\frac{p-1}{2}} \quad \text{and} \quad \left(\frac{2}{p}\right) = (-1)^{\frac{p^2-1}{8}}.$$

**Solution.** To evaluate  $(-1/p)$  in the former case, we should realize that  $\mu$  tells the number of least (in absolute value) negative remainders of integers in the set

$$\{-1, -2, \dots, -\frac{p-1}{2}\}.$$

However, those are exactly the desired remainders and they are all negative; hence we have  $\mu = \frac{p-1}{2}$  and  $(-1/p) = (-1)^{\frac{p-1}{2}}$ .

In the latter case, we need to express the number of least (in absolute value) negative remainders of integers in the set

$$\{1 \cdot 2, 2 \cdot 2, 3 \cdot 2, \dots, \frac{p-1}{2} \cdot 2\}.$$

First, we solve the congruence  $x^2 \equiv 15 \equiv 1 \pmod{7}$ , which has at most 2 solutions, and those are  $x \equiv \pm 1 \pmod{7}$ . These solutions can be expressed in the form  $x = \pm 1 + 7t$ , where  $t \in \mathbb{Z}$ , and substituted into the congruence modulo 49, whence we get the solution  $x \equiv \pm 8 \pmod{49}$  (if we were interested solely in the number of solutions, we would not even have to finish the calculation as it follows straight from Hensel's lemma that every solution modulo 7 gives a unique solution modulo 49 because for  $f(x) = x^2 - 15$ , we have  $7 \nmid f'(\pm 1)$ ).

**11.4.7. Congruences modulo a prime.** The solution of general higher-order congruences has thus been reduced to the solution of congruences modulo a prime. As we will see, this is where the stumbling block is since no (much) more efficient universal procedure than trying out all possibilities is known. We can at least mention several statements describing the solvability and number of solutions of such congruences. We will then prove some detailed results for some special cases in further paragraphs.

**Theorem.** Let  $p$  be a prime,  $f(x) \in \mathbb{Z}[x]$ . Every congruence  $f(x) \equiv 0 \pmod{p}$  is equivalent to a congruence of degree at most  $p - 1$ .

**PROOF.** Since it holds for any  $a \in \mathbb{Z}$  that  $p \mid a^p - a$  (simple consequence of Fermat's little theorem), the congruence  $x^p - x \equiv 0 \pmod{p}$  is satisfied by all integers. Dividing the polynomial  $f(x)$  by  $x^p - x$  with remainder, we get

$$f(x) = q(x) \cdot (x^p - x) + r(x)$$

for suitable  $f(x), r(x) \in \mathbb{Z}$ , where the degree of  $r(x)$  is less than that of the divisor, i.e.  $p$ . We thus get that the congruence  $r(x) \equiv 0 \pmod{p}$  is equivalent to the congruence  $f(x) \equiv 0 \pmod{p}$ , yet it is of degree at most  $p - 1$ .  $\square$

**11.4.8. Theorem.** Let  $p$  be a prime,  $f(x) \in \mathbb{Z}[x]$ . If the congruence  $f(x) \equiv 0 \pmod{p}$  has more than  $\deg(f)$  solutions, then each of the coefficients of the polynomial  $f$  is a multiple of  $p$ .

**PROOF.** In algebraic words, we are actually interested in the number of roots of a non-zero polynomial over a finite field  $\mathbb{Z}_p$ , and by 12.3.4, there are at most  $\deg(f)$  of them.  $\square$

**Corollary** (Another proof of Wilson's theorem). If  $p$  is a prime, then

$$(p - 1)! \equiv -1 \pmod{p}.$$

**PROOF.** The statement is clearly true for  $p = 2$ , so we can consider only odd primes  $p$  from now on. By Fermat's little theorem, the congruence

$$(x - 1)(x - 2) \cdots (x - (p - 1)) - (x^{p-1} - 1) \equiv 0 \pmod{p}$$

is satisfied by any integer  $a$  which is not divisible by  $p$ ; i.e., there are  $p - 1$  solutions. However, its degree is equal to  $p - 2$  (which is less than the number of solutions). It follows from 11.4.7 that all of the coefficients of the left-hand polynomial

For any  $k \in \{1, 2, \dots, \frac{p-1}{2}\}$ , the integer  $2k$  leaves a negative remainder if and only if  $2k > \frac{p-1}{2}$ , i.e., iff  $k > \frac{p-1}{4}$ . Now, it remains to determine the number of such integers  $k$ .

If  $p \equiv 1 \pmod{4}$ , then this number is equal to  $\frac{p-1}{2} - \frac{p-1}{4} = \frac{p-1}{4}$ , so

$$\left(\frac{-1}{p}\right) = (-1)^\mu = (-1)^{\frac{p-1}{4}} = (-1)^{\frac{p-1}{4} \cdot \frac{p+1}{2}} = (-1)^{\frac{p^2-1}{8}},$$

since  $\frac{p+1}{2}$  is odd in this case.

Similarly, for  $p \equiv 3 \pmod{4}$ , the number of such integers  $k$  equals  $\frac{p-1}{2} - \frac{p-3}{4} = \frac{p+1}{4}$ , so

$$\left(\frac{-1}{p}\right) = (-1)^{\frac{p+1}{4}} = (-1)^{\frac{p+1}{4} \cdot \frac{p-1}{2}} = (-1)^{\frac{p^2-1}{8}},$$

since  $\frac{p-1}{2}$  is odd in this case as well. □

**11.D.29.** Solve the congruence  $x^2 - 23 \equiv 0 \pmod{77}$ .

**Solution.** Factoring the modulus, we get the system

$$\begin{aligned} x^2 - 1 &\equiv 0 \pmod{11}, \\ x^2 - 2 &\equiv 0 \pmod{7}. \end{aligned}$$

Clearly, 1 is a quadratic residue modulo 11, so the first congruence of the system has (exactly) two solutions:  $x \equiv \pm 1 \pmod{11}$ . Further,  $(2/7) = (9/7) = 1$ , and it should not take much effort to notice the solution:  $x \equiv \pm 3 \pmod{7}$ .

We have thus obtained four simple systems of two linear congruences each. Solving them, we will get that the original congruence has the following four solutions:  $x \equiv 10, 32, 45$  or  $67 \pmod{77}$ . □

**11.D.30.** Solve the congruence  $7x^2 + 112x + 42 \equiv 0 \pmod{473}$ . ○

**Jacobi symbol.** Jacobi symbol  $(a/b)$  is a generalization of the Legendre symbol to the case where the “lower” argument  $b$  need not be a prime, but any odd positive integer. It is defined as the product of the Legendre symbols corresponding to the prime factors of  $b$ : if  $b = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ , then

$$\left(\frac{a}{b}\right) = \left(\frac{a}{p_1}\right)^{\alpha_1} \cdots \left(\frac{a}{p_k}\right)^{\alpha_k}.$$

The primary motivation for introducing the Jacobi symbol is the necessity to evaluate the Legendre symbol (and thus to decide the solvability of quadratic congruences) without having to factor integers to primes. We will illustrate such calculation on an example having in mind that Jacobi symbol shares with the Legendre one not only the notation but also almost all of the (computational) properties.

**11.D.31.** Decide whether the congruence  $x^2 \equiv 219 \pmod{383}$  is solvable.

are multiples of  $p$ . In particular, this applies to the absolute term, which equals  $(p-1)!+1$ . This proves Wilson’s theorem. □

**11.4.9. Binomial congruences.** This part will be devoted to solving special types of higher-order polynomial congruences, the so-called *binomial congruences*. It is an analog to the binomial equations, where the polynomial  $f(x)$  is  $x^n - a$ . It can easily be shown that we can restrict ourselves to the condition that  $a$  be coprime with the modulus of the congruence – otherwise, we can always equivalently transform the congruence into this form or decide that it has no solution.

QUADRATIC AND POWER RESIDUES

Let  $m \in \mathbb{N}$ ,  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ . The integer  $a$  is said to be a *n-th power residue modulo m*, or *residue of degree n modulo m* if and only if the congruence

$$x^n \equiv a \pmod{m}$$

is solvable. Otherwise, we call  $a$  a *n-th power nonresidue modulo m*, or *nonresidue of degree n modulo m*.

For  $n = 2, 3, 4$ , we use the adjectives quadratic, cubic, and quartic residue (or nonresidue) modulo  $m$ .

Now, we will show how to solve binomial congruences modulo  $m$ , if there are primitive roots modulo  $m$  (in particular, when the modulus is an odd prime or its power).

**11.4.10. Theorem.** Let  $m \in \mathbb{N}$  be such that there are primitive roots modulo  $m$ . Further, let  $a \in \mathbb{Z}$ ,  $(a, m) = 1$ . Then, the congruence  $x^n \equiv a \pmod{m}$  is solvable (i.e.,  $a$  is an *n-th power residue modulo m*) if and only if  $a^{\varphi(m)/d} \equiv 1 \pmod{m}$ , where  $d = (n, \varphi(m))$ . And if so, it has exactly  $d$  solutions.

**PROOF.** Let  $g$  be a primitive root modulo  $m$ . Then, for any  $x$  coprime to  $m$ , there is a unique integer  $y$  (its discrete logarithm) with the property  $0 \leq y < \varphi(m)$  such that  $x \equiv g^y \pmod{m}$ . Similarly, for a given  $a$ , there is a unique  $b \in \mathbb{Z}$ ;  $0 \leq b < \varphi(m)$  such that  $a \equiv g^b \pmod{m}$ . After this substitution, the binomial congruence in question is thus equivalent to the congruence  $(g^y)^n \equiv g^b \pmod{m}$  and, invoking theorem 11.3.13, to the linear congruence  $n \cdot y \equiv b \pmod{\varphi(m)}$  as well.

However, this congruence

$$n \cdot y \equiv b \pmod{\varphi(m)}$$

is solvable if and only if  $d = (n, \varphi(m)) \mid b$  (and if so, it has  $d$  solutions).

It remains to prove that  $d \mid b$  if and only if  $a^{\varphi(m)/d} \equiv 1 \pmod{m}$ . However, the congruence

$$1 \equiv a^{\varphi(m)/d} \equiv g^{b\varphi(m)/d} \pmod{m}$$

is true if and only if  $\varphi(m) \mid \frac{b\varphi(m)}{d}$ , which happens if and only if  $d \mid b$ . □

**Solution.** Since 383 is a prime, the congruence will be solvable if the Legendre symbol will satisfy  $(219/383) = 1$ .

$$\begin{aligned} \left(\frac{219}{383}\right) &= -\left(\frac{383}{219}\right) \text{ (Jacobi) as } 383 \equiv 219 \equiv 3 \pmod{4} \\ &= -\left(\frac{164}{219}\right) = -\left(\frac{41}{219}\right) \quad 164 = 2^2 \cdot 41 \\ &= -\left(\frac{219}{41}\right) \text{ (Jacobi) as } 41 \equiv 1 \pmod{4} \\ &= -\left(\frac{14}{41}\right) = -\left(\frac{2}{41}\right)\left(\frac{7}{41}\right) \\ &= -\left(\frac{7}{41}\right) \quad \text{as } 41 \equiv 1 \pmod{8} \\ &= -\left(\frac{41}{7}\right) \quad \text{as } 41 \equiv 1 \pmod{4} \\ &= -\left(\frac{-1}{7}\right) = 1 \quad \text{as } 7 \equiv 3 \pmod{4}. \end{aligned}$$

□

Now, we introduce several exercises proving that the Jacobi symbol has properties similar to the Legendre one, which relieves us of the necessity to factor the integers that appear when working purely with the Legendre symbol.

**11.D.32.** Prove that all odd positive numbers  $b, b'$  and all integers  $a, a_1, a_2$  satisfy (the symbols used here are always the Jacobi ones):

- i) if  $a_1 \equiv a_2 \pmod{b}$ , then  $\left(\frac{a_1}{b}\right) = \left(\frac{a_2}{b}\right)$ ,
- ii)  $\left(\frac{a_1 a_2}{b}\right) = \left(\frac{a_1}{b}\right)\left(\frac{a_2}{b}\right)$ ,
- iii)  $\left(\frac{a}{bb'}\right) = \left(\frac{a}{b}\right)\left(\frac{a}{b'}\right)$ .

○

**11.D.33.** Prove that if  $a, b$  are odd natural numbers, then

- i)  $\frac{ab-1}{2} \equiv \frac{a-1}{2} + \frac{b-1}{2} \pmod{2}$ ,
- ii)  $\frac{a^2 b^2 - 1}{8} \equiv \frac{a^2 - 1}{8} + \frac{b^2 - 1}{8} \pmod{2}$ .

**Solution.**

- i) Since the integer  $(a-1)(b-1) = (ab-1) - (a-1) - (b-1)$  is a multiple of 4, we get  $(ab-1) \equiv (a-1) + (b-1) \pmod{4}$ , which gives what we want when divided by two.
- ii) Similarly to above,  $(a^2-1)(b^2-1) = (a^2 b^2 - 1) - (a^2 - 1) - (b^2 - 1)$  is a multiple of 16. Therefore,  $(a^2 b^2 - 1) \equiv (a^2 - 1) + (b^2 - 1) \pmod{16}$ , which gives the wanted statement when divided by eight (see also exercise 11.A.2). □

**11.D.34.** Prove that if  $a_1, \dots, a_k$  are odd natural numbers, then

- i)  $\prod_{\ell=1}^k \frac{a_\ell - 1}{2} \equiv \sum_{\ell=1}^k \frac{a_\ell - 1}{2} \pmod{2}$ ,
- ii)  $\prod_{\ell=1}^k \frac{a_\ell^2 - 1}{8} \equiv \sum_{\ell=1}^k \frac{a_\ell^2 - 1}{8} \pmod{2}$ .

**Corollary.** If the assumptions of the above theorem hold and, moreover,  $(n, \varphi(m)) = 1$ , the congruence  $x^n \equiv a \pmod{m}$  always has a unique solution. In other words, exponentiation to the  $n$ -th power (where  $n$  is coprime to  $\varphi(m)$ ) is a bijection on the set  $\mathbb{Z}_m^\times$  of invertible residue classes modulo  $m$  (it is even an automorphism of the group  $(\mathbb{Z}_m^\times, \cdot)$ ).

**11.4.11. Quadratic congruences and the Legendre symbol.** Now, our task is to find an efficient condition determining whether a quadratic congruence

$$ax^2 + bx + c \equiv 0 \pmod{m}$$

is solvable (and if so, how many solutions it has). It can easily be seen from the presented theory that if we want to decide whether this congruence is solvable, it suffices to decide this for the (binomial) congruence

$$x^2 \equiv a \pmod{p},$$

where  $p$  is an odd prime and  $a$  is an integer coprime to it. A congruence modulo a composite  $m$  can be decomposed to an equivalent system of congruences modulo the particular factors of the integer  $m$ , which are powers of primes. Such congruences can be transformed to quadratic congruences with prime modulus using the procedure described in Hensel's lemma 11.4.6. Norming this congruence and completing the square then results in the aforementioned form.

To decide the solvability of a congruence, we can, of course, use the theorem 11.4.10 about the solvability of binomial congruences. Its application is, however, often limited by time resources; we will thus try to find a criterion which will be computationally easier in (not only) the quadratic case.

**Example.** Let us determine the number of solutions of the congruence  $x^2 \equiv 219 \pmod{383}$ .

Since 383 is a prime and  $(2, \varphi(383)) = 2$ , it follows from theorem 11.4.10 that the given congruence is solvable (and it has 2 solutions) if and only if  $219^{\frac{\varphi(383)}{2}} = 219^{191} \equiv 1 \pmod{383}$ . It is not easy to verify this proposition without some computational power (though, this can still be calculated on a "piece of paper"). However, we will show that this condition can be verified much more easily using the properties of the so-called Legendre symbol.

#### LEGENDRE SYMBOL

Let  $p$  be an odd prime and  $a$  an integer. The Legendre symbol is defined by

$$\left(\frac{a}{p}\right) = \begin{cases} 1 & \text{for } p \nmid a, a \text{ is a quadratic residue modulo } p, \\ 0 & \text{for } p \mid a, \\ -1 & \text{if } a \text{ is a quadratic nonresidue modulo } p. \end{cases}$$

The Legendre symbol is also often written as  $(a/p)$  and usually read as "a on p".

**Example.** Since the congruence  $x^2 \equiv 1 \pmod{p}$  is solvable for an arbitrary odd prime  $p$ , we have  $(1/p) = 1$ . Further,

**11.D.35.** Prove the law of quadratic reciprocity for the Jacobi symbol, i.e., prove that if  $a, b$  are odd natural numbers, then

- i)  $\left(\frac{-1}{a}\right) = (-1)^{\frac{a-1}{2}}$ ,
- ii)  $\left(\frac{2}{a}\right) = (-1)^{\frac{a^2-1}{8}}$ ,
- iii)  $\left(\frac{a}{b}\right) = \left(\frac{b}{a}\right) \cdot (-1)^{\frac{a-1}{2} \frac{b-1}{2}}$ .

**Solution.** Let (just like in the definition of the Jacobi symbol)  $a$  factor to (odd) primes as  $p_1 p_2 \cdots p_k$ .

- i) The properties of the Legendre symbol and the aforementioned statement imply that

$$\begin{aligned} \left(\frac{-1}{a}\right) &= \left(\frac{-1}{p_1}\right) \cdot \left(\frac{-1}{p_2}\right) \cdots \left(\frac{-1}{p_k}\right) = \\ &= (-1)^{\frac{p_1-1}{2}} \cdots (-1)^{\frac{p_k-1}{2}} = \\ &= (-1)^{\sum_{i=1}^k \frac{p_i-1}{2}} = \\ &= (-1)^{\prod_{i=1}^k \frac{p_i-1}{2}} = (-1)^{\frac{a-1}{2}}. \end{aligned}$$

- ii) Analogously to above.
- iii) Further, let  $b$  factor to (odd) primes as  $q_1 q_2 \cdots q_\ell$ . If we have  $p_i = q_j$  for some  $i$  and  $j$ , then the symbols on both sides of the equality are equal to zero. Otherwise, the law of quadratic reciprocity for the Legendre symbol implies that for all pairs  $(p_i, q_j)$ , we have

$$\left(\frac{p_i}{q_j}\right) = \left(\frac{q_j}{p_i}\right) \cdot (-1)^{\frac{p_i-1}{2} \frac{q_j-1}{2}}.$$

Therefore,

$$\begin{aligned} \left(\frac{a}{b}\right) &= \prod_{i=1}^k \prod_{j=1}^{\ell} \left(\frac{p_i}{q_j}\right) = \\ &= \prod_{i=1}^k \prod_{j=1}^{\ell} \left(\frac{q_j}{p_i}\right) \cdot (-1)^{\frac{p_i-1}{2} \frac{q_j-1}{2}} = \\ &= \prod_{i=1}^k (-1)^{\frac{p_i-1}{2} \sum_{j=1}^{\ell} \frac{q_j-1}{2}} \prod_{j=1}^{\ell} \left(\frac{q_j}{p_i}\right) = \\ &= \prod_{i=1}^k (-1)^{\frac{p_i-1}{2} \frac{\prod_{j=1}^{\ell} q_j-1}{2}} \prod_{j=1}^{\ell} \left(\frac{q_j}{p_i}\right) = \\ &= \prod_{i=1}^k (-1)^{\frac{p_i-1}{2} \frac{b-1}{2}} \prod_{j=1}^{\ell} \left(\frac{q_j}{p_i}\right) = \\ &= (-1)^{\frac{b-1}{2} \sum_{i=1}^k \frac{p_i-1}{2}} \prod_{i=1}^k \prod_{j=1}^{\ell} \left(\frac{q_j}{p_i}\right) = \\ &= (-1)^{\frac{a-1}{2} \frac{b-1}{2}} \left(\frac{b}{a}\right). \end{aligned}$$

We utilized the result of part (i) of the previous exercise in the calculations.  $\square$

**11.D.36.** Determine whether the congruence  $x^2 \equiv 38 \pmod{165}$  is solvable.

$(-1/5) = (4/5) = 1$ , because the congruence  $x^2 \equiv -1 \pmod{5}$  is equivalent to the congruence  $x^2 \equiv 4 \pmod{5}$ , whose solutions are  $x \equiv \pm 2 \pmod{5}$ .

The statement of the following lemma will be very often used when evaluating the Legendre symbol in practice.

**11.4.12. Lemma.** Let  $p$  be an odd prime,  $a, b \in \mathbb{Z}$  arbitrary. Then:

- (1)  $\left(\frac{a}{p}\right) \equiv a^{\frac{p-1}{2}} \pmod{p}$ .
- (2)  $\left(\frac{ab}{p}\right) = \left(\frac{a}{p}\right) \left(\frac{b}{p}\right)$ .
- (3) If  $a \equiv b \pmod{p}$ , then  $\left(\frac{a}{p}\right) = \left(\frac{b}{p}\right)$ .

**PROOF.** (1) The statement is clear for  $p \mid a$ ; if  $a$  is a quadratic residue modulo  $p$ , then the statement follows from the theorem about the solvability of quadratic congruences, which claims (in this case, we have  $(\varphi(p), 2) = 2$ ) that the necessary and sufficient condition for the congruence  $x^2 \equiv a \pmod{p}$  to be solvable that

$$a^{\frac{p-1}{2}} \equiv 1 \pmod{p}.$$

The same theorem implies for the case of a quadratic non-residue as well that we have  $a^{\frac{p-1}{2}} \not\equiv 1 \pmod{p}$ . However, then (since we have  $p \mid a^{p-1} - 1 = (a^{\frac{p-1}{2}} - 1)(a^{\frac{p-1}{2}} + 1)$  by Fermat's theorem), necessarily  $p \mid a^{\frac{p-1}{2}} + 1$ , i.e.,  $a^{\frac{p-1}{2}} \equiv -1 \pmod{p}$ .

- (2) From (1), we have

$$\left(\frac{ab}{p}\right) \equiv (ab)^{\frac{p-1}{2}} = a^{\frac{p-1}{2}} b^{\frac{p-1}{2}} \equiv \left(\frac{a}{p}\right) \left(\frac{b}{p}\right) \pmod{p}.$$

However, since the values of the Legendre symbol belong to the set  $\{-1, 0, 1\}$ , this congruence immediately implies that the left and right sides are equal.

- (3) Apparent from the definition.  $\square$

**Corollary.** (1) Any reduced residue system modulo  $p$  contains the same number of quadratic residues as non-residues.

- (2) The product of two quadratic residues as well as the product of two quadratic nonresidues is a residue; the product of a residue and a nonresidue is a nonresidue.
- (3)  $(-1/p) = (-1)^{\frac{p-1}{2}}$ , i.e., the congruence  $x^2 \equiv -1 \pmod{p}$  is solvable if and only if  $p \equiv 1 \pmod{4}$ .

**PROOF.** (1) Considering the elements of a reduced residue system modulo  $p$  (we can take, for instance, the set  $\{-\frac{p-1}{2}, \dots, -1, 1, \dots, \frac{p-1}{2}\}$ ), the quadratic residues are exactly those integers which are congruent to one of  $(\pm 1)^2, \dots, (\pm \frac{p-1}{2})^2$ . Thus there are exactly  $\frac{p-1}{2}$  of quadratic residues, so there are  $p-1 - \frac{p-1}{2} = \frac{p-1}{2}$  of the other ones (the quadratic nonresidues).

- (2) This follows immediately from part (2) and the previous lemma.

**Solution.** The Jacobi symbol is equal to

$$\left(\frac{38}{165}\right) = \left(\frac{2}{165}\right) \cdot \left(\frac{19}{165}\right) = \left(\frac{2}{3}\right) \cdot \left(\frac{2}{5}\right) \cdot \left(\frac{2}{11}\right) \cdot \left(\frac{19}{3}\right) \cdot \left(\frac{19}{5}\right) \cdot \left(\frac{19}{11}\right) = (-1)^3 \left(\frac{1}{3}\right) \cdot \left(\frac{-1}{5}\right) \cdot \left(\frac{2}{11}\right)^3 = 1.$$

This result does not answer the question of the existence of a solution. However, if we split the congruence to a system of congruences according to the factors of the modulus, we obtain

$$\begin{aligned} x^2 &\equiv -1 \pmod{3}, \\ x^2 &\equiv 3 \pmod{5}, \\ x^2 &\equiv 5 \pmod{11}, \end{aligned}$$

whence we can easily see that the first and second congruences have no solution. In particular,

$$\left(\frac{-1}{3}\right) = -1 \quad \text{and} \quad \left(\frac{3}{5}\right) = \left(\frac{5}{3}\right) = \left(\frac{2}{3}\right) = -1.$$

Therefore, neither the original congruence has a solution.  $\square$

**11.D.37.** Find all primes  $p$  such that the integer below is a quadratic residue modulo  $p$ :

- i) 3,    ii)  $-3$ ,    iii) 6.

**Solution.**

- i) We are looking for primes  $p \neq 3$  such that  $x^2 \equiv 3 \pmod{p}$  is solvable. Since  $p = 2$  satisfies the above, we will consider only odd primes  $p \neq 3$  from now on. For  $p \equiv 1 \pmod{4}$ , it follows from the law of quadratic reciprocity that  $1 = (3/p) = (p/3)$ , which occurs if and only if  $p \equiv 1 \pmod{3}$ . On the other hand, if  $p \equiv -1 \pmod{4}$ , then  $1 = (3/p) = -(p/3)$ , which holds for  $p \equiv -1 \pmod{3}$ . Putting the conditions of both cases together, we arrive at  $p \equiv \pm 1 \pmod{12}$ , which, together with  $p = 2$ , completes the set of all primes satisfying the given condition.
- ii) The condition  $1 = (-3/p) = (-1/p)(3/p)$  is satisfied if either  $(-1/p) = (3/p) = 1$  or  $(-1/p) = (3/p) = -1$ . In the former case (using the result of the previous item), this means that  $p \equiv 1 \pmod{4}$  and  $p \equiv \pm 1 \pmod{12}$ . In the latter case, we must have  $p \equiv -1 \pmod{4}$  and  $p \equiv \pm 5 \pmod{12}$ , at the same time – we can take, for instance, the set  $\{-5, -1, 1, 5\}$  for a reduced residue system modulo 12, and since  $(3/p) = 1$  for  $p \equiv \pm 1 \pmod{12}$ , we surely have  $(3/p) = -1$  whenever  $p \equiv \pm 5 \pmod{12}$ . We have thus obtained four systems of two congruences each. Two of them have no solution, and the remaining two are satisfied by  $p \equiv 1 \pmod{12}$  and  $p \equiv -5 \pmod{12}$ , respectively.
- iii) In this case,  $(6/p) = (2/p)(3/p)$  and once again, there are two possibilities: either  $(2/p) = (3/p) = 1$  or  $(2/p) = (3/p) = -1$ . The former case occurs if  $p$  satisfies  $p \equiv \pm 1 \pmod{8}$  as well as  $p \equiv \pm 1 \pmod{12}$ . Solving the corresponding systems of linear congruences leads to the condition  $p \equiv \pm 1 \pmod{24}$ . In the latter case, we get  $p \equiv \pm 3 \pmod{8}$  as well as  $p \equiv \pm 5 \pmod{12}$ , which together gives  $p \equiv \pm 5 \pmod{24}$ .

Let us remark that thanks to Dirichlet's theorem 11.2.5, the number of primes we were interested in is infinite in each of the three problems.  $\square$

- (3) It follows from part (1) of the lemma that  $(-1/p) \equiv (-1)^{\frac{p-1}{2}} \pmod{p}$ ; both sides, however, take on the values  $\pm 1$ , so they must be equal.  $\square$

These basic statements about the values of the Legendre symbol are already sufficient for proving the theorem on the infinitude of primes of the form  $4k + 1$  (see paragraph 11.2.3).

**Proposition.** *There are infinitely many primes of the form  $4k + 1$ .*

**PROOF.** We will proceed by contradiction. Suppose that  $p_1, p_2, \dots, p_\ell$  is the enumeration of all primes of the form  $4k + 1$ , and consider the integer  $N = (2p_1 \cdots p_\ell)^2 + 1$ . This integer is of the form  $4k + 1$  as well. The assumption that  $N$  is a prime would lead to an immediate contradiction, since  $N$  is surely greater than any of the integers  $p_1, p_2, \dots, p_\ell$ . Therefore, from now on, let us suppose that it is thus composite. Then, there must exist a prime  $p$  which divides  $N$ . Apparently, none of the primes  $2, p_1, p_2, \dots, p_\ell$  divides  $N$ , so we will be finished if we prove that  $p$  is also of the form  $4k + 1$ . It follows from the congruence  $(2p_1 \cdots p_\ell)^2 \equiv -1 \pmod{p}$ , that  $(-1/p) = 1$ , and this is true (by the previous corollary) if and only if  $p \equiv 1 \pmod{4}$ . Altogether, we have reached a contradiction (a prime  $p$  not belonging to the original list of all primes of the form  $4k + 1$ ) in the case of composite  $N$  as well, which proves that there are infinitely many such primes.  $\square$

The most important theorem which allows us to efficiently compute the value of the Legendre symbol (and thus determine the solvability of a quadratic congruence), is the so-called *law of quadratic reciprocity*.

#### LAW OF QUADRATIC RECIPROCITY

**11.4.13. Theorem.** *Let  $p, q$  be odd primes. Then,*

- (1)  $\left(\frac{-1}{p}\right) = (-1)^{\frac{p-1}{2}}$ ,
- (2)  $\left(\frac{2}{p}\right) = (-1)^{\frac{p^2-1}{8}}$ ,
- (3)  $\left(\frac{q}{p}\right) = \left(\frac{p}{q}\right) \cdot (-1)^{\frac{p-1}{2} \cdot \frac{q-1}{2}}$ .

The theorem is put this way mainly because we can calculate the value  $(a/p)$  for any integer  $a$  using these three formulae and the basic rules for the Legendre symbol.

**Example.** Let us calculate the value  $(79/101)$  using the properties of the Legendre symbol.

**11.D.38.** The following exercise illustrates that if the modulus of a quadratic congruence is a prime  $p$  satisfying  $p \equiv 3 \pmod{4}$ , then we are able not only to decide the solvability of the congruence, but also to describe all of its solutions in a simple way.

Consider a prime  $p \equiv 3 \pmod{4}$  and an integer  $a$  such that  $(a/p) = 1$ . Prove that the solution of the congruence  $x^2 \equiv a \pmod{p}$  is

$$x \equiv \pm a^{\frac{p+1}{4}} \pmod{p}.$$

**Solution.** It can be easily verified (using lemma 11.4.12) that  $(a^{\frac{p+1}{4}})^2 \equiv a^{\frac{p+1}{2}} \equiv a \cdot \left(\frac{a}{p}\right) \equiv a \pmod{p}$ .  $\square$

**11.D.39.** Determine whether the congruence

$$x^2 \equiv 3 \pmod{59}$$

is solvable. If so, find all of its solutions.

**Solution.** Calculating the Legendre symbol

$$\left(\frac{3}{59}\right) = -\left(\frac{59}{3}\right) = -\left(\frac{2}{3}\right) = -(-1) = 1,$$

we find out that the congruence has two solutions. Thanks to the statement above, we can immediately see  $(59 \equiv 3 \pmod{4})$  that the congruence is satisfied by

$$\begin{aligned} x &\equiv \pm 3^{\frac{59+1}{4}} = \pm 3^{15} \equiv (3^5)^3 \equiv \\ &\equiv \pm 7^3 = \pm 343 \equiv \mp 11 \pmod{59}, \end{aligned}$$

since  $3^5 = 243 \equiv 7 \pmod{59}$ .  $\square$

### E. Diophantine equations

Here, we limit ourselves only to the small class of equations which can be solved using divisibility or can be reduced to solving congruences.

**11.E.1. Linear Diophantine equations.** Decide whether it is possible to use a balance scale to weigh 50 grams of given goods provided we have only (an arbitrary number of) three kinds of masses; their weights are 770, 630, and 330 grams, respectively.

If so, how to do that?

**Solution.** Our task is to solve the equation

$$770x + 630y + 330z = 50,$$

where  $x, y, z \in \mathbb{Z}$  (a negative value in the solution would mean that we put the corresponding masses on the other scale). Dividing both sides of the equation by  $(770, 630, 330) = 10$ , we get an equivalent equation

$$77x + 63y + 33z = 5.$$

Considering this equation modulo  $(77, 63) = 7$ , we get the following linear congruence:

$$\begin{aligned} 33z &\equiv 5 \pmod{7}, \\ 5z &\equiv 5 \pmod{7}, \\ z &\equiv 1 \pmod{7}. \end{aligned}$$

$$\begin{aligned} \left(\frac{79}{101}\right) &= \left(\frac{101}{79}\right) \quad \text{since 101 is congruent to 1 modulo 4} \\ &= \left(\frac{22}{79}\right) \\ &= \left(\frac{2}{79}\right) \cdot \left(\frac{11}{79}\right) \\ &= \left(\frac{11}{79}\right) \quad \text{since 79 is congruent to } -1 \text{ modulo 8} \\ &= (-1) \left(\frac{79}{11}\right) \quad \text{since } 11 \equiv 79 \equiv 3 \pmod{4} \\ &= (-1) \left(\frac{2}{11}\right) = 1 \quad \text{since } 11 \equiv 3 \pmod{8}. \end{aligned}$$

Many proofs of the the quadratic reciprocity law can be found in literature<sup>6</sup>. However, many of them (especially the shorter ones) usually make use of deeper knowledge from algebraic number theory. We will present an elementary proof of this theorem here.

Let  $S$  denote the reduced residue system of the least residues (in absolute value) modulo  $p$ , i.e.,

$$S = \left\{ -\frac{p-1}{2}, -\frac{p-3}{2}, \dots, -1, 1, \dots, \frac{p-3}{2}, \frac{p-1}{2} \right\}.$$

Further, for  $a \in \mathbb{Z}$ ,  $p \nmid a$ , let  $\mu_p(a)$  denote the number of negative least residues (in absolute value) of the integers

$$1 \cdot a, 2 \cdot a, \dots, \frac{p-1}{2} \cdot a,$$

i.e., we decide for each of these integers to which integer from the set  $S$  it is congruent and count the number of the negative ones. If it is clear from context which values  $a, p$  we mean, we will usually omit the parameters and write only  $\mu$  instead of  $\mu_p(a)$ .

**Example.** We determine  $\mu_p(a)$  for the prime  $p = 11$  and the integer  $a = 3$ .

Now, the reduced residue system we are interested in is  $S = \{-5, \dots, -1, 1, \dots, 5\}$ , and for  $a = 3$ , we calculate

$$\begin{aligned} 1 \cdot 3 &\equiv 3 \pmod{11} \\ 2 \cdot 3 &\equiv -5 \pmod{11} \\ 3 \cdot 3 &\equiv -2 \pmod{11} \\ 4 \cdot 3 &\equiv 1 \pmod{11} \\ 5 \cdot 3 &\equiv 4 \pmod{11}, \end{aligned}$$

whence  $\mu_{11}(3) = 2$ .

We will show in the following statement that this integer is tightly connected to the Legendre symbol – the value of the symbol  $(3/11)$  can be determined in terms of the  $\mu$  function as  $(-1)^{\mu_{11}(3)} = (-1)^2 = 1$ .

<sup>6</sup>In 2000, F. Lemmermeyer stated 233 proofs – see F. Lemmermeyer, *Reciprocity laws. From Euler to Eisenstein*, Springer, 2000

This congruence is thus satisfied by those integers  $z$  of the form  $z = 1 + 7t$ , where  $t$  is an integer parameter.

Substituting the form of  $z$  into the original equation, we get

$$\begin{aligned} 77x + 63y &= 5 - 33(1 + 7t), \\ 11x + 9y &= -4 - 33t. \end{aligned}$$

Now, we consider this (parametrized) equation modulo 11:

$$\begin{aligned} 9y &\equiv -4 - 33t \pmod{11}, \\ -2y &\equiv -4 \pmod{11}, \\ y &\equiv 2 \pmod{11}. \end{aligned}$$

Therefore, this congruence is satisfied by integers  $y = 2 + 11s$  for any  $s \in \mathbb{Z}$ . Now, it only remains to calculate  $x$ :

$$\begin{aligned} 11x &= -4 - 33t - 9(2 + 11s), \\ 11x &= -22 - 33t - 9 \cdot 11s, \\ x &= -2 - 3t - 9s. \end{aligned}$$

We have found out that the equation is satisfied if and only if  $(x, y, z)$  is in the set

$$\{(-2 - 3t - 9s, 2 + 11s, 1 + 7t); s, t \in \mathbb{Z}\}.$$

Particular solutions can be obtained by evaluating the triple at concrete values of  $t, s$ . For instance, setting  $t = s = 0$  gives the triple  $(-2, 2, 1)$ ; putting  $t = -4, s = 1$  leads to  $(1, 13, -27)$ .

Of course, the unknowns can be eliminated in any order – the result may seem “syntactically” different, but it must still describe the same set of solutions (that is given by a particular coset of an appropriate subgroup (in our case, it is the subgroup  $(2, 2, 1) + (3, 0, 7)\mathbb{Z} + (-9, 11, 0)\mathbb{Z}$ ) in the commutative group  $\mathbb{Z}^3$ , which is an apparent analog to the fact that the solution of such an equation over a field forms an affine subspace of the corresponding vector space).  $\square$

**Other types of Diophantine equations reducible to congruences.** Some Diophantine equations are such that one of the unknowns can be expressed explicitly as a function of the other ones. In this case, it makes sense to examine for which integer arguments it holds that the value of the function is also an integer.

For instance, having an equation of the form

$$mx_n = f(x_1, \dots, x_{n-1}),$$

where  $m$  is a natural number and  $f(x_1, \dots, x_{n-1}) \in \mathbb{Z}[x_1, \dots, x_{n-1}]$  is a polynomial with integer coefficients, an  $n$ -tuple of integers  $x_1, \dots, x_n$  is a solution of it if and only if

$$f(x_1, \dots, x_{n-1}) \equiv 0 \pmod{m}.$$

**11.E.2.** Solve the Diophantine equation  $x(x + 3) = 4y - 1$ .

**Solution.** The equation can be rewritten as  $4y = x^2 + 3x + 1$ . Now, we will solve the congruence

$$x^2 + 3x + 1 \equiv 0 \pmod{4}.$$

This congruence has no solution since for any integer  $x$ , the polynomial  $x^2 + 3x + 1$  evaluates to an odd integer (the

**11.4.14. Lemma (Gauss).** If  $p$  is an odd prime,  $a \in \mathbb{Z}$ ,  $p \nmid a$ , then the value of the Legendre symbol satisfies

$$\left(\frac{a}{p}\right) = (-1)^{\mu_p(a)}.$$

**PROOF.** For each integer  $i \in \{1, 2, \dots, \frac{p-1}{2}\}$ , we set a value  $m_i \in \{1, 2, \dots, \frac{p-1}{2}\}$  so that  $i \cdot a \equiv \pm m_i \pmod{p}$ . We can easily see that if  $k, l \in \{1, 2, \dots, \frac{p-1}{2}\}$  are different, then the values  $m_k, m_l$  are also different (the equality  $m_k = m_l$  would imply that  $k \cdot a \equiv \pm l \cdot a \pmod{p}$ , and hence  $k \equiv \pm l \pmod{p}$ , which cannot be satisfied unless  $k = l$ ).

Therefore, the sets  $\{1, 2, \dots, \frac{p-1}{2}\}$  and  $\{m_1, m_2, \dots, m_{\frac{p-1}{2}}\}$  coincide, which is also illustrated by the above example. Multiplying the congruences

$$\begin{aligned} 1 \cdot a &\equiv \pm m_1 \pmod{p}, \\ 2 \cdot a &\equiv \pm m_2 \pmod{p}, \end{aligned}$$

$\vdots$

$$\frac{p-1}{2} \cdot a \equiv \pm m_{\frac{p-1}{2}} \pmod{p}$$

leads to

$$\frac{p-1}{2}! \cdot a^{\frac{p-1}{2}} \equiv (-1)^\mu \cdot \frac{p-1}{2}! \pmod{p},$$

since there are exactly  $\mu$  negative values on the right-hand sides of the congruences. Dividing both sides by the integer  $\frac{p-1}{2}!$ , we get the wanted statement, making use of lemma 11.4.12, whence  $(a/p) \equiv a^{\frac{p-1}{2}} \pmod{p}$ .  $\square$

Now, with the help of Gauss’s lemma, we will prove the law of quadratic reciprocity.

**PROOF OF THE LAW OF QUADRATIC RECIPROCITY.** The first part has been already proven; for the rest, we first derive a lemma which will be utilized in the proof of both of the remaining parts.

Let  $a \in \mathbb{Z}$ ,  $p \nmid a$ ,  $k \in \mathbb{N}$  and let  $[x]$  and  $\langle x \rangle$  denote the integer part (i.e. floor) and the fractional part, respectively, of a real number  $x$ . Then,

$$\left[\frac{2ak}{p}\right] = \left[2\left[\frac{ak}{p}\right] + 2\left\langle\frac{ak}{p}\right\rangle\right] = 2\left[\frac{ak}{p}\right] + \left[2\left\langle\frac{ak}{p}\right\rangle\right].$$

This expression is odd if and only if  $\langle \frac{ak}{p} \rangle > \frac{1}{2}$ , which is if and only if the least residue (in absolute value) of the integer  $ak$  modulo  $p$  is negative (a watchful reader should notice the return from the calculations of (ostensibly) irrelevant expressions back to the conditions close to the Legendre symbol). The integer  $\mu_p(a)$  thus has the same parity (is congruent to, modulo 2) as  $\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{2ak}{p}\right]$ , whence (thanks to Gauss’s lemma) we get that

$$\left(\frac{a}{p}\right) = (-1)^{\mu_p(a)} = (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{2ak}{p}\right]}.$$

fact that the congruence is not solvable can also be established by trying out all four possible remainders modulo 4 into it).  
□

**11.E.3.** Solve the following equation in integers:

$$379x + 314y + 183y^2 = 210$$

**Solution.** The equation is linear in  $x$ , so the other unknown,  $y$ , must satisfy the congruence

$$183y^2 + 314y - 210 \equiv 0 \pmod{379}.$$

Now, we can complete the left-hand polynomial to square in order to get rid of the linear term. First of all, we must find a  $t \in \mathbb{Z}$  such that  $183 \cdot t \equiv 1 \pmod{379}$ . (In other words, we need to determine the inverse of the integer 183 modulo 379). For this purpose, we will use the Euclidean algorithm:

$$\begin{aligned} 379 &= 2 \cdot 183 + 13, \\ 183 &= 14 \cdot 13 + 1, \end{aligned}$$

whence

$$\begin{aligned} 1 &= 183 - 14 \cdot 13 = 183 - 14 \cdot (379 - 2 \cdot 183) = \\ &= 29 \cdot 183 - 14 \cdot 379. \end{aligned}$$

Therefore, we can take, for instance, the integer 29 to be our  $t$ . Now, multiplying both sides of the congruence by  $t = 29$  and rearranging it, we get an equivalent congruence:

$$y^2 + 10y - 26 \equiv 0 \pmod{379}$$

Now, we can complete the left-hand polynomial to square, which leads to (substituting  $z = y + 5$ )

$$\begin{aligned} (y + 5)^2 - 5^2 - 26 &\equiv 0 \pmod{379}, \\ z^2 &\equiv 51 \pmod{379}. \end{aligned}$$

Invoking the law of quadratic reciprocity, we calculate the Legendre symbol  $(51/379)$ :

$$\begin{aligned} \left(\frac{51}{379}\right) &= \left(\frac{3}{379}\right) \cdot \left(\frac{17}{379}\right) = \left(\frac{379}{3}\right) \cdot (-1) \cdot \left(\frac{379}{17}\right) \cdot (+1) = \\ &= \left(\frac{1}{3}\right) \cdot (-1) \cdot \left(\frac{5}{17}\right) = (1) \cdot (-1) \cdot \left(\frac{17}{5}\right) \cdot (+1) = \\ &= (-1) \cdot \left(\frac{2}{5}\right) = (-1) \cdot (-1) = 1, \end{aligned}$$

whence it follows that the congruence is solvable, and, in particular, it has two solutions modulo 379.

The proposition of exercise 11.D.38 implies that the solutions are of the form

$$z \equiv \pm 51^{\frac{380}{4}},$$

where  $51^3 \equiv 1 \pmod{379}$ , whence  $51^{95} = (51^3)^{31} \cdot 51^2 \equiv -52 \pmod{379}$ . The solution is thus  $z \equiv \pm 52 \pmod{379}$ , which gives for the original unknown that

$$y \equiv 47 \pmod{379}, \quad y \equiv -57 \pmod{379}.$$

Therefore, the given Diophantine equation is satisfied by those pairs  $(x, y)$  with  $y \in \{47 + 379 \cdot k; k \in \mathbb{Z}\} \cup \{-57 +$

Furthermore, if  $a$  is odd, then  $a + p$  is even and we get

$$\begin{aligned} \left(\frac{2a}{p}\right) &= \left(\frac{2a + 2p}{p}\right) = \left(\frac{4 \frac{a+p}{2}}{p}\right) = \left(\frac{2}{p}\right)^2 \cdot \left(\frac{a+p}{p}\right) \\ &= (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{(a+p)k}{p}\right]} = (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{ak}{p}\right]} \cdot (-1)^{\sum_{k=1}^{\frac{p-1}{2}} k}. \end{aligned}$$

Since the sum of the arithmetic series  $\sum_{k=1}^{\frac{p-1}{2}} k$  is  $\frac{1}{2} \frac{p-1}{2} \frac{p+1}{2} = \frac{p^2-1}{8}$ , we get (for  $a$  odd) the relation

$$\left(\frac{2}{p}\right) \cdot \left(\frac{a}{p}\right) = (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{ak}{p}\right]} \cdot (-1)^{\frac{p^2-1}{8}},$$

which, for  $a = 1$ , gives the wanted statement of item 2.

By part (2), which we have already proved, and the previous equality, we now get for odd integers  $a$  that

$$(1) \quad \left(\frac{a}{p}\right) = (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{ak}{p}\right]}.$$

Now, let us consider, for given primes  $p \neq q$ , the set

$$\begin{aligned} T &= \{q \cdot x; x \in \mathbb{Z}, 1 \leq x \leq (p-1)/2\} \times \\ &\quad \times \{p \cdot y; y \in \mathbb{Z}, 1 \leq y \leq (q-1)/2\}. \end{aligned}$$

We apparently have  $|T| = \frac{p-1}{2} \cdot \frac{q-1}{2}$ . We will show that we also have

$$(-1)^{|T|} = (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{pk}{q}\right]} \cdot (-1)^{\sum_{k=1}^{\frac{p-1}{2}} \left[\frac{qk}{p}\right]},$$

which will be sufficient thanks to the above.

Since the equality  $qx = py$  can happen for no pair of  $x, y$  from the permissible domain, the set  $T$  can be partitioned to (disjoint) subsets  $T_1$  and  $T_2$  so that  $T_1 = T \cap \{(u, v); u, v \in \mathbb{Z}, u < v\}$ ,  $T_2 = T \setminus T_1$ . Clearly,  $|T_1|$  is the number of pairs  $(qx, py)$  for which  $x < \frac{p}{q}y$ . Since  $\frac{p}{q}y \leq \frac{p}{q} \cdot \frac{q-1}{2} < \frac{p}{2}$ , we have  $\left[\frac{p}{q}y\right] \leq \frac{p-1}{2}$ . For a fixed  $y$ , in  $T_1$ , there are thus exactly those pairs  $(qx, py)$  for which  $1 \leq x \leq \left[\frac{p}{q}y\right]$ ; hence  $|T_1| = \sum_{y=1}^{(q-1)/2} \left[\frac{p}{q}y\right]$ . Analogously,  $|T_2| = \sum_{x=1}^{(p-1)/2} \left[\frac{q}{p}x\right]$ .

By (1), we thus have  $\left(\frac{p}{q}\right) = (-1)^{|T_1|}$  and  $\left(\frac{q}{p}\right) = (-1)^{|T_2|}$ , which finishes the proof of the law of quadratic reciprocity. □

$379 \cdot k; k \in \mathbb{Z}$  and  $x = \frac{1}{379} \cdot (210 - 314y - 183y^2)$ ; e. g.  $(-1105, 47)$  or  $(-1521, -57)$  (which are the only solutions with  $|x| < 10^5$ ).  $\square$

**11.E.4.** Solve the equation  $2^x = 1 + 3^y$  in integers.

**Solution.** If  $y < 0$ , then  $1 < 1 + 3^y < 2$ , whence  $0 < x < 1$ , so  $x$  could not be an integer. Therefore,  $y \geq 0$ , hence  $2^x = 1 + 3^y \geq 2$  and  $x \geq 1$ . We will show that we also must have  $x \leq 2$ . If not (i.e., if  $x \geq 3$ ), then we would have

$$1 + 3^y = 2^x \equiv 0 \pmod{8},$$

whence it follows that

$$3^y \equiv -1 \pmod{8}.$$

However, this is impossible since the order of 3 modulo 8 equals 2, so the powers of three are congruent to 3 and 1 only. Now, it remains to examine the possibilities  $x = 1$  and  $x = 2$ .

For  $x = 1$ , we get

$$3^y = 2^1 - 1 = 1,$$

hence  $y = 0$ . If  $x = 2$ , we have

$$3^y = 2^2 - 1 = 3,$$

whence  $y = 1$ . Thus, the equations has two solutions:  $x = 1, y = 0$ ; and  $x = 2, y = 1$ .  $\square$

**F. Primality tests**

**11.F.1. Mersenne primes.** The following problems are in deep connection with testing Mersenne numbers for primality.

For any  $q \in \mathbb{N}$ , consider the integer  $M_q = 2^q - 1$  and prove:

- i) If  $q$  is composite, then so is  $M_q$ .
- ii) If  $q$  is a prime,  $q \equiv 3 \pmod{4}$ , then  $2q + 1$  divides  $M_q$  if and only if  $2q + 1$  is a prime (hence it follows that if  $q \equiv 3 \pmod{4}$  is a Sophie Germain prime<sup>3</sup>, then  $M_q$  is not a prime).
- iii) If a prime  $p$  divides  $M_q$ , then  $p \equiv \pm 1 \pmod{8}$  and  $p \equiv 1 \pmod{q}$ .

**Solution.**

<sup>3</sup>See Wikipedia, *Sophie Germain prime*, [http://en.wikipedia.org/wiki/Sophie\\_Germain\\_prime](http://en.wikipedia.org/wiki/Sophie_Germain_prime) (as of July 28, 2013, 14:43 GMT).

The evaluation of the Legendre symbol (as we saw in the example above) allows us to only use the law of quadratic reciprocity for primes, so it forces us to factor integers to primes, which is a very hard operation from the computational point of view. This can be mended by extending the definition of the Legendre symbol to the so-called *Jacobi symbol* with similar properties.

**Definition.** Let  $a \in \mathbb{Z}, b \in \mathbb{N}, 2 \nmid b$ . Let  $b$  factor as  $b = p_1 p_2 \cdots p_k$  to (odd) primes (here, we exceptionally do not group the same primes to a power of the prime, rather we write each one explicitly, e.g.  $135 = 3 \cdot 3 \cdot 3 \cdot 5$ ). The symbol

$$\left(\frac{a}{b}\right) = \left(\frac{a}{p_1}\right) \cdot \left(\frac{a}{p_2}\right) \cdots \left(\frac{a}{p_k}\right)$$

is called the *Jacobi symbol*.

We show in the practical column that the Jacobi symbol has similar properties as the Legendre one. However, there is a substantial aberration – it is not generally true that  $(a/b) = 1$  implies that the congruence  $x^2 \equiv a \pmod{b}$  is solvable.

**Example.**

$$\left(\frac{2}{15}\right) = \left(\frac{2}{3}\right) \cdot \left(\frac{2}{5}\right) = (-1) \cdot (-1) = 1,$$

but the congruence

$$x^2 \equiv 2 \pmod{15}$$

has no solution (the congruence  $x^2 \equiv 2$  is solvable neither modulo 3 nor modulo 5).

**Theorem** (Law of quadratic reciprocity for the Jacobi symbol). *Let  $a, b \in \mathbb{N}$  be odd integers. Then,*

- (1)  $\left(\frac{-1}{a}\right) = (-1)^{\frac{a-1}{2}}$ ,
- (2)  $\left(\frac{2}{a}\right) = (-1)^{\frac{a^2-1}{8}}$ ,
- (3)  $\left(\frac{a}{b}\right) = \left(\frac{b}{a}\right) \cdot (-1)^{\frac{a-1}{2} \cdot \frac{b-1}{2}}$ .

**PROOF.** The proof is simple, utilizing the law of quadratic reciprocity for the Legendre symbol. See exercise 11.D.35.  $\square$

There is another application of the law of quadratic reciprocity in a certain sense – we can consider the question: *For which primes is a given integer  $a$  a quadratic residue?* We are already able to answer this question for  $a = 2$ , for example. The first step in answering this question is to do so for primes since the answer for composite values of  $a$  depends on the factorization of the integer  $a$ .

**Theorem.** *Let  $q$  be an odd prime.*

- If  $q \equiv 1 \pmod{4}$ , then  $q$  is a quadratic residue modulo those primes  $p$  which satisfy  $p \equiv r \pmod{q}$ , where  $r$  is a quadratic residue modulo  $q$ .
- If  $q \equiv 3 \pmod{4}$ , then  $q$  is a quadratic residue modulo those primes  $p$  which satisfy  $p \equiv \pm b^2 \pmod{4q}$ , where  $b$  is odd and coprime to  $q$ .

- i) If  $n \mid q$ , then it follows from exercise 11.A.7 that  $2^n - 1 \mid 2^q - 1$ , so  $M_n \mid M_q$ . Therefore,  $M_q$  is not a prime for  $n > 1$ .
- ii) Let  $n = 2q+1$  be a divisor of  $M_q$ . We will show that  $n$  is a prime invoking Lucas' theorem 11.6.10. Since  $n - 1 = 2q$  has only two prime divisors, it suffices to find compositeness witnesses for the integers 2 and  $q$ . We have  $2^{\frac{n-1}{q}} = 2^2 \not\equiv 1 \pmod{n}$ ,  $(-2)^{\frac{n-1}{2}} = -2^q \equiv -1 \not\equiv 1 \pmod{n}$ , thanks to the assumption  $n \mid M_q = 2^q - 1$ . Further, since  $(-2)^{n-1} = 2^{n-1} = 2^{2q} - 1 = (2^q + 1)M_q \equiv 0 \pmod{n}$ , it follows from Lucas' theorem that  $n$  is a prime.

Now, let  $p = 2q + 1 \equiv -1 \pmod{8}$  be a prime. Since  $(2/p) = 1$ , there exists an  $m$  such that  $2 \equiv m^2 \pmod{p}$ . Hence,  $2^q \equiv 2^{\frac{p-1}{2}} \equiv m^{p-1} \equiv 1 \pmod{p}$ , so  $p \mid 2^q - 1 = M_q$ .

- iii) If  $p \mid M_q = 2^q - 1$ , then the order of 2 modulo  $p$  must divide the prime  $q$ , hence it equals  $q$ . Therefore,  $q \mid p-1$ , and there exists a  $k \in \mathbb{Z}$  such that  $2qk = p - 1$ . Altogether, we get

$$(2/p) \equiv 2^{\frac{p-1}{2}} \equiv 2^{qk} \equiv 1 \pmod{p},$$

i.e.,  $p \equiv \pm 1 \pmod{8}$ . □

**11.F.2.** For each of the following Mersenne numbers, determine whether it is prime or composite:  $2^{11} - 1$ ,  $2^{15} - 1$ ,  $2^{23} - 1$ ,  $2^{29} - 1$ , and  $2^{83} - 1$ .

**Solution.** In the case of the integer  $2^{15} - 1$ , the exponent is composite; therefore, the whole integer is composite as well (we even know that it is divisible by  $2^3 - 1$  and  $2^5 - 1$ ). In the other cases, the exponent is always a prime. We can notice that these primes, namely  $q = 11, 23, 29$ , and  $83$ , are even Sophie Germain primes (i.e.,  $2q + 1$  is also a prime). It thus follows from part (ii) of the previous exercise that  $23 \mid 2^{11} - 1$ ,  $47 \mid 2^{23} - 1$ , and  $167 \mid 2^{83} - 1$ .

We cannot use this proposition for the last case since  $29 \not\equiv 3 \pmod{4}$  and, indeed,  $59 \nmid 2^{29} - 1$ . Now, however, it follows from part (iii) of the above exercise that if there is a prime  $p$  which divides  $2^{89} - 1$ , then it must satisfy

$$\begin{aligned} p &\equiv \pm 1 \pmod{8} \\ p &\equiv 1 \pmod{29}, \end{aligned}$$

i.e.,  $p \equiv 1 \pmod{232}$  or  $p \equiv 175 \pmod{232}$ . If we are looking for a prime divisor of the integer  $n = 2^{29} - 1 = 536\,870\,911$ , then it suffices to check the primes (of the above form) up to  $\sqrt{n} \approx 23\,170$ . There are 50 of them, so we are able to decide whether  $n$  is a prime quite easily (even with paper and pencil). In this case, fortunately,  $n$  is divisible already by the least prime, 233. □

**11.F.3.** Show that the integer 341 is a Fermat pseudoprime to base 2, yet it is not a Euler-Jacobi pseudoprime to base 2. Further, prove that the integer 561 is a Euler-Jacobi pseudoprime to base 2, but not to base 3. Prove that, on the other hand, the integer

**PROOF.** The first theorem follows trivially from the law of quadratic reciprocity. Let us consider  $q \equiv 3 \pmod{4}$ , i.e.,  $(q/p) = (-1)^{\frac{p-1}{2}}(p/q)$ . First of all, let  $p \equiv +b^2 \pmod{4q}$ , where  $b$  is odd, and hence  $b^2 \equiv 1 \pmod{4}$ . Then,  $p \equiv b^2 \equiv 1 \pmod{4}$  and  $p \equiv b^2 \pmod{q}$ . Therefore,  $(-1)^{\frac{p-1}{2}} = 1$  and  $(p/q) = 1$ , whence  $(q/p) = 1$ . Now, if  $p \equiv -b^2 \pmod{4q}$ , then we similarly get that  $p \equiv -b^2 \equiv 3 \pmod{4}$  and  $p \equiv -b^2 \pmod{q}$ . Therefore,  $(-1)^{\frac{p-1}{2}} = -1$  and  $(p/q) = -1$ , whence we get again that  $(q/p) = 1$ .

For the opposite way, suppose that  $(q/p) = 1$ . There are two possibilities – either  $(-1)^{\frac{p-1}{2}} = 1$  and  $(p/q) = 1$ , or  $(-1)^{\frac{p-1}{2}} = -1$  and  $(p/q) = -1$ . In the former case, we have  $p \equiv 1 \pmod{4}$  and there is a  $b$  such that  $p \equiv b^2 \pmod{q}$ . Further, we can assume without loss of generality that  $b$  is odd (if not, we could have taken  $b + q$  instead). However, then we get  $b^2 \equiv 1 \equiv p \pmod{4}$ , and altogether  $p \equiv b^2 \pmod{4q}$ .

In the latter case, we have  $p \equiv 3 \pmod{4}$  and  $(-p/q) = (-1/q)(p/q) = (-1)(-1) = 1$ . Therefore, there is a  $b$  (which can also be chosen so that it is odd) such that  $-p \equiv b^2 \pmod{q}$ . We thus get  $-b^2 \equiv 3 \equiv p \pmod{4}$ , and altogether  $p \equiv -b^2 \pmod{4q}$ . □

### 5. Diophantine equations

It is as early as in the third century AD when Diophantus of Alexandria dealt with miscellaneous equations while admitting only integers as solutions. And there is no wonder – in many practical problems that lead to equations, non-integer solutions may fail to have a meaningful interpretation. As an example, we can consider the problem of how to pay an exact amount of money with coins of given values.

In honor of Diophantus, equations for which we are interested in integer solutions only are called *Diophantine equations*.

Another nice example of a Diophantine equation is Euler's relation

$$v - e + f = 2$$

from graph theory, connecting the number of vertices, edges, and faces of a planar graph. Furthermore, if we restrict ourselves to regular graphs only, we get to the problem about existence of the so-called Platonic solids, which can be smartly described just as a solution of this Diophantine equation – for more information, see 13.1.22.

Unfortunately, there is no universal method for solving this kind of equations. There is even no method (algorithm) to decide whether a given polynomial Diophantine equation has a solution. This question is well-known as *Hilbert's tenth problem*, and the proof of algorithmic unsolvability of this problem was given by Юрий Матиясевич (Yuri Matiyasevich) in 1970.<sup>7</sup>

However, there are cases in which we are able to find the solution of a Diophantine equation, or – at least – to reduce

<sup>7</sup>See the elementary text M. Davis, *Hilbert's Tenth Problem is Unsolv-able*, The American Mathematical Monthly 80(3): 233–269. 1973.

121 is a Euler-Jacobi pseudoprime to base 3, but not to base 2.

**Solution.** The integer 341 is a Fermat pseudoprime to base 2 since  $2^{10} \equiv 1 \Rightarrow 2^{340} \equiv 1 \pmod{341}$ . It is not a Euler-Jacobi pseudoprime since  $2^{170} \equiv 1 \pmod{341}$ , but  $(\frac{2}{341}) = -1$ , which follows from the fact that  $341 \equiv -3 \pmod{8}$ . For the integer 561, we have  $2^{280} \equiv 1 \pmod{561}$  and  $(\frac{2}{561}) = 1$ , since  $561 \equiv 1 \pmod{8}$ . Therefore, it is a Euler-Jacobi pseudoprime to base 2. But not to base 3, since  $3 \mid 561$ . On the other hand, the integer 121 satisfies  $3^5 \equiv 1 \pmod{121} \Rightarrow 3^{60} \equiv 1 \pmod{121}$  and  $(\frac{3}{121}) = 1$ , but  $2^{60} \equiv 89 \not\equiv 1 \pmod{121}$ .  $\square$

**11.F.4.** Prove that the integers 2465, 2821, and 6601 are Carmichael numbers, i.e., denoting any of them as  $n$ , then every integer  $a$  coprime to  $n$  satisfies

$$a^{n-1} \equiv 1 \pmod{n}.$$

**Solution.** We have  $2465 = 5 \cdot 17 \cdot 29$ ,  $2821 = 7 \cdot 13 \cdot 31$ ,  $6601 = 7 \cdot 23 \cdot 41$ , and the proposition follows from Korselt's criterion 11.6.6 since all of the integers 4, 16, 28 divide  $2464 = 2^5 \cdot 7 \cdot 11$ , all of the integers 6, 12, 30 divide  $2820 = 2^2 \cdot 3 \cdot 5 \cdot 47$ , and 6, 22, 40 divide  $6600 = 2^3 \cdot 3 \cdot 5^2 \cdot 11$ .  $\square$

**11.F.5.** Prove that the integer 2047 is a strong pseudoprime to base 2, but not to base 3. Further, prove that the integer 1905 is a Euler-Jacobi pseudoprime to base 2 but not a strong pseudoprime to this base.

**Solution.** In order to verify whether 2047 is a strong pseudoprime to base 2, we factor

$$(2^{2046} - 1) = (2^{1023} - 1)(2^{1023} + 1).$$

Since  $2^{1023} \equiv 1 \pmod{2047}$ , the statement is true. However, it is not a strong pseudoprime to base 3 as

$$3^{1023} \equiv 1565 \not\equiv \pm 1 \pmod{2047}.$$

Notice that for the integer 2047, the strong pseudoprimality test is identical to the Euler one (this is because the integer 2046 is not divisible by four).

The integer 1905 is a Euler-Jacobi pseudoprime to base 2 since  $2^{1904/2} \equiv 1 \pmod{1905}$  and the Jacobi symbol  $(2/1905)$  is equal to 1. Since  $1904 = 2^4 \cdot 7 \cdot 17$ , 1905 will be a strong pseudoprime to base 2 only if at least one of the following congruences holds:

$$\begin{aligned} 2^{952} &\equiv -1 \pmod{1905}, \\ 2^{476} &\equiv -1 \pmod{1905}, \\ 2^{238} &\equiv -1 \pmod{1905}, \\ 2^{119} &\equiv \pm 1 \pmod{1905}. \end{aligned}$$

However,  $2^{952} \equiv 2^{476} \equiv 1 \pmod{1905}$ ,  $2^{238} \equiv 1144 \pmod{1905}$ , and  $2^{119} \equiv 128 \pmod{1905}$ . Therefore, 1905 is not a strong pseudoprime to base 2.  $\square$

the problem to solving congruences, which is besides the already mentioned applications another motivation for studying them. Now, we will describe several such types of Diophantine equations.

**Linear Diophantine equation.** A linear Diophantine equation is an equation of the form

$$a_1x_1 + a_2x_2 + \dots + a_nx_n = b,$$

where  $x_1, \dots, x_n$  are unknowns and  $a_1, \dots, a_n, b$  are given non-zero integers.

*We can see that the ability to solve Diophantine equations is sometimes important in "practical" life as well, as is proved by Bruce Willis and Samuel Jackson in Die Hard with a Vengeance, where they have to do away with a bomb using 4 gallons of water, having only 3- and 5-gallon containers at their disposal. A mathematician would say that the gentlemen were to find a solution of the Diophantine equation  $3x + 5y = 4$ .*

One can use congruences in order to solve these equations. Apparently, it is necessary for the equation to be solvable that the integer  $d = (a_1, \dots, a_n)$  divides  $b$ . Provided that, dividing both sides of the equation by the number  $d$  leads to an equivalent equation

$$a'_1x_1 + a'_2x_2 + \dots + a'_nx_n = b',$$

where  $a'_i = a_i/d$  for  $i = 1, \dots, n$  and  $b' = b/d$ . Here, we have

$$d \cdot (a'_1, \dots, a'_n) = (da'_1, \dots, da'_n) = (a_1, \dots, a_n) = d,$$

so  $(a'_1, \dots, a'_n) = 1$ .

Further, we will show that the equation

$$a_1x_1 + a_2x_2 + \dots + a_nx_n = b,$$

where  $a_1, a_2, \dots, a_n, b$  are integers such that  $(a_1, \dots, a_n) = 1$ , always have a solution in integers and all such solutions can be described in terms of  $n - 1$  integer parameters.

We will prove this proposition by mathematic induction on  $n$ , the number of unknowns. The situation is trivial for  $n = 1$  – there is a unique solution (which does not depend

**11.F.6.** Applying Pocklington-Lehmer test 11.6.11, show that 1321 is a prime.

**Solution.** Let us set  $N = 1321$ , then  $N - 1 = 1320 = 2^3 \cdot 3 \cdot 5 \cdot 11$ .

For the sake of simplicity, we will assume that the trial division is executed only for primes below 10, then  $F = 2^3 \cdot 3 \cdot 5 = 120$ ,  $U = 11$ , where  $(F, U) = (120, 11) = 1$ .

In order to prove the primality of 1321 by the Pocklington-Lehmer test, we need to find a primality witness  $a_p$  for each  $p \in \{2, 3, 5\}$ .

Since  $(2^{\frac{1320}{3}} - 1, 1321) = 1$  and  $(2^{\frac{1320}{5}} - 1, 1321) = 1$ , we can lay  $a_3 = a_5 = 2$ . However, for  $p = 2$ , we have  $(2^{\frac{1320}{2}} - 1, 1321) = 1321$ , so we have to look for another primality witness. We can take  $a_2 = 7$  since  $(7^{\frac{1320}{2}} - 1, 1321) = 1$ . In both cases, we have  $2^{1320} \equiv 7^{1320} \equiv 1 \pmod{1321}$ . The primality witnesses of the integer 1321 are thus  $a_2 = 7, a_3 = a_5 = 2$ . Instead, we could also have chosen for all primes  $p$  the same number (e. g. 13), which is a primitive root modulo 1321.  $\square$

**11.F.7.** Factor the integer 221 to primes by Pollard's  $\rho$ -method. Use the function  $f(x) = x^2 + 1$  with initial value  $x_0 = 2$ .

**Solution.** Let us set  $x = y = 2$ . The procedure from 11.6.14 gives:

$x := f(x)$	$y := f(f(y))$	$( x - y , 221) \pmod{221}$
5	26	1
26	197	1
14	104	1
197	145	13

We have thus found a non-trivial divisor, so now it is easy to calculate  $221 = 13 \cdot 17$ .  $\square$

**11.F.8.** Find a non-trivial divisor of the integer 455459.

**Solution.** Consider the function  $f(x) = x^2 + 1$  (we silently assume that this function behaves randomly modulo an unknown prime divisor  $p$  of the integer  $n$  and has the required properties). In the particular iterations, we compute  $a \leftarrow f(a) \pmod{n}$ ,  $b \leftarrow f(f(b)) \pmod{n}$  while evaluating  $d = (a - b, n)$ .

a	b	d
5	26	1
26	2871	1
677	179685	1
2871	155260	1
44380	416250	1
179685	43670	1
121634	164403	1
155260	247944	1
44567	68343	743

We have found a divisor 743, and now we can easily compute that  $455459 = 613 \cdot 743$ .  $\square$

on any parameters). Further, let  $n \geq 2$  and suppose that the statement holds for equations having  $n - 1$  unknowns. Denoting  $d = (a_1, \dots, a_{n-1})$ , any  $n$ -tuple  $x_1, \dots, x_n$  that satisfies the equation must also satisfy the congruence

$$a_1x_1 + a_2x_2 + \dots + a_nx_n \equiv b \pmod{d}.$$

Since  $d$  is the greatest common divisor of the integers  $a_1, \dots, a_{n-1}$ , this congruence is of the form

$$a_nx_n \equiv b \pmod{d},$$

which (since  $(d, a_n) = (a_1, \dots, a_n) = 1$ ) has a unique solution

$$x_n \equiv c \pmod{d},$$

where  $c$  is a suitable integer, i.e.,  $x_n = c + dt$ , where  $t \in \mathbb{Z}$  is arbitrary. Substituting into the original equation and refining it leads to the equation

$$a_1x_1 + \dots + a_{n-1}x_{n-1} = b - a_nc - a_ndt$$

with  $n - 1$  unknowns and one parameter,  $t$ . However, the number  $(b - a_nc)/d$  is an integer, so we can divide the equation by  $d$ . This leads to

$$a'_1x_1 + \dots + a'_{n-1}x_{n-1} = b',$$

where  $a'_i = a_i/d$  for  $i = 1, \dots, n - 1$  and  $b' = ((b - a_nc)/d) - a_nt$ , satisfying

$$(a'_1, \dots, a'_{n-1}) = (da'_1, \dots, da'_{n-1}) \cdot \frac{1}{d} = (a_1, \dots, a_{n-1}) \cdot \frac{1}{d} = 1.$$

By the induction hypothesis, this equation has, for any  $t \in \mathbb{Z}$ , a solution which can be described in terms of  $n - 2$  integer parameters (different from  $t$ ), which together with the condition  $x_n = c + dt$  gives what we wanted.

**11.5.1. Pythagorean equation.** In this section, we will deal with enumeration of all right triangles with integer side lengths. This is a Diophantine equation where we will only seldom use the methods described above; nevertheless, we will look at it in detail.

The task is to solve the equation

$$x^2 + y^2 = z^2$$

in integers.

**Solution.** Clearly, we can assume that  $(x, y, z) = 1$  (otherwise, we simply divide both sides of the equation by the integer  $d = (x, y, z)$ ).

Further, we can show that the integers  $x, y, z$  are pairwise coprime: if there were a prime  $p$  dividing two of them, then we can easily see that it would have to divide the third one as well, which it may not according to our assumption. Therefore, at most one of the integers  $x, y$  is even. If neither of them were, we would get

$$z^2 \equiv x^2 + y^2 \equiv 1 + 1 \pmod{8},$$

which is impossible (see exercise 11.A.2). Altogether, we get that exactly one of the integers  $x, y$  is even. However, since the roles of these integers in the equation are symmetric, we

**G. Encryption**

**11.G.1. RSA.** We have overheard that the integers 29, 7, 21 were sent by means of RSA with public key (7, 33). Try to break the cipher and find the messages (integers) that were originally sent.

**Solution.** In order to find the private key  $d$ , we need to solve the congruence  $7d \equiv 1 \pmod{\varphi(33)}$ . However, since the integer 33 is quite small, we can factor it and easily compute that  $\varphi(33) = (3 - 1)(11 - 1) = 20$ . We are thus looking for a  $d$  such that  $7d \equiv 1 \pmod{20}$ , which is satisfied by  $d \equiv 3 \pmod{20}$ . Since  $29^3 \equiv (-4)^3 \equiv 2$ ,  $7^3 \equiv 13$ , and  $21^3 \equiv 21 \pmod{33}$ , the messages that were encrypted are 2, 13, and 21.  $\square$

**Attacks against RSA.**

Using so-called Fermat's factorization method, we can try to factor  $n = p \cdot q$  if we think that the difference between  $p$  and  $q$  is small.

Then,

$$n = \left(\frac{p+q}{2}\right)^2 - \left(\frac{p-q}{2}\right)^2,$$

where  $s = (p - q)/2$  is small and  $t = (p + q)/2$  is only a bit greater than  $\sqrt{n}$ . Therefore, it suffices to check whether<sup>4</sup>  $t = \lceil\sqrt{n}\rceil, t = \lceil\sqrt{n}\rceil + 1, t = \lceil\sqrt{n}\rceil + 2, \dots$ , until  $t^2 - n$  is a square (this condition can, of course, be checked efficiently).

**11.G.2.** Now, we will try to factor the integer  $n = 23104222007$  this way. (We anticipate that it is a product of two close primes.)

**Solution.** We compute

$$\sqrt{n} \approx 152000,731$$

and check the candidates for  $t$ :

For  $t = 152001$ , we have  $\sqrt{t^2 - n} \approx 286,345$ .

For  $t = 152002$ , it is  $\sqrt{t^2 - n} \approx 621,287$ .

For  $t = 152003$ ,  $\sqrt{t^2 - n} \approx 830,664$ .

Finally, for  $t = 152004$ , we get  $\sqrt{t^2 - n} = 997 \in \mathbb{Z}$ .

Therefore,  $s = 997$  and we can easily calculate the prime divisors of  $n$ :  $p = t + s = 153001, q = t - s = 151007$ .  $\square$

**11.G.3.** The RSA modulus  $n = p \cdot q$  can also be easily factored if the integer  $\varphi(n)$  is known (compromised). Then,

$$\varphi(n) = (p-1)(q-1) = pq - (p+q) + 1, \text{ odkud } p+q = n+1 - \varphi(n).$$

We are thus to find two integers whose sum and product are known, which can be done by Viète's formulas relating the roots and the coefficients of a polynomial, whence it follows that  $p$  and  $q$  are the roots of the polynomial

$$x^2 - (n + 1 - \varphi(n))x + n.$$

<sup>4</sup>The symbol  $\lceil x \rceil$  denotes the *ceiling* if a real number  $x$ , i.e., the integer which satisfies  $\lceil x \rceil - 1 < x \leq \lceil x \rceil$ .

can, without loss of generality, select  $x$  to be even and set  $x = 2r, r \in \mathbb{N}$ . Hence, we have

$$4r^2 = z^2 - y^2,$$

so

$$r^2 = \frac{z+y}{2} \cdot \frac{z-y}{2}.$$

Now, let us denote  $u = \frac{1}{2}(z + y), v = \frac{1}{2}(z - y)$  (then, the inverse substitution is  $z = u + v, y = u - v$ ). Since  $y$  is coprime to  $z$ , so is  $u$  to  $v$  (if there were a prime  $p$  dividing both  $u$  and  $v$ , then it would divide their sum as well as their difference, i.e., the integers  $y$  and  $z$ ). It follows from

$$r^2 = u \cdot v$$

that there are coprime positive integers  $a, b$  such that  $u = a^2, v = b^2$ . Moreover, since  $u > v$ , we must have  $a > b$ . Altogether, we get

$$x = 2r = 2ab,$$

$$y = u - v = (a^2 - b^2),$$

$$z = u + v = (a^2 + b^2),$$

which indeed satisfies the given equation for any coprime  $a, b \in \mathbb{N}$  with  $a > b$ . Further solutions can be obtained by interchanging  $x$  and  $y$ . Finally, relinquishing the condition  $(x, y, z) = 1$ , each solution will yield infinitely many more if we multiply each of its component by a fixed positive integer  $d$ .  $\square$

**11.5.2. Fermat's Last Theorem for  $n = 4$ .** Thanks to the parametrization of Pythagorean triples, we will be able to prove that the famous Fermat's Last Theorem

$$x^n + y^n = z^n$$

has no solution for  $n = 4$  in integers. For this task it is sufficient to prove that the equation  $x^4 + y^4 = z^2$  has no solution in  $\mathbb{N}$ .

**Solution.** We will use the so-called method of infinite descent, which was introduced by Pierre de Fermat. This method utilizes the fact that every non-empty set of natural numbers has a least element (in other words,  $\mathbb{N}$  is a well-ordered set).

Therefore, suppose that the set of solutions of the equation  $x^4 + y^4 = z^2$  is non-empty and let  $(x, y, z)$  denote (any) solution with  $z$  as small as possible. The integers  $x, y, z$  are thus pairwise distinct. Since the equation can be written in the form

$$(x^2)^2 + (y^2)^2 = z^2,$$

it follows from the previous exercise that there exist  $r, s \in \mathbb{N}$  such that

$$x^2 = 2rs, \quad y^2 = r^2 - s^2, \quad z = r^2 + s^2.$$

Hence,  $y^2 + s^2 = r^2$ , where  $(y, s) = 1$  (if there were a prime  $p$  dividing both  $y$  and  $s$ , then it would divide  $x$  as well as  $z$ , which contradicts that they are coprime). Making the

**11.G.4.** Consider (as above) the integer  $n = 23104222007$  and factor it with the additional knowledge that  $\varphi(n) = 23103918000$ .

**Solution.** Following the procedure described above, we get the quadratic equation

$$x^2 - 304008x + 23104222007 = 0,$$

whose solutions are

$$p = \frac{1}{2}(304008 + \sqrt{304008^2 - 4 \cdot 23104222007}) = 153001,$$

$$q = \frac{1}{2}(304008 - \sqrt{304008^2 - 4 \cdot 23104222007}) = 151007. \quad \square$$

**11.G.5. ElGamal.** Martin and John want to communicate using the ElGamal encryption (designed by Egyptian mathematician Taher ElGamal, who was inspired by the Diffie-Hellman key exchange protocol). Martin chose the prime 41 and its primitive root  $g = 11$  as well as the integer 10. Then, he published the triple  $(41, 11, A)$ , where  $A \equiv 11^{10} \pmod{41}$ ; he kept the integer 10 to himself – it is his private key. John used a public channel to send the pair  $(22, 6)$  to him. What is the original message John sent?

**Solution.** For completeness, we will first compute the whole public key  $A = 9$  (however, this integer was only needed by John when he encrypted the message for Martin; it is no longer necessary for decryption). The message  $M$  can be obtained as  $M \equiv (6/22^{10}) \pmod{41}$ . First, we compute

$$\begin{aligned} 22^{10} &\equiv 22^2 \cdot (22^2)^2 \cdot ((22^2)^2)^2 \equiv \\ &\equiv (-8) \cdot (-8)^2 \cdot (-8)^2 \equiv \\ &\equiv (-8) \cdot 23 \cdot 23 \equiv -9 \pmod{41} \end{aligned}$$

and  $(-9)^{-1} \equiv 9 \pmod{41}$ . Therefore, the decrypted message is the integer

$$M = 9 \cdot 6 \equiv 13 \pmod{41}. \quad \square$$

**11.G.6. Rabin cryptosystem.** Alice has chosen  $p = 23, q = 31$  as her private key in Rabin cryptosystem. The public key is  $n = pq = 713$ , then. Encrypt the message  $M = 327$  for Alice and show how Alice will decrypt it.

**Solution.** We compute  $C = (327)^2 \equiv 692 \pmod{713}$  and send this cipher to Alice. According to the decryption procedure, we determine

$$\begin{aligned} r &\equiv C^{(p+1)/4} \equiv 692^{\frac{23+1}{4}} \equiv 18 \pmod{23}, \\ s &\equiv C^{(q+1)/4} \equiv 692^{\frac{31+1}{4}} \equiv 14 \pmod{31}, \end{aligned}$$

and further the coefficients  $a, b$  into Bézout's identity  $23 \cdot a + 31 \cdot b = 1$  (using the Euclidean algorithm). We get  $a = -4, b = 3$ ; the candidates for the original message are thus

Pythagorean substitution once again, we get natural numbers  $a, b$  with ( $y$  is odd)

$$y = a^2 - b^2, \quad s = 2ab, \quad r = a^2 + b^2.$$

The inverse substitution leads to

$$x^2 = 2rs = 2 \cdot 2ab(a^2 + b^2),$$

and since  $x$  is even, we get

$$\left(\frac{x}{2}\right)^2 = ab(a^2 + b^2).$$

The integers  $a, b, a^2 + b^2$  are pairwise coprime (which can be derived easily from the fact that  $y$  is coprime to  $s$ ). Therefore, each of them is a square of a natural number:

$$a = c^2, \quad b = d^2, \quad a^2 + b^2 = e^2,$$

whence  $c^4 + d^4 = e^2$ , and since  $e \leq a^2 + b^2 = r < z$ , we get a contradiction with the minimality of  $z$ .  $\square$

## 6. Applications – calculation with large integers, cryptography

**11.6.1. Computational aspects of number theory.** In

many practical problems which utilize the results of number theory, it is necessary to execute one or more of the following computations fast:

- common arithmetic operations (sum, product, modulo) on integers;
- to determine the remainder of a (natural)  $n$ -th power of an integer  $a$  when divided by a given  $m$ ;
- to determine the multiplicative inverse of an integer  $a$  modulo  $m \in \mathbb{N}$ ;
- to determine the greatest common divisor of two integers (and the coefficients of corresponding Bézout's identity);
- to decide whether a given integer is a prime or composite number.
- to factor a given integer to primes.

Basic arithmetic operations are usually executed on large integers in the same way as we were taught at primary school, i.e., we add in *linear* time and multiply and divide with remainder in *quadratic* time. The multiplication, which is a base for many other operations, can be performed asymptotically more efficiently (there exist algorithms of the type *divide and conquer*) – for instance, the Karatsuba algorithm (1960), running in time  $\Theta(n^{\log_2 3})$  or the Schönhage-Strassen algorithm (1971), which runs in  $\Theta(n \log n \log \log n)$  and uses Fast Fourier Transforms – see also 7.2.5. Although it is asymptotically much better, in practice, it becomes advantageous for integers of at least ten thousand digits (it is thus used, for example, when looking for large primes in the GIMPS project).

the integers  $\mp 4 \cdot 23 \cdot 14 \pm 3 \cdot 31 \cdot 18 \pmod{713}$ . We thus know that one of the integers

$$386, 603, 110, 327$$

is the message that was sent.  $\square$

**11.G.7.** Show how to encrypt and decrypt the message  $M = 321$  in Rabin cryptosystem with  $n = 437$ .

**Solution.** The encrypted text can be obtained as the square modulo  $n$ :  $C = 321^2 \equiv (-116)^2 = 13456 \equiv 346 \pmod{437}$ . On the other hand, when decrypting, we will use the factorization (its knowledge is the private key of the message receiver)  $n = 437 = 19 \cdot 23$ , and we compute  $r = 346^{\frac{19+1}{4}} = 346^5 \equiv 17 \equiv -2 \pmod{19}$  and  $s = 246^{\frac{23+1}{4}} = 346^6 \equiv 1 \pmod{23}$ . Applying Euclidean algorithm to the pair  $(19, 23) = 1$ , we determine the coefficients into Bézout's identity

$$19 \cdot (-6) + 23 \cdot 5 = 1.$$

Then, the message is one of the integers  $\pm 6 \cdot 19 \cdot 1 \pm 5 \cdot 23 \cdot (-2) \pmod{437}$ , i.e.,  $M = \pm 116$  or  $M = \pm 344$ . Indeed,  $M = -116 \equiv 321 \pmod{437}$ .  $\square$

### 11.6.2. Greatest common divisor and modular inverses.

As we have already shown, the computation of the solution of the congruence  $a \cdot x \equiv 1 \pmod{m}$  in variable  $x$  can be easily reduced (thanks to Bézout's identity) to the computation of the greatest common divisor of the integers  $a$  and  $m$  and looking for the coefficients  $k, l$  in Bézout's identity  $k \cdot a + l \cdot m = 1$  (the integer  $k$  is then the wanted inverse of  $a$  modulo  $m$ ).

```
function extended_gcd(a,m)
  if m == 0:
    return (1,0)
  else
    (q,r) := divide(a,m)
    (k,l) := extended_gcd(m,r)
    return (1,k - q*l)
```

A thorough analysis<sup>8</sup> shows that the problem of computing the greatest common divisor has *quadratic* time complexity.

**11.6.3. Modular exponentiation.** The algorithm for modular exponentiation is based on the idea that when computing, for instance  $2^{64} \pmod{1000}$ , one need not calculate  $2^{64}$  and then divide it with remainder by 1000, but that it is better to multiply the 2's gradually and reduce the temporary result modulo 1000 whenever it exceeds this value. More importantly, there is no need to perform such a huge number of multiplications: in this case, 63 naive multiplications can be replaced with six squarings, as

$$2^{64} = (((((2^2)^2)^2)^2)^2)^2.$$

```
function modular_pow (base, exp, mod)
  result := 1
  while exp > 0
    if (exp % 2 == 1):
      result := (result * base) % mod
    exp := exp >> 1
    base := (base * base) % mod
  return result
```

The algorithm squares the base modulo  $n$  for every binary digit of the exponent (which can be done in quadratic time in the worst case) and it performs a multiplication for every one in the binary representation of the exponent. Altogether, we are able to do modular exponentiation in *cubic* time in the worst case. We can also notice that the complexity is a good deal dependent on the binary appearance of the exponent.

**Example.** Let us compute  $2^{560} \pmod{561}$ .

Since  $560 = (1000110000)_2$ , the mentioned algorithm gives

<sup>8</sup>See, for example, D. Knuth, *Art of Computer Programming, Volume 2: Seminumerical Algorithms*, Addison-Wesley 1997 or Wikipedia, *Euclidean algorithm*, [http://en.wikipedia.org/wiki/Euclidean\\_algorithm](http://en.wikipedia.org/wiki/Euclidean_algorithm) (as of July 29, 2017).

exp	base	result	last digit exp
560	2	1	0
280	4	1	0
140	16	1	0
70	256	1	0
35	460	1	1
17	103	460	1
8	511	256	0
4	256	256	0
2	460	256	0
1	103	256	1
0	511	1	0

Therefore,  $2^{560} \equiv 1 \pmod{561}$ .

**11.6.4. Primality testing.** Although we have the Fundamental theorem of arithmetic, which guarantees that every natural number can be uniquely factored to a product of primes, this operation is very hard from the computational point of view. In practice, it is usually done in the following steps:

- (1) finding all divisors below a given threshold (by trying all primes up to the threshold, which is usually somewhere around  $10^6$ );
- (2) testing the remaining factor for compositeness (deciding whether some necessary condition for primality holds);
  - (a) if the compositeness test did not find the integer to be composite, i.e., it is likely to be a prime, then we test it for primality to verify that it is indeed a prime;
  - (b) if the compositeness test proved that the integer was composite, then we try to find a non-trivial divisor.

The mentioned steps are executed in this order because the corresponding algorithms are gradually (and strongly) increasing in time complexity. In 2002, Agrawal, Kayal, and Saxena published an algorithm for primality testing in polynomial time, but it is still more efficient to use the above procedure in practice.

**11.6.5. Compositeness tests – how to recognize composite numbers with certainty?** The so-called compositeness tests check for some necessary condition for primality. The easiest of such conditions is Fermat’s little theorem.

**Proposition** (Fermat’s test). *Let  $N$  be a natural number. If there is an  $a \not\equiv 0 \pmod{N}$  such that  $a^{N-1} \not\equiv 1 \pmod{N}$ , then  $N$  is not a prime.*

Unfortunately, having a composite  $N$ , it still may not be easy to find such an integer  $a$  which reveals the compositeness of  $N$ . There are even such exceptional integers  $N$  for which the only integers  $a$  with the mentioned property are those which are not coprime to  $N$ . To find them is thus equivalent to finding a divisor, and thus to factoring  $N$  to primes.

There are indeed such ugly (or extremely nice?) composite numbers  $N$  for which every integer  $a$  which is coprime to  $N$  satisfies  $a^{N-1} \equiv 1 \pmod{N}$ . These are called

*Carmichael numbers*, the least of which<sup>9</sup> is  $561 = 3 \cdot 11 \cdot 17$ , and it was no sooner than in 1992 that it was proved<sup>10</sup> that there are even infinitely many of them.

**Example.** We will prove that 561 is a Carmichael number, i.e., that it holds for every  $a \in \mathbb{N}$  which is coprime to  $3 \cdot 11 \cdot 17$  that  $a^{560} \equiv 1 \pmod{561}$ .

Thanks to the properties of congruences, we know that it suffices to prove this congruence modulo 3, 11, and 17. However, this can be obtained straight from Fermat's little theorem since such an integer  $a$  satisfies  $a^2 \equiv 1 \pmod{3}$ ,  $a^{10} \equiv 1 \pmod{11}$ ,  $a^{16} \equiv 1 \pmod{17}$ , where all of 2, 10, and 16 divide 560, hence  $a^{560} \equiv 1$  modulo 3, 11 as well as 17 for all integers  $a$  coprime to 561 (see also Korselt's criterion mentioned below).

**11.6.6. Proposition** (Korselt's criterion). *A composite number  $n$  is a Carmichael number if and only if both of the following conditions hold*

- $n$  is square-free (divisible by the square of no prime),
- $p - 1 \mid n - 1$  holds for all primes  $p$  which divide  $n$ .

PROOF. “ $\Leftarrow$ ” We will show that if  $n$  satisfies the above two conditions and it is composite, then every  $a \in \mathbb{Z}$  which is coprime to  $n$  satisfies  $a^{n-1} \equiv 1 \pmod{n}$ . Let us thus factor  $n$  to the product of distinct odd primes:  $n = p_1 \cdots p_k$ , where  $p_i - 1 \mid n - 1$  for all  $i \in \{1, \dots, k\}$ . Since  $(a, p_i) = 1$ , we get from Fermat's little theorem that  $a^{p_i-1} \equiv 1 \pmod{p_i}$ , whence (thanks to the condition  $p_i - 1 \mid n - 1$ ) it also follows that  $a^{n-1} \equiv 1 \pmod{p_i}$ . This is true for all indices  $i$ , hence  $a^{n-1} \equiv 1 \pmod{n}$ , so  $n$  is indeed a Carmichael number.

“ $\Rightarrow$ ” A Carmichael number  $n$  cannot be even since then we would get for  $a = -1$  that  $a^{n-1} \equiv -1 \pmod{n}$ , which would (since  $a^{n-1} \equiv 1 \pmod{n}$ ) mean that  $n$  is equal to 2 (and thus is not composite). Therefore, let  $n$  factor as  $n = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$ , where  $p_i$  are distinct odd primes and  $\alpha_i \in \mathbb{N}$ . Thanks to theorem 11.3.16, we can choose for every  $i$  a primitive root  $g_i$  modulo  $p_i^{\alpha_i}$ , and the Chinese remainder theorem then yields an integer  $a$  which satisfies  $a \equiv g_i \pmod{p_i^{\alpha_i}}$  for all  $i$  and which is apparently coprime to  $n$ . Further, we know from the assumption that  $a^{n-1} \equiv 1 \pmod{n}$ , so this holds modulo  $p_i^{\alpha_i}$ , and thus  $g_i^{n-1} \equiv 1 \pmod{p_i^{\alpha_i}}$  as well. Since  $g_i$  is a primitive root modulo  $p_i^{\alpha_i}$ , the integer  $n-1$  must be a multiple of its order, i.e. a multiple of  $\varphi(p_i^{\alpha_i}) = p_i^{\alpha_i-1}(p_i - 1)$ . At the same time, we have  $(p_i, n-1) = 1$  (since  $p_i \mid n$ ), so necessarily  $\alpha_i = 1$  and  $p_i - 1 \mid n - 1$ .  $\square$

Fermat's primality test can be slightly improved to Euler's test or even more with the help of the Jacobi symbol, yet this still does not mend the presented problem completely.

<sup>9</sup>The first discoverer of the first seven Carmichael numbers is apparently Czech priest and mathematician Václav Šimerka (1819–1887), who occupied himself with them much earlier than the American mathematician R. D. Carmichael (1879–1967), whose name they bear.

<sup>10</sup>W. R. Alford, A. Granville and C. Pomerance, *There are Infinitely Many Carmichael Numbers*, Annals of Mathematics, Vol. 139, No. 3 (1994), pp. 703–722.

**Proposition** (Euler’s test). *Let  $N$  be an odd natural number. If there is an integer  $a \not\equiv 0 \pmod{N}$  such that  $a^{\frac{N-1}{2}} \not\equiv \pm 1 \pmod{N}$ , then  $N$  is not a prime.*

**PROOF.** This follows directly from Fermat’s theorem and the fact that for  $N$  odd, we have  $a^{N-1} = (a^{\frac{N-1}{2}} - 1)(a^{\frac{N-1}{2}} + 1)$ .  $\square$

**Proposition** (Euler-Jacobi test). *Let  $N$  be an odd natural number. If there is an integer  $a \not\equiv 0 \pmod{N}$  such that  $a^{\frac{N-1}{2}} \not\equiv \left(\frac{a}{N}\right) \pmod{N}$ , then  $N$  is not a prime.*

**PROOF.** This follows immediately from lemma 11.4.12.  $\square$

**Example.** Let us consider  $N = 561 = 3 \cdot 11 \cdot 17$  as before and let  $a = 5$ . Then, we have  $5^{280} \equiv 1 \pmod{3}$  and  $5^{280} \equiv 1 \pmod{10}$ , but  $5^{280} \equiv -1 \pmod{17}$ , so surely  $5^{280} \not\equiv \pm 1 \pmod{561}$ . Here, it did not hold that  $a^{(N-1)/2} \equiv \pm 1 \pmod{N}$ , so we even did not need to check the value of the Jacobi symbol  $(5/561)$ . However, the Euler-Jacobi test can often reveal a composite number even in the case when this power is equal to  $\pm 1$ .

**Example.** Euler’s test cannot detect the compositeness of the integer  $N = 1729 = 7 \cdot 13 \cdot 19$  since the integer  $\frac{N-1}{2} = 864 = 2^5 \cdot 3^3$  is divisible by 6, 12, and 18, and so it follows from Fermat’s theorem that  $a^{(N-1)/2} \equiv 1 \pmod{N}$  holds for all integers  $a$  coprime to  $N$ . On the other hand, we get already for  $a = 11$  that  $(11/1729) = -1$ , so the Euler-Jacobi is able to recognize the integer 1729 as composite.

Let us notice that the value of the Legendre or Jacobi symbol  $(a/n)$  can be computed very efficiently thanks to the law of quadratic reciprocity<sup>11</sup>, namely in time  $O((\log a)(\log n))$ .

#### PSEUDOPRIMES

A composite number  $n$  is called a *pseudoprime* if it passes the corresponding test of compositeness without being revealed. We thus have

- (1) Fermat pseudoprimes to base  $a$ ,
- (2) Euler (or Euler-Jacobi) pseudoprimes to base  $a$ ,
- (3) strong pseudoprimes to base  $a$ , which are composite numbers which pass the following compositeness test:

The subsequent test is simple, yet (as shown in theorem 11.6.8) very efficient. It is a further specification of Fermat’s test, which we have introduced at the beginning.

**11.6.7. Theorem.** *Let  $p$  be an odd prime. Let us write  $p-1 = 2^t \cdot q$ , where  $t$  is a natural number and  $q$  is odd. Then, every integer  $a$  which is not a multiple of  $p$  satisfies  $a^q \equiv 1 \pmod{p}$  or there exists an  $e \in \{0, 1, \dots, t-1\}$  such that  $a^{2^e q} \equiv -1 \pmod{p}$ .*

<sup>11</sup>See H. Cohen, *A Course in Computational Algebraic Number Theory*, Springer, 1993.

PROOF. It follows from Fermat's little theorem that

$$\begin{aligned}
 p \mid a^{p-1} - 1 &= (a^{\frac{p-1}{2}} - 1)(a^{\frac{p-1}{2}} + 1) = \\
 &= (a^{\frac{p-1}{4}} - 1)(a^{\frac{p-1}{4}} + 1)(a^{\frac{p-1}{2}} + 1) = \\
 &\quad \vdots \\
 &= (a^q - 1)(a^q + 1)(a^{2q} + 1) \cdots (a^{2^{t-1}q} + 1),
 \end{aligned}$$

whence the statement follows easily since  $p$  is a prime.  $\square$

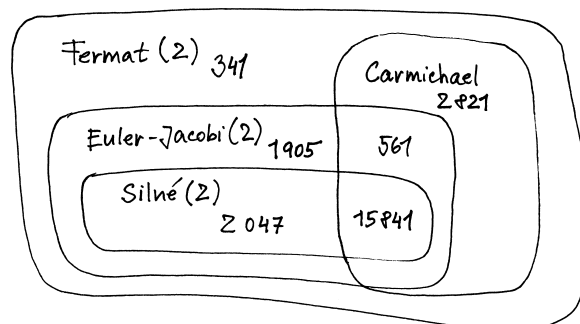

**Proposition** (Miller-Rabin compositeness test). *Let  $N$ ,  $t$ ,  $q$  be natural numbers such that  $N$  is odd and  $N - 1 = 2^t \cdot q$ ,  $2 \nmid q$ . If there is an integer  $a \not\equiv 0 \pmod{N}$  such that*

$$a^q \not\equiv 1 \pmod{N}$$

$$a^{2^e q} \not\equiv -1 \pmod{N} \quad \text{for } e \in \{0, 1, \dots, t-1\},$$

then  $N$  is not a prime.

PROOF. The correctness of the test follows directly from the previous theorem.  $\square$

*Miscellaneous types of pseudoprimes*

In practice, this easy test rapidly increases the ability to recognize composite numbers. The least strong pseudoprime to base 2 is 2047 (while the least Fermat pseudoprime to base 2 was already 341), and considering the bases 2, 3, and 5, the least strong pseudoprime is 25326001. In other words, if we are to test integers below  $2 \cdot 10^7$ , then it is sufficient to execute this compositeness test already for the bases 2, 3, and 5. If the tested integer is not revealed to be composite, then it is surely a prime. On the other hand, it has been proved that no finite basis is sufficient for testing all natural numbers.

The Miller-Rabin test is a practical application of the previous statement, and we are even able to bound the probability of failure thanks to the following theorem, which we present without a proof <sup>12</sup>.

**11.6.8. Theorem.** *Let  $N > 10$  be an odd composite number. Let us write  $N - 1 = 2^t \cdot q$ , where  $t$  is a natural number and  $q$  is odd. Then, at most a quarter of the integers from the set  $\{a \in \mathbb{Z}; 1 \leq a < N, (a, N) = 1\}$  satisfies the following condition:*

$$a^q \equiv 1 \pmod{N}$$

<sup>12</sup>Schoof, René (2004), "Four primality testing algorithms" (PDF), Algorithmic Number Theory: Lattices, Number Fields, Curves and Cryptography, Cambridge University Press, ISBN 978-0-521-80854-5

or there is an  $e \in \{0, 1, \dots, t - 1\}$  satisfying

$$a^{2^e q} \equiv -1 \pmod{N}.$$

In practical implementations, one usually tests about 20 random bases (or the least prime bases). In this case, the above theorem states that the probability of failing to reveal a composite number is less than  $2^{-40}$ .

The time complexity of the algorithm is same as in the case of modular exponentiation, i.e. *cubic* in the worst case. However, we should realize that the test is non-deterministic and the reliability of its deterministic version depends on the so-called generalized Riemann hypothesis (GRH<sup>13</sup>).

**11.6.9. Primality tests.** Primality tests are usually applied

when the used compositeness test claims that the examined integer is *likely* to be a prime, or they are executed straightaway for special types of integers. Let us first give a list of the most known tests, which includes historical tests as well as very modern ones.

- (1) AKS – a general polynomial primality test discovered by Indian mathematicians Agrawal, Kayal, and Saxena in 2002.
- (2) Pocklington-Lehmer test – primality test of subexponential complexity.
- (3) Lucas-Lehmer test – primality test for Mersenne numbers.
- (4) Pépin's test – primality test for Fermat numbers from 1877.
- (5) ECPP - primality test based on the so-called elliptic curves.

Now, we will introduce a standard primality test for Mersenne numbers.

**Proposition** (Lucas-Lehmer test). *Let  $q \neq 2$  be a prime, and let a sequence  $(s_n)_{n=0}^\infty$  be defined recursively by*

$$s_0 = 4, s_{n+1} = s_n^2 - 2.$$

*Then, the integer  $M_q = 2^q - 1$  is a prime if and only if  $M_q$  divides  $s_{q-2}$ .*

**PROOF.** We will be working in the ring  $R = \mathbb{Z}[\sqrt{3}] = \{a + b\sqrt{3}; a, b \in \mathbb{Z}\}$ , where the division with remainder behaves similarly as in the integers (see also 12.3.5). Let us set  $\alpha = 2 + \sqrt{3}$ ,  $\beta = 2 - \sqrt{3}$  and note that  $\alpha + \beta = 4$ ,  $\alpha \cdot \beta = 1$ .

First, we prove by induction that it holds for all  $n \in \mathbb{N}_0$  that

$$(1) \quad s_n = \alpha^{2^n} + \beta^{2^n} = \beta^{2^n} \left( 1 + \alpha^{2^{n+1}} \right).$$

The statement is true for  $n = 0$  since  $s_0 = 4 = \alpha + \beta$ . Now, let us suppose that it is true for  $n - 1$ , then  $s_n = s_{n-1}^2 - 2$  is, by the induction hypothesis, equal to  $\left( \alpha^{2^{n-1}} + \beta^{2^{n-1}} \right)^2 - 2 = \alpha^{2^n} + \beta^{2^n}$ .

<sup>13</sup>Wikipedia, *Riemann hypothesis*, [http://en.wikipedia.org/wiki/Riemann\\_hypothesis](http://en.wikipedia.org/wiki/Riemann_hypothesis) (as of July 29, 2017).

Further, since  $M_q \equiv -1 \pmod{8}$ , we have  $(2/M_q) = 1$ , and it follows from the law of quadratic reciprocity that

$$\left(\frac{3}{M_q}\right) = -\left(\frac{M_q}{3}\right) = -\left(\frac{2^q - 1}{3}\right) = -\left(\frac{1}{3}\right) = -1,$$

since we have  $2^q - 1 \equiv 1 \pmod{3}$  for  $q$  odd. Both of these expressions are valid even if  $M_q$  is not a prime (in this case, it is the Jacobi symbol).

Let us note that in the last part of the proof, we will use the extension of the congruence relation to the elements of the domain  $\mathbb{Z}[\sqrt{3}] = \{a+b\sqrt{3}; a, b \in \mathbb{Z}\}$ ; just like in the case of the integers, we write for  $\alpha, \beta \in \mathbb{Z}[\sqrt{3}]$  that  $\alpha \equiv \beta \pmod{p}$  if  $p \mid \alpha - \beta$ . Further, an analog of proposition (ii) from 11.C.6 holds as well – if  $p$  is a prime, then  $(\alpha + \beta)^p \equiv \alpha^p + \beta^p \pmod{p}$  (the proof is identical to the one for the integers).

“ $\implies$ ” Suppose that  $M_q$  is a prime. We will prove that  $\alpha^{2^{q-1}} \equiv -1 \pmod{M_q}$ , which will imply (thanks to 1) that  $M_q \mid s_{q-2}$ . Since  $2^{(M_q-1)/2} \equiv (2/M_q) = 1 \pmod{M_q}$ , there is a  $y \in \mathbb{Z}$  such that  $2y^2 \equiv 1 \pmod{M_q}$ . We have

$$(y(1 + \sqrt{3}))^2 = y^2(4 + 2\sqrt{3}) \equiv \alpha \pmod{M_q},$$

whence, invoking Fermat's theorem and the relation  $2^{q-1} = \frac{M_q+1}{2}$ , we get

$$\begin{aligned} \alpha^{2^{q-1}} &\equiv \left(y(1 + \sqrt{3})\right)^{M_q+1} \\ &\equiv y^2 \cdot y^{M_q-1} (1 + \sqrt{3}) \cdot (1 + \sqrt{3})^{M_q} \\ &\equiv y^2 (1 + \sqrt{3}) \cdot (1 - \sqrt{3}) = -2y^2 \\ &\equiv -1 \pmod{M_q}. \end{aligned}$$

When deriving this, we made use of the fact that 3 is a quadratic nonresidue modulo  $M_q$ , so

$$\begin{aligned} (1 + \sqrt{3})^{M_q} &\equiv 1 + (\sqrt{3})^{M_q} = 1 + 3^{(M_q-1)/2} \cdot \sqrt{3} \\ &\equiv 1 - \sqrt{3} \pmod{M_q}. \end{aligned}$$

“ $\impliedby$ ” For the other direction, let  $M_q \mid s_{q-2}$ . However, then

$$M_q \mid s_{q-2} \cdot \alpha^{2^{q-2}} = 1 + \alpha^{2^{q-1}}.$$

If  $p \neq 2, 3$  is a prime divisor of  $M_q$ , then  $\alpha^{2^{q-1}} \equiv -1 \pmod{p}$  as well and  $\alpha^{2^q} \equiv 1 \pmod{p}$ . Hence it follows that  $2^q$  is the order of  $\alpha$  in the multiplicative group  $T_p = \{a + b\sqrt{3}; 0 \leq a, b < p\} \setminus \{0\}$ .

If we had  $(3/p) = 1$ , then we would get

$$\begin{aligned} \alpha^{p-1} &= \beta \cdot \alpha^p \equiv \beta \cdot \left(2^p + (\sqrt{3})^p\right) \\ &\equiv \beta \cdot \left(2 + \sqrt{3} \cdot 3^{(p-1)/2}\right) \equiv \beta \cdot (2 + \sqrt{3}) = 1, \end{aligned}$$

whence  $p - 1$  would be a multiple of the order of  $\alpha$ , i.e.  $2^q$ . However, this would mean that  $p > p - 1 \geq 2^q > 2^q - 1 = M_q$ , which contradicts the fact that  $p$  is a divisor of  $M_q$ .

Therefore, we have  $(3/p) = -1$  and

$$\begin{aligned}\alpha^{p+1} &\equiv (2 + \sqrt{3}) (2 + \sqrt{3})^p \\ &\equiv (2 + \sqrt{3}) (2 - \sqrt{3}) \\ &\equiv 1 \pmod{p}.\end{aligned}$$

The order of  $\alpha$  modulo  $p$  is  $2^q$ , hence  $2^q \mid p+1$  and especially  $p \geq 2^q - 1 = M_q$ . At the same time,  $p$  is a prime divisor of  $M_q$ , therefore,  $M_q = p$  is a prime.  $\square$

Unlike the proof, implementation of this algorithm is very easy.

**Algorithm (Lucas-Lehmer primality test):**

```
function LL_is_prime(q)
  s := 4; M := 2q - 1
  repeat q - 2 times
    s := s2 - 2 (mod M)
  if s = 0 return PRIME.
  else return COMPOSITE.
```

The time complexity of this test is asymptotically the same as in the case of the Miller-Rabin test. It is, however, more efficient in concrete instances.

*Fermat numbers* are integers of the form  $F_n = 2^{2^n} + 1$ .

Pierre de Fermat conjectured in the 17th century that all of the integers of this form are primes (apparently driven by the effort to generalize the observation for  $F_0 = 3$ ,  $F_1 = 5$ ,  $F_2 = 17$ ,  $F_3 = 257$ , and  $F_4 = 65537$ ). However, in the 18th century, Leonhard Euler found out that  $F_5 = 641 \times 6700417$ , and we have not been able to discover any other Fermat primes so far. Since their size increases rapidly, it takes much time resources to compute with them (so the following test is not much used). Nowadays, the least Fermat number which has not been tested is  $F_{33}$ , which has 2 585 827 973 digits, and it is thus much greater than the largest discovered prime.

**Proposition** (Pépin's test). *A necessary and sufficient condition for the  $n$ -th Fermat number  $F_n$  to be a prime is*

$$3^{\frac{F_n - 1}{2}} \equiv -1 \pmod{F_n}.$$

We can see that this is a very simple test, which is actually a mere part of Euler's compositeness test.

**PROOF OF CORRECTNESS OF PÉPIN'S TEST.** First, suppose that  $3^{(F_n - 1)/2} \equiv -1 \pmod{F_n}$ . Then,  $3^{F_n - 1} \equiv 1 \pmod{F_n}$ . Since  $F_n - 1$  is a power of two,  $F_n - 1$  is necessarily the order of 3 modulo  $F_n$ . However, the order of every integer modulo  $F_n$  is at most  $\varphi(F_n) \leq F_n - 1$ , hence in this case, we have  $\varphi(F_n) = F_n - 1$ , which means that  $F_n$  is a prime.

For the other direction, let  $F_n$  be a prime. From part (i) of lemma 11.4.12, we get that  $3^{(F_n-1)/2} \equiv (3/F_n) \pmod{F_n}$ , so it suffices to determine the value  $(3/F_n)$ . However, this is easy, because  $F_n \equiv 2 \pmod{3}$ , and thus  $(F_n/3) = -1$ . Further, we have  $F_n \equiv 1 \pmod{4}$ , and the law of quadratic reciprocity thus yields  $(3/F_n) = -1$ , which is what we wanted to prove.  $\square$

Now, we will introduce a primality test which is a bit old, yet it is still widely used in modern computation systems – the so-called *Pocklington-Lehmer* test. However, first of all, we will describe a simpler primality test for illustration, the so-called *Lucas's test*:

**11.6.10. Theorem (Lucas).** *If for all prime divisors  $q$  of  $N - 1$ , there is an  $a$  such that  $a^{N-1} \equiv 1 \pmod{N}$ ,  $a^{\frac{N-1}{q}} \not\equiv 1 \pmod{N}$ , then  $N$  is a prime.*

**PROOF.** It suffices to prove that  $N - 1$  divides  $\varphi(N)$  (which is a condition apparently unsatisfied by composite numbers). If not, then there is a prime  $q$  and  $r \in \mathbb{N}$  such that  $q^r$  divides  $N - 1$ , but it does not divide  $\varphi(N)$ . The order  $e$  of the integer  $a$  divides  $N - 1$  (the first condition) and does not divide  $(N - 1)/q$  (the second condition), hence  $q^r$  divides  $e$ . Furthermore,  $e$  divides  $\varphi(N)$ , and so  $q^r$  does, a contradiction.  $\square$

The integer  $a$  from the previous theorem is called a *primality witness* for the integer  $N$  (in this as well as in the other primality tests).

Another general primality test is based on the above one. It is good if we want to make the high probability of the answer of the Miller-Rabin compositeness test into certainty.

**11.6.11. Theorem (Pocklington–Lehmer).** *Let  $N$  be a natural number,  $N > 1$ . Let  $p$  be a prime which divides  $N - 1$ . Further, let us suppose that there is an integer  $a_p$  such that*

$$a_p^{N-1} \equiv 1 \pmod{N} \quad \text{and} \quad \left( a_p^{\frac{N-1}{p}} - 1, N \right) = 1.$$

*Let  $p^{\alpha_p}$  be the highest power of  $p$  which divides  $N - 1$ . Then every positive divisor  $d$  of the integer  $N$  satisfies*

$$d \equiv 1 \pmod{p^{\alpha_p}}.$$

**PROOF OF THE POCKLINGTON–LEHMER THEOREM.** Every positive divisor  $d$  of the integer  $N$  is a product of prime divisors of  $N$ , so it suffices to prove the theorem for prime values of  $d$ . The condition  $a_p^{N-1} \equiv 1 \pmod{N}$  implies that the integers  $a_p, N$  are coprime (any divisor they have in common must divide the right-hand side of the congruence as well). Then,  $(a_p, d) = 1$  as well, and we have  $a_p^{d-1} \equiv 1 \pmod{d}$  by Fermat's theorem. Since  $(a_p^{(N-1)/p} - 1, N) = 1$ , we get  $a_p^{(N-1)/p} \not\equiv 1 \pmod{d}$ .

Let  $e$  denote the order of  $a_p$  modulo  $d$ . Then,  $e \mid d - 1$ ,  $e \mid N - 1$ , and  $e \nmid (N - 1)/p$ .

If  $p^{\alpha_p} \nmid e$ , then  $e \mid N - 1$  would imply that  $e \mid \frac{N-1}{p}$ , which is a contradiction. Therefore,  $p^{\alpha_p} \mid e$ , and so  $p^{\alpha_p} \mid d - 1$ .  $\square$

**11.6.14. Looking for divisors.** If one of the compositeness tests verifies that a given integer is indeed composite, we usually want to find one of its non-trivial divisors. However, this task is much more difficult than mere revealing that it is composite – let us recall that the compositeness tests can guarantee the compositeness, yet they provide us with no divisors (which is, on the other hand, advantageous for RSA and similar cryptographic protocols). Therefore, we will present here only a short summary of methods used in practice and one sample for inspiration.

- (1) Trial division
- (2) Pollard's  $\rho$ -algorithm
- (3) Pollard's  $p - 1$  algorithm
- (4) Elliptic curve method (ECM)
- (5) Quadratic sieve (QS)
- (6) Number field sieve (NFS)

For illustration, we demonstrate in the exercises (11.F.8) one of these algorithms – Pollard's  $\rho$ -method – on a concrete instance. This algorithm is especially suitable for finding *relatively* small divisors (since its expected complexity depends on the size of these divisors), and it is based on the idea that having a random function  $f : S \rightarrow S$ , where  $S$  is a finite set having  $n$ -elements, the sequence  $(x_n)_{n=0}^{\infty}$ , where  $x_{n+1} = f(x_n)$ , must loop. The expected length of the tail as well as the period is then  $\sqrt{\pi \cdot n/8}$ .

The algorithm described below is again a straightforward implementation of the mentioned reasonings.

**Algorithm (Pollard's  $\rho$ -method):**

Input:  $n$  — the integer to be factored,  
and an appropriate function  $f(x)$

$a := 2; b := 2; d := 1$

While  $d = 1$  do

$a := f(a)$

$b := f(f(b))$

$d := \gcd(a - b, n)$

If  $d = n$ , return FAILURE.

Else return  $d$ .

**11.6.15. Public-key cryptography.** In present-day practice, the most important application of number theory is the so-called public-key cryptography. We shall only briefly touch this fascinating area of Mathematics.

The main objectives are to provide

- encryption; the message *encrypted* with the public key of the receiver can be decrypted by no one else (to be precise, by no one who does not know his private key);
- signature; the integrity of the message *signed* with the private key of the sender can be verified by anyone with access to his public key.

The most basic and most often used protocols in public-key cryptography are:

- *RSA* (encryption) and the derived system for signing messages,
- *Digital Signature Algorithm* – DSA and its variant based on elliptic curves (ECDSA),
- *Rabin cryptosystem* (and signature scheme),
- *ElGamal cryptosystem* (and signature scheme),
- *elliptic curve cryptography* (ECC),
- *Diffie-Hellman key exchange protocol* (DH).

**11.6.16. Encryption – RSA.** First, we describe the most known public-key cipher – RSA. The simple principle of the protocol *RSA*<sup>14</sup> is based on the Euler’s theorem 11.3.12:

- The user *A* needs a pair of keys – a public one ( $V_A$ ) and a private one ( $S_A$ ).
- Key generating: the user selects two large primes  $p, q$ , and calculates  $n = pq$ ,  $\varphi(n) = (p - 1)(q - 1)$ . The integer  $n$  is part of the public key; the main idea is that it is too hard to compute  $\varphi(n)$  without knowing the decomposition.
- Then, the user chooses the second half of the *public key*,  $e$ , and verifies that  $(e, \varphi(n)) = 1$ .
- Using the Euclidean algorithm, the *private key*  $d$  is computed so that  $e \cdot d \equiv 1 \pmod{\varphi(n)}$ .

THE PRINCIPLE OF RSA

The secret communication runs in the following steps (for the sake of simplicity, we will further identify the encryption procedure with the public key  $V_A$  and the decryption procedure with the private key  $S_A$ ):

- Encrypting a numerical *code* of a message  $M$  addressed to the user  $A$  (by any other participant who has got access to the public key  $V_A$ ):

$$C = V_A(M) \equiv M^e \pmod{n}.$$

- Decrypting the cipher  $C$  by the user  $A$ :

$$OT = S_A(C) \equiv C^d \pmod{n}.$$

<sup>14</sup>Ron Rivest, Adi Shamir, Leonard Adleman (1977); C. Cocks, the secret service GCHQ (not publicly) as early as 1973.

The proof of correctness of this protocol (i.e., that  $A$  indeed receives what was meant) is a straightforward application of Euler's theorem: Thanks to 11.3.13, it holds for any message  $M$  which is coprime to  $n$  that  $(M^e)^d \equiv M^1 = M \pmod{n}$ . In the (extremely unlikely) case that the message  $M$  would not be coprime to  $n$ , the statement holds as well, although the proof needs to be modified with the help of the Chinese remainder theorem (however, we should realize that if the message  $M$  with property  $0 < M < n$  is not coprime to  $n$ , then it means that  $(M, n)$  is a non-trivial divisor of  $n$ , so the key of the receiver is actually discredited).

The security of RSA has been tested since it was invented in 1977, and no meaningful weakness (except for side channels or some singular keys) has been discovered yet (provided a sufficiently large key is used; nowadays it is recommended to use at least 2048 bits). Nevertheless, it has not been proved that the RSA problem *really* relies on the hardness of integer factorization.

The requirements on a secure choice of the key for practical reasons are:

- $d$  is large enough (defense against the so-called Wiener's attack),
- $p$  and  $q$  are not too close to each other (see the exercise 11.G.1),
- the public key is selected to be at least  $e = 65537$  (although no direct attack against a small public key  $e$  has been noticed).

**11.6.17. Rabin cryptosystem.** Further, we mention a simplified variant of the protocol named *Rabin cryptosystem*<sup>15</sup>, which has been the first public cryptosystem where one demonstrably needs to factorize the modulus to break it (unlike RSA, for which this has not been proved):

Every participant  $A$  needs a pair of keys – a public one ( $V_A$ ) and a private one ( $S_A$ ).

- Key generating:  $A$  chooses two large primes of roughly the same size –  $p, q \equiv 3 \pmod{4}$ , and computes  $n = pq$ .
- The public key is  $V_A = n$ , the private key is the pair  $S_A = (p, q)$ .

The secret communication then runs as follows:

- Encryption of the numerical *code* of the message  $M$ :  $C = V_A(M) \equiv M^2 \pmod{n}$ .
- Decryption of the cipher  $C$ : the (four) roots of  $C$  modulo  $n$  are computed and it is easily found out which one of them is the original message (for instance, the other three make no sense or do not contain the agreed identification).

As we can see from the description of the protocol, the process of decryption requires the *computation of the square*

<sup>15</sup>Rabin, Michael. *Digitalized Signatures and Public-Key Functions as Intractable as Factorization* (in PDF). MIT Laboratory for Computer Science, January 1979.

root of  $C$  modulo  $n = pq$ , where  $p \equiv q \equiv 3 \pmod{4}$ . This can be done as follows:

- The values  $r \equiv C^{(p+1)/4} \pmod{p}$  and  $s \equiv C^{(q+1)/4} \pmod{q}$  are computed.
- Further, we need to determine the coefficients  $a, b$  in Bézout's identity, i.e., integers for which  $ap + bq = 1$ .
- We set  $x \equiv (aps + bqr) \pmod{n}$ ,  $y \equiv (aps - bqr) \pmod{n}$ .
- The square roots of  $C$  modulo  $n$  are then  $\pm x, \pm y$ .

Let us mention that this is in fact an application of the Chinese remainder theorem and the fact that we are able to easily find the solutions of the quadratic congruence  $x^2 \equiv a \pmod{p}$  provided  $p \equiv 3 \pmod{4}$  (see exercise 11.D.38). Indeed, it holds that

$$\begin{aligned} (\pm x)^2 &= (aps + bqr)^2 \equiv (bqr)^2 \\ &\equiv r^2 \equiv C^{(p+1)/2} \equiv C \pmod{p}, \end{aligned}$$

where we made use of the fact that  $bq \equiv 1 \pmod{p}$  and that  $C \equiv M^2 \pmod{p}$  is a quadratic residue modulo  $p$ , hence  $C^{(p-1)/2} \equiv (C/p) = 1 \pmod{p}$ . Similarly, we have  $(\pm x)^2 \equiv C \pmod{q}$  as well, thus  $\pm x$  is a square root of  $C$  modulo  $n$ . The derivation of the same result for  $y$  is nearly identical.

**11.6.18. Digital signature.** Now, let us briefly describe the principle of digital signature.

PRINCIPLE OF THE DIGITAL SIGNATURE

**Creating the signature:**

- (1) A digest (hash)  $H_M$  of the message is generated, the length of the hash is fixed (160 or 256 bits, for instance) – we should realize that such a mapping is surely not injective (there will be many messages sharing the same hash).
- (2) The signature of the message  $S_A(H_M)$  is created from this hash using the knowledge of the private key of the signer (similarly to decryption of a message's text).
- (3) The message  $M$  is sent (optionally encrypted with the public key of the receiver) together with the created signature.

The **signature verification** then runs as follows:

- (1) A digest  $H'_M$  is generated for the received message  $M$  (after decryption, if it has been encrypted)
- (2) Using the public key of the (declared) sender of the message, the original digest of the message is reconstructed:  $V_A(S_A(H_M)) = H_M$ .
- (3) The digests are then compared; i.e., it is found out whether  $H_M = H'_M$ .

The (cryptographic) hash function mentioned above must have the following properties:

- It is easy to find the hash of any message.

- It is impossible (in real time) to find (any) message with the desired hash.
- It is impossible (in real time) to find two messages with the same hash (the function must be *collision-resistant*).
- Every change of the message changes the hash as well.

The most known examples of such functions are:

- MD5 (128 bit, Rivest 1992) – not collision-resistant
- SHA-1 (160 bit, NSA 1995) – from 2005 considered insufficiently collision-resistant
- RIPEMD-320
- SHA-3

**11.6.19. Diffie-Hellman key exchange system.** Another important type of protocol, which is very often used in practice, is a *protocol for key exchange in symmetric cryptography – Diffie-Hellman key exchange*<sup>16</sup>, whose discovery was a breakthrough in this discipline, making it possible to replace one-time keys, messengers with cases (and similar) with mathematical means, in particular without the necessity of prior communication of both sides.

The protocol for the agreement of two sides (Alice, Bob) on a common key (integer) is as follows:

PRINCIPLE OF DH KEY EXCHANGE PROTOCOL

- Both sides agree on a prime  $p$  and a primitive root  $g$  modulo  $p$  (this need not be done secretly).
- Alice chooses a random integer  $a$  and sends  $g^a \pmod{p}$ .
- Bob chooses a random integer  $b$  and sends  $g^b \pmod{p}$ .
- The common key for the communication is then  $g^{ab} \pmod{p}$ .

The security of this protocol relies on the fact that it is hard to compute the discrete logarithm (the so-called *discrete logarithm problem*) – see also part 11.3.15.

There is another encryption algorithm which is based on the Diffie-Hellman key exchange protocol – *algorithm ElGamal*, which we will also describe in short:

- Every participant chooses a prime  $p$  with a primitive root  $g$ .
- Further, they choose a *private key*  $x$ , compute  $h = g^x \pmod{p}$ , and publish the *public key*  $(p, g, h)$ .

The secret communication then runs as follows:

- Encryption of the numerical code of the message  $M$ : choosing a random  $y$  and computing  $C_1 = g^y \pmod{p}$  and  $C_2 = M \cdot h^y \pmod{p}$ , then sending the pair  $(C_1, C_2)$  to participant  $A$ .
- The participant  $A$  then decrypts the message by computing  $C_2/C_1^x$ .

<sup>16</sup> Whitfield Diffie, Martin Hellman (1976); M. Williamson (secret service GCHQ) as early as 1974 (not published).

**Remark.** The mechanism of digital signature can be derived from the ElGamal algorithm just like in the case of RSA.

**H. Additional exercises to the whole chapter**

- 11.H.1.** Find all three-digit  $n \in \mathbb{N}$ , for which  $11 \mid n$  and  $\frac{n}{11}$  is the sum of squares of the digits of  $n$ .
- 11.H.2.** Someone falsely memorized Fermat's little theorem, and claims that for  $p \nmid a$  we have  $a^p \equiv 1 \pmod{p}$ . Find all pairs  $(a, p)$  for which this is true.
- 11.H.3.** Prove that last four digits of  $5^n$ , ( $n = 4, 5, 6, \dots$ ) form a periodical sequence. Find this period.
- 11.H.4.** Prove that there are infinitely many odd natural numbers  $k$  such that the integer  $2^{2^n} + k$  is composite for every  $n \in \mathbb{N}$ .
- 11.H.5.** Prove that for every integer  $k \neq 1$ , there are infinitely many natural numbers  $n$  such that the integer  $2^{2^n} + k$  is composite.
- 11.H.6.** Consider the sequence  $(a_n)_{n=1}^{\infty}$  defined by
- $$a_n = 2^n + 3^n + 6^n - 1.$$
- Prove that for every prime  $p$ , this sequence contains a multiple of  $p$ .
- 11.H.7.** Prove that no natural number  $n$  greater than 1 satisfies  $n \mid 2^n - 1$ .
- 11.H.8.** Prove that for every odd prime  $p$ , there are infinitely many natural numbers  $n$  such that  $p \mid n \cdot 2^n + 1$ .
- 11.H.9.** Let a function  $f : \mathbb{N} \rightarrow \mathbb{N}$  satisfy  $(f(a), f(b)) = (f(a), f(|a - b|))$  for all  $a, b \in \mathbb{N}$ . Prove that  $(f(a), f(b)) = f((a, b))$ . Show that this implies the result of exercise 11.A.7 as well as the fact that  $(F_a, F_b) = F_{(a,b)}$ , where  $F_a$  denotes the  $a$ -th term of the Fibonacci sequence.
- 11.H.10.** Let the RSA parameters be  $n = 143 = 11 \cdot 13$ ,  $e = 7$ ,  $d = 103$ . Sign the message  $m = 8$ , and verify this signature. Decide, whether  $s = 42$  is the signature of the message  $m = 26$ .

## Key to the exercises

**10.C.10.** The answer is  $\frac{3}{5} \cdot \frac{2}{3} + \frac{2}{5} \cdot 1 = \frac{4}{5}$ .

**10.E.17.** Simply,  $a = \frac{3}{8}$ . Thus, the distribution function of the random variable  $X$  is  $F_X(t) = \frac{1}{8}t^3$  for  $t \in (0, 2)$ , zero for smaller values of  $t$ , and one for greater. Let  $Z = X^3$  denote the random variable corresponding to the volume of the considered cube. It lies in the interval  $(0, 8)$ . Thus, for  $t \in (0, 8)$  and the distribution function  $F_Z$  of the random variable  $Z$ , we can write  $F_Z(t) = P[Z < t] = P[X^3 < t] = P[X < \sqrt[3]{t}] = F_X(\sqrt[3]{t}) = \frac{1}{8}t$ . Then, the density is  $f_Z(t) = \frac{1}{8}$  on the interval  $(0, 8)$  and zero elsewhere. Since this is the uniform distribution on the given interval, the expected value is equal to 4.

**10.E.21.**  $f_{(X,Y)}(u, v) = uv$ , for  $(u, v) \in (0, 1) \times (0, 2)$ ,  $f_{(X,Y)}(u, v) = 0$  otherwise. Then, the wanted probability is

$$P = \int_0^1 \int_{x^2}^2 xy \, dy \, dx = \frac{11}{12}.$$

**10.E.22.**  $P = \int_0^{\sqrt[3]{2}} \int_{x^3}^2 xy \, dy \, dx = \frac{\sqrt[3]{4}}{12}$ .

**10.F.9.**  $EU = 1 \cdot 0.6 + 2 \cdot 0.4 = 1.4$ ,  $EU^2 = 0.4 + 4 \cdot 0.6 = 2.8$ ,  $EV = 0.4 + 0.6 + 1.2 = 2.1$ ,  $EV^2 = 0.3 + 1.2 + 3.6 = 5.1$ ,  $E(UV) = 2.8$ ,  $\text{var}(U) = 2.8 - 1.4^2 = 2.8 - 1.96 = 0.84$ ,  $\text{var}(V) = 5.1 - 4.41 = 0.69$ ,  $\text{cov}(UV) = 2.8 - 1.4 \cdot 2.1 = -0.14$ ,  $\rho_{U,V} = \frac{-0.14}{\sqrt{0.84 \cdot 0.69}}$ .

**10.F.10.**  $EX = 1/3$ ,  $\text{var}^2 X = 4/45$ .

**10.F.11.**

$$\rho_{X,Y} = -1.$$

**10.F.12.**  $\rho_{U,V} \doteq -0,421$ .

## Algebraic structures

*The more abstraction, the more chaos?  
– no, it is often the other way round...*

### A. Boolean algebras and lattices

**12.A.1.** Find the (complete) disjunctive normal form of the proposition

$$(B \Rightarrow C) \wedge [(A \vee C) \wedge B]'$$

#### Solution.

If the propositional formula contains only a few variables (in our case, it is three), the most advantageous procedure is to build the truth table of the formula and build the disjunctive normal form from that. The table will consist of  $2^3 = 8$  rows. The examined formula is denoted  $\varphi$ .

In this chapter, we begin a seemingly very formal study. But the concepts reflect many properties of things and phenomena surrounding us. This is one of the parts of the book which is not in the prerequisites of any other chapter. Large parts serve as a quick illustration of interesting uses of mathematical tools and models.

The simplest properties of real objects are used for encoding in terms of algebraic operations. Thus, “algebra” considers algorithmic manipulations with letters which usually correspond to computations or descriptions of processes.

Strictly speaking, this chapter builds only on the first and sixth parts of chapter one, where abstract views on numbers and relations between objects are introduced. But it is a focal point for abstract versions of many concepts already met.

The first two sections aim at direct generalizations of the familiar algebraic structure of numbers. This leads to a discussion of rings of polynomials. Only then we provide an introduction to group theory, for which there is only a single operation.

The last two sections provide some glimpses of direct applications. The construction of (self-correcting) codes often used in data transfer is considered. The last section explains the elementary foundations of computer algebra. This includes solving polynomial equations and algorithmic methods for manipulation and calculations with formal expressions.

### 1. Posets and Boolean algebras

Familiarity with the properties of addition and multiplication of scalars and matrices is assumed. Likewise, the binary operations of set intersection and union in elementary set theory, as indicated in the end of the first chapter.

We proceed to work with symbols which stand for miscellaneous objects resulting in the universal applicability of the results.

This allows the relating of the basic set operations, to propositional logic which formalizes methods for expressing propositions and evaluating truth values.

**12.1.1. Algebraic operations.** For any set  $M$ , there is a set  $K = 2^M$  consisting of all subsets of  $M$ , together with the operations of union  $\vee : K \times K \rightarrow K$  and intersection  $\wedge :$

A	B	C	$B' \Rightarrow C$	$[(A \vee C) \wedge B]'$	$\varphi$
0	0	0	0	1	0
0	0	1	1	1	1
0	1	0	1	1	1
0	1	1	1	0	0
1	0	0	0	1	0
1	0	1	1	1	1
1	1	0	1	0	0
1	1	1	1	0	0

The resulting complete disjunctive normal form is the disjunction of the formula that correspond to the rows with one in the last column (the formula is true for the given valuation of the atomic propositions). The row corresponds to conjunction of the variables (if the corresponding value is 1) or their negations (if it is 0). In our case, it is the disjunction of conjunctions corresponding to the second, third, and sixth rows, i. e., the result is

$$(A' \wedge B' \wedge C) \vee (A' \wedge B \wedge C') \vee (A \wedge B' \wedge C).$$

We can also rewrite the formula by expanding the connective  $\Rightarrow$  with  $\wedge$  and  $\vee$ , using the De Morgan laws and distributivity:

$$\begin{aligned} & (B' \Rightarrow C) \wedge [(A \vee C) \wedge B] \iff \\ \iff & (B \vee C) \wedge [(A \vee C)' \vee B'] \iff \\ \iff & (B \vee C) \wedge [(A' \wedge C') \vee B'] \iff \\ \iff & [(B \vee C) \wedge (A' \wedge C')] \vee [(B \vee C) \wedge B'] \iff \\ \iff & [(B \wedge A' \wedge C') \vee (C \wedge A' \wedge C')] \vee [(B \wedge B') \vee (C \wedge B')] \iff \\ \iff & (B \wedge A' \wedge C') \vee (C \wedge B'), \end{aligned}$$

which is an (incomplete) disjunctive normal form of the given formula. Clearly, it is equivalent to our result above (the word “complete” means that each disjunct (called *clause* in this context) contains each of the three variables or their negations (these are called *literals*)).  $\square$

**12.A.2.** Find a disjunctive normal form of the formula

$$((A \wedge B) \vee C)' \wedge (A' \vee (B \wedge C' \wedge D))$$

We know several logical connectives:  $\wedge, \vee, \implies, \equiv$  and the unary  $'$ . Any propositional formula with these connectives can be equivalently written using only some of them, for instance  $\vee$  and  $'$ . There are also connectives which alone suffice to express any propositional formula. From binary connectives, these are NAND and NOR ( $A \text{ NAND } B = (A \wedge B)'$ ,  $A \text{ NOR } B = (A \vee B)'$ ). Try to express each of the known connectives using only NAND, and then only NOR. These connectives are implemented in electric circuits as the so-called “gates”.

**12.A.3.** Express the propositional formula  $(A \Rightarrow B)$  using only the NAND gates.  $\circ$

$K \times K \rightarrow K$ . This is an instance of an algebraic structure on the set  $K$  with two *binary operations*. In general, write  $(K, \vee, \wedge)$ . In the special case of sets, these binary operations are denoted rather by  $\cup$  and  $\cap$ , respectively.

To every set  $A \in K$ , its complement  $A' = K \setminus A$  can be assigned. This is another operation  $' : K \rightarrow K$  with only one argument. Such operations are called *unary operations*.

In general, there are algebraic structures with  $k$  operations  $\mu_1, \dots, \mu_k$ , each of them

$$\mu_j : K \times \dots \times K \rightarrow K$$

with  $i_j$  arguments, and write  $(K, \mu_1, \dots, \mu_k)$  for such a structure. The number  $i_j$  of arguments is called the *parity* of the operation (“unary”, “binary”, etc.). If  $i_j = 0$ , then the operation has no arguments which means it is a distinguished element in  $K$ .

With subsets in  $K = 2^M$ , there is the unique “greatest object”, i.e. the entire set  $M$ , which is neutral for the  $\wedge$  operation. Similarly, the empty set  $\emptyset \in K$  is the only neutral element for  $\vee$ . Notice that if  $M$  is empty, then  $K$  contains the only element  $\emptyset$ .

**12.1.2. Set algebra.** View the algebraic structure on the set  $K = 2^M$  from the previous paragraph as  $(K, \vee, \wedge, ', 1, 0)$ , with two binary operations, one unary operation (the complement), and two special elements  $1 = M, 0 = \emptyset$ .

It is easily verified that all elements  $A, B, C \in K$  satisfy the following properties:

AXIOMS OF BOOLEAN ALGEBRAS

- (1)  $A \wedge (B \wedge C) = (A \wedge B) \wedge C,$
- (2)  $A \vee (B \vee C) = (A \vee B) \vee C,$
- (3)  $A \wedge B = B \wedge A, \quad A \vee B = B \vee A,$
- (4)  $A \wedge (B \vee C) = (A \wedge B) \vee (A \wedge C),$
- (5)  $A \vee (B \wedge C) = (A \vee B) \wedge (A \vee C),$
- (6) there is a  $0 \in K$  such that  $A \vee 0 = A,$
- (7) there is a  $1 \in K$  such that  $A \wedge 1 = A,$
- (8)  $A \wedge A' = 0, \quad A \vee A' = 1.$

Compare these properties with those of the scalars  $(\mathbb{K}, +, \cdot, 0, 1)$ : Properties (1) and (2) say that both the operations  $\wedge$  and  $\vee$  are associative. Property (3) says that both operations are also commutative. So far, this is the same as for the addition and multiplication of scalars. Also there are neutral elements for both operations there.

However, the properties (4) and (5) are stronger now: they require the distributivity of  $\wedge$  over  $\vee$  as well as  $\vee$  over  $\wedge$ . Of course, this cannot be the case for addition and multiplication of numbers. In the case of numbers, multiplication distributes over addition but not vice versa.

**12.A.4.** Write down a logic table for the Boolean proposition

$$((A \wedge B) \vee C)'$$

**Solution.** Using de Morgan's and distributive laws we express

$$((A \wedge B) \vee C)' = (A \wedge B)' \wedge C' = A' \wedge B' \wedge C'$$

Setting 1 for the value *True* and 0 for *False* for  $A, B, C$  we obtain the table for  $\varphi(A, B, C) = A' \wedge B' \wedge C'$ :

A	B	C	$\varphi$
0	0	0	1
0	0	1	0
0	1	0	1
1	0	0	1
0	1	1	0
1	0	1	0
1	1	0	0
1	1	1	0

□

**12.A.5.** For  $A = 0, B = 0, C = 1$  find the value of the Boolean proposition

$$A \wedge B \vee C$$

**Solution.**  $A \wedge B \vee C = 0 \wedge 0 \vee 1 = 0 \vee 1 = 1$ , which has value *True*. □

**12.A.6.** A switching circuit is an electrical network that consists of switches being open or closed as on fig. .. If switch  $a$  is open we set  $a = 0$ , if switch  $a$  is closed we set  $a = 1$  and so on. Switches labeled with the same letter must be either all open or all closed simultaneously. Switch  $a'$  is open if and only if switch  $a$  is closed. If current can flow between the extreme left and right ends of the circuit, the output of the circuit is 1 and 0 otherwise. The switching circuit representing  $a \wedge b$  is called series circuit, while the circuit representing  $a \vee b$  is called parallel circuit.

Represent the switching circuit at the figure?? as a Boolean proposition.

**Solution.** We can write this circuit as proposition  $\varphi = a \wedge X \wedge b$ , where

$$X = b \vee d' \vee c \wedge (a \vee d \vee c')$$

Thus,

$$\varphi = a \wedge (b \vee d' \vee c \wedge (a \vee d \vee c')) \wedge b.$$

□

**12.A.7.** Draw a switching circuit representing Boolean proposition

$$(a \wedge ((b \wedge c') \vee (b' \wedge c))) \vee (a \wedge b \wedge c)$$

**Solution.** see fig???

□

Properties (6)–(8) require the existence of neutral elements for both operations as well as the existence of an analog to the “inverse” of each element. (Note however, that the intersection with the complement results in the neutral element for union and vice versa. This is the other way round for numbers.)

There are only a few structures that possess such restrictive properties.

BOOLEAN ALGEBRAS

**Definition.** A set  $K$  together with two binary operations  $\wedge, \vee$ , a unary operation  $'$ , and two special elements  $1, 0$ , which satisfy the properties (1)–(8) is called a *Boolean algebra*. The  $\wedge$  operation is called *infimum* or *meet*, and the  $\vee$  operation is called *supremum* or *join*. The element  $A'$  is called the *complement* of  $A$ .

Note that the axioms of Boolean algebras are symmetric with respect to interchanging the operations  $\wedge$  and  $\vee$  together with the interchange of 0 and 1. This means that any proposition that can be derived from the axioms has a valid *dual proposition*, created by interchanging  $\wedge$  with  $\vee$  and 0 with 1. This is the *principle of duality*.

**12.1.3. Properties of Boolean algebras.** As usual, we derive several elementary corollaries of the axioms. In particular, note that in the special case of the Boolean algebra of all subsets of a given set, this proves all the elementary properties known from set algebra. The special elements 1 and 0 are unique as the neutral elements for  $\wedge$  and  $\vee$ . If there is  $\tilde{0}$  with the same properties then  $\tilde{0} = \tilde{0} \vee 0 = 0$ . Similarly 1 is also unique. Next, if  $B, C \in K$  satisfy the properties of  $A'$  (axiom (8) in the above definition), then

$$\begin{aligned} B &= B \vee 0 = B \vee (A \wedge C) = \\ &= (B \vee A) \wedge (B \vee C) = 1 \wedge (B \vee C) = B \vee C \end{aligned}$$

and similarly

$$C = C \vee B = B \vee C.$$

Therefore,  $B = C$  and so the complement to any  $A \in K$  is determined uniquely by its properties.

Generally the above observation means that given  $(K, \wedge, \vee)$ , there exists at most one operation  $'$  which completes it to a Boolean algebra  $(K, \wedge, \vee, ', 1, 0)$ , together with unique elements 1 and 0. Generally  $(K, \wedge, \vee)$  is written, omitting the other three symbols for operations.

The properties of the following proposition have their own names in set algebra: (2) is called *absorption laws*, (3) is the *idempotency* of the operations  $\wedge$  and  $\vee$ , and the equalities of (4) are the *De Morgan laws*.

**12.A.8.** Verify equivalence of the following two Boolean propositions

$$(a \vee b) \wedge (c \vee d) \quad \text{and} \quad (a \wedge c) \vee (a \wedge d) \vee (b \wedge c) \vee (b \wedge d)$$

**Solution.** Distributive laws yield

$$(a \vee b) \wedge (c \vee d) = ((a \vee b) \wedge c) \vee ((a \vee b) \wedge d) = a \wedge c \vee b \wedge c \vee a \wedge d \vee b \wedge d$$

□

**12.A.9.** Determine whether the following two Boolean propositions

$$((a' \wedge b) \vee (a \wedge c'))' \quad \text{and} \quad (a \vee b') \wedge (a \vee c')$$

are equivalent?

**Solution.** setting  $a = 1, b = 1, c = 0$  implies  $((a' \wedge b) \vee (a \wedge c'))' = 0$  and  $(a \vee b') \wedge (a \vee c') = 1$ . Hence, these propositions are not equivalent. □

**12.A.10.** Determine whether the following two Boolean propositions

$$(a \wedge b \wedge c) \vee (a \vee c)' \quad \text{and} \quad (a \wedge c) \vee (a' \wedge c')$$

are equivalent?

**Solution.** setting  $a = 1, b = 0, c = 1$  implies  $(a \wedge b \wedge c) \vee (a \vee c)' = 0$  and  $(a \wedge c) \vee (a' \wedge c') = 1$ . Hence, these propositions are not equivalent. □

**12.A.11.** Show that the negation  $a'$  can not be obtained by a combinatorial circuit that consists of  $\wedge$  and  $\vee$  operations only.

**Solution.** We prove the claim by the induction on the number of operations  $n$  in the circuit. For  $n = 1$  it is clear that neither proposition  $b \wedge c$  or  $b \vee c$  is equivalent to  $a'$ . Suppose  $a'$  can not be achieved by a combinatorial circuit, containing  $\vee$  and  $\wedge$ . Consider a circuit with  $n + 1$  operations and the first occurrence of the input of  $a$ . It can be either  $\wedge$  or  $\vee$ . If it is  $\wedge$  with the second argument either  $a$  or  $1$ , then the outcome of it is the same as input  $a$  and this operation  $\wedge$  can be deleted from the circuit with input  $a$  going to the next available operation. If the second argument is  $0$ , then  $a \wedge 0 = 0$  and operation can again be deleted with  $0$  going as input to the next available operation. If  $a$  enters the circuit at the  $\vee$ , and the second argument of this  $\vee$  is either  $a$  or  $0$ , then the  $\vee$  can be deleted with  $a$  entering the next operation. If the second argument equals  $1$ , then the result of  $\vee$  is  $1$ , and it can be entered to the next available operation. □

**12.A.12.** Simplify the formula

$$((A \wedge B) \vee (A \Rightarrow B)) \wedge ((B' \Rightarrow C) \vee (B \wedge C')).$$

**Solution.** In Boolean algebra, we obtain

$$(a \cdot b + a' + b) \cdot (b + c + b \cdot c') = \dots = a' \cdot c + b.$$

This means that the given formula is equivalent to  $(A' \wedge C) \vee B$ . □

FURTHER PROPERTIES OF BOOLEAN ALGEBRAS

**Proposition.** In every Boolean algebra  $(K, \wedge, \vee)$ ;

- (1)  $A \wedge 0 = 0, \quad A \vee 1 = 1,$
  - (2)  $A \wedge (A \vee B) = A, \quad A \vee (A \wedge B) = A,$
  - (3)  $A \wedge A = A, \quad A \vee A = A,$
  - (4)  $(A \wedge B)' = A' \vee B', \quad (A \vee B)' = A' \wedge B',$
  - (5)  $(A')' = A.$
- for all  $A, B \in K$ .

**PROOF.** By the principle of duality, it suffices to prove only one of the claims in each item. Begin with (3), of course using just the axioms of the Boolean algebras

$$A = A \wedge 1 = A \wedge (A \vee A') = (A \wedge A) \vee 0 = A \wedge A.$$

Now, (1) is proved easily:

$$A \wedge 0 = A \wedge (A \wedge A') = (A \wedge A) \wedge A' = A \wedge A' = 0.$$

(2) is also easy (read the second equality from right to left):

$$\begin{aligned} A \wedge (A \vee B) &= (A \vee 0) \wedge (A \vee B) = \\ &= A \vee (0 \wedge B) = A \vee 0 = A. \end{aligned}$$

In order to prove the De Morgan laws, it suffices to verify that  $A' \vee B'$  has the properties of the complement of  $A \wedge B$ . By the above, it must be the complement. Using (1), compute

$$\begin{aligned} (A \wedge B) \wedge (A' \vee B') &= ((A \wedge B) \wedge A') \vee ((A \wedge B) \wedge B') \\ &= (0 \wedge B) \vee (A \wedge 0) = 0. \end{aligned}$$

Similarly,

$$\begin{aligned} (A \wedge B) \vee (A' \vee B') &= (A \vee (A' \vee B')) \wedge (B \vee (A' \vee B')) \\ &= (1 \vee B') \wedge (1 \vee A') = 1. \end{aligned}$$

Finally, from the definition,  $A' \wedge A = 0$  and  $A' \vee A = 1$ . Hence,  $A$  has the required properties of the complement of  $A'$ , which means that  $A = (A')'$ . □

**12.1.4. Examples of Boolean algebras.** The intersection and union on all subsets in a given set  $M$  always define a Boolean algebra. The smallest is the set of all subsets of a singleton  $M$ . It contains two elements, namely  $0 = \emptyset$  and  $1 = M$  with the obvious equalities  $0 \wedge 1 = 0, 0 \vee 1 = 1$ , etc. The operations  $\wedge$  and  $\vee$  are the same as multiplication and addition in the remainder class ring  $\mathbb{Z}_2$  of even and odd numbers. This is called the Boolean algebra  $\mathbb{Z}_2$ . This is the only case when a Boolean algebra is a field of scalars at the same time!

As in the case of rings of scalars or vector spaces, the algebraic structure of a Boolean algebra can be extended to all spaces of functions whose codomain is a Boolean algebra. For the set  $S = \{f : M \rightarrow K\}$  of all functions from a set  $M$  to a Boolean algebra  $(K, \wedge, \vee)$ , the necessary operations and the distinguished elements  $0$  and  $1$  on  $S$  can be defined

**12.A.13.** Design a logic proposition in three boolean that takes value *True* if and only if the majority of variables also have *True* values.

**Solution.** For this purpose, a dijunctive normal form is quite suitable. Consider the proposition:

$$a \wedge b \wedge c' \vee a \wedge b' \wedge c \vee a' \wedge b \wedge c \vee a \wedge b \wedge c.$$

**12.A.14.** Let  $A$  be a free boolean algebra, generated by countably many generators  $a_1, \dots, a_n, \dots$  with operations  $\wedge, \vee$  and  $'$  and elements being finitely many of these generators, linked by the operations. Prove that these algebra is atomless.

**Solution.** Suppose  $f$  is an atom in  $A$ . Without loss of generality  $f$  can be expressed in terms of the first  $n$  generators  $a_1, \dots, a_n$ . Then  $f \wedge a_{n+1}$  is neither  $f$  nor  $0$ , so  $f$  can not be an atom in  $A$ .  $\square$

**12.A.15.** Prove monotonicity laws for Boolean algebras: if  $A \leq \tilde{A}$  and  $B \leq \tilde{B}$  then

- i)  $A \vee B \leq \tilde{A} \vee \tilde{B}$ ;
- ii)  $A \wedge B \leq \tilde{A} \wedge \tilde{B}$ ;
- iii)  $(\tilde{A})' \leq A'$

**Solution.** Since

$$(A \vee B) \vee (\tilde{A} \vee \tilde{B}) = (A \vee \tilde{A}) \vee (B \vee \tilde{B}) = \tilde{A} \vee \tilde{B},$$

it implies the first assertion. The second follows from the duality the fact that  $A \leq \tilde{A}$  if and only if  $A \wedge \tilde{A} = A$ . Application of de Morgan's law

$$(\tilde{A})' \vee A' = (A \wedge \tilde{A}') = A'$$

verifies the third.  $\square$

**12.A.16.** For Boolean algebras prove

- i)  $A \leq B$  if and only if  $B' \leq A'$ ;
- ii)  $A \leq B$  if and only if  $A \wedge B' = 0$ ;
- iii)  $C \wedge A \leq B$  if and only if  $A \leq C' \vee B$ .

**Solution.** By previous exercise,  $A \leq B$  yields  $B' \leq A'$ , and vice versa

$$A = (A')' \leq (B')' = B.$$

If  $A \leq B$ , then  $A = A \wedge B$  and  $A \wedge B' = A \wedge B \wedge B' = 0$ .

Conversely, from  $A \wedge B' = 0$  follows that

$$A = A \wedge (B \vee B') = A \wedge B \vee A \wedge B' = A \wedge B,$$

so  $A \leq B$ . For the third assertion, since  $C \wedge A \leq B$  and  $C' \wedge A \leq C'$ , by monotonicity of the  $\vee$ ,

$$A = C \wedge A \vee C' \wedge A \leq B \vee C'.$$

On the other hand, if  $A \leq C' \vee B$ , by monotonicity of the  $\wedge$ ,

$$C \wedge A \leq C \wedge (C' \vee B) \leq C \wedge B \leq B.$$

as functions of an argument  $x \in M$  as follows:

$$(f_1 \wedge f_2)(x) = (f_1(x)) \wedge (f_2(x)) \in K,$$

$$(f_1 \vee f_2)(x) = (f_1(x)) \vee (f_2(x)) \in K,$$

$$(1)(x) = 1 \in K, (0)(x) = 0 \in K,$$

$$(f)')(x) = (f(x))' \in K.$$

$\square$  It is easy and straightforward to verify that these new operations define a Boolean algebra.

Recall that the subsets of a given set  $M$  can be viewed as mappings  $M \rightarrow \mathbb{Z}_2$  (the elements of the subset in question are mapped to 1 while all others go to 0). Then, the union and intersection can be defined in the above manner — for instance, evaluating the expression  $(A \vee B)(x)$  for a point  $x \in M$ , This determines whether it lies in  $A$  or whether it lies in  $B$ , and whether the join of the results is in  $\mathbb{Z}_2$ . The result is 1 if and only if  $x$  lies in the union.  $\square$

**12.1.5. Propositional logic.** The latter simple observation

brings us close to the calculus of elementary logic. View the notations for operations in a Boolean algebra as creating “words” from the elements  $A, B, \dots \in K$ , the operations  $\vee, \wedge, '$  and parentheses, which clarify the desired precedence of the operations.

The axioms of the Boolean algebras and their corollaries say how different words may produce the same result in  $K$ .

This is clear in the case of  $K = 2^M$ , the set of all subsets of a given set; it is just equality of subsets. Now, another interpretation is mentioned in terms of operations in formal logic.

Work with words as above but view them as propositions composed from elementary (atomic) propositions  $A, B, \dots$  and the logical operations AND (the binary operation  $\wedge$ ), OR (the binary operation  $\vee$ ), and the negation NOT (the unary operation  $'$ ). These words are called *propositions*. They are assigned a truth value depending on the truth values of the individual atomic propositions. The truth value is an element of the trivial Boolean algebra  $\mathbb{Z}_2$ , i.e. either 0 or 1.

The truth value of a proposition is completely determined by assigning the truth values for the simplest propositions  $A \wedge B, A \vee B$  and  $A'$ .  $A \wedge B$  is defined to be true if and only if both  $A$  and  $B$  are true.  $A \vee B$  is false if and only if both  $A$  and  $B$  are false. The value of  $A'$  is complementary to  $A$ .

A proposition with  $n$  elementary propositions defines a function  $(\mathbb{Z}_2)^n \rightarrow \mathbb{Z}_2$ . Two propositions are called logically equivalent if and only if they define the same function. In the previous paragraph, it is already verified that the set of all classes of logically equivalent propositions has the structure of a Boolean algebra. Propositional logic satisfies everything proved for general Boolean algebras.

Next, we consider how other usual simple propositions of propositional logic are represented as elements of the Boolean algebra. Expressions always correspond to a class of logically equivalent propositions:  $\square$

**12.A.17.** For any two elements  $A, B$  of a Boolean algebra, the *symmetric difference* of  $A$  and  $B$  is defined as

$$A \triangle B = A \wedge B' \vee B \wedge A'.$$

This is analogous of taking symmetric difference  $A \triangle B = (A \setminus B) \cup (B \setminus A)$ . Show that

- i)  $A = B$  if and only if  $A \triangle B = 0$ .
- ii)  $A \triangle (B \triangle C) = (A \triangle B) \triangle C$
- iii)  $A \wedge (B \triangle C) = (A \wedge B) \triangle (A \wedge C)$ .

**Solution.**

- i) If  $A = B$  then  $A \leq B$  and  $B \leq A$ , and therefore, by previous exercise,  $A \wedge B' = 0$  and  $B \wedge A' = 0$ , thus  $A \triangle B = 0$ . On the other hand,  $A \triangle B = 0$  implies that both  $A \wedge B' = 0$  and  $B \wedge A' = 0$ , which yield  $A \leq B$  and  $B \leq A$ , thus  $A = B$ .
- ii) Expanding  $(B \triangle C)'$  using distributivity and de Morgan's laws, we obtain

$$(B \triangle C)' = (B' \vee C) \wedge (C' \vee B) = B \wedge C \vee B' \wedge C'.$$

Further expanding  $A \triangle (B \triangle C)$  we get

$$\begin{aligned} A \triangle (B \triangle C) &= A \wedge (B \wedge C \vee B' \wedge C') \vee A' \wedge (B \wedge C' \vee B' \wedge C) \\ &= A \wedge B \wedge C \vee A \wedge B' \wedge C' \vee A' \wedge B \wedge C' \vee A' \wedge B' \wedge C, \end{aligned}$$

which equals  $(A \triangle B) \triangle C$  by obvious symmetry.

iii) Follows from

$$A \wedge (B \triangle C) = A \wedge (B \wedge C' \vee C \wedge B') = A \wedge B \wedge C' \vee A \wedge C \wedge B'$$

and

$$(A \wedge B) \triangle (A \wedge C) = A \wedge B \wedge (A' \vee C') \vee A \wedge C \wedge (A' \vee B') = A \wedge B \wedge C' \vee A \wedge C \wedge B'$$

□

**12.A.18.** The Sheffer stroke is defined as:

$$A | B = A' \wedge B'.$$

The *Pierce arrow* can be defined as:

$$A \uparrow B = A' \vee B'.$$

Prove that  $|$  and  $\uparrow$  define  $A \vee B$ ,  $A \wedge B$  and  $A'$ .

**Solution.** It is clear from de Morgan's laws, in particular, that  $A' = A \uparrow A$ ,  $A \vee B = (A \uparrow A) \uparrow (B \uparrow B)$ . Since  $A \wedge B = (A' \vee B')'$ , we obtain that  $\uparrow$  generates all Boolean operations. Analogously,  $A' = A | A$  and  $A \wedge B = A' | B' = (A | A) | (B | B)$ . De Morgan's law  $A \vee B = (A' \wedge B')'$  proves that  $|$  also generates all three Boolean operations. □

**12.A.19.** The *exclusive or* binary operation in Boolean algebra is defined as:

$$A \oplus B = (A \vee B) \wedge (A' \vee B').$$

Prove that  $\oplus$  and  $\wedge$  do not generate all Boolean operations.

**Solution.** If we only apply  $\oplus$  and  $\wedge$  operations, from the inputs with all values *False* we'll be getting outputs with the same *False* value. Thus,  $A'$  can not be obtained using only  $\oplus$  and  $\wedge$  out of a *False* proposition  $A$ . □

THE STANDARD LOGICAL OPERATORS

- (1)  $A$  AND  $B$  corresponds to  $A \wedge B$ ,
- (2)  $A$  OR  $B$  corresponds to  $A \vee B$ ,
- (3) the implication  $A \Rightarrow B$  can be obtained as  $A' \vee B$ ,
- (4) the equivalence  $A \Leftrightarrow B$  corresponds to  $(A \wedge B) \vee (A' \wedge B')$ ,
- (5) the exclusive OR, known as  $A$  XOR  $B$ , is given as  $(A \wedge B') \vee (A' \wedge B)$ ,
- (6) the negation of OR,  $A$  NOR  $B$ , is expressed as  $A' \wedge B'$ ,
- (7) the negation of AND,  $A$  NAND  $B$ , is given as  $A' \vee B'$ ,
- (8) tautology (proposition always true) is given in terms of an arbitrary atomic proposition as  $A \vee A'$ , its negation (always false) is  $A \wedge A'$ .

Note that in set algebra, XOR corresponds to the symmetric difference.

**12.1.6. Switch boards as Boolean algebras.** A switch is a black box with only two states – it is either on (and the signal goes through) or off (and the signal does not go through).

One or more switches may be interconnected in a series circuit or a parallel circuit. The series circuit corresponds to the binary operation  $\wedge$ , while the parallel circuit corresponds to  $\vee$ . The unary operation  $A'$  defines a switch whose state is always the opposite than that of  $A$ . Every finite word created from the switches  $A, B, \dots$  and the operations  $\wedge, \vee$ , and  $'$  can be transformed to a diagram that represents a system of switches, connected by wires, similarly as in the above subsection, where each choice of states of the individual switches gives the value “on/off” for the entire system. The discussion is about switchboards and their logical evaluation function.

Again, it is easy to verify all the axioms of Boolean algebras for the system. The following diagram illustrates one of the distributivity axioms.

The circuit without a switch corresponds to 1. When the endpoints are not connected, this corresponds to 0 (consider a series circuit of  $A$  and  $A'$ ). Draw diagrams for all axioms of Boolean algebras and verify them!

We return to this example shortly, showing that each expression in propositional logic can be modeled by a switch board.

**12.1.7. Algebra of divisors.** There are other natural examples of Boolean algebras. Choose a positive integer  $p \in \mathbb{N}$ . The underlying set  $D_p$  is the set of all divisors  $q$  of  $p$ . For two such divisors  $q, r$ , define  $q \wedge r$  to be the greatest common divisor of  $q$  and  $r$ , and  $q \vee r$  is defined to be their least common multiple (cf. the

**12.A.20.** Translate the following sentence as a logical proposition considering ambiguity of English language: *Either school X improves its performance and continues to perform well or school Y wins academic competition.*

**Solution.** Modern English is sometimes vague about the meaning of *or*. Therefore, the sentence can be translated using  $\vee$  or  $\oplus$  in place of the *or*. Let  $A, B, C$  represent propositions *School X improves its performance*, *School X continues to perform well*, and *School Y wins academic competition*. Then the proposition of the sentence can be interpreted as

- i)  $(A \wedge B) \vee C$ ;
- ii)  $(A \wedge B) \oplus C$ ;

This two propositions differ when all three propositions  $A, B, C$  have *True* value. □

**12.A.21.** Let logical implication  $\rightarrow$  mean  $A \rightarrow B = A' \vee B$ . Prove the equivalence of the following logical propositions

- i)  $(A' \rightarrow (B \rightarrow C)) = (B \rightarrow (A \vee C))$ ;
- ii)  $(A \rightarrow B')' \wedge (A \vee B)' = 0$ , that is, it is always *False*.
- iii)  $(A \vee B) \wedge (B' \vee C) \rightarrow (B \vee C) = 1$  that is, it is always *True*

**12.A.22.** Show that the following divisibility relations are partial orders on  $X$ . Is any one of them a linear order?

- i)  $X = \mathbb{N}$ . Relation  $|$  is defined as:  $m|n$  if  $m$  divides  $n$ .
- ii) Let  $X$  be a set of all integer divisors of 36.

**Solution.**

- i) As  $n|n$  for each  $n$ , the relation is reflexive. IF  $m|n$  and  $n|m$ , then  $m = n$ . Since  $r|m$  and  $m|n$  implies  $r|n$ , it is also transitive. The order is not linear, since, for example, 4 and 5 are not divisors of each other.
- ii)  $X = \{1, 2, 3, 4, 6, 9, 12, 18, 36\}$ . By previous item,  $|$  is reflexive, antisymmetric and transitive. However, divisors 2 and 3 are not related. (DRAW HASSE DIAGRAM!) □

**12.A.23.** Given a partial order  $\leq$  on a set  $A$ , one can also define a corresponding strict order  $<$ , that is also useful in various situations. A relation  $R$  on  $A$  is called irreflexive if  $(x, x) \notin R$  for all  $x \in A$ .  $R$  is called asymmetric if with every  $(x, y) \in R$ ,  $(y, x) \notin R$ . Relation  $R$  on  $A$  is a strict order if  $R$  is a partial order and, in addition, it is irreflexive and asymmetric. Let  $A$  be a set

- i) If  $\leq$  is a partial order on  $A$ , then the relation  $<$ , defined as  $a < b$  if  $a \leq b$  and  $a \neq b$  is a strict order on  $A$ .
- ii) Given strict order  $<$  on  $A$  then the partial order  $\leq$  can be defined as  $a \leq b$  if  $a < b$  or  $a = b$ .

**Solution.** Suppose,  $\leq$  is a partial order with  $<$  defined by  $a < b$  for  $a \leq b$  and  $a \neq b$ . Then  $<$  is irreflexive: if  $a < b$  then  $a \neq b$ . Now, suppose that  $a < b$  and  $b < c$ , then  $a \leq c$  by transitivity of  $\leq$ . If  $a = c$ , then by asymmetry of  $\leq$ , we would have  $a = b$ . Hence,  $a < c$ . □

previous chapter for the definitions and context). The distinguished element  $1 \in D_p$  is defined to be  $p$  itself. The neutral element 0 for join on  $D_p$  is the integer  $1 \in \mathbb{N}$ . The unary operation  $'$  is defined using division as  $q' = p/q$ .

**Proposition.** *The set  $D_p$  together with the above operations  $\wedge, \vee$ , and  $'$  is a Boolean algebra if and only if the factorization of  $p$  contains no squares (i.e., in the unique factorization  $p = q_1 \dots q_n$ , the prime numbers  $q_i$  are pairwise distinct).*

**PROOF.** It is easy to verify the axioms of Boolean algebras under the assumptions of the proposition. It might be interesting to see where the assumption squarefree is needed.

The greatest common divisor of a finite number of integers is independent of their order. This also holds for the least common multiple. This corresponds to the axioms (1) and (2) in 12.1.2. The commutativity (3) is clear.

For any three elements  $a, b, c$ , write their factorizations without loss of generality as  $a = q_1^{n_1} \dots q_s^{n_s}$ ,  $b = q_1^{m_1} \dots q_s^{m_s}$ ,  $c = q_1^{k_1} \dots q_s^{k_s}$ . Zero powers are allowed and all  $q_j$  are pairwise coprime. Thus,  $a \wedge b \in D_p$  corresponds to the element in which each  $q_i$  occurs with the power that is the minimum of the powers in  $a$  and  $b$ . This holds analogously for  $a \vee b$  and maximum. The distributivity laws (4) and (5) of 12.1.2 now follow easily.

There is no problem with the existence of the distinguished elements 0 and 1. These are already defined directly and clearly satisfy the axioms (6) and (7). However, if there are squares in the factorizations, then this prevents the existence of complements. For instance, in  $D_{12} = \{1, 2, 3, 4, 6, 12\}$ ,  $6 \wedge 6' = 1$  cannot be reached since 6 has a non-trivial divisor which is common to all other elements of  $D_{12}$  except for 1, but  $6 \vee 1 = 6 \neq 12$ . (The number 1 is the potential smallest element in  $D_{12}$ ; it plays the role of 0 from the axioms.)

Nevertheless, if there are no squares in the factorization of the integer  $p$ , then the complement can be defined as  $q' = p/q$ , and it can be verified easily that this definition satisfies the axiom 12.1.2(8). □

If there are no squares in the decomposition of  $p$ , then the number of all divisors is a power of 2. This suggests that these Boolean algebras are very similar to the set algebras we started with. We return to the classification of all finite Boolean algebras. Before that, we consider structures like the divisors above for general  $p$ .

**12.1.8. Partial order.** There is a much more fundamental concept, the *partial order*. See the end of chapter 1. Recall that the definition of a partial order is a reflexive, antisymmetric, and transitive relation  $\leq$  on a set  $K$ . A set with partial order  $(K, \leq)$  is called a *partially ordered set*, or *poset* for short. The adjective “partial” means that in general, this relation does not say whether  $a \leq b$  or  $b \leq a$  for every two different elements  $a, b \in K$ . If it does for each pair, it is called a *linear order* or a *total order*.

**12.A.24.** Prove that a finite poset  $A$  can be embedded in a totally ordered set, whose order extends the original order on  $A$ .

**Solution.** Let  $(A, \leq)$  be a finite poset with a minimal element  $a_1$ . Set  $A \setminus \{a_1\}$  remains a poset with some minimal element  $a_2$ . Choose  $a_3, \dots, a_n$  similarly until  $A$  is exhausted. Define  $a_i \leq a_j$  for  $i \leq j$ , which defines a total order on  $A$ .  $\square$

**12.A.25.** Convert the poset of divisors of 36 into a linearly ordered set in different ways

**Solution.** One order is the natural order in  $\mathbb{N}$ : 1, 2, 3, 4, 6, 9, 12, 18, 36. Another order can be chosen as 1, 2, 4, 3, 6, 12, 9, 18, 36.  $\square$

**12.A.26.** Prove that lattices of the *diamond* and *pentagon* types are not distributive.

**Solution.**

i) For the diamond lattice

$$a \wedge (b \vee c) = a \wedge 1 = a, \quad \text{while} \quad (a \wedge b) \vee (a \wedge c) = 0 \vee 0 = 0.$$

ii) For the pentagon lattice

$$a \wedge (b \vee c) = a \wedge 1 = a, \quad \text{and} \quad (a \wedge b) \vee (a \wedge c) = 0 \vee 0 = 0.$$

also hold.  $\square$

**12.A.27.** Prove uniqueness of completeness in distributive lattices, i.e. if  $(A, \leq)$  is a bounded distributive lattice with minimum 0 and maximum 1 then complements are unique.

**Solution.** Let  $x'$  and  $z$  denote complements of  $x \in A$ . Then

$$\begin{aligned} (1) \quad x' &= x' \wedge 1 \\ &= x' \wedge (x \vee z) \\ &= (x' \wedge x) \vee (x' \wedge z) \\ &= 0 \vee (x' \wedge z) \\ &= (x' \wedge z) \vee (x' \wedge z) \\ &= (x \vee x') \wedge z \\ &= 1 \wedge z = z \end{aligned} \quad \square$$

**12.A.28.** Anne, Brenda, Kate, and Dana want to set out on a trip. Find out which of the girls will go if the following must hold: At least one of Brenda and Dana will go; at most one of Anne and Kate will go; at least one of Anne and Dana will go; at most one of Brenda and Kate will go; Brenda will not go unless Anne goes; and Kate will go if Dana goes.

**Solution.** Transforming the problem to Boolean algebra, simplifying it, and transforming it back, we find out that either Anne and Brenda will go or Kate and Dana will go.  $\square$

There is always a partial order on the set  $K = 2^M$  of all subsets of a given set  $M$  – the inclusion. In terms of intersections or joins, the inclusion can be defined as  $A \subseteq B$  if and only if  $A \wedge B = A$ , or equivalently,  $A \subseteq B$  if and only if  $A \vee B = B$ . In general, each Boolean algebra is a very special poset:

**Lemma.** Let  $(K, \wedge, \vee)$  be a Boolean algebra. Then the relation  $\leq$  defined by  $A \leq B$  if and only if  $A \wedge B = A$  is a partial order. Moreover, for all  $A, B, C \in K$ :

- (1)  $A \wedge B \leq A$ ,
- (2)  $A \leq A \vee B$ ,
- (3) if  $A \leq C$  and  $B \leq C$ , then  $A \vee B \leq C$ ,
- (4)  $A \leq B$  if and only if  $A \wedge B' = 0$ ,
- (5)  $0 \leq A$  and  $A \leq 1$ .

**PROOF.** All the properties to be proved are results of simple calculations in the Boolean algebra  $K$ . Begin with the properties of a partial order for  $\leq$ . Reflexivity is a direct corollary of idempotency:  $A \wedge A = A$ , i.e.  $A \leq A$ . Similarly, the commutativity of  $\wedge$  guarantees the antisymmetry of  $\leq$ , since if both  $A \wedge B = A$  and  $B \wedge A = B$ , then

$$A = A \wedge B = B \wedge A = B.$$

Finally, if  $A \wedge B = A$  and  $B \wedge C = B$ , then

$$A \wedge C = (A \wedge B) \wedge C = A \wedge (B \wedge C) = A \wedge B = A,$$

which verifies the transitivity of  $\leq$ .

Similarly,  $(A \wedge B) \wedge A = (A \wedge A) \wedge B = A \wedge B$ , that is,  $A \wedge B \leq A$ .

It follows from  $A \wedge (A \vee B) = A$ , see 12.1.3(2), that  $A \leq A \vee B$ . This proves the claim (2).

Distributivity together with assumption (3) provides

$$(A \vee B) \wedge C = (A \wedge C) \vee (B \wedge C) = A \vee B,$$

so that (3) holds.

The proposition (5) follows directly from the axioms for the distinguished elements 1 and 0.

It remains to prove (4). If  $A \leq B$ , then  $A \wedge B' = A \wedge B \wedge B' = 0$ . On the other hand, if  $A \wedge B' = 0$ , then  $A = A \wedge 1 = A \wedge (B \vee B') = (A \wedge B) \vee (A \wedge B') = (A \wedge B) \vee 0 = A \wedge B$ . Hence  $A \leq B$ , and the proof is finished.  $\square$

Note that as for the algebra of subsets, in all Boolean algebras  $A \wedge B = A$  if and only if  $A \vee B = B$ . If  $A \wedge B = A$ , then the absorption laws imply that  $A \vee B = (A \wedge B) \vee B = B$ , and vice versa. Therefore, the operation  $\vee$  can also be used in the definition of a partial order.

Every poset  $(K, \leq)$  corresponds to a (oriented) graph (cf. the beginning of chapter 13 for definitions if necessary): the vertex set is  $K$ , and there is an edge leading from  $a$  to  $b$  if and only if  $a \leq b$ . This is a convenient way how to represent finite posets.

A *Hasse diagram* of a poset is a drawing of this graph in the plane so that greater elements are drawn above lower ones. Since the edge orientation is implicitly given by this, it need not be drawn explicitly. Furthermore, loops and edges

**12.A.29.** Solve the following problem by transforming it to Boolean algebra: Tom, Paul, Sam, Ralph, and Lucas are suspected of having committed a murder. It is certain that at the crime scene, there were: at least one of Tom and Ralph, at most one of Lucas and Paul, and at least one of Lucas and Tom. Sam could be there only if so was Ralph. However, if Sam was there, then so was Tom. Paul could never cooperate with Ralph, but Paul and Tom are an inseparable pair. Who committed the murder?

**Solution.** Transforming into Boolean algebra, using the first letter of each name, we get

$$(t + r)(l' + p')(l + t)(r + s')(s' + t)(p' + r')(pt + p't')$$

and thanks to  $x^2 = x$ ,  $xx' = 0$ ,  $x + x' = 1$ , we can rearrange the above to  $s'r'ptl' + s'rp't'l$ . Thus, the murder was committed either by Tom and Paul or by Ralph and Lucas.  $\square$

**12.A.30.** A vote box for three voters is a box which processes three votes and outputs “yes” if and only if majority of the voters is for. Design this box using from switch circuits.

**Solution.**

$\square$

**12.A.31.** Find a finite subset of the set of positive integers which is not a lattice with respect to divisibility.  $\circ$

**12.A.32.** Find the number of partial orders on a given 4-element set. Draw the Hasse diagram of each isomorphism class and determine whether it is a lattice. Is one of them a Boolean algebra?

**Solution.** We go through all Hasse diagrams of the partial orders on a 4-element set  $M$  and for each diagram, we count the number of partial orders (i. e. subsets of  $M \times M$ ) that correspond to it; see the picture:

$\dots$	$\vdots$	$\vdots \vdots$	$\wedge$	$\vee$	$\vdots$	$N$	$\times$
1	$\frac{4!}{2}$	$\frac{4!}{2}$	$\frac{4!}{2}$	$\frac{4!}{2}$	$4!$	$4!$	$\frac{4!}{4}$
$\wedge$	$\vee$	$\vdots$	$\vdots$	$\vee$	$\wedge$	$\diamond$	$\vdots$
$\frac{4!}{2}$	$\frac{4!}{6}$	$4!$	$4!$	$\frac{4!}{2}$	$\frac{4!}{2}$	$\frac{4!}{2}$	$4!$

Therefore, there are 219 partial orders on a given 4-element set.

Note that the condition of existence of suprema and infima of any pair of elements in a lattice implies (by induction) the existence of them for any finite non-empty subset. In particular, this means that every non-empty finite lattice has a greatest element as well as a least element.

which are implied by transitivity and reflexivity are omitted in the diagram. Especially when  $K$  has only a few elements, this is a very transparent way of discussing several cases; see the examples in the exercise column.

**12.1.9. Lattices.** Not every poset is created the latter way from a Boolean algebra. For instance, the trivial partial order is defined on any set as  $A \leq A$  for each  $A$ , but all pairs of different elements are incomparable. Such a poset cannot rise from a Boolean algebra if  $K$  contains more than one element (as seen, the least and greatest elements of a Boolean algebra are comparable to every element).

Think to what extent the operations  $\wedge$  and  $\vee$  can be built from a partial order. They are the suprema and infima in the following definition:

LOWER AND UPPER BOUNDS, SUPREMA, INFIMA

Consider a fixed poset  $(K, \leq)$ . An element  $C \in K$  is said to be a *lower bound* for a subset  $L \subseteq K$  if and only if  $C \leq A$  for all  $A \in L$ . An element  $C \in K$  is said to be the *greatest lower bound* (or *infimum*) of a subset  $L \subseteq K$  if and only if it is a lower bound and for every lower bound  $D$  of  $L$ ,  $D \leq C$ .

By replacing  $\leq$  with  $\geq$  in the above, the definitions of an *upper bound* and of the *least upper bound* (or *supremum*) of a subset  $L$  are obtained.

If the suprema and infima exist for all couples  $A, B$ , they define the binary operations  $\vee$  and  $\wedge$ , respectively.

LATTICES

**Definition.** A *lattice* is a poset  $(K, \leq)$  where every two-element set  $\{A, B\}$  has a supremum  $A \vee B$  and an infimum  $A \wedge B$ .

The poset  $(K, \leq)$  is said to be a *complete lattice* if and only if every subset of  $K$  has a supremum and an infimum.

The binary operations  $\wedge$  and  $\vee$  on a lattice  $(K, \leq)$  are clearly commutative and associative (prove this in detail!). The latter properties (of associativity and commutativity) ensure that all finite non-empty subsets in  $K$  possess infima and suprema.

Note that any element of a lattice  $K$  is an upper bound for the empty set. Thus in a complete lattice, the supremum of the empty set is the least element  $0$  of  $K$ . Similarly, the infimum of the empty set is the greatest element  $1$  of  $K$ . Of course, a finite lattice  $(K, \leq)$  is always complete (with  $1$  being the supremum of all elements in  $K$  and  $0$  the infimum of all elements in  $K$ ).

**Remark.** The poset of real numbers, completed with the greatest and least elements  $\pm\infty$ , is a complete lattice (with the standard ordering). We may view it as a completion of the poset of rational numbers. The classical Dedekind cut construction of this completion of rational numbers extends

Using this criterion, we can see that only the last two Hasse diagrams may be lattices. Indeed, they are lattices; the first one is even a Boolean algebra.  $\square$

**12.A.33.** Find the number of partial orders on the set  $\{1, 2, 3, 4, 5\}$  such that there are exactly two pairs of incomparable elements.  $\circ$

**12.A.34.** Draw the Hasse diagram of the lattice of all (positive) divisors 36. Is this lattice distributive? Is it a Boolean algebra?

**Solution.** The lattice is distributive (it does not contain a sublattice isomorphic to diamond or pentagon).

**12.A.35.** Draw the Hasse diagram of the lattice of all (positive) divisors 30. Is this lattice distributive? Is it a Boolean algebra?

**Solution.** This lattice is a Boolean algebra, and it has 8 elements. All finite Boolean algebras are of size  $2^n$  for an appropriate  $n$ , and they are all isomorphic for a fixed  $n$  (see 12.1.16). This Boolean algebra is a “cube”: its graph can be drawn as projection of a cube onto the plane.

to all posets. Indeed, the so called Dedekind-MacNeille completion provides the unique smallest complete lattice containing a given poset. We shall not go into any details here.

A lattice is said to be *distributive* if and only the operations  $\wedge$  and  $\vee$  satisfy the distributivity axioms (4) and (5) of subsection 12.1.2 on page 1041. There are lattices which are not distributive; see the Hasse diagrams of two such simple lattices below (and check that in both cases  $x \wedge (y \vee z) \neq (x \wedge y) \vee (x \wedge z)$ ).

Now, Boolean algebras can be defined in terms of lattices: a Boolean algebra is a complete distributive lattice such that each element has its complement (i.e. the axiom 12.1.2(8) is satisfied).

It is already verified that the latter requirement implies that complements are unique (see the ideas at the beginning of subsection 12.1.3), which means that the alternative definition of Boolean algebras is correct.

During the discussion of divisors of any given integer  $p$ , distributive lattices  $D_p$  are encountered. These distributive lattices are Boolean algebras if and only if  $p$  is squarefree, see 12.1.7.

**12.1.10. Homomorphisms.** Dealing with mathematical structures, most information about objects can be obtained/understood from the homomorphisms. These are mappings which preserve the corresponding operations. The linear mappings between vector spaces, or continuous mappings on  $\mathbb{R}^n$  or any metric spaces with the given topology of open neighbourhoods represent very good examples.

This concept is particularly simple for posets:

POSET HOMOMORPHISMS

Let  $(K, \leq_K)$  and  $(L, \leq_L)$  be posets. A mapping  $f : K \rightarrow L$  is called a *poset homomorphism* (also *order-preserving mapping*, *monotone mapping* or *isotone mapping*) if for all  $A \leq_K B$  the same relation  $f(A) \leq_L f(B)$  is true.

Although the structure of any Boolean algebra is completely determined by its subordinated poset structure, an isotone mapping does not necessarily respect the suprema and infima. Non-comparable elements  $A, B$  can be mapped to the same image  $f(A) = f(B)$ , while their suprema could map to  $f(A \vee B)$  strictly larger.

add a simple example to the other column, e.g. complete the graf K3,3 as Hasse diagram of a poset.

**12.A.36.** Decide whether every lattice on a 3-element set is a *chain*, i. e., whether each pair of elements are necessary comparable.

**Solution.** As we have noticed in exercise 12.A.32, every finite non-empty lattice must contain a greatest element and a least element. Each of these is thus comparable to any other, which means that the remaining one is comparable with these two; and there are no other elements.  $\square$

**12.A.37.** Find an example of two lattices and a poset homomorphism between them which is not a lattice homomorphism.

**Solution.** Again, we return to exercise 12.A.32 and consider the following mapping:

**12.A.38.** Decide whether every lattice homomorphism between finite non-empty lattices  $K, L$  maps the least element of  $K$  to the least element of  $L$ .

**Solution.** No, any constant mapping between two lattices is a lattice homomorphism. Thus, if we sent everything to an element different from the least one, we get the wanted counterexample homomorphism.  $\square$

**12.A.39.** Decide whether every chain which has a greatest element and a least element is a complete lattice.

**Solution.** No. Consider the set of non-zero integers and order it as follows: any positive integer is greater than any negative integer, but the ordering among the positive integers will be reversed, as well as among the negative integers. Then, 1 will be the greatest element of the resulting chain, and  $-1$  will be the least element. However, the subset of all positive integers does not have an infimum in this poset.

Formally we define the linear order  $\prec$  on  $\mathbb{Z} \setminus \{0\}$  by:

$$a \prec b \iff [(\text{sgn}(a) \cdot \text{sgn}(b) = 1 \wedge b > a) \vee (\text{sgn}(a) > \text{sgn}(b))].$$

$\square$  In the case of Boolean algebras, homomorphisms are defined as follows:

LATTICE AND BOOLEAN-ALGEBRA HOMOMORPHISMS

A mapping  $f : (K, \wedge, \vee) \rightarrow (L, \wedge, \vee)$  is a *homomorphism of Boolean algebras* if and only if for all  $A, B \in K$

- (1)  $f(A \wedge B) = f(A) \wedge f(B)$ ,
- (2)  $f(A \vee B) = f(A) \vee f(B)$ ,
- (3)  $f(A') = f(A)'$ .

Moreover, if  $f$  is bijective, it is an *isomorphism of Boolean algebras*.

Similarly, lattice homomorphisms are defined as mappings which satisfy the properties (1) and (2).

It is easily verified that if a homomorphism  $f$  is bijective, then  $f^{-1}$  is also a homomorphism.

It is clear from the definition of the partial order on Boolean algebras or lattices that every homomorphism  $f : K \rightarrow L$  also satisfies  $f(A) \leq f(B)$  for all  $A, B \in K$  such that  $A \leq B$ , i.e. it is in particular a poset homomorphism. In particular,  $f(0) = 0$  and  $f(1) = 1$ .

The converse of the above is generally not true, that is, it may happen that a poset homomorphism is not a lattice homomorphism.

**12.1.11. Fixed-point theorems.** Many practical problems lead to discussion on the existence and properties of fixed points of a mapping  $f : K \rightarrow K$  on a set  $K$ , i.e. of elements  $x \in K$  such that  $f(x) = x$ . The concepts of infima and suprema allows the derivation of very strong propositions of this type surprisingly easily. There follows here a classical theorem proved by Knaster and Tarski<sup>1</sup>:

TARSKI'S FIXED-POINT THEOREM

**Theorem.** Let  $(K, \wedge, \vee)$  be a complete lattice and  $f : K \rightarrow K$  a poset homomorphism. Then,  $f$  has a fixed point, and the set of all fixed points of  $f$ , together with the restricted ordering from  $K$ , is again a complete lattice.

**PROOF.** Denote  $M = \{x \in K; x \leq f(x)\}$ . Since  $K$  has a least element,  $M$  is non-empty. Since  $f$  is order-preserving,  $f(M) \subseteq M$ . Moreover, denote  $z_1 = \sup M$ . Then, for  $x \in M, x \leq z_1$ , which means that  $f(x) \leq f(z_1)$ . At the same time,  $x \leq f(x)$ , hence  $f(z_1)$  is an upper bound for  $M$ . Then  $z_1 \leq f(z_1)$ , and also  $z_1 \in M$ , and hence  $f(z_1) \leq z_1$ . It follows that  $f(z_1) = z_1$ , so a fixed point is found.

<sup>1</sup>Knaster and Tarski proved this in the special case of the Boolean algebra of all subsets in a given set already in 1928, cf. Ann. Soc. Polon. Math. 6: 133–134. Much later in 1955, Tarski published the general result, cf. Pacific Journal of Mathematics. 5:2: 285–309. Alfred Tarski (1901-1983) was a renowned and influential Polish logician, mathematician and philosopher, who worked most of his active career in Berkeley, California. His elder colleague Bronisław Knaster (1893-1980) was also a Polish mathematician.

□

**12.A.40.** Give an example of an infinite chain which is a complete lattice.

**Solution.** We can take the set of real numbers together with  $-\infty, \infty$ , where  $-\infty$  is the least element (and thus the supremum of the empty set) and  $\infty$  is the greatest element (and thus the infimum of the empty set). The lattice suprema and infima are thus defined in accordance with these concepts in the real numbers. Moreover,  $-\infty$  is the infimum of subsets which are not bounded from below, and similarly  $\infty$  is the supremum of subsets which are not bounded from above. □

**12.A.41.** Decide whether the set of all convex subsets of  $\mathbb{R}^3$  is a lattice (with respect to suitably defined operations of suprema and infima). If so, is this lattice complete, distributive?

**Solution.** It is a lattice. The infimum is simply the intersection, since the intersection of convex subsets is again convex. The supremum is the convex hull of the union. It is clear that the lattice axioms are indeed satisfied for these operations (think this out!).

The lattice is complete, since the above operations work for infinite subsets as well, and clearly, the lattice has both a least element (the empty set) and a greatest element (the entire space).

However, the lattice is not distributive. For example, consider three unit balls  $B_1, B_2, B_3$  centered at  $[3, 0, 0], [-3, 0, 0], [0, 0, 0]$ , respectively. Then,

$$K_1 \vee (K_2 \wedge K_3) = K_1 \neq (K_1 \vee K_3) \wedge (K_1 \vee K_2).$$

□

**12.A.42.** Decide whether the set of all vector subspaces of  $\mathbb{R}^3$  is a lattice (with respect to suitably defined operations of suprema and infima). If so, is this lattice complete, distributive?

**Solution.** This is a lattice, infima correspond to intersections and suprema to sums of vector spaces (it is easy to verify that these operations satisfy the lattice axioms).

This lattice is complete (the operations work for infinite subsets as well, the least element is the zero-dimensional subspace, and the greatest element is the entire space).

However, it is not distributive (consider three lines in a plane). □

It is more difficult to verify the last statement of the theorem, namely that the set  $Z \subseteq K$  of all fixed points of  $f$  is a complete lattice. The greatest element  $z_1 = \max Z$  is found already. Analogously, using infimum and the property  $f(x) \leq x$  in the definition of  $M$ , we find the least element  $z_0 = \min Z$ .

Consider any non-empty set  $Q \subseteq Z$  and denote  $y = \sup Q$ . This supremum need not lie in  $Z$ . However, as seen shortly, the set has a supremum in  $Z$  with respect to the partial order in  $K$ , restricted to  $Z$ . For that purpose, denote  $R = \{x \in K; y \leq x\}$ . It is clear from the definitions that this set together with the partial order in  $K$ , restricted to  $R$ , is again a complete lattice, and that the restriction of  $f$  to  $R$  is again a poset homomorphism  $f|_R : R \rightarrow R$ . By the above,  $f|_R$  has a least fixed point  $\bar{y}$ . Of course,  $\bar{y} \in Z$ , and  $\bar{y}$  is the supremum of the fixed set  $Q$  with respect to the inherited order on  $Z$ . Note that it is possible that  $\bar{y} > y$ . Analogously, the infimum of any non-empty subset of  $Z$  can be found. Since the least and greatest elements are already found, the proof is finished. □

**Remark.** In the literature, one may find many variants of the fixed-point theorems, in various contexts. One of very useful variants is *Kleene's recursion theorem*, which can be determined from the theorem just proved and formulated as follows:

Consider a poset homomorphism  $f$  and a countable subset of  $K$  (using the notation of Tarski's fixed-point theorem), formed by the *Kleene chain*

$$0 \leq f(0) \leq f(f(0)) \leq \dots$$

Then, the supremum  $z$  of this subset cannot be greater than any fixed point of  $f$ . If  $y$  is a fixed point of  $f$ , it follows from  $0 \leq y$  that  $f(0) \leq f(y) = y$ , etc. Moreover, if  $f$  is assumed *continuous* in a certain sense of reasonably preserving suprema, then it can be shown that  $f(z)$  is also the supremum of this chain and hence is a fixed point. Therefore, it is the smallest fixed point. This theorem is called *Kleene's fixed-point theorem*. It has many applications in recursion theory, when discussing termination of algorithms, etc.

We omit details about the necessary "continuity" of mappings between posets and further generalizations.<sup>2</sup> We point out the added value to the general formulation of Tarski's theorem — the Kleene's theorem provides an iterative computational process approaching the fixed point with the given "seed", the minimal point.

<sup>2</sup>Stephen Cole Kleene (1909-1994) was a famous American mathematician working with Church, Turing, Post and others. The interested reader may consult full exposition of the above mentioned theorem in chapter 1 of the book: *Mathematical Theory of Domains*, Cambridge Tracts in Theoretical Computer Science, Cambridge University Press, 1994, by V. Stoltenberg-Hansen, I. Lindström, E. R. Griffor.

**B. Rings**

**12.B.1.** Decide whether the set  $R$  with the operations  $\oplus, \odot$  form a ring, a commutative ring, an integral domain or a field:

- i)  $R = \mathbb{Z}, a \oplus b = a + b + 3, a \odot b = -3,$
- ii)  $R = \mathbb{Z}, a \oplus b = a + b - 3, a \odot b = a \cdot b - 1,$
- iii)  $R = \mathbb{Z}, a \oplus b = a + b - 1, a \odot b = a + b - a \cdot b,$
- iv)  $R = \mathbb{Q}, a \oplus b = a + b, a \odot b = b,$
- v)  $R = \mathbb{Q}, a \oplus b = a + b + 1, a \odot b = a + b + a \cdot b,$
- vi)  $R = \mathbb{Q}, a \oplus b = a + b - 1, a \odot b = a + b + a \cdot b.$

**Solution.**

- i) not a ring (but is a commutative rng),
- ii) not a ring,
- iii) an integral domain,
- iv) not a ring,
- v) a field, □
- vi) not a ring.

**12.B.2.** Prove that the subset  $\mathbb{Z}[i] = \{a + bi \mid a, b \in \mathbb{Z}\}$  of the complex numbers is an integral domain. Is it a field?

**Solution.** Any subring of an integral domain must be an integral domain again. In this case, we are talking about a subset of the field  $\mathbb{C}$  (thus also an integral domain). Since the subset is closed with respect to all the operations (sum, additive inverse, multiplication) and contains both 0 and 1, it is indeed a subring. However, multiplicative inverses exist only for the numbers 1,  $i$ ,  $-1$ ,  $-i$  (these form the so-called subgroup of units – invertible elements), so it is not a field. □

**12.B.3.** In the ring of 2-by-2 matrices over the real numbers, consider the subring of matrices of the form  $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$ .

Prove that this subring is isomorphic to  $\mathbb{C}$ .

**Solution.** We will show that the isomorphism is given by the mapping  $\varphi : \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \mapsto a + ib$ . The multiplication in the subring works as follows:

$$\begin{pmatrix} a & -b \\ b & a \end{pmatrix} \cdot \begin{pmatrix} c & -d \\ d & c \end{pmatrix} = \begin{pmatrix} ac - bd & -bc - ad \\ bc + ad & ac - bd \end{pmatrix},$$

and in  $\mathbb{C}$ , we have  $(a + ib)(c + id) = ac - bd + i(bc + ad)$ . Hence we can see that  $\varphi$  is a homomorphism with respect to multiplication. Since addition is defined componentwise,  $\varphi$  is a homomorphism to it as well. Moreover, this mapping is clearly both injective and surjective, thus it is an isomorphism. □

**12.B.4.** Prove that the identity is the only automorphism of the field of real numbers.

**Solution.** Consider an automorphism  $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ . Clearly, it must satisfy  $\varphi(0) = 0$  and  $\varphi(1) = 1$ . Since  $\varphi$  respects addition, we must have for all positive integers  $n$  that  $\varphi(n) = \varphi(1 + 1 + \dots + 1) = n\varphi(1) = n$  and  $\varphi(-n) = -n$ . Since it respects multiplication, we must have for any integers

**12.1.12. Back to Boolean algebras.** When discussing propositional logic, there is the problem of what exactly are the elements of the corresponding Boolean algebra. Formally, they are defined as the classes of equivalent propositions. In other words, we work with truth-value functions for propositions with a given number of arguments. There is the problem of recognizing propositions which are equivalent in this sense. There is the question of whether every function  $(\mathbb{Z}_2)^n \rightarrow \mathbb{Z}_2$  can be defined in terms of the basic logical operations. Clearly all such functions form a Boolean algebra, since their values are in the Boolean algebra  $\mathbb{Z}_2$ .

Similarly, there is the problem of deciding whether or not two systems of switches can have the same function. Just as for propositions, a system consisting of  $n$  switches corresponds to a function  $(\mathbb{Z}_2)^n \rightarrow \mathbb{Z}_2$ . There are  $2^{2^n}$  such functions. A Boolean algebra can be naturally defined on these functions (again using the fact that the function values are in the Boolean algebra  $\mathbb{Z}_2$ ).

We summarize a few such questions:

SOME BASIC QUESTIONS

*Question 1:* Are all finite Boolean algebras  $(K, \wedge, \vee)$  defined on sets  $K$  with  $2^n$  elements?

*Question 2:* Can each function  $(\mathbb{Z}_2)^n \rightarrow \mathbb{Z}_2$  be the truth function of some logical expression built of  $n$  elementary propositions and the logical operators?

*Question 3:* How to recognize whether two such expressions represent the same function?

*Question 4:* Can each function  $(\mathbb{Z}_2)^n \rightarrow \mathbb{Z}_2$  be realized by some switch board with  $n$  switches?

*Question 5:* How to recognize whether two switchboards represent the same function?

All these questions are answered by finding the normal form of every element of a general Boolean algebra. This is achieved by writing it as the join of certain particularly simple elements. By comparing the normal forms of any pair of elements, it is easily determined whether or not they are the same.

This helps to classify all finite Boolean algebras, giving the affirmative answer to question 1.

**12.1.13. Atoms and normal forms.** First, define the “simplest” elements of a Boolean algebra:

ATOMS IN A BOOLEAN ALGEBRA

Let  $K$  be a Boolean algebra. An element  $A \in K, A \neq 0$ , is called an *atom* if and only if for all  $B \in K, A \wedge B = A$  or  $A \wedge B = 0$ .

In other words,  $A \neq 0$  is an atom if and only if there are only two elements  $B$  such that  $B \leq A$ , namely  $B = 0$  and  $B = A$ .

Note that 0 is not considered an atom, just as the integer 1 is not considered a prime. Let us remark that infinite Boolean algebras may contain no atoms at all.

$p, q$  ( $q \neq 0$ ) that  $\varphi(p) = \varphi(q \cdot \frac{p}{q}) = \varphi(p) \cdot \varphi(\frac{p}{q})$ . Hence,  $\varphi(\frac{p}{q}) = \frac{p}{q}$ , i. e.,  $\varphi(r) = r$  for all rational numbers  $r$ .

Consider a positive number  $x \in \mathbb{R}$ . Then,  $\varphi(x) = \varphi(\sqrt{x^2}) = \varphi(\sqrt{x})^2 \geq 0$ . Thus, for any  $x, y \in \mathbb{R}$  such that  $x < y$ , we must have  $\varphi(x) < \varphi(y)$ . Now, assume that  $\varphi$  is not the identity, i. e., there exists a  $z \in \mathbb{R}$  such that  $\varphi(z) \neq z$ . We can assume without loss of generality that  $\varphi(z) < z$ . Since  $\mathbb{Q}$  is dense in  $\mathbb{R}$ , there exists an  $r \in \mathbb{Q}$  for which  $\varphi(z) < r < z$ . However, we know that  $\varphi(r) = r$ , which means that  $r < z$  implies  $\varphi(r) < \varphi(z)$ . Altogether, we get the wanted contradiction  $\varphi(z) < \varphi(r) < \varphi(z)$ .  $\square$

**12.B.5.** Let  $p$  be a prime and  $R$  a ring which contains  $p^2$  elements. Prove that  $R$  is commutative.

**Solution.** Since  $(R, +)$  is a finite commutative group with  $p^2$  elements, it is by 12.4.8 isomorphic to either  $\mathbb{Z}_{p^2}$  or  $\mathbb{Z}_p \times \mathbb{Z}_p$ . In the first case,  $(R, +)$  is cyclic, so there exists an element  $x \in R$  such that each element of  $R$  is of the form  $nx$  for some  $1 \leq n \leq p^2$ . Since all these elements commute, we get that the entire  $R$  is commutative.

In the second case, each element (except 0) must have order  $p$  with respect to addition. Let  $x \in R$  be any element that is not in the additive subgroup generated by 1. Then, each element of  $R$  is of the form  $m + nx$ , where  $1 \leq m, n \leq p$ . Again, all these elements commute, so  $R$  is commutative.  $\square$

**12.B.6.** Find the inverses of 17, 18, and 19 in  $(\mathbb{Z}_{131}^*, \cdot)$  (the group of all invertible elements in  $\mathbb{Z}_{131}$  with multiplication).

**Solution.** Applying the Euclidean algorithm, we get

$$\begin{aligned} 131 &= 7 \cdot 17 + 12, \\ 17 &= 1 \cdot 12 + 5, \\ 12 &= 2 \cdot 5 + 2, \\ 5 &= 2 \cdot 2 + 1. \end{aligned}$$

Therefore,  $1 = 5 - 2 \cdot 2 = 5 - 2(12 - 2 \cdot 5) = 5 \cdot 5 - 2 \cdot 12 = 5 \cdot (17 - 12) - 2 \cdot 12 = 5 \cdot 17 - 7 \cdot 12 = 5 \cdot 17 - 7 \cdot (131 - 7 \cdot 17) = 54 \cdot 17 - 7 \cdot 131$ . The inverse of 17 is 54. Similarly,  $[18]^{-1} = 51$  and  $[19]^{-1} = 69$ .  $\square$

**12.B.7.** Find the inverse of  $[49]_{\mathbb{Z}_{253}}$  in  $\mathbb{Z}_{253}$  ○

**12.B.8.** Find the inverse of  $[37]_{\mathbb{Z}_{208}}$  in  $\mathbb{Z}_{208}$ . ○

**12.B.9.** Find the inverse of  $[57]_{\mathbb{Z}_{359}}$  in  $\mathbb{Z}_{359}$ . ○

**12.B.10.** Find the inverse of  $[17]_{\mathbb{Z}_{40}}$  in  $\mathbb{Z}_{40}$ . ○

### C. Polynomial rings

**12.C.1. Eisenstein's irreducibility criterion** This criterion provides a sufficient condition for a polynomial over  $\mathbb{Z}$  to be irreducible over  $\mathbb{Q}$  (which is the same as to be irreducible over  $\mathbb{Z}$ ):

Let

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$$

be a polynomial over  $\mathbb{Z}$  and  $p$  be a prime such that

- $p$  divides  $a_j, j = 0, \dots, n - 1,$

The situation is very simple in the Boolean algebra of all subsets of a given finite set  $M$ . Clearly, the atoms are precisely the singletons  $A = \{x\}$ . For every subset  $B$ , either  $A \wedge B = A$  (if  $x \in B$ ) or  $A \wedge B = 0$  (if  $x \notin B$ ). The requirements fail whenever there is more than one element in  $A$ .

Next, consider which elements are atoms in the Boolean algebra of functions of the switch boards with  $n$  switches  $A_1, \dots, A_n$ . It can be easily verified that there are  $2^n$  atoms, which are of the form  $A_1^{\sigma_1} \wedge \dots \wedge A_n^{\sigma_n}$ , where either  $A_i^{\sigma_i} = A_i$  or  $A_i^{\sigma_i} = A_i'$ .

The infimum  $\varphi \wedge \psi$  of functions  $\varphi$  and  $\psi$  is the function whose values are given by the products of the corresponding values in  $\mathbb{Z}_2$ . Therefore,  $\varphi \leq \psi$  if  $\varphi$  takes the value 1 in  $\mathbb{Z}_2$  only on arguments where  $\psi$  also has value 1. Hence in the Boolean algebra of truth-value functions, a function  $\varphi$  is an atom if and only if  $\varphi$  returns 1 in  $\mathbb{Z}_2$  for exactly one of the  $2^n$  possible choices of arguments. All these functions can be created in the above mentioned manner.

Now, the promised theorem can be formulated. While this one is called the *disjunctive normal form*, there is also the opposite version with the suprema and infima interchanged (the *conjunctive normal form*).

#### DISJUNCTIVE NORMAL FORM

**Theorem.** Each element  $B$  of a finite Boolean algebra  $(K, \wedge, \vee)$  can be written as a supremum of atoms

$$B = A_1 \vee \dots \vee A_k.$$

*This expression is unique up to the order of the atoms.*

The proof takes several paragraphs, but the basic idea is quite simple: Consider all atoms  $A_1, A_2, \dots, A_k$  in  $K$  which are less or equal to  $B$ . From the properties of the order on  $K$ , (see 12.1.8(3)) it follows that

$$Y = A_1 \vee \dots \vee A_k \leq B.$$

The main step of the proof is to verify that  $B \wedge Y' = 0$ , which by 12.1.8(4) guarantees that  $B \leq Y$ . That proves the equality  $B = Y$ .

**12.1.14. Three useful claims.** We derive several technical properties of atoms, in order to complete the proof of the theorem on disjunctive normal form. We retain the notation of the previous subsection.

**Proposition.** (1) If  $Y, X_1, \dots, X_\ell$  are atoms in  $K$ , then  $Y \leq X_1 \vee \dots \vee X_\ell$  if and only if  $Y = X_i$  for some  $i = 1, \dots, \ell$ .

(2) For each  $Y \in K, Y \neq 0$ , there is an atom  $X \in K$  such that  $X \leq Y$ .

(3) If  $X_1, \dots, X_r$  are precisely all the atoms of  $K$ , then  $Y = 0$  if and only if  $Y \wedge X_i = 0$  for all  $i = 1, \dots, r$ .

**PROOF.** (1) If the inequality of the proposition holds, then

$$Y \wedge (X_1 \vee \dots \vee X_\ell) = Y.$$

- $p$  does not divide  $a_n$ ,
- $p^2$  does not divide  $a_0$ .

Then,  $f(x)$  is irreducible over  $\mathbb{Z}$  ( $\mathbb{Q}$ ). Prove this criterion.

○

**12.C.2.** Factorize over  $\mathbb{C}$  and  $\mathbb{R}$  the polynomial

$$x^4 + 2x^3 + 3x^2 + 2x + 1.$$

**Solution.** This polynomial can be factorized either by looking for multiple roots or as a reciprocal equation:

- Let us compute the greatest common divisor of the polynomial and its derivative  $4x^3 + 6x^2 + 6x + 2$ , using the Euclidean algorithm. The greatest common divisor is given in any ring up to a multiple by a unit, and during the Euclidean algorithm, we may multiply the partial results by units of the ring. In the case of a polynomial ring over a field of scalars, the units are exactly the non-zero scalars. We perform the multiplication in the way to avoid calculations with fractions as much as possible.

$$2x^4 + 4x^3 + 6x^2 + 4x + 2 : 2x^3 + 3x^2 + 3x + 1 = x + \frac{1}{2}$$

$$\begin{aligned} 2x^4 + 3x^3 + 3x^2 + x \\ x^3 + 3x^2 + 3x + 2 \\ x^3 + \frac{3}{2}x^2 + \frac{3}{2}x + \frac{1}{2} \\ \frac{3}{2}x^2 + \frac{3}{2}x + \frac{3}{2} \end{aligned}$$

Further, we divide the polynomial  $2x^3 + 3x^2 + 3x + 1$  by the remainder  $\frac{3}{2}x^2 + \frac{3}{2}x + \frac{3}{2}$  (multiplied by the unit  $\frac{2}{3}$ )

$$\begin{aligned} 2x^3 + 3x^2 + 3x + 1 : x^2 + x + 1 = 2x + 1 \\ 2x^3 + 2x^2 + 2x \\ x^2 + x + 1 \end{aligned}$$

The roots of the greatest common divisor of the original polynomial and its derivative are exactly the multiple roots of the original polynomial. In this case, the roots of  $x^2 + x + 1$  are  $-\frac{1}{2} \pm i\sqrt{3}/2$ , which are thus double roots of the original polynomial. The factorization over  $\mathbb{C}$  is thus to root factors (this is always the case over  $\mathbb{C}$ , as stated by the fundamental theorem of algebra):

$$\begin{aligned} x^4 + 2x^3 + 3x^2 + 2x + 1 = \\ = \left(x + \frac{1}{2} - i\frac{\sqrt{3}}{2}\right)^2 \cdot \left(x + \frac{1}{2} + i\frac{\sqrt{3}}{2}\right)^2. \end{aligned}$$

The factorization over  $\mathbb{R}$  can be obtained by multiplying the factors corresponding to pairs of complex-conjugated roots of the polynomial (verify that such a product must always result in a polynomial with real coefficients!):

$$x^4 + 2x^3 + 3x^2 + 2x + 1 = (x^2 + x + 1)^2.$$

- Let us solve the equation

$$x^4 + 2x^3 + 3x^2 + 2x + 1 = 0.$$

By distributivity, the equality can be rewritten as

$$(Y \wedge X_1) \vee \dots \vee (Y \wedge X_\ell) = Y.$$

However, for all  $i$  either  $Y \wedge X_i = 0$  or  $Y \wedge X_i = X_i$ . If all these intersections are 0, then  $Y = 0$ . Thus, there is an  $i$  for which  $Y \wedge X_i = X_i$ . Since  $Y$  is also an atom, the desired equality  $Y = X_i$  is proved.

The other implication is trivial.

(2) If  $Y$  is an atom itself, choose  $X = Y$ . If  $Y$  is not an atom, then it follows from the definition that there must exist a non-zero element  $Z_1 \neq Y$  for which  $Z_1 \leq Y$ . If  $Z_1$  is not an atom either, then similarly find a  $Z_2 \leq Z_1$ , etc., leading to a sequence of pairwise distinct elements

$$\dots \leq Z_k \leq Z_{k-1} \leq \dots \leq Z_1 \leq Y,$$

which cannot be infinite since the entire Boolean algebra  $K$  is finite. Therefore, it must end with an atom  $Z_k$ .

(3) Assume that  $Y \wedge X_i = 0$  for all indices  $i$ . If  $Y \neq 0$ , then due to the above claim, there must exist an atom  $X_j$  for which  $X_j \wedge Y = X_j$ , which is a contradiction.

The other implication is trivial. □

**12.1.15. Completion of the proof of theorem 12.1.13.**

Write

$$Y = A_1 \vee \dots \vee A_k \leq B,$$

where  $A_i$  are all the atoms in  $K$  which are less than or equal to  $B$ . Compute

$$B \wedge Y' = B \wedge (A_1 \vee \dots \vee A_k)' = B \wedge A_1' \wedge \dots \wedge A_k'.$$

If an atom  $A = A_i$  is contained in the join  $Y$ , then  $B \wedge Y' \wedge A = 0$ . However, if  $A$  is an atom which does not occur in  $Y$ , then also  $B \wedge Y' \wedge A = 0$ , since  $Y$  contains exactly those atoms which are  $\leq B$ . Hence  $B \wedge Y' \wedge A = 0$  for all atoms  $A$  in  $K$ .

Thus it is proved that the intersection of  $B \wedge Y'$  and any atom is zero, which means that it must be zero itself, by the third claim in the latter proposition. Therefore,  $B \leq Y$  (cf. 12.1.8(4)). The definition of  $Y$  implies  $Y \leq B$ , so the anti-symmetry of the order implies that  $B = Y$ .

It remains to prove the uniqueness of the expression, up to order. Thus, suppose  $B$  can be written in two ways as

$$B = A_1 \vee \dots \vee A_k = \tilde{A}_1 \vee \dots \vee \tilde{A}_\ell.$$

Since each  $A_i$  satisfies  $A_i \leq B$ , the first claim in the proposition above ensures it must equal one of the  $\tilde{A}_j$ . Repeating this argument gives the desired uniqueness and finishes the proof.

**12.1.16. Classification.** To end the discussion of Boolean algebras, we prove that all the examples of finite Boolean algebras (of given size) are isomorphic.

In particular, each of the  $2^{2^n}$  truth-value functions for  $n$  atomic propositions can be expressed as an appropriate proposition, just like each of the  $2^{2^n}$  switch board functions can be defined in terms of  $n$  suitably arranged switches. In both cases, the algebra in question behaves the

Dividing by  $x^2$  and substituting  $t = x + \frac{1}{x}$ , we get the equation

$$t^2 + 2t + 1 = 0$$

with double root  $-1$ . Now, substituting this into the definition of  $t$ , we get the known equation  $x^2 + x + 1 = 0$ , which was solved above.

**Remark.** Let us remark that the only irreducible polynomials over  $\mathbb{R}$  are linear polynomials and quadratic polynomials with negative discriminant. This also follows from the reasonings in the above exercise.

**12.C.3.** Factorize the polynomial  $x^5 + 3x^3 + 3$  to irreducible factors over

- i)  $\mathbb{Q}$ ,
- ii)  $\mathbb{Z}_7$ .

**Solution.**

- i) By Eisenstein's criterion, the given polynomial is irreducible over  $\mathbb{Z}$  and  $\mathbb{Q}$  (we use the prime 3).
- ii)  $(x - 1)^2(x^3 + 2x^2 - x + 3)$ . Using Horner's scheme, for instance, we find the double root 1. When divided by the polynomial  $(x - 1)^2$ , we get  $(x^3 + 2x^2 - x + 3)$ , which has no roots over  $\mathbb{Z}_7$ . Since it is only of degree 3, this means that it must be irreducible (if it were reducible, one of the factors would have to be linear, which means that the cubic polynomial  $(x^3 + 2x^2 - x + 3)$  would have a root).

**12.C.4.** Factorize the polynomial  $x^4 + 1$  over

- $\mathbb{Z}_3$ ,
- $\mathbb{C}$ ,
- $\mathbb{R}$ .

**Solution.**

- $(x^2 + x + 2)(x^2 + 2x + 2)$
- The roots are the fourth roots of  $-1$ , which lie in the complex plane on the unit circle, and their arguments are  $\pi/4$ ,  $\pi/4 + \pi/2$ ,  $\pi/4 + \pi$ , and  $\pi/4 + 3\pi/2$  i. e., they are the numbers  $\pm\sqrt{2}/2 \pm i\sqrt{2}/2$ . Thus, the factorization is

$$\left(x - \frac{\sqrt{2}}{2} - i\frac{\sqrt{2}}{2}\right) \left(x - \frac{\sqrt{2}}{2} + i\frac{\sqrt{2}}{2}\right) \left(x + \frac{\sqrt{2}}{2} - i\frac{\sqrt{2}}{2}\right) \left(x + \frac{\sqrt{2}}{2} + i\frac{\sqrt{2}}{2}\right)$$

- Multiplying the root factors of complex-conjugated roots in the factorization over  $\mathbb{C}$ , we get the factorization over  $\mathbb{R}$ : □

$$(x^2 - \sqrt{2}x + 1)(x^2 + \sqrt{2}x + 1) ..$$

**12.C.5.** Find a polynomial with rational coefficients of the lowest degree possible which has  $\sqrt[2007]{2}$  as a root.

**Solution.**  $P(x) = x^{2007} - 2$ . Let us show that there is no polynomial of lower degree with root  $\sqrt[2007]{2}$ : Let  $Q(x)$  be a non-zero polynomial of the lowest degree with root  $\sqrt[2007]{2}$ . Then,  $\deg Q(x) \leq 2007$ . Let us divide  $P(x)$  by  $Q(x)$  with remainder:  $P(x) = Q(x) \cdot D(x) + R(x)$ , where  $D(x)$  is the quotient and  $R(x)$  is the remainder, and either  $\deg R(x) < \deg Q(x)$  or  $R(x) = 0$ . Substituting the number  $\sqrt[2007]{2}$  into the last equation, we can see that  $\sqrt[2007]{2}$  is also a root of  $R(x)$ . By the definition of  $Q(x)$ , this means that  $R(x)$  must be the zero polynomial, which means that  $Q(x)$  divides  $P(x)$ . However,  $P(x)$  is irreducible (by Eisenstein's criterion for 2), so its only

same way as the Boolean algebra of all subsets of a given  $2^n$ -element set.

Moreover, each of these expressions can be written in a unique normal form, so it can be decided algorithmically whether two switch boards have the same behaviour without comparing their values for all  $2^n$  possible inputs (which on the other hand might still be faster, in particular the resulting normal formula tends to be exponentially large).

**Theorem.** Every finite Boolean algebra is isomorphic to the Boolean algebra  $K = 2^M$  where  $M$  is the set of atoms in  $K$ .

**PROOF.** The idea of the proof is quite straightforward. Every isomorphism of a Boolean algebra  $(K, \wedge, \vee)$  must map atoms to atoms. Let  $M$  be the set of all atoms in  $K$  and consider the Boolean algebra  $(2^M, \cap, \cup)$ . This defines a natural correspondence between the atoms of  $K$  and the atoms of  $2^M$ .

Next, use the disjunctive normal form to extend the mapping to all of  $K$ . Each element  $X \in K$  can be written uniquely (up to order) as a join of atoms:

$$X = A_1 \vee \dots \vee A_k$$

Define the function  $f : K \rightarrow 2^M$  by

$$f(X) = f(A_1) \cup \dots \cup f(A_k) = \{A_1, \dots, A_k\},$$

as the union of the singletons  $A_i \subseteq M$  that occur in the expression.

The uniqueness of the normal form implies that  $f$  is a bijection. It remains to show that it is a homomorphism of the Boolean algebras.

Let  $X, Y \in K$ . The normal form of their supremum contains exactly the atoms which occur in at least one of  $X, Y$ ; while the infimum involves just those atoms which occur in both. This verifies that  $f$  preserves the operations  $\wedge$  and  $\vee$ . As for the complements, note that an atom  $A$  occurs in the normal form of  $X'$  if and only if  $X \wedge A = 0$ . Hence  $f$  preserves complements, which finishes the proof. □

The classification of infinite Boolean algebras is far more complicated. It is not the case that each would be isomorphic to the Boolean algebra of all subsets of an appropriate set  $M$ . However, every Boolean algebra is isomorphic to a Boolean subalgebra of a Boolean algebra  $2^M$  for an appropriate set  $M$ . This result is known as *Stone's representation theorem*<sup>3</sup>.

## 2. Elements of Logic

This section provides a quick introduction to logic. Mastering the calculus of Boolean algebras will become useful, but we have to start from scratch.

<sup>3</sup>The American mathematician Marshall Harvey Stone (1903 – 1989) proved this theorem in 1936 when dealing with the spectral theory of operators on Hilbert spaces, required for analysis and topology. Nowadays, it belongs to standard material in advanced textbooks.

non-trivial divisor is itself (up to multiplication by a unit of the polynomial ring over  $\mathbb{Q}$ , i. e. a non-zero rational constant). Thus, we have  $Q(x) = P(x)$  up to multiplication by a unit. For instance, the polynomial  $\frac{1}{3}x^{2007} - \frac{2}{3}$  also satisfies the stated conditions. However, if we require the polynomial to be monic (i. e., with leading coefficient 1), then the only solution is the mentioned polynomial  $P(x)$ .  $\square$

**12.C.6.** Find all irreducible polynomials of degree at most 2 over  $\mathbb{Z}_3$ .

**Solution.** By definition, all linear polynomials are irreducible. As for quadratic irreducible polynomials, the easiest way is to simply enumerate them all and leave out the reducible ones, i. e. those which are a product of two linear polynomials. The reducible polynomials are  $(x + 1)^2 = x^2 + 2x + 1$ ,  $(x + 2)^2 = x^2 + x + 1$ ,  $(x + 1)(x + 2) = x^2 + 2$ ,  $x^2$ ,  $x(x + 1) = x^2 + x$ ,  $x(x + 2) = x^2 + 2x$ . (It suffices to consider monic polynomials, since the non-monic can be obtained by multiplication by 2.) The remaining quadratic polynomials over  $\mathbb{Z}_3$  are irreducible; these are  $x^2 + 2x + 2$ ,  $x^2 + x + 2$ ,  $x^2 + 1$ .  $\square$

**12.C.7.** Decide whether the following polynomial is irreducible over  $\mathbb{Z}_3$ ; if not, factorize it:

$$x^4 + x^3 + x + 2.$$

**Solution.** Evaluating the polynomial at 0, 1, 2, we find that it has no root in  $\mathbb{Z}_3$ . This means that it is either irreducible or a product of two quadratic polynomials. Assume it is reducible. Then, we may assume without loss of generality that it is a product of two monic polynomials (the only other option is that it is a product of two polynomials with leading coefficients equal to 2 – then both can be multiplied by 2 in order to become monic). Thus, let us look for constants  $a, b, c, d \in \mathbb{Z}_3$  so that

$$\begin{aligned} x^4 + x^3 + x + 2 &= (x^2 + ax + b)(x^2 + cx + d) = \\ &= x^4 + (a + c)x^3 + (ac + b + d)x^2 + \\ &\quad + (ad + bc)x + bd. \end{aligned}$$

Comparing the coefficients of individual power of  $x$ , we get the following system of four equations in four variables:

$$\begin{aligned} 1 &= a + c, \\ 0 &= ac + b + d, \\ 1 &= ad + bc, \\ 2 &= bd. \end{aligned}$$

From the last equation, we get that one of the numbers  $b, d$  is equal to 1 and the other one to 2. Thanks to symmetry of the system in the pairs  $(a, b)$  and  $(c, d)$ , we can choose  $b = 1$ ,  $d = 2$ . From the second equation, we get  $ac = 0$ , i. e., at least one of the numbers  $a, c$  is 0. From the first equation, we get that the other one is 1. From the third equation, we get  $2a + c = 1$ , i. e.,  $a = 0, c = 1$ . Altogether,

$$x^4 + x^3 + x + 2 = (x^2 + 1)(x^2 + x + 2). \quad \square$$

**12.2.1. From set algebra to logical propositions.** Let us recall that in 12.1.2, we abstracted Boolean algebras from the properties of set operations; in particular, the  $\vee$  operation corresponded to the union of sets. We understand sets as collections of elements with some property. So, if an element  $x$  is in the union of sets  $C$  and  $B$ , then it has "property  $C$ " or "property  $B$ ." Furthermore, if we know that element  $x$  does not have "property  $C$ ," then we know for sure that it has "property  $B$ ." In other words, from the fact that element  $x$  has "property  $C$ " or "property  $B$ ," but not "property  $C$ ," we can conclude that element  $x$  definitely has "property  $B$ ." Symbolically,

$$\frac{x \in C \cup B}{x \notin C} \quad , \quad \frac{}{x \in B} \quad ,$$

or more succinctly using Boolean operations,

$$\frac{C \vee B}{C}$$

This simple observation can be reformulated as follows: "From  $C \vee B$  and  $C'$ , it logically follows that  $B$ ." For the sake of simplicity, let's denote  $A = C'$ , which means  $C = A'$ , and rewrite the previous observation as:

$$(1) \quad \frac{A' \vee B}{A}$$

and read it as: "From  $A' \vee B$  and  $A$ , it necessarily implies  $B$ ."

Next, let's perform three simple Boolean calculations:

$$\begin{aligned} A' \vee (B' \vee A) &= (A' \vee A) \vee B = 1 \vee B = 1, \\ (A' \vee B)' \vee ((A' \vee B)') \vee A &= (A' \vee B)' \vee ((A \wedge B) \vee A') \\ &= (A' \vee B)' \vee (B \vee A') = 1, \\ (A' \vee B)' \vee (A' \vee C) &= (A \wedge B') \vee A' \vee C \\ &= (A \vee A' \vee C) \wedge (B' \vee A' \vee C) = 1 \wedge (A' \vee B' \vee C) \\ &= (A' \vee (B' \vee C)). \end{aligned}$$

Now, we will use the axioms (8) of Boolean algebras, and we obtain the following formulas:

$$(2) \quad \begin{aligned} A' \vee (B' \vee A) &= 1, \quad A' \vee A = 1 \\ (A' \vee B)' \vee ((A' \vee B)') \vee A &= 1, \\ (A' \vee (B' \vee C))' \vee ((A' \vee B)' \vee (A' \vee C)) &= 1. \end{aligned}$$

We already noticed the connections between Boolean algebras and propositional logic in paragraph 12.1.5. In this sense, we can see that the left sides of the previous equations express true propositions. Now, let's transition more thoroughly from the "Boolean world" to the "world of logic." We will do this by replacing uppercase letters with lowercase letters, replacing the symbol  $\vee$  with the symbol  $\rightarrow$ , and changing the "postfix" symbol  $'$  to the "prefix" symbol  $\neg$ . So, instead of  $A' \vee B$ , we will write  $a \rightarrow b$ , and instead of  $A'$ , we will write  $\neg a$ ."

**12.C.8.** For any odd prime  $p$ , find all roots of the polynomial

$$P(x) = x^{p-2} + x^{p-3} + \cdots + x + 2$$

over the field  $\mathbb{Z}_p$ .

**Solution.** Considering the equality

$$x^{p-1} - 1 = (x - 1)(P(x) - 1),$$

we can see that all numbers of  $\mathbb{Z}_p$ , except 0 and 1, are roots of  $P(x) - 1$ , so they cannot be roots of  $P(x) + 1$ . Clearly, 0 is never a root of  $P(x)$ , and 1 is always a root, which means that it is the only root.  $\square$

**12.C.9.** Factorize the polynomial  $p(x) = x^2 + x + 1$  in  $\mathbb{Z}_5[x]$  and  $\mathbb{Z}_7[x]$ .

**Solution.** Irreducible in  $\mathbb{Z}_5[x]$ ;  $p(x) = (x - 2)(x - 4)$  in  $\mathbb{Z}_7[x]$ .  $\square$

**12.C.10.** Factorize the polynomial  $p(x) = x^6 - x^4 - 5x^2 - 3$  in  $\mathbb{C}[x]$ ,  $\mathbb{R}[x]$ ,  $\mathbb{Q}[x]$ ,  $\mathbb{Z}[x]$ ,  $\mathbb{Z}_5[x]$ ,  $\mathbb{Z}_7[x]$ , knowing that it has a multiple root.

**Solution.** Applying the Euclidean algorithm, we find out that the greatest common divisor of  $p$  and its derivative  $p'$  is  $x^2 + 1$ . Dividing the polynomial  $p(x)$  twice by this factor, we get

$$p(x) = (x^2 + 1)^2(x^2 - 3).$$

Clearly, these factors are irreducible in the rings  $\mathbb{Q}[x]$  and  $\mathbb{Z}[x]$ .

In  $\mathbb{C}[x]$ , we can always factorize a polynomial to linear factors. In this case, it suffices to factorize  $x^2 + 1$ , which is easy:  $x^2 + 1 = (x + i)(x - i)$ . The factor  $x^2 - 3$  is equal to  $(x - \sqrt{3})(x + \sqrt{3})$  even in  $\mathbb{R}[x]$ . Thus, in  $\mathbb{C}[x]$ , we have

$$p(x) = (x + i)^2(x - i)^2(x - \sqrt{3})(x + \sqrt{3}),$$

while in  $\mathbb{R}[x]$ , we have

$$p(x) = (x^2 + 1)^2(x - \sqrt{3})(x + \sqrt{3}).$$

In  $\mathbb{Z}_5[x]$ , the polynomial  $x^2 + 1$  has roots  $\pm 2$ , and the polynomial  $x^2 - 3$  has no roots, which means that

$$p(x) = (x - 2)^2(x + 2)^2(x^2 - 3).$$

In  $\mathbb{Z}_7[x]$ , neither polynomial has a root, so the factorization to irreducible factors is identical to that in  $\mathbb{Q}[x]$  and  $\mathbb{Z}[x]$ .  $\square$

**12.C.11.** Knowing that the polynomial  $p = x^6 + x^5 + 4x^4 + 2x^3 + 5x^2 + x + 2$  has multiple root  $x = i$ , factorize it to irreducible polynomials over  $\mathbb{C}[x]$ ,  $\mathbb{R}[x]$ ,  $\mathbb{Z}_2[x]$ ,  $\mathbb{Z}_5[x]$ , and  $\mathbb{Z}_7[x]$ . Divide the polynomial  $q = x^2y^2 + y^2 + xy + x^2y + 2y + 1$  by the irreducible factors of  $p$  in  $\mathbb{R}[x]$ , and use the result to solve the system of polynomial equations  $p = q = 0$  over  $\mathbb{C}$ .

**Solution.**  $p = (x^2 + 1)^2(x^2 + x + 2)$ , in  $\mathbb{Z}_2$ :  $p = x(x + 1)^5$ , in  $\mathbb{Z}_5$ :  $p = (x - 2)^2(x + 2)^2(x^2 + x + 2)$ , in  $\mathbb{Z}_7$ :  $p = (x^2 + 1)^2(x + 4)^2$ . For the second polynomial, we get  $q = (y^2 + y)(x^2 + x + 2) - y^2(x + 1) + 1$  and  $q = (y^2 + y)(x^2 + 1) + y(x + 1) + 1$ . Thus, if  $x = \alpha$  is a root of  $x^2 + x + 2$ , i. e.,  $\alpha = -\frac{1}{2} \pm \frac{1}{2}i\sqrt{7}$ ,

**12.2.2. Classical Propositional Logic.** The alphabet of classical propositional logic consists of lowercase Latin letters  $a, b, c, \dots$  possibly with subscripts  $a_1, a_2, a_3, \dots$ , special symbols  $\neg, \rightarrow$ , and parentheses  $(, )$ .

These letters are called "atomic propositions" or "propositional variables." We can think of them as declarative statements that can be either true or false. (Truth in this context is understood in the usual vague sense; the concept of truth has not been precisely defined yet.) The symbols  $\neg, \rightarrow$  are called "operators" or "connectives," sometimes also "propositional functors."

#### WHAT ARE THE PROPOSITIONS?

**Definition.** "Propositions" are defined by the following rules:

- (i) Every atomic proposition is a proposition.
- (ii) If  $A$  is a proposition, then  $\neg A$  is also a proposition.
- (iii) If  $A$  and  $B$  are propositions, then  $(A \rightarrow B)$  is also a proposition.

In this definition, uppercase letters are actually parameters that represent any proposition.

**Example.**  $a, b, \neg a, (a \rightarrow b)$  are propositions;  $A, B, C$  are parameters that represent arbitrary propositions.

A statement created according to rule (ii) will be called *negation of statement A*. We can read it as 'not A,' 'non-A,' 'A is not true,' and similar expressions. A statement created according to rule (iii) is called an *implication*, where statement  $A$  is called the *antecedent of the implication*, and statement  $B$  is called the *consequent of the implication*. We can read it as 'A logically implies B,' 'if A, then B,' 'A is a sufficient condition for B,' 'B is a necessary condition for A,' 'A implies B,' and similar expressions.

If there is no risk of misunderstanding, we will omit the outer parentheses in statements created according to rule (iii). The last statement from the previous example will then have the form  $\neg((b \rightarrow a) \rightarrow \neg a) \rightarrow (b \rightarrow a)$ .

We consider the alphabet of propositional calculus as primitive concepts. From them, we construct, delineate, and define further concepts using rules. In Kantian terminology, atomic statements are synthetic, while other statements are analytical—they can be broken down into atomic statements.

Statements are understood as declarative sentences that are clear enough to decide whether they are true or not. Since 'truth' is still a very vague concept, we will use the word 'validity.' However, we do not yet know any valid statements. We will now declare as valid statements those that are prescribed by the Boolean expressions on the left sides of equations (2).

then  $y = \frac{1}{\sqrt{1+\alpha}}$ . If  $x = \beta$  is a root of  $x^2 + 1$ , i. e.,  $\beta = \pm i$ , then  $y = -\frac{1}{1+\beta}$  □

**12.C.12.** Factorize the following polynomial to irreducible polynomials in  $\mathbb{R}[x]$  and in  $\mathbb{C}[x]$ :

$$4x^5 - 8x^4 + 9x^3 - 7x^2 + 3x - 1.$$

**12.C.13.** Factorize the following polynomial to irreducible polynomials in  $\mathbb{R}[x]$  and in  $\mathbb{C}[x]$ :

$$x^5 + 3x^4 + 7x^3 + 9x^2 + 8x + 4.$$

**12.C.14.** Factorize  $x^4 - 4x^3 + 10x^2 - 12x + 9$  to irreducible polynomials in  $\mathbb{R}[x]$  and in  $\mathbb{C}[x]$ :

**12.C.15.** Decide whether the following polynomial over  $\mathbb{Z}_3$  is irreducible; if not, factorize it to irreducible polynomials:

$$x^5 + x^2 + 2x + 1.$$

**12.C.16.** Decide whether the following polynomial over  $\mathbb{Z}_3$  is irreducible; if not, factorize it to irreducible polynomials:

$$x^4 + 2x^3 + 2.$$

**12.C.17.** Find all monic quadratic irreducible polynomials over  $\mathbb{Z}_5$ .

**Solution.** We write out all monic quadratic polynomials over  $\mathbb{Z}_5$  and exclude those which are not irreducible, i. e., have a root:

$$x^2 \pm 2, x^2 \pm x + 2, x^2 \pm 2x - 2, x^2 - x \pm 1, x^2 \pm 2x - 1.$$

**D. Rings of multivariate polynomials**

**12.D.1.** Find the remainder of the polynomial  $x^3y + x + yz + yz^4$  with respect to the basis  $(x^2y + z, y + z)$  and the orderings  $<_{\text{lex}}, <_{\text{grlex}}$ .

**Solution.** □

For illustration, we present examples of several varieties defined by polynomials.

**12.D.2. Curves in the affine plane  $\mathbb{R}^2$ .** Every non-zero polynomial  $f(x, y)$  in two variables defines a “curve” in  $\mathbb{R}^2$  by the equation  $f(x, y) = 0$ . Thus, it is the set of zero points of a polynomial  $f$ , and it will be denoted  $K = \mathcal{V}(f)$ . You can derive that if  $f = f_1 \dots f_k$ , then  $\mathcal{V}(f) = \mathcal{V}(f_1) \cup \dots \cup \mathcal{V}(f_k)$ .

The subsequent pictures depict examples of such curves.

**12.D.3.** Using your favorite software, draw the curve given by the equation  $x^3 + x^2 - y^2 = 0$  in the plane.

**Solution.** See picture 1. □

AXIOMS OF CLASSICAL PROPOSITIONAL CALCULUS

**Definition.** *Axioms* of classical propositional calculus are:

- (kvp1)  $A \rightarrow (B \rightarrow A)$ ,
- (kvp2)  $(A \rightarrow B) \rightarrow ((A \rightarrow \neg B) \rightarrow \neg A)$ ,
- (kvp3)  $(A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C))$ ,
- (kvp4)  $\neg\neg A \rightarrow A$ ,

where  $A, B, C$  denote statements.

Axiom (kvp1) can be interpreted as follows: if statement  $A$  is valid, then we don’t need to know where it follows from; a valid statement follows from anything.

Axiom (kvp2) can be read as follows: if statement  $B$  follows from statement  $A$ , then if the negation of statement  $B$  also follows from statement  $A$ , statement  $A$  must necessarily not be valid. In other words, an implication is valid if its antecedent is not valid. In other words, a sufficient (but not necessary!) condition for the validity of an implication is the invalidity of the antecedent.

Axiom (kvp3) is called the axiom of deduction, and the reason for this name will become clear later. Axiom (kvp3), together with axiom (kvp1), expresses the transitivity of implication. However, this might not be immediately evident (if it is, I apologize to the reader for underestimating them). Therefore, we will also address the transitivity of implication later.

Axiom (kvp4) simply states that when it’s not true that statement  $A$  is not valid, then statement  $A$  is valid.

The selection of axioms for classical propositional calculus was arbitrary, and nothing forced us to choose them. However, as we will see later, this selection is very useful. Although it’s not the only possible one.

We can now construct statements and know four valid statements. What remains is to clarify how to derive new valid statements from valid ones. For this purpose, we will use the rule (1).

**Definition.** The *modus ponens inference rule* is of the form:

$$\frac{A \rightarrow B \quad A}{B}.$$

This rule states that if an implication is valid and its antecedent is valid, then its consequent is also valid. In other words, from the implication, we *deduce* the valid antecedent, and the valid consequent remains. Hence the name of this rule, *the method of detachment*.

We can summarize the first part of our considerations: The propositional logic system consists of three components. Countably infinite *alphabets* together with finitely many *syntactic rules* tell us how to construct *words* and *sentences*, i.e., *statements*, from individual *letters* of the alphabet. Further, a finite number of *axioms*, i.e., statements that we consider valid. The third component consists of a finite number of *inference rules*.

FIGURE 1.  $\mathfrak{V}(x^3 + x^2 - y^2)$

FIGURE 2.  $\mathfrak{V}(2x^4 - 3x^2y + y^2 - 2y^3 + y^4)$

**12.D.4.** Using your favorite software, draw the curve given by the equation  $2x^4 - 3x^2y + y^2 - 2y^3 + y^4 = 0$  in the plane.

**Solution.** See picture 2. □

We can also attempt to defined curves by equations  $x = f(t), y = g(t)$ , where  $f, g \in \mathbb{R}[t]$ . In that case, the curve is defined as a “polynomial inclusion” of the real line into the plane.

**12.D.5.** Parametrize the curve (variety)  $\mathfrak{V}(x^3 + x^2 - y^2)$ .

The specific choice of the alphabet with rules, axioms, and inference rules assigns some attribute to propositional calculus. In this case, that attribute is “classical.”

So far, we have introduced the primitive concepts of propositional calculus. It is already evident that the subject of (propositional) logic is the validity or invalidity of correctly constructed statements and logical deduction. Logic, in this sense, is a part of mathematics and has nothing to do with psychology or “rules of proper thinking.”

#### INFERENCE AND PROOFS

**Definition.** *Deriving a statement  $A$  from statements  $A_1, A_2, \dots, A_n$  is a finite sequence of statements, where each member is either an axiom, one of the statements  $A_1, A_2, \dots, A_n$ , or a statement derived from the previous members of the sequence using an inference rule. The last member of the derivation is the statement  $A$ .*

If there exists a derivation of statement  $A$  from statements  $A_1, A_2, \dots, A_n$ , we say that statement  $A$  can be derived from statements  $A_1, A_2, \dots, A_n$ , and we write

$$\{A_1, A_2, \dots, A_n\} \vdash A.$$

The statements in the set  $\{A_1, A_2, \dots, A_n\}$  are called the *premises* of the derivation, and statement  $A$  is called the *conclusion*.

If the premises of the derivation are valid statements, then the conclusion is also valid.

**Examples** that can be considered **claims**.

1) Transitivity of implication in classical propositional calculus

$$\{A \rightarrow B, B \rightarrow C\} \vdash A \rightarrow C.$$

We write down the derivation in a table. In the first column is the ordinal number of the statement in the derivation, in the second column is the corresponding statement, and in the third column is the justification for why the statement is included in the derivation. Typically, the justification refers to an axiom or refers to the lines from which the statement is derived using the modus ponens rule. Remember that uppercase letters are, in fact, parameters and can be replaced by any statement.

1.	A → B	premise
2.	B → C	premise
3.	(B → C) → (A → (B → C))	(kvp1)
4.	A → (B → C)	2., 3.
5.	(A → (B → C)) → ((A → B) → (B → C))	(kvp3)
6.	(A → B) → (B → C)	4., 5.
7.	A → C	1., 6.

We used exactly two axioms (kvp1) and (kvp3) in the derivation.

2) The Law of Excluded Middle

$$\{A, \neg A\} \vdash B,$$

also known as *ex impossibili sequitur quodlibet* (from nonsense, anything follows).

**Solution.** The parametrization can be found by computing intersections of lines  $y = tx$  with the given curve, i. e., we parametrize by the tangent of these lines. Technically, this means that we substitute  $tx$  for  $y$  and express  $x$  in terms of  $t$  from the equation:

$$x^3 + x^2 - t^2x^2 = x^2(x + 1 - t) \implies x = t - 1 \vee x = 0.$$

Then,  $y = t^2(t - 1)$ , or for  $x = 0$ , the only satisfying point on the curve is  $y = 0$ . The point  $[0, 0]$  can be obtained by choosing  $t = 1$  in the mentioned parametrization, so it suffices to consider only this parametrization.  $\square$

We obtain more curves if we consider quotients of polynomials in the parametrization, i. e.,  $f = \frac{f_1}{f_2}, g = \frac{g_1}{g_2}$ . Then, we talk about a rational parametrization.

**12.D.6.** Derive the parametrization of a circle using stereographic projection (see the picture).

**Solution.** Substituting the equation of the line  $y = \frac{x}{t} + 1$  into the equation of the circle, we get the equation

$$x^2 + \left( \frac{x^2}{t^2} - \frac{2x}{t} + 1 \right) = 1,$$

with solution  $x = 0$  or the parametric expression

$$x = \frac{2t}{1 + t^2}, y = \frac{t^2 - 1}{1 + t^2},$$

which does not include the point  $[0, 1]$ , however.  $\square$

**Remark.** Note that in this case, the inclusion of the real line gives only “almost all points” of the parametrized variety, since one of them (i. e., the point from which we project) is not reachable for any value of the parameter  $t$ . This is not our fault – it follows from different topological properties of the line and the circle that there exists no global parametrization.

**Remark.** Since  $\mathbb{R}$  is not an algebraically closed field, we have problems with existence of roots of polynomials. As a result, a mere perturbation of coefficients of the defining equation may drastically change the resulting variety. It is possible to work with complex polynomials  $\mathbb{C}[x, y]$  and with the subsets they define in  $\mathbb{C}^2$ . We need not be scared by that; on the contrary, our originally real curves are contained in their “complexifications” (real polynomials are simply viewed as complex which happen to have real coefficients), and we just

1. $A$	premise
2. $\neg A$	premise
3. $A \rightarrow (\neg B \rightarrow A)$	(kvp1)
4. $\neg B \rightarrow A$	1., 3.
5. $(\neg B \rightarrow A) \rightarrow ((\neg B \rightarrow \neg A) \rightarrow \neg\neg B)$	(kvp2)
6. $(\neg B \rightarrow \neg A) \rightarrow \neg\neg B$	4., 5.
7. $\neg A \rightarrow (\neg B \rightarrow \neg A)$	(kvp1)
8. $\neg B \rightarrow \neg A$	2., 7.
9. $\neg\neg B$	6., 8.
10. $\neg\neg B \rightarrow B$	(kvp4)
11. $B$	9., 10.

In these examples, we can see that it is easy to follow the derivation process. However, the construction of derivations can be very challenging. (This was not the case with the presented derivations.)

DEDUCTION AND PROOFS

**Definition.** Proof of statement  $A$  is a derivation from the empty set of premises. If there exists a proof of statement  $A$ , we say that this statement is *provable* and write  $\vdash A$ .

$A$  theorem is a provable statement.

**Example.** Theorem [1]:  $\vdash A \rightarrow A$ .

$A \rightarrow (A \rightarrow A)$	(kvp1)
$A \rightarrow ((A \rightarrow A) \rightarrow A)$	(kvp1)
$(A \rightarrow ((A \rightarrow A) \rightarrow A)) \rightarrow ((A \rightarrow (A \rightarrow A)) \rightarrow (A \rightarrow A))$	(kvp3)
$(A \rightarrow (A \rightarrow A)) \rightarrow (A \rightarrow A)$	2., 3.
$A \rightarrow A$	1., 4.

Derivations and proofs can be shortened by using previously derived statements or proven theorems. In the initial definition, we add that in the derivation of statement  $A$  from statements  $A_1, A_2, \dots, A_n$ , a theorem or a statement previously derived from the same premises can be included.

**Example.**  $\{A\} \vdash \neg\neg A$ .

1. $A$	premise
2. $A \rightarrow (\neg A \rightarrow A)$	(kvp1)
3. $\neg A \rightarrow A$	1., 2.
4. $(\neg A \rightarrow A) \rightarrow ((\neg A \rightarrow \neg A) \rightarrow \neg\neg A)$	(kvp2)
5. $(\neg A \rightarrow \neg A) \rightarrow \neg\neg A$	3., 4.
6. $\neg A \rightarrow \neg A$	Theorem [1]
7. $\neg\neg A$	5., 6.

A statement that can be derived from valid statements is also valid. Similarly, a theorem is a valid statement. In the propositional logic system, we naturally obtain an inclusion (hierarchy) of statements:

obtain richer tools for description of their properties (imaginary tangent lines, etc.).

Moreover, we are missing “improper points”. For instance, when parametrizing a circle, we can describe the missing points as the image of the only improper point of the real line, i. e. the point “at infinity”. These problems can be best avoided by working in the so-called projective extension of the (real or complex) plane.

The projective extension is advantageous to use in various problems, we will also use its application when defining the group operation on the points of an elliptic curve (see J).

**12.D.7. (The complex circle).** Consider the sets of points  $X^\varepsilon = \mathcal{V}(z_1^2 + z_2^2 - \varepsilon) \subseteq \mathbb{C}^2$  for any  $\varepsilon \in \mathbb{R} \setminus \{0\}$ . The corresponding real curves are

$$X_{\mathbb{R}}^\varepsilon = X^\varepsilon \cap \mathbb{R}^2 = \begin{cases} \text{circle with radius } \sqrt{\varepsilon} & \varepsilon > 0, \\ \emptyset & \varepsilon < 0. \end{cases}$$

We will write  $z_j = x_j + iy_j = x_j + \sqrt{-1}y_j$ . Therefore,  $X^\varepsilon$  is given as a subset in  $\mathbb{R}^4$  by a system of two real equations:

$$\begin{aligned} \operatorname{Re}(z_1^2 + z_2^2 - \varepsilon) &= x_1^2 + x_2^2 - y_1^2 - y_2^2 - \varepsilon = 0, \\ \operatorname{Im}(z_1^2 + z_2^2 - \varepsilon) &= 2(x_1y_1 + x_2y_2) = 0. \end{aligned}$$

Thus, we can assume that  $X^\varepsilon$  will be a “two-dimensional surface” in  $\mathbb{R}^4$ . We will try to imagine it as a surface in  $\mathbb{R}^3$  in a suitable projection  $\mathbb{R}^4 \rightarrow \mathbb{R}^3$ . For this purpose, we choose the mapping

$$\varphi_+ : (x_1, x_2, y_1, y_2) \mapsto \left( x_1, x_2, \frac{x_1y_2 - x_2y_1}{\sqrt{x_1^2 + x_2^2}} \right)$$

Denote by  $V$  the subset of  $\mathbb{R}^4$  which is given by our second equation, i. e.,

$$V = \{(x_1, x_2, y_1, y_2); x_1y_1 + x_2y_2 = 0, (x_1, x_2) \neq (0, 0)\}.$$

The restriction of  $\varphi_+$  to  $V$  is invertible, and its inverse  $\psi_+$  is given by

$$\psi_+ : (u, v, w) \mapsto \left( u, v, -\frac{vw}{\sqrt{u^2 + v^2}}, \frac{uw}{\sqrt{u^2 + v^2}} \right).$$

Now, note that

$$\left( \frac{x_1y_2 - x_2y_1}{\sqrt{x_1^2 + x_2^2}} \right)^2 = y_1^2 + y_2^2,$$

and hence it follows that

$$\varphi_+(V \cap X^\varepsilon) = H^\varepsilon = \{(u, v, w); u^2 + v^2 - w^2 - |\varepsilon| = 0\}.$$

Now, we can compose the constructed mappings

$$\varphi_\varepsilon : X^\varepsilon \rightarrow V @ > \varphi_+ >> \mathbb{R}^3 \setminus \{(0, 0, 0)\} \supseteq H^\varepsilon,$$

and for every  $\varepsilon > 0$ , we get a bijection  $\varphi_\varepsilon : X^\varepsilon \rightarrow H^\varepsilon$ . The real part of this variety is the “thinnest circle” on the one-part rotational hyperboloid  $H^\varepsilon$ ; see the picture.

The relationship between theorems and valid statements is discussed in the following

**Deduction Theorem.**

$$\begin{aligned} \{A_1, A_2, \dots, A_{n-1}, A_n\} \vdash A \\ \text{if and only if} \\ \{A_1, A_2, \dots, A_{n-1}\} \vdash A_n \rightarrow A. \end{aligned}$$

**PROOF.** First, assume that  $\{A_1, \dots, A_n\} \vdash A$ , i.e., we have some derivation of statement  $A$  from statements  $A_1, \dots, A_n$ , and this derivation has  $m$  steps. By induction on  $m$ , we will show that for each statement  $B$  in the derivation, statement  $A_n \rightarrow B$  can be derived from the statements  $\{A_1, \dots, A_{n-1}\}$ ; in particular, this holds for the last statement in the derivation,  $B = A$ .

If  $m = 1$ , the derivation consists of a single statement  $A$ . Then,  $A$  is either an axiom or one of the statements  $A_1, \dots, A_n$ . If  $A = A_n$ , then according to Theorem [1],  $A_n \rightarrow A$ . If  $A \neq A_n$ , then statement  $A_n \rightarrow A$  can be derived from axiom (kvp1) rewritten as  $A \rightarrow (A_n \rightarrow A)$  using one application of the modus ponens rule.

Now, assume that the statement holds for some  $m$ , and we have a derivation of statement  $A$  from statements  $A_1, \dots, A_n$  with a length of  $m + 1$ . The last statement in this derivation,  $A$ , necessarily resulted from applying the modus ponens rule (because we have no other rules) to some statements of the form  $\tilde{A}$  and  $\tilde{A} \rightarrow A$ , which appeared among the first  $m$  steps of the derivation. Therefore, the derivations of each of the statements  $\tilde{A}$  and  $\tilde{A} \rightarrow A$  can have a length of at most  $m$ . According to the induction hypothesis, we have:

$$\{A_1, \dots, A_{n-1}\} \vdash A_n \rightarrow \tilde{A}, \quad \{A_1, \dots, A_{n-1}\} \vdash A_n \rightarrow (A_n \rightarrow \tilde{A}).$$

We can now obtain statement  $A_n \rightarrow A$  by applying the modus ponens rule twice to the statement

$$(A_n \rightarrow (\tilde{A} \rightarrow A)) \rightarrow ((A_n \rightarrow \tilde{A}) \rightarrow (A_n \rightarrow A)),$$

which is axiom (kvp3).

The necessity of the condition is proven. Its sufficiency is trivial since adding statement  $A_n$  to the premises  $A_1, \dots, A_{n-1}$  and using the modus ponens rule once yields  $\{A_1, \dots, A_{n-1}, A_n\} \vdash A$ .  $\square$

**Corollary.** Statement  $B$  can be derived from statement  $A$  if and only if statement  $A \rightarrow B$  is a theorem.

From this and the previous example, we can conclude that statement  $A \rightarrow \neg\neg A$  is a theorem. This statement is the converse of axiom (kvp4).

**Example.** 1) Theorem [2]:  $\vdash (A \rightarrow B) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C))$ .

We will show  $\{A \rightarrow B\} \vdash (B \rightarrow C) \rightarrow (A \rightarrow C)$ , and from this, using the Deduction Theorem, the statement follows. The abbreviation “TI.” in the sixth line of the derivation refers to the already proven transitivity of implication.

For  $\varepsilon < 0$ , we can repeat the above reasoning, merely interchanging  $x$  and  $y$  and the signs in the definition of  $\varphi_+$ :

$$\varphi_- : (x_1, x_2, y_1, y_2) \mapsto \left( -y_1, -y_2, \frac{-y_1x_2 + y_2x_1}{\sqrt{y_1^2 + y_2^2}} \right),$$

which changes the inversion  $\psi_-$

$$\psi_+ : (u, v, w) \mapsto \left( -\frac{vw}{\sqrt{u^2 + v^2}}, \frac{uw}{\sqrt{u^2 + v^2}}, -u, -v \right).$$

Now,  $H^\varepsilon$  is again a one-part rotational hyperboloid, but its real part is  $X_{\mathbb{R}}^\varepsilon = \emptyset$ .

In the complex case, we can observe that when continuously changing the coefficients, the resulting variety changes only a bit, except for certain “catastrophic” points, where a qualitative leap may occur. This is called the *principle of permanence*. In the real case, this principle does not hold at all.

**12.D.8. The projective extension of the line and the plane.**

The real projective space  $\mathbb{P}_1(\mathbb{R})$  is defined as the set of all directions in  $\mathbb{R}^2$ , i. e., its points are one-dimensional subspaces of  $\mathbb{R}^2$ .

The complex projective space  $\mathbb{P}_1(\mathbb{C})$  is defined as the set of all directions in  $\mathbb{C}^2$ , i. e., its points are one-dimensional subspaces of  $\mathbb{C}^2$ .

Similarly, the points of the real and complex two-dimensional projective spaces are defined as directions in  $\mathbb{R}^3$  and  $\mathbb{C}^3$ , respectively.

$A \rightarrow B$	premise
$(A \rightarrow B) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow B))$	(kvp1)
$(B \rightarrow C) \rightarrow (A \rightarrow B)$	1., 2.
$(B \rightarrow C) \rightarrow (A \rightarrow (B \rightarrow C))$	(kvp1)
$(A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C))$	(kvp3)
$(B \rightarrow C) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C))$	4., 5., TI.
$((B \rightarrow C) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C))) \rightarrow$	
$((B \rightarrow C) \rightarrow (A \rightarrow B)) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C))$	(kvp3)
$((B \rightarrow C) \rightarrow (A \rightarrow B)) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C))$	6., 7.
$(B \rightarrow C) \rightarrow (A \rightarrow C)$	3., 8.

2) Theorem [3]:  $\vdash (A \rightarrow (B \rightarrow C)) \rightarrow (B \rightarrow (A \rightarrow C))$ .

We will show  $\{A \rightarrow (B \rightarrow C), B, A\} \vdash C$ :

- |    |                                   |         |
|----|-----------------------------------|---------|
| 1. | $A \rightarrow (B \rightarrow C)$ | premise |
| 2. | $A$                               | premise |
| 3. | $B \rightarrow C$                 | 1., 2.  |
| 4. | $B$                               | premise |
| 5. | $C$                               | 3., 4.  |

Now we use the Deduction Theorem three times to get

$$\{A \rightarrow (B \rightarrow C), B\} \vdash A \rightarrow C, \quad \{A \rightarrow (B \rightarrow C)\} \vdash B \rightarrow (A \rightarrow C), \\ \vdash (A \rightarrow (B \rightarrow C)) \rightarrow (B \rightarrow (A \rightarrow C)).$$

SEMANTICS OF CLASSICAL PROPOSITIONAL LOGIC

Classical propositional logic was introduced purely formally and axiomatically. An alphabet and syntax (rules for constructing “letters,” “words,” and “sentences”) were introduced, some statements (axioms) were declared valid, and a rule was specified for deriving other valid statements from valid ones. The idea that statements are or represent “declarative sentences that can be designated as true or false” and that we can somehow “read” propositional connectives is entirely unnecessary when creating a propositional logic system.

Now we will “fill the form with content,” show “what it is about.” More precisely, we will give meanings to statements. Let’s start somewhat broadly: We somehow understand linguistic expressions; they express some “meaning” for us. This meaning helps us determine or identify a fact or reality in the real (or fictional, or virtual) world that the respective linguistic expression denotes. This fact or reality is the “meaning” of the linguistic expression. Schematically:

A classic example, mentioned by Gottlob Frege, is the linguistic expression “Morning Star.” Its sense is the “brightest star in the morning sky.” Its meaning in the real world is the planet Venus. The sense of another expression, “Evening Star,” is the “brightest star in the evening sky.” But its meaning is the same—Venus.

**E. Algebraic structures**

First of all, we practice general properties of operations and we find out what structures the known sets and operations actually are.

**12.E.1.** Decide about the following sets and operations what algebraic structures they are (groupoid, semigroup (with potential one-sided neutral elements), monoid, group):

- i) the set of all subsets of the integers with union,
- ii) the set of positive integers with the greatest common divisor as the binary operation,
- iii) the set of positive integers with the least common multiple as the binary operation,
- iv) the set of all 2-by-2 invertible matrices over  $\mathbb{R}$  with addition,
- v) the set of all 2-by-2 matrices over  $\mathbb{R}$  with multiplication,
- vi) the set of all 2-by-2 matrices over  $\mathbb{R}$  with subtraction,
- vii) the set of all 2-by-2 invertible matrices over  $\mathbb{Z}_2$  with multiplication,
- viii) the set  $\mathbb{Z}_6$  with multiplication (modulo 6),
- ix) the set  $\mathbb{Z}_7$  with multiplication (modulo 7).

Construct the table of the operation for the last-but-two structure.

**Solution.**

- i) a monoid (the empty set being neutral),
- ii) a semigroup (with no neutral elements),
- iii) a monoid (1 being neutral),
- iv) not even a groupoid (consider  $A+(-A)$  for an invertible matrix  $A$ ),
- v) a monoid,
- vi) a groupoid (not associative),
- vii) a group,
- viii) a monoid (the class  $[1]$  being neutral),
- ix) a monoid (the class  $[1]$  being neutral).

The group in vii) consists of the following elements:

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, C = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix},$$

$$D = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}, E = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, F = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}.$$

The table of the matrix multiplication looks as follows:

	A	B	C	D	E	F
A	A	B	C	D	E	F
B	B	A	E	F	C	D
C	C	D	A	B	F	E
D	D	C	F	E	A	B
E	E	F	B	A	D	C
F	F	E	D	C	B	A

Note that each row and column (disregarding the heading ones) contains each element exactly once (why is it so?). Thus, we do not have to calculate each product and instead we can play “sudoku” as soon as we have filled enough entries of the table. □

The example shows that different expressions can have the same sense; conversely, we can also encounter expressions that have no sense. Statements in classical propositional logic are represented by various expressions. However, the meaning of a statement will be exactly one of the possibilities “true” or “false.” These meanings are symbolically denoted as T and F, sometimes as P and N in Czech, alternatively as 1 and 0. We will use this last notation. Sometimes it will be appropriate to interpret the symbols “0” and “1” directly as numbers, between which an order and arithmetic operations are naturally defined.

It is reasonable to consider the negation of a statement to be true precisely when the original statement is false, and vice versa. From the modus ponens rule, it follows that if an implication is true, and its antecedent is also true, then the consequent must also be true. Axiom (kvp2) implies that if the antecedent of an implication is false, then the entire implication is true. These considerations allow us to formulate a definition.

**Definition.** An interpretation of the classical propositional logic system is a mapping  $\mathcal{I}$  from the set of statements to the set  $\{0, 1\}$  such that

- (i1)  $\mathcal{I}(\neg A) = 1$  if and only if  $\mathcal{I}(A) = 0$ ,
- (i2)  $\mathcal{I}(A \rightarrow B) = 0$  if and only if  $\mathcal{I}(A) = 1$  and simultaneously  $\mathcal{I}(B) = 0$ .

The set  $\{0, 1\}$  is called the *set of truth values*.

The interpretations of primitive statements  $\neg A$  and  $A \rightarrow B$  can be written in tables:

A	$\neg A$	A	B	$A \rightarrow B$
0	1	0	0	1
0	1	0	1	1
1	0	1	0	0
1	0	1	1	1

We will use the notation  $|A| = \mathcal{I}(A)$ , which is often found in logic textbooks. Then we can express the interpretation of primitive statements as follows:

$$|\neg A| = 1 - |A|, \quad |A \rightarrow B| = \max\{1 - |A|, |B|\} = \max\{|\neg A|, |B|\}.$$

From the definition of interpretation, it is clear that the truth value of any statement can be computed for any interpretation of atomic statements by a finite number of subtractions and searching for the greater of the two values.

**Example.** Let  $|a| = 1, |b| = 0$ . Then

$$\begin{aligned} |\neg((b \rightarrow a) \rightarrow \neg a) \rightarrow (b \rightarrow a)| &= \max\{1 - |\neg((b \rightarrow a) \rightarrow \neg a)|, |b \rightarrow a|\} \\ &= \max\{|\neg((b \rightarrow a) \rightarrow \neg a)|, \max\{1 - |b|, |a|\}\} = \\ &= \max\{\max(1 - |b \rightarrow a|, |\neg a|), 1\} = 1. \end{aligned}$$

This ordered computation is, of course, not very efficient. A much shorter evaluation would be achieved using a truth table.

□ **Definition.**

**12.E.2.** Let  $X$  be a set and  $\mathcal{P}(X)$  denote the set of all subsets of  $X$ . Decide whether the set  $\mathcal{P}(X)$  together with each of the following operations forms a groupoid, semigroup, monoid, group and whether the operation is commutative:

- i) set intersection,
- ii) set union,
- iii) set symmetric difference (xor).

**Solution.** If the set  $X$  is empty, then  $\mathcal{P}(X)$  together with any of the mentioned operations is the trivial (1-element) group. Otherwise:

- i) with the set intersection, the resulting structure is a commutative monoid,
- ii) with the set union, the resulting structure is a commutative monoid,
- iii) with the set xor, the resulting structure is a commutative group where the empty set is neutral and each element is self-inverse.  $A^{-1} = A$ .

**12.E.3.** Decide about the following sets and operations what algebraic structures they are (groupoid, semigroup, group), whether they have one-sided or two-sided neutral elements, and whether the operation is commutative:

- i) the set of all 3-by-3 invertible matrices over  $\mathbb{R}$  with addition,
- ii) the set of all 3-by-3 matrices over  $\mathbb{R}$  with multiplication,
- iii) the set of all 3-by-3 matrices over  $\mathbb{R}$  with addition,
- iv) the set of all 3-by-3 invertible matrices over  $\mathbb{Z}_2$  with multiplication,
- v)  $(\mathbb{Z}_9, +)$ ,
- vi)  $(\mathbb{Z}_9, \cdot)$ .

**12.E.4.** Decide about the following subsets  $G$  of the complex numbers what algebraic structures they form together with multiplication (groupoid, semigroup, group), and whether the operation is commutative:

- i)  $G = \{a + bi \mid a, b \in \mathbb{Z}\}$ ,
- ii)  $G = \{a + bi \mid a, b \in \mathbb{R}, a^2 + b^2 = 1\}$ ,
- iii)  $G = \{a + b \cdot \sqrt{5} \mid a, b \in \mathbb{Q}, a^2 + b^2 \neq 0\}$ .

**12.E.5.** Decide whether  $\mathbb{Z}$  together with the operation  $\heartsuit$  forms a groupoid, semigroup, monoid, group, and whether  $\heartsuit$  is commutative, provided it is defined by:

- i)  $a \heartsuit b = (a, b)$ ,
- ii)  $a \heartsuit b = a^{|b|}$ ,
- iii)  $a \heartsuit b = 2a + b$ ,
- iv)  $a \heartsuit b = |a|$ ,
- v)  $a \heartsuit b = a + b + a \cdot b$ ,
- vi)  $a \heartsuit b = a + b - a \cdot b$ ,
- vii)  $a \heartsuit b = a + (-1)^a b$ .

- We say that a statement  $A$  is a *tautology* if, for every interpretation of the statements from which  $A$  is composed,  $|A| = 1$ .
- We say that a statement  $A$  is a *contradiction* if, for every interpretation of the statements from which  $A$  is composed,  $|A| = 0$ .
- We say that a statement  $A$  follows from a set of statements  $\{A_1, A_2, \dots\}$  (finite or countable) if, for an interpretation of the statements  $A_1, A_2, \dots$  such that  $|A_1| = |A_2| = \dots = 1$ , it holds that  $|A| = 1$ .
- We say that a set of statements  $\{A_1, A_2, \dots\}$  is semantically consistent if there exists an interpretation such that  $|A_1| = |A_2| = \dots = 1$ .

A tautology follows from an empty set of statements.

**Examples.**

- (1) The statement  $A \rightarrow \neg\neg A$  is a tautology:  
 If  $|A| = 1$ , then  $|A \rightarrow \neg\neg A| = \max\{1 - |A|, |\neg\neg A|\} = \max\{0, 1 - (1 - 1)\} = 1$ ,  
 If  $|A| = 0$ , then  $|A \rightarrow \neg\neg A| = \max\{1 - |A|, |\neg\neg A|\} = \max\{1, 1 - (1 - 0)\} = 1$ .

The given statement is also a theorem in classical vector calculus.

- (2) The statements  $A \rightarrow B$  and  $B \rightarrow C$  are semantically consistent.

We construct a table

$A$	$B$	$C$	$A \rightarrow B$	$B \rightarrow C$
0	0	0	1	1
0	0	1	1	1
0	1	0	1	0
0	1	1	1	1
1	0	0	0	1
1	0	1	0	1
1	1	0	1	0
1	1	1	1	1

and from it, we can see that both statements have an interpretation of 1 in four cases, specifically in rows 1, 2, 4, and 8.

- (3) The statement  $A \rightarrow C$  follows from the set of statements  $\{A \rightarrow B, B \rightarrow C\}$ .

From the previous example, we already know that the given set of statements is semantically consistent. In the interpretation table, we only need to focus on the rows where both statements have a truth value of 1.

$A$	$B$	$C$	$A \rightarrow B$	$B \rightarrow C$	$A \rightarrow C$
0	0	0	1	1	1
0	0	1	1	1	1
0	1	1	1	1	1
1	1	1	1	1	1

All truth values in the last column of the table are equal to 1. Recall that the statement  $A \rightarrow C$  is also derivable from the set of statements  $\{A \rightarrow B, B \rightarrow C\}$ ; this is the transitivity of implication.

**12.E.6.** In how many ways can we fill the following table so that  $(\{a, b, c\}, *)$  would be a

- i) groupoid
- ii) commutative groupoid
- iii) a groupoid with a neutral element
- iv) a monoid
- v) a group

*	a	b	c
a	c	b	a
b			b
c			

**Solution.**

- i)  $3^5$
- ii) 9
- iii) 9
- iv) 1
- v) 0

□

**12.E.7.** Find the number of groupoids on a given three-element set.

**Solution.** Since the set is given, it remains to define the binary operation. In a groupoid, there is no restriction except that the result of the operation must be an element of the underlying set. Thus, for any pair of elements, there are three possibilities for the result. By the product rule, this gives

$$3^{3 \cdot 3} = 19683$$

groupoids.

□

**12.E.8.** Decide whether the set  $G = (\mathbb{R} \setminus \{0\} \times \mathbb{R})$  together with the operation  $\Delta$  defined by  $(x, y)\Delta(u, v) = (xu, xv+y)$  for all  $(x, y), (u, v) \in G$  is a groupoid, semigroup, monoid, group, and whether  $\Delta$  is commutative.

○

**12.E.9.** Let  $\Omega$  be a set with the multiplication operation defined by  $ab = a$  for all  $a, b$  in  $\Omega$ . Prove that such multiplication is associative.

○

**Solution.** For  $a, b, c \in \Omega$  we have:

$$a(bc) = ab = a = ac = (ab)c$$

□

**12.E.10.** Suppose that  $abc = e$  for some  $a, b, c$  in a group  $G$ . Show that  $bca = e$  as well.

○

**Solution.** Set  $x = bc$ . Then  $ax = e$  i.e.  $x^{-1} = a$  since  $x$  is invertible and so  $xa = (bc)a = e$ .

□

### F. Groups

We begin with recalling permutations and their properties. We have already met permutations in chapter two, see ??, where we used them to define the determinant of a matrix.

**12.F.1.** For each of the following conditions, find all permutations  $\pi \in \mathbb{S}_7$  which satisfy it:

- i)  $\pi^4 = (1, 2, 3, 4, 5, 6, 7)$

There are four possible truth tables for unary logical connectors. One of them is the table for the negation interpretation. We will show that the remaining three possible tables also express interpretations of statements formed using the unary connector  $\neg$  and the binary connector  $\rightarrow$ .

A	♠A	A → A	A	♣A	¬(A → A)	A	♥A	A
0	1	1	0	1	0	0	1	0
1	1	1	1	1	0	1	1	1

The first connector is called *unary verum*, the second *unary falsum*, and the third *assertion*; the symbols used are not standard.

Similarly, any truth table for binary logical connectors is satisfied by a statement created using the connectors  $\neg$  and  $\rightarrow$ . We will demonstrate this with at least one example.

A	B	A ↔ B	¬((A → B) → ¬(B → A))
0	0	1	1
0	1	0	0
1	0	0	0
1	1	1	1

You probably know that the connector  $\leftrightarrow B$  is called *equivalence*.

#### BASIC PROPERTIES OF CLASSICAL PROPOSITIONAL LOGIC

First, let's emphasize that it's essential to distinguish between concepts that are *axiomatic*, i.e., introduced using axioms and rules of inference, and those that are *semantic*, i.e., introduced using interpretation. (And let's also note that the concepts referred to as axiomatic are commonly called syntactic, but that's misleading because it leads to mixing axioms with syntax in the narrower sense—rules for forming statements.)

However, we've already seen that both the axiomatics and semantics include concepts that are related to each other—a "theorem" corresponds to a "tautology," "derivation" corresponds to "entailment." But this is the case only in classical propositional logic; in other propositional logic systems, it may not hold.

We've already formulated the basic properties of classical propositional logic, or at least hinted at them. Now let's summarize them without proofs:

**Deduction.:** The concept of a "theorem" is defined using the concept of "derivation" and is thus reducible to this concept. Conversely, the deduction theorem implies that the concept of "derivation from a finite set of statements" is reducible to the concept of a "theorem." The set of theorems coincides with the set of derivable statements.

The semantic counterpart of the deduction theorem also holds:

Statement  $A$  follows from a set of statements  $\{A_1, \dots, A_{n-1}, A_n\}$  if and only if statement  $A_n \rightarrow A$  follows from the set of statements  $\{A_1, \dots, A_{n-1}\}$ .

- ii)  $\pi^2 = (1, 2, 3) \circ (4, 5, 6)$
- iii)  $\pi^2 = (1, 2, 3, 4)$

○

**12.F.2.** Find the signature (parity) of each of the following permutations:

- i)  $\begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & \dots & 3n-2 & 3n-1 & 3n \\ 2 & 3 & 1 & 5 & 6 & 4 & \dots & 3n-1 & 3n & 3n-2 \end{pmatrix},$
- ii)  $\begin{pmatrix} 1 & 2 & 3 & \dots & n & n+1 & n+2 & \dots & 2n \\ 2 & 4 & 6 & \dots & 2n & 1 & 3 & \dots & 2n-1 \end{pmatrix}.$

**Solution.** The parity of a permutation corresponds to the number of transpositions from which it is built or, equivalently, to the number of its inversions, see 2.2.2. The number of inversions can be read easily from the two-row representation of the permutation. For each number of the second row, we count the number of numbers that are less and lie more to the right than the current number. Thus, the first permutation is even (the signature is 1), and in the second case, the signature depends on  $n$  and is equal to  $(-1)^{\frac{n \cdot (n+1)}{2}}$ . □

**12.F.3.** Find all permutations  $\rho \in \mathbb{S}_9$  such that

$$[\rho \circ (1, 2, 3)]^2 \circ [\rho \circ (2, 3, 4)]^2 = (1, 2, 3, 4).$$

**Solution.** No such permutation exists, since the left-hand side is always an even permutation, while the right-hand side is an odd one. □

**12.F.4.** Find all permutations  $\rho \in \mathbb{S}_9$  such that

$$\rho^2 \circ (1, 2) \circ \rho^2 = (1, 2) \circ \rho^2 \circ (1, 2).$$

○

**12.F.5.** Consider the permutation  $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ 3 & 6 & 5 & 7 & 1 & 2 & 4 \end{pmatrix}.$

Find the order of  $\sigma$  in the group  $(\mathbb{S}_7, \circ)$ , the inverse of  $\sigma$  and compute  $\sigma^{2013}$ . Show that  $\sigma$  does not commute with the transposition  $\tau = (2, 3)$ .

**Solution.**  $\sigma = (1, 3, 5) \circ (2, 6) \circ (4, 7)$ . Therefore, the order of  $\sigma$  is the least common multiple of the cycle lengths 3, 2, 2, which is 6. Furthermore,  $\sigma^{-1} = (1, 5, 3) \circ (2, 6) \circ (4, 7)$  and

$$\sigma^{2013} = (\sigma^3 35)^6 \circ \sigma^3 = \sigma^3 = (2, 6) \circ (4, 7).$$

Finally, we have  $\sigma \circ \tau = (1, 3, 6, 2, 5) \circ (4, 7)$ , but  $\tau \circ \sigma = (1, 2, 6, 3, 5) \circ (4, 7)$ . □

**12.F.6.** Find  $\sigma^{-1}$  and  $\sigma^{2013}$ , where

- (a)  $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ 4 & 5 & 7 & 6 & 1 & 2 & 3 \end{pmatrix}$  in the symmetric group  $(\mathbb{S}_7, \circ)$ .
- (b)  $\sigma = [4]_{11}$  in the group  $(\mathbb{Z}_{11}^\times, \cdot)$ .

**Solution.** (a)  $\sigma = (1, 4, 6, 2, 5) \circ (3, 7)$ ,  $\sigma^{-1} = (1, 5, 2, 6, 4) \circ (3, 7)$ , since the order of  $(1, 4, 6, 2, 5)$  is 5 and the order of the transposition  $(3, 7)$  is 2, we get that the order of  $\sigma$  is the least

**Compactness.:** A trivial consequence of the definition of derivation is that a statement is derivable from any set of statements if and only if it is derivable from some of its finite subsets. (This follows from the fact that derivation is a finite sequence.) This also holds for entailment:

A statement follows from an infinite set of statements if and only if it follows from some of its finite subsets.

It should be noted that proving this statement is not trivial.

**Correctness.:** Classical propositional logic is *correct*, meaning that every theorem is a tautology. "What can be proven is true."

**Completeness.:** Classical propositional logic is *complete*, meaning that every tautology is a theorem. "What is true can be proven."

**Strong Correctness and Completeness.:** Classical propositional logic is *strongly correct*, meaning that whenever a statement is derivable from a set of statements, it follows from it. Classical propositional logic is also *strongly complete*, meaning that whenever a statement follows from a set of statements, it is derivable from it.

Therefore, a statement in classical propositional logic follows from a set of statements if and only if it is derivable from it.

**Denotational Saturation.:** An operator with any truth table can be expressed using the operators  $\neg$  and  $\rightarrow$ ; that is, for any  $n$ -ary operator defined by a truth table, there exists a statement constructed solely using  $\neg$  and  $\rightarrow$  that has the same truth table.

**Decidability.:** For any (correctly formulated) statement, it can be decided whether it is a tautology or not. For any statement, it can be decided whether it is a theorem or not.

This statement follows directly from the definition of interpretation. Every statement is composed of only finitely many parts, that is, only finitely many atomic statements. And then, it can be decided by finite computation or a finite truth table whether the value is 1 for all evaluations of atomic parts.

ALTERNATIVE FORMULATIONS OF PROPOSITIONAL LOGIC

The primitive operations of propositional logic are, by definition, negation  $\neg$  and implication  $\rightarrow$ . The first is unary, the second is binary. Using them, we introduce several other binary operations on the set of statements, i.e., propositional functors:

statement	definition	name	
common multiple of 2 and 5, which is 10, i. e., $\sigma^{10} = 1$	$A \wedge B$	$\neg(A \rightarrow \neg B)$	conjunction
Then,	$A \vee B$	$\neg A \rightarrow B$	[inclusive] disjunction
$\sigma^{2013} = (\sigma^{10})^{201} \circ \sigma^3 = \sigma^3 = (1, 2, 4, 5, 6) \circ (3, 7)$	$A \underline{\vee} B$	$(A \wedge \neg B) \vee (\neg A \wedge B)$	exclusive disjunction
.	$A   B$	$\neg(A \wedge B)$	Sheffer's function, incompatibility
(b) For the sake of simplicity, we will write only $k$ for the	$A \downarrow B$	$\neg(A \vee B)$	Peirce's function
residue class $[k]_{11}$ , $k \in \mathbb{Z}$ . Then,	$A \leftrightarrow B$	$(A \rightarrow B) \wedge (B \rightarrow A)$	equivalence

$$4^5 \equiv 1 \pmod{11} \Rightarrow \sigma^{-1} = 4^4 \equiv 3 \pmod{11}$$

$$\sigma^{2013} = 4^{2013} \equiv 4^3 \equiv 9 \pmod{11}.$$

□

**12.F.7.** Prove that every group whose number of elements is even contains a non-trivial (i. e., different from the identity) element which is self-inverse.

**Solution.** Since each element which is not self-inverse can be paired with its inverse, we see that there are an even number of elements which are not-self inverse. Thus, there remain an even number of elements which are self-inverse, and one of them is the identity, so there must be at least one more such element. □

**12.F.8.** Prove that there exists no non-commutative group of order 4.

**Solution.** By Lagrange's theorem (see 12.4.10), the non-trivial elements of a 4-element group are of order 2 or 4. If there is an element of order 4, then the group is cyclic, and thus commutative. So the only remaining case is that there are (besides the identity  $e$ ) three elements of order 2, call them  $a$ ,  $b$ ,  $c$ . We are going to show that we must have  $ab = c$ : It cannot be that  $ab = e$ , since the inverse of  $a$  is  $a$  itself, and not  $b$ . It cannot be that  $ab = a$ , since this would mean that  $b = e$ , and similarly, it cannot be that  $ab = b$ , since this would mean that  $a = e$ . Therefore, the only remaining possibility is that indeed  $ab = c$ , and it can be shown analogously that the product of any two non-trivial elements, regardless of the order, must be equal to the third one, so this group is commutative, too. Altogether, we have shown that there are exactly two groups of order 4, up to isomorphism. The latter is called the Klein group, and one instance of it is the group  $\mathbb{Z}_2 \times \mathbb{Z}_2$ . □

**12.F.9.** Show that there exists no non-commutative group of order 5.

**Solution.** By Lagrange's theorem (see 12.4.10), the non-trivial elements of a 5-element group are of order 5, so the group must be cyclic, and thus commutative. □

**Remark.** The same argumentation show that each group of prime order must be cyclic, and thus commutative. In particular, there are neither 2-element nor 3-element non-commutative groups. As we have shown (see 12.F.8), there is even no 4-element non-commutative group. Therefore, the smallest non-commutative group may be of order 6. As we have seen (see 12.E.1(vii)), this is indeed the case.

All the connectors introduced in this way are not strictly part of propositional logic; they are meta-symbols. However, this strict distinction is not significant for our purposes, and we can freely add the symbols  $\wedge$ ,  $\vee$ ,  $\underline{\vee}$ ,  $|$ ,  $\leftrightarrow$ , and  $\downarrow$  to the propositional alphabet.

The conjunction  $A \wedge B$  can be read as "A and B" or "A simultaneously with B" and so on.

The disjunction  $A \vee B$  can be read as "A or B." The grammatical connector "or" here has a similar meaning to the Latin "vel," indicating possible but not always necessary alternatives, so at least one of the statements  $A$ ,  $B$  is true. Similarly, in the Czech sentence: "Tonight I will go to the pub or study mathematics." I can study mathematics with my classmates in the pub. In contrast, the exclusive disjunction  $A \underline{\vee} B$ , which can be read as "either A or B," expresses "or" in an exclusionary sense, meaning that exactly one of the statements  $A$ ,  $B$  is true, as in the Czech sentence: "Tonight I will go to the pub or somewhere else." The Czech language has another meaning for the word "or," which is that at most one of the options will occur, for example, in the sentence: "Tonight I will sleep either in Brno or in New York." This possibility is formalized by Sheffer's connector, and the statement  $A | B$  is suitable to read as "A is incompatible with B."

**Statement**  $A \downarrow B$  can be read as "neither A nor B," and the equivalence  $A \leftrightarrow B$  can be read as "A if and only if B" or "A is a necessary and sufficient condition for B."

Furthermore, it should be noted that the exclusive disjunction  $A \underline{\vee} B$  is sometimes denoted as  $A \leftrightarrow B$ , and the negation of implication  $\neg(A \rightarrow B)$  is sometimes called "inhibition" and denoted as  $A \rightarrow B$ . Alternative names for the Peirce function are  $\nabla$ ,  $\cdot|$ , or NOR.

The semantics of these propositional connectors can be easily derived from their definitions. Let's summarize them in a truth table:

A	B	$A \wedge B$	$A \vee B$	$A \underline{\vee} B$	$A   B$	$A \downarrow B$	$A \leftrightarrow B$
0	0	0	0	0	1	1	1
0	1	0	1	1	1	0	0
1	0	0	1	1	1	0	0
1	1	1	1	0	0	0	1

As an exercise, you can verify some "standard" tautologies:

**12.F.10.** Prove that any group  $G$  where each element is self-inverse must be commutative.

**Solution.** Let  $a, b \in G$ . Since each of  $ba, b, a$  is assumed to be self-inverse, we get

$$ab = ab((ba)(ba)) = a(bb)aba = (aa)ba = ba.$$

□

**12.F.11.** Prove that every group  $G$  of order 6 is isomorphic to  $\mathbb{Z}_6$  or  $\mathbb{S}_3$ .

**Solution.**

By Lagrange's theorem (see 12.4.10), the non-trivial elements of a 6-element group are of order 2, 3, or 6. If there is an element of order 6, then  $G$  is cyclic, and thus isomorphic to  $\mathbb{Z}_6$ .

Therefore, assume from now on that the order of each non-trivial element is 2 or 3. Since an element  $a$  of order 3 is not self-inverse (we have  $a^{-1} = a^2$  since  $a \cdot a^2 = a^3 = 1$ ), we get from exercise 12.F.7 that there must be at least one element of order 2.

As we are going to show, there must also be an element of order 3. For the sake of contradiction, assume that each element of  $G$  is self-inverse, and let  $a \neq b$  be any two elements different from the identity  $e$ . The same argumentation as in 12.F.8 shows that the product  $ab$  cannot be any of  $e, a, b$ . Thus,  $H = \{e, a, b, ab\}$  is a 4-element subset of  $G$ . Thanks to the self-inverseness, we can see that  $H$  is closed under the operation, with the possible exception of  $b \cdot a, b \cdot ab$ , and  $ab \cdot a$ . However, we get from the above exercise that  $G$  is commutative, so that these 3 products also lie in  $H$ , and it follows that  $H$  is actually a subgroup of  $G$ . However, this contradicts theorem 12.4.10, by which a 6-element group cannot have a 4-element subgroup.

The only remaining case is that there is an element of order 2 (call it  $a$ ) as well as an element of order 3 (call it  $b$ ). Then,  $b^2$  is also of order 3 (and different from  $b$ ), so  $G$  contains the 4 elements  $e, a, b, b^2$ . Furthermore,  $G$  must also contain  $ab, ba, ab^2, b^2a$ , and by uniqueness of inverses, none of these is equal to  $e$ . Moreover, none of these may be equal to any of  $a, b, b^2$  (e. g. if we had  $a = ab$ , then multiplication by  $a^{-1}$  from the left yields  $e = b$ ; the other equalities can be refuted similarly). Since  $G$  contains only 6 elements, the set  $\{ab, ba, ab^2, b^2a\}$  has at most two. Again, we can have neither  $ab = ab^2$  nor  $ba = b^2a$ . If  $ab = ba$ , then  $(ab)^2 = a^2b^2 = b^2 \neq e$  and  $(ab)^3 = a^3b^3 = a \neq e$ , so the order of  $ab$  is greater than 3, which contradicts our assumption. Therefore, it must be that  $ab = b^2a$  and  $ba = a^2b$ , so that  $G$  is indeed isomorphic to  $\mathbb{S}_3$  ( $a$  corresponds to a transposition and  $b$  does to a cycle of length 3). This group can also be viewed as the group of symmetries of an equilateral triangle ( $a$  corresponds to a reflection and  $b$  does to a rotation by  $120^\circ$ ), see also 12.4.3.

We have discussed all possibilities, so the proof is finished. □

$A \vee \neg A, \neg(A \wedge \neg A)$	Law of excluded middle
$(A \wedge \neg A) \rightarrow B, \neg A \rightarrow (A \rightarrow B)$	Law of Duns Scotus
$((A \rightarrow B) \wedge A) \rightarrow B$	Modus ponens
$(\neg B \rightarrow \neg A) \rightarrow (A \rightarrow B)$	Reductio ad absurdum, indirect
$((A \wedge \neg B) \rightarrow (C \wedge \neg C)) \rightarrow (A \rightarrow B)$	Proof by contradiction
$((A \rightarrow B) \wedge (B \rightarrow C)) \rightarrow (A \rightarrow C)$	Transitivity of implication
$((A \wedge B) \rightarrow C) \rightarrow (A \rightarrow (B \rightarrow C))$	Deduction

We can declare other connectors, such as  $\neg, \wedge,$  and  $\vee,$  as primitive operations alongside  $\rightarrow$ . In this sense, Propositional Calculus can be treated as discussed in Section 11.48. For constructing propositional calculus, one of either  $\wedge$  or  $\vee$  alongside  $\neg$  is sufficient, as implication  $\rightarrow$  can be expressed using them:

$$A \rightarrow B = \neg A \vee B, \quad \text{or} \quad A \rightarrow B = \neg(A \wedge \neg B).$$

Axioms can then be rewritten using the respective connector. The inference rules will take the following form:

$$\frac{A \vee B}{\neg A} \quad \frac{A \vee B}{\neg B} \quad \text{or} \quad \frac{\neg(A \wedge B)}{A} \quad \frac{\neg(A \wedge B)}{B}$$

Each of the Sheffer and Peirce functions can serve as a single propositional connector. Specifically:

$$\neg A = A | A, \quad A \rightarrow B = A | (B | B),$$

and

$$\neg A = A \downarrow A, \quad A \rightarrow B = ((A \downarrow A) \downarrow B) \downarrow ((A \downarrow A) \downarrow B).$$

The inference rules can then be written as:

$$\frac{A | B}{A} \quad \frac{A | B}{B} \quad \text{and} \quad \frac{A \downarrow B}{A \downarrow A} \quad \frac{A \downarrow B}{B \downarrow B}$$

As previously mentioned, Propositional Calculus can be built using other connectors than  $\neg$  and  $\rightarrow$ . However, any combination of these connectors will suffice, as shown in Section 11.48. The construction of Propositional Calculus will only require one of  $\wedge$  or  $\vee$  in addition to negation, as implication can be expressed using them.

Therefore, the axioms for classical propositional calculus can be either:

$$\begin{aligned} \text{(kvp1)} \quad & A \rightarrow (B \rightarrow A) \\ \text{(kvp2')} \quad & (\neg A \rightarrow \neg B) \rightarrow ((\neg A \rightarrow B) \rightarrow A) \\ \text{(kvp3)} \quad & (A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C)) \end{aligned}$$

Or, a single axiom known as the "Meredith's Axiom":

$$\left( \left( \left( (A \rightarrow B) \rightarrow (\neg C \rightarrow \neg D) \right) \rightarrow C \right) \rightarrow E \right) \rightarrow ((E \rightarrow A) \rightarrow (D \rightarrow A)).$$

On the other hand, if we consider  $\neg, \rightarrow, \wedge,$  and  $\vee$  as primitive connectors (i.e., not defining conjunction and disjunction in terms of implication and negation), we would need

**12.F.12.** Find all commutative groups of order 8 (up to isomorphism). Then, for each of the following groups, decide to which of the found ones it is isomorphic (the operation is always multiplication):

- $\mathbb{Z}_{15}^\times$ ,
- $\mathbb{Z}_{16}^\times$ ,
- $\mathbb{Z}_{17}^\times / \{[1], [-1] = [16], \cdot\}$ ,
- the complex roots of the polynomial  $z^8 - 1$ .

**Solution.**

By theorem 12.4.8, every commutative group is a product of cyclic groups. By 12.4.10, their orders divide 8. This means that there are only 3 possibilities:  $\mathbb{Z}_8$ ,  $\mathbb{Z}_2 \times \mathbb{Z}_4$ , and  $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$ .

- The group  $\mathbb{Z}_{15}^\times$  contains the residue classes which are coprime to 15. There are  $\varphi(15) = (5 - 1)(3 - 1) = 8$  of them, so indeed  $|\mathbb{Z}_{15}^\times| = 8$ . In particular, these are 1, 2, 4, 7, 8, 11, 13, 14. Their orders are either 2 (for 4, 11, 14) or 4 (for 2, 7, 8, 13), which means that  $\mathbb{Z}_{15}^\times$  is isomorphic to  $\mathbb{Z}_2 \times \mathbb{Z}_4$ .
- $\mathbb{Z}_{16}^\times = \{1, 3, 5, 7, 9, 11, 13, 15\}$ . Again, this group contains 8 elements, and their orders are either 2 (for 7, 9, 15) or 4 (for 3, 5, 11, 13), which means that  $\mathbb{Z}_{16}^\times$  is also isomorphic to  $\mathbb{Z}_2 \times \mathbb{Z}_4$ .
- $\mathbb{Z}_{17}^\times = \{\pm 1, \pm 2, \dots, \pm 8\}$ . Thus, the quotient  $\mathbb{Z}_{17}^\times / (\pm 1) = \{1, 2, \dots, 8\}$  has 8 elements. We can easily calculate that the order of 3 is 8. Therefore, 3 generates the entire group, which means that  $\mathbb{Z}_{17}^\times / (\pm 1) \cong \mathbb{Z}_8$ .
- The complex roots of the polynomial  $z^8 - 1$  are  $e^{\frac{n\pi}{4}i}$ , where  $n = 1, 2, \dots, 8$ . Clearly, these form a cyclic group of order 8, isomorphic to  $\mathbb{Z}_8$ .

**12.F.13.** Let  $G$  be a commutative group and denote  $H = \{g \in G \mid g^2 = e\}$ , where  $e$  is the identity of  $G$ . Prove that  $H$  is a subgroup of  $G$ .

**Solution.** Clearly,  $e \in H$ . If  $a \in H$ , then we also have  $a^{-1} \in H$ , because  $a = a^{-1}$  (since  $a^2 = e$ ). Moreover, if  $b \in H$ , then  $(ab)^2 = a^2b^2 = e$  (this is where we use the commutativity of  $G$ ), which means that  $ab \in H$ . Thus,  $H$  is closed under the operation, and it is indeed a subgroup.  $\square$

**12.F.14.** Let  $\mathcal{GL}_n(\mathbb{R})$  denote the set of all  $n$ -by- $n$  regular matrices with real coefficients. Prove that  $G = \mathcal{GL}_2(\mathbb{R})$  with multiplication is a group and decide for each of the following subsets  $H$  of  $G$  whether it is a subgroup of  $G$ :

- i)  $H = \mathcal{GL}_2(\mathbb{Q})$ ,
- ii)  $H = \mathcal{GL}_2(\mathbb{Z})$ ,
- iii)  $H = \{A \in \mathcal{GL}_2(\mathbb{Z}) \mid |A| = 1\}$ ,
- iv)  $H = \left\{ \begin{pmatrix} 0 & a \\ a & b \end{pmatrix} \in G \mid a, b \in \mathbb{Q} \right\}$ ,
- v)  $H = \left\{ \begin{pmatrix} 1 & 0 \\ a & 1 \end{pmatrix} \in G \mid a \in \mathbb{Z} \right\}$ ,
- vi)  $H = \left\{ \begin{pmatrix} 1 & a \\ a & 1 \end{pmatrix} \in G \mid a \in \mathbb{Q} \right\}$ ,
- vii)  $H = \left\{ \begin{pmatrix} 0 & a \\ b & c \end{pmatrix} \in G \mid a, b, c \in \mathbb{R} \right\}$ ,

a more extensive system of axioms. Kleene introduced such axioms in 1967:

- (Kkvp1)  $A \rightarrow (B \rightarrow A)$
- (Kkvp2)  $((A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C)))$
- (Kkvp3)  $(A \wedge B) \rightarrow A$
- (Kkvp4)  $(A \wedge B) \rightarrow B$
- (Kkvp5)  $A \rightarrow (B \rightarrow (A \wedge B))$
- (Kkvp6)  $A \rightarrow (A \vee B)$
- (Kkvp7)  $B \rightarrow (A \vee B)$
- (Kkvp8)  $(A \rightarrow C) \rightarrow ((B \rightarrow C) \rightarrow ((A \vee B) \rightarrow C))$
- (Kkvp9)  $(A \rightarrow B) \rightarrow ((A \rightarrow \neg B) \rightarrow \neg A)$
- (Kkvp10)  $\neg\neg A \rightarrow A$

Notably, axioms (Kkvp1), (Kkvp2), (Kkvp9), and (Kkvp10) are the same as axioms (kvp1), (kvp3), (kvp2), and (kvp4).

#### ALTERNATIVES TO CLASSICAL PROPOSITIONAL CALCULUS

Classical propositional calculus possesses beautiful properties, particularly decidability and strong completeness and correctness. This means that in classical propositional calculus, the axiom system essentially aligns with semantics. However, this can also pose a danger - one might blur the line between semantics and axiomatics and perceive all of mathematics as precise formal calculations.

One of the problems with classical propositional calculus is the primitive concept of  $\rightarrow$ . It is meant to correspond to the intuitive notion of implication. However, consider the Czech sentences: "If it is dry in the Sahara, then beer is brewed in the Czech Republic" (which is true due to the truth of the consequent) and "If the Illuminati rule the world, they caused a tsunami in Sri Lanka" (which is true due to the falsity of the antecedent). These are certainly not exemplary true statements. Sometimes, constructions like these, which are consequences of axiom (kvp1) and theorem  $\neg A \rightarrow (A \rightarrow B)$ , are referred to as "paradoxes of implication."

Another problem is posed by axiom (kvp4), which is semantically interpreted as implying that if a statement is not false, then it is true. This appears to be self-evident, but it conceals an unspoken assumption that there are no truth values other than "true" and "false." A statement could have another truth value, such as "possible," or it could have no truth value, expressing uncertainty or "I don't know." Accepting this possibility means relinquishing the "view from God's eye."

Alternative approaches to propositional calculus may involve "improving implication" or introducing multiple truth values. We will explore some significant cases.

**(1) Intuitionistic Propositional Calculus.** This arises through a slight modification of classical propositional calculus. Axiom (kvp4) is replaced by a weaker axiom:

- (ivp4)  $A \rightarrow (\neg A \rightarrow B)$ .

This axiom is weaker in the sense that it is a theorem of classical propositional calculus (which can be easily verified by showing that (ivp4) is a tautology of classical propositional

viii)  $H = \left\{ \begin{pmatrix} 1 & a \\ b & c \end{pmatrix} \in G \mid a, b, c \in \mathbb{R} \right\}$ .

**12.F.15.**

- i) Decide whether the set  $H = \{a \in \mathbb{R}^* \mid a^2 \in \mathbb{Q}\}$  is a subgroup of the group  $(\mathbb{R}^*, \cdot)$
- ii) Decide whether the set  $H = \{a \in \mathbb{R} \mid a^2 \in \mathbb{Q}\}$  is a subgroup of the group  $(\mathbb{R}, +)$

**12.F.16.** Find all positive integers  $m \neq 5$  such that the group  $\mathbb{Z}_m^\times$  is isomorphic to  $\mathbb{Z}_5^\times$ .

**12.F.17.** How many cycles of length  $p$  ( $1 < p \leq n$ ) are there in  $\mathbb{S}_n$ ?

**Solution.** The elements of the cycle (i. e., the non-fixed points of the permutation) can be selected in  $\binom{n}{p}$  ways. Now, without loss of generality, we can proclaim one of the  $p$  elements to be the first element in the cycle representation (for instance the least one, if we are working with numbers). This element can be mapped to any of the  $p - 1$  remaining elements, that one can be mapped to any of the  $p - 2$  remaining elements, etc. Altogether, we get by the product rule that there are  $\binom{n}{p \cdot (p-1)!}$  cycles of length  $p$ .  $\square$

**12.F.18.** Let  $G$  be the set of real-valued matrices with zeros above the diagonal and ones on it. Prove that  $G$  with matrix multiplication forms a group, i. e., a subgroup in  $\mathcal{GL}(3, \mathbb{R})$ , and find the center of  $G$  (i. e., the subgroup defined by  $Z(G) = \{z \in G \mid \forall g \in G : zg = gz\}$ ).

**Solution.** We can either verify all the group axioms or make use of the known fact that  $\mathcal{GL}(3, \mathbb{R})$  is a group, and we verify only that  $G$  is closed with respect to multiplication and inverses. Clearly, the neutral element (the identity matrix) lies in  $G$ .

$$\begin{pmatrix} 1 & 0 & 0 \\ a & 1 & 0 \\ b & c & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ a_1 & 1 & 0 \\ b_1 & c_1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ a + a_1 & 1 & 0 \\ b + ca_1 + b_1 & c + c_1 & 1 \end{pmatrix} \in G,$$

$$\begin{pmatrix} 1 & 0 & 0 \\ a & 1 & 0 \\ b & c & 1 \end{pmatrix}^{-1} = \begin{pmatrix} 1 & 0 & 0 \\ -a & 1 & 0 \\ -b + ac & -c & 1 \end{pmatrix} \in G.$$

It follows from the form of the products in  $G$  that the center contains precisely the matrices of the form

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ b & 0 & 1 \end{pmatrix}.$$

**12.F.19.** For any subset  $X \subseteq G$ , we define its centralizer as  $C_G(X) = \{y \in G \mid xy = yx, \text{ for all } x \in X\}$ . Prove that if  $X \subseteq Y$ , then  $C_G(Y) \subseteq C_G(X)$ . Further, prove that  $X \subseteq C_G(C_G(X))$  and  $C_G(X) = C_G(C_G(C_G(X)))$ .

**Solution.** The first proposition is clear: The elements of  $G$  which commute with everything from  $Y$  also commute with everything from  $X$ . We have from the definition that

calculus), but (kvp4) is not a theorem of intuitionistic propositional calculus. This means that anything provable or derivable in intuitionistic propositional calculus can also be proven in classical propositional calculus. All the theorems of classical propositional calculus proven without using axiom (kvp4) are also theorems of intuitionistic propositional calculus.

In intuitionistic propositional calculus, the Deduction Theorem also holds. In its proof, we did not use axiom (kvp4).

The connection between classical and intuitionistic propositional calculus is further demonstrated by the following

**Reflection Theorem.** If statement  $A$  is derivable from statements  $A_1, \dots, A_n$  in classical propositional calculus, then it is also derivable from statements  $\neg\neg A_1, \dots, \neg\neg A_n$  in intuitionistic propositional calculus.

Classical reasoning is thus mirrored in intuitionistic calculus through double negation. In this sense, intuitionistic propositional calculus is stronger than classical. These observations lead to the conclusion that the  $\rightarrow$  operator has a different meaning in classical and intuitionistic logic, even though it is denoted by the same symbol. (The meaning of an expression can depend on the context in which it is used.)

Therefore, the semantics of intuitionistic logic is different from classical logic. It cannot be defined using truth tables; it is introduced using the concept of possible worlds. However, intuitionistic propositional calculus is just as "beautiful" as classical, being strongly correct and complete, compact, and decidable.

**(2) Lukasiewicz's Three-Valued Propositional Calculus.** The set of truth values includes not only 0 and 1 but also the value  $x$ , which can be interpreted as "I don't know." Their semantics are defined by truth tables as follows:

$A$	$\neg A$
0	1
$x$	$x$
1	0

$A \rightarrow B$	$B$
	0 $x$ 1
$A$	0 1 1 1
	$x$ $x$ $x$ 1
	1 0 $x$ 1

$A \wedge B$	$B$
	0 $x$ 1
$A$	0 0 0 0
	$x$ 0 $x$ $x$
	1 0 $x$ 1

$A \vee B$	$B$
	0 $x$ 1
$A$	0 0 $x$ 1
	$x$ $x$ $x$ 1
	1 1 1 1

The axioms of this propositional calculus are:

- (I<sub>3</sub>vp1)  $A \rightarrow (B \rightarrow A)$ ,
- (I<sub>3</sub>vp2)  $(A \rightarrow B) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C))$ ,
- (I<sub>3</sub>vp3)  $(\neg A \rightarrow \neg B) \rightarrow (B \rightarrow A)$ ,
- (I<sub>3</sub>vp4)  $((A \rightarrow \neg A) \rightarrow A) \rightarrow A$ .

The modus ponens rule is used for inference.

Lukasiewicz's three-valued propositional calculus is decidable, compact, strongly correct, and complete. However, the Deduction Theorem does not hold in it.

**(3) Lukasiewicz's fuzzy propositional calculus.** The set of truth values is a closed interval  $[0, 1]$ . The values 0 and

$C_G(C_G(X)) = \{y \in G \mid xy = yx, \forall x \in C_G(X)\}$ , and this is in particular satisfied by the elements  $y \in X$ . The last statement follows simply using the two above. Substituting  $X := C_G(X)$  into the second one, we get  $C_G(X) \subseteq C_G(C_G(C_G(X)))$ , and applying the first one to the second one, we obtain  $C_G(X) \supseteq C_G(C_G(C_G(X)))$ .  $\square$

**12.F.20.** Suppose that a group  $G$  has a non-trivial subgroup  $H$  which is contained in every non-trivial subgroup of  $G$ . Prove that  $H$  is contained in the center of  $G$ .

**Solution.** For each  $g \in G$ , the centralizer  $C_G(g) = \{x \in G \mid xg = gx\}$  is a non-trivial subgroup, since  $g \in C_G(g)$  and  $C_G(e) = G$ . Thus, the group  $H$  is contained in every  $C_G(g)$ . Therefore, it is contained in their intersection (over all  $g \in G$ ), which is exactly the center of  $G$ .  $\square$

**12.F.21.** Let  $G$  be a finite group. The conjugation class for  $a \in G$  is the set

$$Cl(a) = \{xax^{-1} \mid x \in G\}.$$

Prove that:

- i) the set of conjugation classes of all elements of  $G$  is a partition of  $G$ ,
- ii) the size of each conjugation class divides the order of  $G$ ,
- iii) if  $G$  has only two conjugation classes, then its order is 2.

**Solution.** (i) It suffices to show that we have for any  $a, b \in G$  that either  $Cl(a) = Cl(b)$  or  $Cl(a) \cap Cl(b) = \emptyset$ . Thus, assume that the intersection of  $Cl(a)$  and  $Cl(b)$  is non-empty. Then, by definition, there are  $x, y \in G$  such that  $xax^{-1} = yby^{-1}$ . Multiplying this equality by  $y^{-1}$  from the left and by  $y$  from the right leads to  $y^{-1}xax^{-1}y = b$ . However,  $(y^{-1}x)^{-1} = x^{-1}y$ , which means that  $b$  is of the form  $zaz^{-1}$  for  $z = y^{-1}x$  and thus lies in  $Cl(a)$ . Analogously, we get  $a \in Cl(b)$ , so that both conjugation classes coincide.

(ii) Note that the elements of  $Cl(a)$  are in one-to-one correspondence with the cosets corresponding to the centralizer  $C_G(a) = \{x \in G \mid xax^{-1} = a\}$ . Indeed, if elements  $b$  and  $c$  lie in the same coset (i. e., they satisfy  $b = cz$  for some  $z \in C_G(a)$ ), then

$$bab^{-1} = cza(cz)^{-1} = czaz^{-1}c^{-1} = czz^{-1}ac^{-1} = cac^{-1}.$$

By 10.2.1, we have  $|G| = |C_G(a)| \cdot |G/C_G(a)|$ , which means that  $|Cl(a)| = |G/C_G(a)|$  divides  $|G|$ .

(iii) The neutral element always forms its own conjugation class  $Cl(e) = \{e\}$ . Therefore, if there are only two conjugation classes, then all the other elements  $a \neq e$  must lie in one class. Thus, its size is  $|G| - 1$ , and by (ii), this integer must divide  $|G|$ , which means that  $|G| = 2$ .  $\square$

**12.F.22.** Let  $G$  be a commutative group. Suppose that the order  $r$  of an element  $a \in G$  and the order  $s$  of an element  $b \in G$  are coprime. Prove that the order of  $ab$  is  $rs$ .

**Solution.** We have  $(ab)^{rs} = a^{rs}b^{rs} = (a^r)^s(b^s)^r = e^s e^r = e$ , so the order is at most  $rs$ . For the sake of contradiction, assume that  $(ab)^q = e$  for some  $q < rs$ . Since  $q$  is less than the least common multiple of  $r$  and  $s$  (recall that  $r, s$  are

1 represent truth and falsehood, just like in classical propositional calculus. The values in between can be seen as the degree of certainty about the statement. The interpretation is governed by the rules:

$$|\neg A| = 1 - |A|, \quad |A \rightarrow B| = \max\{1 - |A|, |B|\} = \max\{|\neg A|, |B|\},$$

$$|A \wedge B| = \min\{|A|, |B|\}, \quad |A \vee B| = \max\{|A|, |B|\}.$$

The first two rules are the same as in classical propositional calculus. The degree of certainty of a statement cannot be interpreted as its probability, even when the statements are about random events. In such cases, the conjunction  $\wedge$  would express the simultaneous occurrence of events. The degree of certainty is calculated directly from the degrees of certainty of individual events, not their probabilities, as it also depends on the stochastic dependence or independence of the relevant events.

The axioms of this propositional calculus are:

- (1<sub>F</sub>vp1)  $A \rightarrow (B \rightarrow A)$ ,
- (1<sub>F</sub>vp2)  $(A \rightarrow B) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C))$ ,
- (1<sub>F</sub>vp3)  $(\neg A \rightarrow \neg B) \rightarrow (B \rightarrow A)$ ,
- (1<sub>F</sub>vp4)  $((A \rightarrow B) \rightarrow B) \rightarrow ((B \rightarrow A) \rightarrow A)$ .

The modus ponens rule is used for inference. The first three axioms of fuzzy propositional calculus are the same as the axioms of the three-valued propositional calculus.

Fuzzy propositional calculus is decidable and compact, but it is not strongly correct or complete. The Deduction Theorem does not hold in it.

#### (4) Paraconsistent four-valued propositional calculus.

We previously interpreted the truth value  $x$  in Lukasiewicz's three-valued propositional calculus as "I don't know." However, we can also interpret it as meaning that a given statement has no truth value, i.e., "neither true nor false." Now, to the three truth values 0, 1, and  $x$ , we add a fourth value, denoted as  $\mathfrak{g}$ , and interpret it as "simultaneously true and false." This may sound nonsensical at first, but these introduced truth values can have meaning when "seeking the truth" in the real world. For example, imagine that we have witness statements about a situation that can be expressed by a statement (declarative sentence). If the witnesses agree that the situation occurred, we assign a truth value of 1 to the statement. If they agree that the situation did not occur, we assign a value of 0. However, it's possible that witness statements may differ. In such a case, we assign the truth value  $\mathfrak{g}$  to the statement. And if there is no testimony at all, the statement will have the value  $x$ .

The value  $x$  is also referred to as a "truth-value gap," while the value  $\mathfrak{g}$  is called a "truth-value glut." We can define the interpretation as an ordered pair  $(\mathcal{I}_1, \mathcal{I}_2)$  of interpretations of atomic statements in Lukasiewicz's three-valued logic, with two witnesses interpreting the statement. Each of them can respond with "yes," "no," or "I don't know." To these pairs of interpretations, we assign truth values in the interpretation  $\mathcal{I}$  according to the table:

coprime), at least one of them does not divide  $q$ . Assume that it is  $r$  (the other case can be refuted analogously). Taking the  $s$ -th power of the equality  $(ab)^q = e$ , we get  $e = ((ab)^q)^s = (ab)^{qs} = a^{qs}b^{qs} = a^{qs}(b^s)^q = a^{qs}e^q = a^{qs}$ . Since  $r$  does not divide  $q$  and is coprime to  $s$ , we get that  $r$  (the order of  $a$ ) does not divide  $qs$ , but  $a^{qs} = e$ , which is a contradiction.  $\square$

**12.F.23.** Prove that every finite group  $G$  whose order is greater than 2 has a non-trivial automorphism.

**Solution.** If  $G$  is not commutative and  $a$  is an element that does not lie in the center, then the conjugation  $x \mapsto axa^{-1}$  defines a non-trivial automorphism. For a cyclic group of order  $m$ , we have, for any  $n$  coprime to  $m$ , the automorphism  $x \mapsto x^n$ . If  $G$  is commutative, then it is a product of cyclic groups (see 10.1.8). If the order of at least one of the factors is greater than 2, then we can use the above automorphism for cyclic groups. If the order of each factor is 2, then permuting any pair of factors is a non-trivial automorphism.  $\square$

**12.F.24.** Consider the group  $(\mathbb{Q}, +)$  of the rational numbers with addition and the group  $(\mathbb{Q}^+, \cdot)$  of the positive rational numbers with multiplication. Find all homomorphisms  $(\mathbb{Q}, +) \rightarrow (\mathbb{Q}^+, \cdot)$ .

**Solution.** There is only one homomorphism, the trivial one. For the sake of contradiction, assume that there exists a non-trivial homomorphism  $\varphi$ , i. e.,  $\varphi(a) = b \neq 1$  for some  $a, b \in \mathbb{Q}$ . Then, for all  $n \in \mathbb{N}$ , we have  $b = \varphi(a) = \varphi(n \frac{a}{n}) = \varphi(\frac{a}{n})^n$ . This is a contradiction, since only some  $n$ -th roots of  $b$  are rational (cf. ??).  $\square$

**12.F.25.** Let  $G$  be the group of matrices of the form  $\begin{pmatrix} a & 0 \\ b & a^{-1} \end{pmatrix}$ , where  $a, b \in \mathbb{R}$  and  $a > 0$ , and let  $N$  be the set of matrices of the form  $\begin{pmatrix} 1 & 0 \\ b & 1 \end{pmatrix}$ , where  $b \in \mathbb{R}$ . Show that  $N$  is a normal subgroup of  $G$  and prove that  $G/N$  is isomorphic to  $\mathbb{R}$ .

**Solution.** The key to the proof is the formula for multiplication in  $G$ :

$$\begin{pmatrix} a & 0 \\ b & a^{-1} \end{pmatrix} \begin{pmatrix} a_1 & 0 \\ b_1 & a_1^{-1} \end{pmatrix} = \begin{pmatrix} aa_1 & 0 \\ ba_1 + a^{-1}b_1 & a^{-1}a_1^{-1} \end{pmatrix}.$$

Hence we can see that the mapping  $\begin{pmatrix} a & 0 \\ b & a^{-1} \end{pmatrix} \mapsto a$  is a homomorphism with kernel  $N$ . Thus,  $N$  is a normal subgroup of  $G$ . Moreover,  $G/N$  is isomorphic to the multiplicative group  $\mathbb{R}^+$ , which is isomorphic to the additive group  $\mathbb{R}$ .  $\square$

**12.F.26.** Let  $G$  be the group with operation of matrix multiplication of  $2 \times 2$  matrices  $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$  where  $ad - bc \neq 0$  and  $a, b, c, d$  are integers from  $\mathbb{Z}_3$ . Show that

- i)  $|G| = 48$ .
- ii) if  $ad - bc = 1$  then  $|G| = 24$ .

**Solution.**

$(\mathcal{I}_1, \mathcal{I}_2)$	$(0, 0)$	$(0, \times)$	$(\times, 0)$	$(\times, \times)$	$(0, 1)$	$(1, 0)$	$(\times, 1)$	$(1, \times)$	$(1, 1)$
$\mathcal{I}$	0	0	0	$\times$	g	g	1	1	1

We create the interpretation of negation by taking the negation interpretations in  $\mathcal{I}_1$  and  $\mathcal{I}_2$  (recall that if  $|A| = \times$ , then  $|\neg A| = \times$  in Lukasiewicz's three-valued logic). This results in the table:

$A$	$\neg A$
0	1
$\times$	$\times$
g	g
1	0

Furthermore, on the set of truth values, we introduce a (partial) ordering:

and we define the interpretation of propositional connectives using the rules:

$$|A \rightarrow B| = \sup\{|\neg A|, |B|\}, |A \vee B| = \sup\{|A|, |B|\}, |A \wedge B| = \inf\{|A|, |B|\}$$

The semantics is thus a straightforward generalization of the semantics of Lukasiewicz's fuzzy propositional calculus.

Within this semantics, we define a tautology as a statement that, for any interpretation of the statements it is composed of, has an interpretation of 1 or g.

Furthermore, we say that statement  $A$  follows from the set of statements  $\{A_1, \dots, A_n\}$  if, for any interpretation of atomic statements such that statements  $A_1, \dots, A_n$  have an interpretation of 1 or g, statement  $A$  has an interpretation of 1 or g.

If statement  $A$  has an interpretation of  $\times$ , then statements  $A \vee \neg A$  and  $\neg(A \wedge \neg A)$  also have an interpretation of  $\times$  and are not tautologies. In the considered paraconsistent logic, the Law of Excluded Middle does not hold.

If statement  $A$  has an interpretation of g, and statement  $B$  has an interpretation of 1, then statement  $A \rightarrow B$  has an interpretation of 1, and statement  $A \rightarrow \neg B$  has an interpretation of g. This means that in paraconsistent logic, "local inconsistency" can occur (a case where a statement and its negation both follow from another statement). If statement  $A$  has an interpretation of g, then statement  $A \wedge \neg A$  also has an interpretation of g, and some statement  $B$  with an interpretation of 0 or  $\times$  does not follow from it. This means that the Law of Non-Contradiction does not hold in paraconsistent logic, and "global inconsistency" (a case where every statement follows from some set of statements) does not occur.

A propositional logic with "local inconsistencies" but without "global inconsistencies" is interesting because people sometimes hold beliefs that are factually contradictory and yet manage to work with them relatively successfully.

- i) For the first row  $(a, b)$  of a  $M \in G$  values  $a, b$  could be arbitrary except for  $a = 0, b = 0$  in  $\mathbb{Z}_3$ . Hence, there are  $3 \times 3 - 1 = 8$  possibilities to fill the first row. The second row should be not a multiple of the first row. The multiplication factor could be 0, 1 or 2. Hence, for the second row there are  $3 \times 3 - 3 = 6$  possibilities to fill the second row once the first row is filled. Thus,  $|G| = 8 \times 6 = 48$ .
- ii) The set of matrices  $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ , such that  $ad - bc = 1$  forms a normal subgroup in  $G$ . Note that for  $\forall g \in G$  values of  $\det g \in \mathbb{Z}_3$  can be either 1 or 2. E.g.  $\det g = 2$  for  $g = \begin{pmatrix} 2 & 2 \\ 1 & 2 \end{pmatrix}$  and  $\det h = 1$  for  $h = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$ . Hence,  $\det g' = 2 \quad \forall g' \in Hg$  and, conversely, if  $\det g' = 2$  then  $g' \in Hg$ . Multiplication by  $g$  bijectively maps  $H$  on  $Hg$ . Hence, index  $H \in G$  equals 2 and, therefore,  $|H| = \frac{|G|}{2} = 24$ .

□

**12.F.27.** If  $N$  is a normal subgroup of  $G$  and  $H$  is any subgroup in  $G$ , then  $NH$  is also a subgroup in  $G$ .

**Solution.** Let  $n_1h_1$  and  $n_2h_2$  are two elements in  $NH$  Then

- i)  $n_1h_1n_2h_2 = n_1h_1n_2(h_1)^{-1}h_1h_2 = n_1n_2'h_1h_2 = n'h' \in NH$ .
- ii)  $(nh)^{-1} = h^{-1}n^{-1} = h^{-1}n^{-1}h^{-1}h = n'h$ .

□

**12.F.28.** Suppose that  $N$  and  $M$  are two normal subgroups of  $G$  and  $N \cap M = \{e\}$ . Show that  $nm = mn$  for any  $n \in N$  and  $m \in M$ .

**Solution.** On the one hand,  $mnm^{-1}n^{-1} = m(nm^{-1}n^{-1}) = mm' \in M$ . On the other hand,  $mnm^{-1}n^{-1} = (mnm^{-1})n^{-1} = n'n^{-1} \in N$ . Hence  $mnm^{-1}n^{-1} \in M \cap N$ . So,  $mnm^{-1}n^{-1} = e$ . Thus,  $mn = nm$ . □

**12.F.29.** Show that the intersection of two normal subgroups of  $G$  is also a normal subgroup of  $G$ .

**Solution.** It is clear that the intersection of two subgroups of  $G$  is also a subgroup of  $G$ . Let  $N$  and  $M$  be normal subgroups of  $G$ . Then for any  $g \in G$  and any  $n \in N$  and any  $m \in M$  we have  $gnm^{-1} \in N$  and  $gmg^{-1} \in M$ . Let  $w \in N \cap M$ . Since  $w \in N$  we have  $gwg^{-1} \in N$  and since  $w \in M$  we have  $gwg^{-1} \in M$ . Hence  $gwg^{-1} \in N \cap M$  for any  $g \in G$  i.e.  $N \cap M$  is a normal subgroup of  $G$ . □

**12.F.30.** Prove that if  $G$  is some group and  $H \subset G$  its subgroup of index 2 then  $H$  is a normal subgroup of  $G$ .

**Solution.** Let  $H$  and  $aH$  be the left cosets of  $H$  in  $G$  and  $H$  and  $Hb$  be right cosets of  $H$  in  $G$ . Since there are only two cosets  $aH = G \setminus H$  and  $Hb = G \setminus H$ , then  $aH = Hb$ . In order to show that  $H$  is normal in  $G$ , we need  $xH = Hx$  for any  $x \in G$ . Let  $x \in G$ . If  $x \in H$  then, obviously,

### 3. Polynomial rings

The operations of addition and multiplication are fundamental in the case of scalars as well as vectors. There are other similar structures. Besides the integers  $\mathbb{Z}$ , rational numbers  $\mathbb{Q}$  and complex numbers  $\mathbb{C}$ , there are polynomials over similar scalars  $\mathbb{K}$  to be considered.

Among others, the abstract algebraic theory can be in many aspects viewed as a straightforward generalization of divisibility properties of integers.

**12.3.1. Rings and fields.** Recall that the integers and all other scalars  $\mathbb{K}$  have the following properties:

#### COMMUTATIVE RINGS AND INTEGRAL DOMAINS

**Definition.** Let  $(M, +, \cdot)$  be an algebraic structure with two binary operations  $+$  and  $\cdot$ . It is a *commutative ring*, if it satisfies

- $(a + b) + c = a + (b + c)$  for all  $a, b, c \in M$ ;
- $a + b = b + a$  for all  $a, b \in M$ ;
- there is an element  $0$  such that for all  $a \in M, 0 + a = a$ ;
- for each  $a \in M$ , there is the unique element  $-a \in M$  such that  $a + (-a) = 0$ .
- $(a \cdot b) \cdot c = a \cdot (b \cdot c)$  for all  $a, b, c \in M$ ;
- $a \cdot b = b \cdot a$  for all  $a, b \in M$ ;
- there is an element  $1$  such that for all  $a \in M, 1 \cdot a = a$ ;
- $a \cdot (b + c) = a \cdot b + a \cdot c$  for all  $a, b, c \in M$ .

If the ring is such that  $c \cdot d = 0$  implies either  $c$  or  $d$  is zero, then it is called an *integral domain*.

The first four properties define the algebraic structure of a *commutative group*  $(M, +)$ . Groups are considered in more detail in the next part of this chapter. The last property in the list of ring axioms is called *distributivity* of multiplication over addition. There are similar axioms for Boolean algebras where each of the operations is distributive over the other.

If the operation " $\cdot$ " is commutative for all elements, then the ring is called a commutative ring. Otherwise, the ring is called a non-commutative ring. In the sequel, rings are commutative unless otherwise stated. Traditionally, the operation " $+$ " is called addition, and the operation " $\cdot$ " multiplication, even if they are not the standard operations on one of the known rings of numbers.

In the literature, there are structures without the assumption of having the identity for multiplication. These are not discussed here, so it is always assumed that a ring has a multiplicative identity denoted by  $1$ . The identity for addition is denoted by  $0$ .

#### FIELDS

A non-trivial ring where all non-zero elements are invertible with respect to multiplication is called a *division ring*. If the multiplication is commutative, it is called a *field*.

$xH = H = Hx$  i.e.  $xH = Hx$ . If  $x \in G \setminus H = aH = Hb$  then there exist  $h_1, h_2 \in H$  such that  $x = ah_1 = h_2b$ . Then  $xH = (ah_1)H = aH = Hb = H(h_2b) = Hx$ , i.e.  $xH = Hx$  for any  $x \in G$ , so  $G^{-1}HG = H$ .  $\square$

**12.F.31.** Show that the intersection of two normal subgroups in  $G$  is a normal subgroup of  $G$ .

**Solution.** It is clear that the intersection of two subgroups of  $G$  is a subgroup of  $G$ : Let  $N$  and  $M$  be normal subgroups of  $G$ : Then for any  $g \in G$  and any  $n \in N$  and any  $m \in M$  we have  $gng^{-1} \in N$  and  $gmg^{-1} \in M$ . Let  $w \in N \cap M$ . Since  $w \in N$  we have  $gwg^{-1} \in N$  and since  $w \in M$  we have  $gwg^{-1} \in M$ . Hence  $gwg^{-1} \in N \cap M$  for any  $g \in G$  i.e.  $N \cap M$  is a normal subgroup in  $G$ .  $\square$

**12.F.32.** If  $N$  and  $M$  are normal subgroups of  $G$  show that  $NM$  is also a normal subgroup of  $G$ .

**Solution.** Let  $nm \in NM$ , then

$$gnmg^{-1} = gng^{-1}gmg^{-1} \in NM,$$

since  $gmg^{-1} \in M$  and  $gng^{-1} \in N$ .  $\square$

**12.F.33.** If  $N$  is a normal subgroup in the finite group such that  $\gcd(|G : N|, |N|) = 1$ . Show that  $N$  must contain any element  $x \in G$  satisfying  $x^{|N|} = e$ .

**Solution.** Let  $x$  be an element in  $G$  such that  $x^{|N|} = e$ . Since  $\gcd(|G : N|, |N|) = 1$  there exist  $m, n \in \mathbb{Z}$  such that

$$m|G : N| + n|N| = 1.$$

Then  $x = x^{m|G:N| + n|N|} = x^{m|G:N|} x^{n|N|}$ . Since  $x^{|N|} = e$  we have  $x = x^{m|G:N|}$ . Consider element  $xN \in G/N$ . Since  $xN^k = x^kN$  for any  $k \in \mathbb{Z}$ , then  $N = (xN)^{|G/N|} = x^{|G/N|}N$ , which is the identity element in  $G/N$ . This means  $x^{|G/N|} \in N$  and so  $x = (x^{|G/N|})^m \in N$ .  $\square$

**12.F.34.** If  $H$  is a subgroup of  $G$  such that the product of any two right cosets of  $H$  in  $G$  is again a right coset of  $H$  in  $G$  show that  $H$  is normal in  $G$ .

**Solution.** Let  $Ha$  and  $Hb$  be two right cosets of  $H \in G$ . By assumption  $HaHb$  is a right coset of  $H$  in  $G$ : The set  $HaHb$  contains the element  $eaeb = ab$ . Since there is only one right coset of  $H$  in  $G$  containing  $ab$ ; which is  $Hab$ ; we have  $HaHb = Hab$  for all  $a, b \in G$ . Hence  $HaH = Ha$  for all  $a \in G$ . i.e.  $h_1ah_2$  is equal to  $h_3a$  for some  $h_3 \in H$ . But  $h_1ah_2 = h_3a$  implies  $ah_2a^{-1} = h_1^{-1}h_3 = h' \in H$  for any  $h_2 \in H$  and  $a \in G$ . So,  $H$  is normal in  $G$ .  $\square$

**12.F.35.** Let  $Z(G)$  be centraliser of group  $G$  and  $xy = z \in Z(G)$  for some  $x, y \in G$ . Show that  $x$  and  $y$  commute.

**Solution.** As  $zx = xz$ , we have  $xyx = zx = xz = xxy$ . Multiplying by  $x^{-1}$  on the left, we obtain  $yx = xy$ .  $\square$

Typical examples of fields are the rational numbers  $\mathbb{Q}$ , the real numbers  $\mathbb{R}$ , and the complex numbers  $\mathbb{C}$ . Furthermore, every remainder class set  $\mathbb{Z}_p$  is a commutative ring, while only  $\mathbb{Z}_p$  for prime  $p$  are also fields. We shall come back to fields in the next part of this chapter, too.

Recall the useful example of a non-commutative ring, the set  $\text{Mat}_k(\mathbb{K})$  of all  $k$ -by- $k$  matrices over a ring  $\mathbb{K}$ ,  $k \geq 2$ . As can be checked for  $\mathbb{K} = \mathbb{Z}_2$  and  $k = 2$ , these rings are never an integral domain (see 2.1.5 on page 87 for the full argument).

As an example of a division ring which is not a field, consider the ring of quaternions  $\mathbb{H}$ . This is constructed as an extension of the complex numbers, by adding another imaginary unit  $j$ , i.e.  $\mathbb{H} = \mathbb{C} \oplus j\mathbb{C} \simeq \mathbb{R}^4$ , just as the complex numbers are obtained from the reals. Another “new” element  $i \cdot j$  is usually denoted  $k$ . It follows from the construction that  $ij = -ji$ . This structure is a division ring. Think out the details as a not completely easy exercise!

**12.3.2. Elementary properties of rings.** The following

lemma collects properties which all seem to be obvious for rings of scalars. But the properties need proof to build an abstract

theory:

**Lemma.** In every commutative ring  $\mathbb{K}$ , the following holds

- (1)  $0 \cdot c = c \cdot 0 = 0$  for all  $c \in \mathbb{K}$ ,
- (2)  $-c = (-1) \cdot c = c \cdot (-1)$  for all  $c \in \mathbb{K}$ ,
- (3)  $-(c \cdot d) = (-c) \cdot d = c \cdot (-d)$  for all  $c, d \in \mathbb{K}$ ,
- (4)  $a \cdot (b - c) = a \cdot b - a \cdot c$ ,
- (5) the entire ring  $\mathbb{K}$  collapses to the trivial set  $\{0\} = \{1\}$  if and only if  $0 = 1$ .

**PROOF.** All of the propositions are direct consequences of the definition axioms. In the first case, for any  $c, a$

$$c \cdot a = c \cdot (a + 0) = c \cdot a + c \cdot 0,$$

and since  $0$  is the only element that is neutral with respect to addition,  $c \cdot 0 = 0$ .

In the second case, it suffices to compute

$$0 = c \cdot 0 = c \cdot (1 + (-1)) = c + c \cdot (-1).$$

This means that  $c \cdot (-1)$  is the inverse of  $c$ , as desired.

The following two propositions are direct consequences of the second proposition and the axioms. If the ring contains only one element, then  $0 = 1$ . On the other hand, if  $1 = 0$ , then for any  $c \in \mathbb{K}$ , necessarily  $c = 1 \cdot c = 0 \cdot c = 0$ .  $\square$

**12.3.3. Polynomials over rings.** The definition of a commu-

tative ring uses precisely the properties that are expected for multiplication and addition. The concept of polynomials can now be extended. A *polynomial* is any expression that can be built from (known) constant elements of  $\mathbb{K}$  and an (unknown) variable using finite number of additions and multiplications. Formally, polynomials are defined as follows:<sup>4</sup>

<sup>4</sup>It is not by accident that the symbol  $\mathbb{K}$  is used for the ring – you can imagine e.g. any of the number rings behind that.

**12.F.36.** Let  $G$  be a group of  $2 \times 2$  matrices  $M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$  such that  $ad - bc \neq 0, a, b, c, d \in \mathbb{R}$ . Let subgroup  $H = \left\{ \begin{pmatrix} 1 & 0 \\ x & 1 \end{pmatrix} \mid x \in \mathbb{Z} \right\} \in G$  and  $g = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}$ . Show that  $H \neq gHg^{-1} \subset H$ .

**Solution.** Obviously, matrix  $\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \in H$ . However,

$$\begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ x & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \frac{1}{2} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 2x & 2 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \frac{1}{2} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 2x & 1 \end{pmatrix}$$

Thus,  $g^{-1}Hg = \left\{ \begin{pmatrix} 1 & 0 \\ 2x & 1 \end{pmatrix} \mid x \in \mathbb{Z} \right\}$  does not contain  $\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \in H$ .  $\square$

**12.F.37.** Let  $G$  be a group of an even order. Prove that it contains a subgroup of order 2.

**Solution.** Consider the set of pairs  $\Omega = \{g, g^{-1}\}$ , where  $g \neq g^{-1}$ . This engages an even number of elements of  $G$ . Those elements  $g \in G$  that are not in  $\Omega$  are the ones satisfying  $g = g^{-1}$  i.e.,  $g^2 = e$ . Therefore if we count  $G \bmod 2$ , we can ignore the pairs  $\{g, g^{-1}\} \in \Omega$  and obtain  $|G| \equiv |\{g \in G \mid g^2 = e\}| \pmod{2}$ . One solution to  $g^2 = e$  is  $e$  itself. If it were the only solution, then  $|G| \equiv 1 \pmod{2}$ , which is false. Therefore some  $g \neq e$  satisfies  $g^2 = e$ , which provides an element and also a subgroup in  $G$  of order 2.  $\square$

**12.F.38.** Let  $G$  be finite abelian group, which order  $n$  is divisible by prime factor  $p$ . Show that  $G$  contains an element of order  $p$  and, hence a cyclic subgroup of that order. This claim is known as abelian case of Cauchy theorem.

**Solution.** We use induction on  $n$ . Case  $n = p$  is trivial. Let  $n > p$  and  $p|n$  and the proposition is true for all abelian groups of orders divisible by  $p$  and less than  $n$ . Assume no element of  $G$  has order  $p$ . Then no element has order divisible by  $p$ , because if  $g \in G$  has order  $r$  and  $p|r$  then  $g^{\frac{r}{p}}$  would have order  $p$ . Let  $G = \{g_1, g_2, \dots, g_n\}$  and let  $g_i$  have order  $m_i$  so  $m_i$  is not divisible by  $p$ . Set  $m$  to be the least common multiple of all  $m_i, i = 1, 2, \dots, n$ , so  $m$  is not divisible by  $p$  and  $g^{m_i} = e$  for all  $i$ . Because  $G$  is abelian, the function  $f : (\mathbb{Z}/m)^n \rightarrow G$  given by

$$f(a_1, \dots, a_n) = g_1^{a_1} \dots g_n^{a_n}.$$

is a homomorphism  $f(a_1, \dots, a_n)f(b_1, \dots, b_n) = f(a_1 + b_1, \dots, a_n + b_n)$ . as, by commutativity of  $G$ ,

$$g_1^{a_1} \dots g_n^{a_n} g_1^{b_1} \dots g_n^{b_n} = g_1^{a_1+b_1} \dots g_n^{a_n+b_n}$$

's. This homomorphism is surjective (each element of  $g_i \in G$  is  $F(a_1, \dots, a_n)$  for  $a_i = 1$  and other  $a_j = 0, j \neq i$ .  $g_i$ , and if  $a_i = 1$  and other  $a_j$ 's are 0 then  $f(a_1, \dots, a_n) = g_i$ ) and the elements where  $f$  takes particular value  $g_i$  is a coset of  $\ker f$ , so  $|G| = \text{number of cosets of } \ker f$  which is a factor of  $|\mathbb{Z}/m|^n$ , which is a factor of  $m^n$ . Since  $p||G|$  and  $m^n$  is not divisible by  $p$ , this is a contradiction.  $\square$

POLYNOMIALS

**Definition.** Let  $\mathbb{K}$  be a commutative ring. A polynomial over  $\mathbb{K}$  is a finite expression

$$f(x) = \sum_{i=0}^k a_i x^i,$$

where  $a_i \in \mathbb{K}, i = 0, 1, \dots, k$  are the *coefficients of the polynomial*. If  $a_k \neq 0$ , then by definition,  $f(x)$  has *degree*  $k$ , written  $\deg f = k$ . The zero polynomial is not assigned a degree. Polynomials of degree zero (called *constant polynomials*) are exactly the non-zero elements of  $\mathbb{K}$ .

Polynomials  $f(x)$  and  $g(x)$  are equal if they have the same coefficients. The set of all polynomials over a ring  $\mathbb{K}$  is denoted  $\mathbb{K}[x]$ .

Every polynomial defines a mapping  $f : \mathbb{K} \rightarrow \mathbb{K}$  by substituting the argument  $c$  for the variable  $x$  and evaluating the resulting expression, i.e.

$$f(c) = a_0 + a_1c + \dots + a_kc^k.$$

Note that constant polynomials define constant mappings in this manner.

A *root of a polynomial*  $f(x)$  is such an element  $c \in \mathbb{K}$  for which  $f(c) = 0 \in \mathbb{K}$ .

It may happen that different polynomials define the same mapping. For instance, the polynomial  $x^2 + x \in \mathbb{Z}_2[x]$  defines the mapping which is constantly equal to zero. More generally, for every finite ring  $\mathbb{K} = \{a_0, a_1, \dots, a_k\}$ , the polynomial  $f(x) = (x - a_0)(x - a_1) \dots (x - a_k)$  defines the constant-zero mapping.

Polynomials  $f(x) = \sum_i a_i x^i$  and  $g(x) = \sum_i b_i x^i$  can be added and multiplied in a natural way (just think to introduce again the structure of a ring and invoke the expected distributivity of multiplication over addition):

$$\begin{aligned} (f + g)(x) &= (a_0 + b_0) + (a_1 + b_1)x + \dots + (a_k + b_k)x^k, \\ (f \cdot g)(x) &= (a_0b_0) + (a_0b_1 + a_1b_0)x + \dots \\ &\quad + (a_0b_r + a_1b_{r-1} + a_r b_0)x^r + \dots + a_k b_\ell x^{k+\ell}, \end{aligned}$$

where  $k \geq \ell$  are the degrees of  $f$  and  $g$ , respectively. Zero coefficients are assumed everywhere where there is no coefficient in the original expression.<sup>5</sup>

This definition corresponds to the addition and multiplication of the function values of  $f, g : \mathbb{K} \rightarrow \mathbb{K}$ , by the properties of "coefficients" in the original ring  $\mathbb{K}$ .

It follows directly from the definition that the set of polynomials  $\mathbb{K}[x]$  over a commutative ring  $\mathbb{K}$  is again a commutative ring, where the multiplicative identity is the element  $1 \in \mathbb{K}$ , perceived as a polynomial of degree zero. The additive identity is the zero polynomial. You should check all the axioms carefully!

<sup>5</sup>To avoid this formal hassle, a polynomial can be defined as an infinite expression (like a formal power series over the ring in question) with the condition that only finitely many coefficients are non-zero. Concerning the order, zero polynomial is also attributed to have order  $-\infty$ .

**12.F.39.** Let  $G$  be finite -abelian group, which order  $n$  is divisible by prime factor  $p$ . Show that  $G$  contains an element of order  $p$  and, hence a cyclic subgroup of that order. This is non-abelian case of Cauchy theorem.

**Solution.** If a proper subgroup  $H$  of  $G$  has order divisible by  $p$ , then by induction there is an element of order  $p$  in  $H$ , which gives us an element of order  $p$  in  $G$ . Thus we may assume no proper subgroup of  $G$  has order divisible by  $p$ . For any proper subgroup  $H \subset G$  we have  $|G| = |H|[G : H]$  and  $|H|$  is not divisible by  $p$ , so  $p \mid [G : H]$  for every proper subgroup  $H$ . Denote conjugacy class of an element  $a \in G$  by  $C(a) = \{b \in G \mid b = g^{-1}ag \text{ for some } g \in G\}$ . Let the conjugacy classes in  $G$  with size greater than 1 be represented by  $g_1, g_2, \dots, g_k$ . The conjugacy classes of size 1 are the elements of the center  $Z(G)$ . Since the conjugacy classes are a partition of  $G$ , counting  $|G|$  by counting conjugacy classes implies

$$|G| = |Z(G)| + \sum_{i=1}^k |C(g_i)| = |Z(G)| + \sum_{i=1}^k [G : Z(g_i)],$$

where  $Z(g_i)$  is the centraliser of  $g_i$ . Every  $[G : Z(g_i)] > 1$  since each  $C(g_i)$  is greater than 1. Since  $\forall j, |G| = |Z(g_i)[G : Z(g_i)]$ , it yields  $p \mid [G : Z(g_i)]$ . Thus,  $|Z(G)|$  is divisible by  $p$  and so is non-trivial. Since proper subgroups of  $G$  do not have order divisible by  $p$ , center  $Z(G)$  has to be all of  $G$ . That means  $G$  is abelian, which is a contradiction.  $\square$

**12.F.40.** Prove that any group of order 15 is cyclic.

**Solution.** Let  $G$  be a group of order 15. By Cauchy's theorem there exists a subgroup  $M$  of order 5 and a subgroup  $N$  of order 3.  $[G : M] = \frac{|G|}{|M|} = 3$ . Both  $M$  and  $N$  are cyclic subgroups. Let  $x$  be a generator of  $M$  and  $y$  - the generator of  $N$ . Let's prove that  $xy$  generates entire  $G$ . (NEED TO COME UP WITH AN ELEGANT PROOF..)

$$(xg)^5 =$$

$\square$

**12.F.41.** Let  $G$  be a group of order 14 which has a normal subgroup  $N$  of order 2. Prove that  $G$  is commutative.

**Solution.** Clearly, the order of the group  $G/N$  is  $|G/N| = \frac{|G|}{|N|} = 7$ . By Lagrange's theorem 12.4.10, the orders of its elements are 1 or 7. Since only the identity has order 1, this means that there is an element of order 7, so that the group  $G/N$  is cyclic. Let  $N = \{e, n\}$ , where  $e$  is the identity of  $G$  and let  $[a]$  be the generator of  $G/N$ . Since  $N$  is normal, we have  $ana^{-1} \in N$ , but  $ana^{-1} = e$  implies  $n = e$ , which means that we must have  $ana^{-1} = n$ , i. e.,  $na = an$ . Since  $[a]$  generates  $G/N$ , we get that each element of  $G/N$  is of the form  $[a]^k, k = 0, \dots, 6$ , i. e.,  $[a^k]$ . Then, each element of  $G$

**Lemma.** A polynomial ring over an integral domain is again an integral domain.

**PROOF.** The task is to show that  $\mathbb{K}[x]$  can contain non-trivial divisors of zero only if they are in  $\mathbb{K}$ . However, this is clear from the expression for polynomial multiplication. If  $f(x)$  and  $g(x)$  are polynomials of degree  $k$  and  $\ell$  as above, then the coefficient at  $x^{k+\ell}$  in the product  $f(x) \cdot g(x)$  is the product  $a_k \cdot b_\ell$ , which is non-zero unless there are zero divisors in  $\mathbb{K}$ .  $\square$

**12.3.4. Multivariate polynomials.** Some objects can be described using polynomials with more variables.

For instance, consider a circle in the plane  $\mathbb{R}^2$  whose center is at  $S = (x_0, y_0)$  and whose radius is  $R$ . This circle can be defined by the equation

$$(x - x_0)^2 + (y - y_0)^2 - R^2 = 0.$$

Rings of polynomials in variables  $x_1, \dots, x_r$  can be defined similarly as in the case of  $\mathbb{K}[x]$ . Instead of the powers  $x^k$  of a single variable  $x$ , consider the *monomials*

$$x_1^{k_1} \dots x_r^{k_r},$$

and their formal linear combinations with coefficients  $a_{k_1 \dots k_r} \in \mathbb{K}$ .

However, it is simpler, both formally and technically, to define them inductively by

$$\mathbb{K}[x_1, \dots, x_r] := (\mathbb{K}[x_1, \dots, x_{r-1}])[x_r].$$

For instance,  $\mathbb{K}[x, y] = \mathbb{K}[x][y]$ . One can consider polynomials in the variable  $y$  over the ring  $\mathbb{K}[x]$ . It can be shown (check this in detail!) that polynomials in variables  $x_1, \dots, x_r$  can be viewed, even with this definition, as expressions created from the variables  $x_1, \dots, x_n$  and the elements of the ring  $\mathbb{K}$  with a finite number of (formal) addition and multiplication in a commutative ring. For example, the elements of  $\mathbb{K}[x, y]$  are of the form

$$\begin{aligned} f &= a_n(x)y^n + a_{n-1}(x)y^{n-1} + \dots + a_0(x) = \\ &= (a_{mn}x^m + \dots + a_{0n})y^n + \dots + (b_{p0}x^p + \dots + b_{00}) = \\ &= c_{00} + c_{10}x + c_{01}y + c_{20}x^2 + c_{11}xy + c_{02}y^2 + \dots \end{aligned}$$

To simplify the notation, we use the multi-index notation (as we did with real polynomials and partial derivatives in infinitesimal analysis).

is of the form  $a^k$  or  $a^k n$ , and since  $a$  and  $n$  commute, we get that actually all elements of  $G$  commute.  $\square$

**12.F.42.** Decide whether the following holds: If the quotient  $G/N$  of a group  $G$  by a normal subgroup  $N$  is commutative, then  $G$  itself is commutative.  $\circ$

**12.F.43.** Prove that any subgroup  $H$  of the symmetric group  $\mathbb{S}_n$  contains either only even permutations or the same number of even and odd permutations.

**Solution.** Consider the homomorphism  $p : H \rightarrow \mathbb{Z}_2$  which maps each permutation to its parity (0 for even and 1 for odd). Then,  $p^{-1}(0) = \text{Ker}(p)$  is a normal subgroup of  $H$ : let  $h \in \text{Ker}(p)$ , then

$$p(ghg^{-1}) = p(g)p(h)p(g^{-1}) = p(g)p(g^{-1}) = p(gg^{-1}) = p(e) = 0,$$

which means that  $ghg^{-1} \in \text{Ker}(p)$ , i. e.,  $\text{Ker}(p)$  is normal. Since  $\mathbb{Z}_2$  has only two elements, it follows that  $H/\text{Ker}(p)$  has either only one coset (i. e., all permutations are even) or two cosets, which must be of equal size (i. e., there are the same number of even and odd permutations).  $\square$

**12.F.44.** Describe the group of symmetries of a regular tetrahedron and find all of its subgroups.

**Solution.** Let us denote the vertices of the tetrahedron as  $a, b, c, d$ . Each symmetry can be described as a permutation of the vertices (to which vertex each one goes). Thus, the group of symmetries of the tetrahedron is isomorphic to a certain subgroup of the symmetric group  $\mathbb{S}_4$ . Given any pair of vertices, there exists a symmetry which swaps this pair and keeps the other two vertices fixed (this is reflection with respect to the plane that is perpendicular to the line segment of the pair and goes through its center). Thus, the wanted subgroup is generated by all transpositions in  $\mathbb{S}_4$ . However, this is the group  $\mathbb{S}_4$  itself.

Thus, let us describe all subgroups of the group  $\mathbb{S}_4$ . This group has 24 elements, which means that the order of any subgroup must be one of 1, 2, 3, 4, 6, 8, 12, 24 (see 12.4.10). Clearly, the only group of order 1 is the trivial subgroup  $\{id\}$ . Similarly, the only group of order 24 is the entire group  $\mathbb{S}_4$ . Now, let us look at the remaining orders of a potential subgroup  $H \subseteq \mathbb{S}_4$ .

(i)  $|H| = 2$ .  $H$  must consist of the identity and another self-inverse element ( $x^2 = id$ ). These are transpositions and double transpositions (compositions of two disjoint transpositions). Geometrically, double transpositions correspond to rotation by  $180^\circ$  around the axis that goes through the centers of opposite edges). Thus, we get nine subgroups:  $\{id, (a, b)\}$ ,  $\{id, (a, c)\}$ ,  $\{id, (a, d)\}$ ,  $\{id, (b, c)\}$ ,  $\{id, (b, d)\}$ ,  $\{id, (c, d)\}$ ,  $\{id, (a, b) \circ (c, d)\}$ ,  $\{id, (a, c) \circ (b, d)\}$ ,  $\{id, (a, d) \circ (b, c)\}$ .

(ii)  $|H| = 3$ . By Lagrange's theorem, such a subgroup must be cyclic, i. e., it must be of the form  $\{id, p, p^2\}$ ,  $p^3 = id$ . Thus, the factorization of  $p$  to independent cycles must contain a cycle of length 3, which means that  $p$  cannot contain anything else. By 12.F.17, there are  $4 \cdot 2$  cycles of length 3, which give rise to the following four

MULTI-INDICES

A *multi-index*  $\alpha$  of length  $r$  is an  $r$ -tuple of non-negative integers  $(\alpha_1, \dots, \alpha_r)$ . The integer  $|\alpha| = \alpha_1 + \dots + \alpha_r$  is called the *size* of the multi-index  $\alpha$ .

Monomials are written shortly as  $x^\alpha$  instead of  $x_1^{\alpha_1} x_2^{\alpha_2} \dots x_r^{\alpha_r}$ . Polynomials in  $r$  variables can be symbolically expressed in a similar way as univariate polynomials:

$$f = \sum_{|\alpha| \leq n} a_\alpha x^\alpha, \quad g = \sum_{|\beta| \leq m} b_\beta x^\beta \in \mathbb{K}[x_1, \dots, x_r].$$

$f$  is said to have total degree  $n$  if at least one coefficient with multi-indices  $\alpha$  of size  $n$  is non-zero, while all the coefficients with multi-indices of larger sizes vanish.

Analogous formulae can be defined for addition and multiplication of multivariate polynomials of degrees  $m$  and  $n$  respectively:

$$f + g = \sum_{|\alpha| \leq \max(m, n)} (a_\alpha + b_\alpha) x^\alpha,$$

$$fg = \sum_{|\gamma|=0}^{m+n} \left( \sum_{\alpha+\beta=\gamma} a_\alpha b_\beta \right) x^\gamma,$$

where the multi-indices are added componentwise, and the formally non-existing coefficients are assumed to be zero. Clearly in the case of univariate polynomials we recover the formula

$$fg(x) = \sum_{i=0}^{k+\ell} \left( \sum_{p+q=i} a_p b_q \right) x^i.$$

**Lemma.** *These formulae describe addition and multiplication in the inductively defined ring of polynomials in  $r$  variables. In particular, in a polynomial ring over integral domain, the total degree of a sum or difference of two polynomials (if defined) is at most the maximum of their total degrees, while the total degree of a product of two polynomials is the sum of their total degrees.*

**PROOF.** The proposition is easily proved by induction on the number of variables. Suppose that the formulae are valid in  $\mathbb{K}[x_1, \dots, x_{r-1}]$ , and calculate the sum

$$f = a_k(x_1, \dots, x_{r-1})x_r^k + \dots + a_0(x_1, \dots, x_{r-1})$$

$$= \left( \sum_{\alpha} a_{k, \alpha} x^\alpha \right) x_r^k + \dots,$$

$$g = b_l(x_1, \dots, x_{r-1})x_r^l + \dots + b_0(x_1, \dots, x_{r-1})$$

$$= \left( \sum_{\beta} b_{l, \beta} x^\beta \right) x_r^l + \dots,$$

$$f + g = (a_0(x_1, \dots, x_{r-1}) + b_0(x_1, \dots, x_{r-1}))$$

$$+ (a_1(x_1, \dots, x_{r-1}) + b_1(x_1, \dots, x_{r-1}))x_r + \dots$$

subgroups:  $\{\text{id}, (a, b, c), (a, c, b)\}$ ,  $\{\text{id}, (a, c, d), (a, d, c)\}$ ,  $\{\text{id}, (a, b, d), (a, d, b)\}$ ,  $\{\text{id}, (b, c, d), (b, d, c)\}$ . The cycles of length 3 correspond to rotation by  $120^\circ$  around the axis that goes through a vertex and the center of the opposite side.

(iii)  $|H| = 4$ . Such a subgroup must be isomorphic to  $\mathbb{Z}_4$  or  $\mathbb{Z}_2 \times \mathbb{Z}_2$ . Considering the factorization to independent cycles, we find out that the only permutation of order 4 is a cycle of length 4. Thus, cyclic subgroups must contain a cycle of length 4, namely exactly two of them, since if  $p$  has order 4, then  $p^{-1} = p^3$  is also of order 4 i. e., a cycle of length 4. Then, the permutation  $p^2$  has order 2, so it must be a double transposition (it is not a single transposition, since  $p^2$  clearly does not have a fixed point). There are six cycles of length 4 (see 12.F.17), and they pair up to the following three subgroups of this type:

$$\begin{aligned} &\{\text{id}, (a, b, c, d), (a, c) \circ (b, d), (a, d, c, b)\}, \\ &\{\text{id}, (a, c, b, d), (a, b) \circ (b, d), (a, d, b, c)\}, \\ &\{\text{id}, (a, b, d, c), (a, d) \circ (bc), (a, c, d, b)\}. \end{aligned}$$

As for subgroups isomorphic to  $\mathbb{Z}_2 \times \mathbb{Z}_2$ , they must contain (besides the identity) only elements of order 2, which are transpositions and double transpositions. By 12.F.43, the subgroup must contain either no or exactly two transpositions. Moreover, it cannot contain two dependent transpositions, since their composition is a cycle of length 3. Thus, the subgroup contains (besides the identity) either two independent transpositions and the double transposition which is their composition (this gives rise to three subgroups), or the three double transpositions. Altogether, we have found:  $\{\text{id}, (a, b), (a, b) \circ (c, d), (c, d)\}$ ,  $\{\text{id}, (a, c), (a, c) \circ (b, d), (b, d)\}$ ,  $\{\text{id}, (a, d), (a, d) \circ (b, c), (b, c)\}$  and  $\{\text{id}, (a, b) \circ (c, d), (a, c) \circ (b, d), (a, d) \circ (b, c)\}$ .

(iv)  $|H| = 6$ . By 12.F.11, this subgroup is isomorphic to  $\mathbb{S}_3$  (it cannot be isomorphic to  $\mathbb{Z}_6$  since there is no element of order 6 in  $\mathbb{S}_4$ ), so it contains (besides the identity) two elements  $x, x^{-1}$  of order 3 and three elements of order 2. Thus,  $x$  and  $x^{-1}$  are cycles of length 3 which fix the same vertex (say  $a$ ). What are the other three elements? There cannot be a double transposition, since its composition with  $x$  yields another cycle of length 3. There cannot be a transposition which does not fix  $a$  since its composition with  $x$  yields a cycle of length 4. Thus, the only possibility is that there are the three transpositions which also fix  $a$ . Since there are four possibilities which vertex is the fixed one, we obtain four subgroups of order 6.

(v)  $|H| = 8$ . The group cannot be a subgroup of the group  $\mathbb{A}_4$  of even permutations (since there are 12 of them, and 8 does not divide 12). Thus, by 12.F.43,  $H$  must contain four even and four odd permutations. The even permutations must form a subgroup of  $\mathbb{A}_4$ , and we could see in (iii) that the only such 4-element subgroup is  $\{\text{id}, (a, b) \circ (c, d), (a, c) \circ (b, d), (a, d) \circ (b, c)\}$ , which is normal. Considering any odd permutation and the coset (with respect to the above normal subgroup) which contains it, we can see that the coset together with the above 4 elements form a subgroup of  $\mathbb{S}_4$ . We thus get three subgroups of  $\mathbb{S}_4$ . It is not hard to realize that

$$\begin{aligned} &= \left( \sum_{\gamma} (a_{k,\gamma} + b_{k,\gamma})(x_1, \dots, x_{r-1})^{\gamma} \right) x_r^k + \dots \\ &+ \left( \sum_{\gamma} (a_{0,\gamma} + b_{0,\gamma})(x_1, \dots, x_{r-1})^{\gamma} \right) \\ &= \sum_{(\gamma,j)} (a_{j,\gamma} + b_{j,\gamma})(x_1, \dots, x_{r-1})^{\gamma} x_r^j. \end{aligned}$$

The proof for multiplication is similar (do it yourselves!).  $\square$

The definition or the above formulae for polynomials over general commutative rings yield the following corollary:

**Corollary.** *If a ring  $\mathbb{K}$  is an integral domain, then the ring  $\mathbb{K}[x_1, \dots, x_r]$  is also an integral domain.*

**PROOF.** Proceed by induction on the number  $r$  of variables.<sup>6</sup> We know the result for the univariate polynomials already. In particular, the product of non-zero polynomials is again non-zero.

If the proposition holds for  $r-1$  variables, then the result follows from the inductive definition of the polynomials.  $\square$

Let us notice that each polynomial  $f \in \mathbb{K}[x_1, \dots, x_n]$  also represents a mapping  $\mathbb{K} \times \dots \times \mathbb{K} \rightarrow \mathbb{K}$  multilinear and symmetric in its  $n$  arguments.

**12.3.5. Divisibility and irreducibility.** The next goal is to understand how polynomials over a general integral domain can be expressed as products of simpler polynomials. In the case of univariate polynomials, this means finding the roots of a polynomial. Since multivariate polynomials can be defined inductively, it suffices to consider univariate polynomials over a general integral domain. This leads to a generalization of the concept of divisibility which forms the basis of elementary number theory in chapter eleven.

Consider an integral domain  $\mathbb{K}$  (for instance, the integers  $\mathbb{Z}$  or the ring  $\mathbb{Z}_p$  for prime  $p$ ).

DIVISIBILITY IN RINGS

For  $a, c \in \mathbb{K}$  we say that  $a$  divides  $c$  in  $\mathbb{K}$  if and only if there is some  $b \in \mathbb{K}$  such that  $a \cdot b = c$ . This is written  $a|c$ .

The divisors of 1 (the multiplicative identity), i.e. the invertible elements of  $\mathbb{K}$ , are called *units*.

The units of a commutative ring always form a commutative group in the sense used for the properties of addition in the definition of rings. This is called the group of units in  $\mathbb{K}$ . The group of units in  $\mathbb{Z}$  is  $\{-1, 1\}$ , while all nonzero elements in a field are units there.

In an integral domain, the divisors are determined uniquely. If  $b = a \cdot c$  and  $b \neq 0$ , then  $c$  is determined by the choice of  $a$  and  $b$ , since if  $b = ac = ac'$ , then  $0 = a \cdot (c - c')$

<sup>6</sup>Alternatively, proceed directly using multi-index formulae for the product, provided an appropriate ordering on monomials is defined, see the last part of this chapter.

each of them is isomorphic to the group of symmetries of a square (the so-called dihedral group  $D_4$ ). From the geometrical point of view, we can describe it as follows: Consider the orthogonal projection of the tetrahedron onto the plane that is perpendicular to the line that goes through the centers of opposite edges. The boundary of this projection is a square. Out of all the symmetries of the tetrahedron, we take only those which induce a symmetry of this square (for instance, it will not be a symmetry which only swaps adjacent vertices of the resulting square). Since there are three pairs of opposite edges in the tetrahedron, we get three 8-element subgroups, isomorphic to the dihedral group  $D_4$ . (vi)  $|H| = 12$ . By 12.F.43, such a subgroup contains either only even permutations, or six even and six odd permutations, and the six even permutations must form a subgroup of  $S_4$ . However, we could see in (iv) that there is no 6-element subgroup of  $S_4$  consisting only of even permutations. Thus, the only possibility is the alternating group  $A_4$  of all even permutations in  $S_4$ . From the geometric point of view, these are the so-called direct symmetries, which are realized by rotations (not reflections), and thus can be performed in the space.  $\square$

**Remark.** In general, the group of symmetries of a solid with  $n$  vertices is a subgroup of the symmetric group  $S_n$ .

**12.F.45.** Which subgroups of the group  $S_4$  are normal?

**Solution.** By definition, a subgroup  $H \subseteq S_4$  is normal iff it is closed under conjugation, i. e.,  $ghg^{-1} \in H$  for any  $g \in S_4$ ,  $h \in H$ . Since conjugation in symmetric groups only renames the permuted items but preserves the permutation structure (i. e. the cycle lengths in the factorization to independent cycles), we can see that  $H$  is normal if and only if it contains either no or all permutations of each type. Examining all the subgroups, which we found in the previous exercise, we find that the normal ones are the trivial group  $\{id\}$ , the so-called Klein group (consisting of the identity and the three double transpositions, which we already met in 12.F.8), the alternating group  $A_4$  of all even permutations, and the entire group  $S_4$ .  $\square$

**12.F.46.** Find the group of symmetries of a cube (describe all symmetries). Is this group commutative?

**Solution.** The group has 48 elements; 24 of them are generated by rotations (these are the so-called direct symmetries), the other 24 are the composition of a direct symmetry and a reflection. The group is not commutative (consider the composition of a reflection with respect to the plane containing the centers of four parallel edges and a rotation by  $90^\circ$  around the axis that lies in the plane and goes through the centers of two opposite sides. The group is isomorphic to  $S_4 \times Z_2$ .  $\square$

**12.F.47.** In the group of symmetries of a cube, find the subgroup generated by a reflection with respect to the plane containing the centers of four parallel edges and the rotation by  $180^\circ$  around the axis that lies in the plane and goes through the centers of two opposite sides. Is this subgroup normal?

$\circ$

and being in an integral domain,  $a \neq 0$  implies  $c = c'$ . The reader should check that the claim is wrong e.g. in  $Z_4$ .

Just as for integers, the following propositions are direct corollaries of the definitions (check the details yourself!):

**Lemma.** Let  $a, b, c \in \mathbb{K}$ . Then,

- (1) if  $a|b$  and  $b|c$ , then  $a|c$ ;
- (2) if  $a|b$  and  $a|c$ , then  $a|(\alpha b + \beta c)$  for all  $\alpha, \beta \in \mathbb{K}$ ;
- (3)  $a|0$  (since  $a \cdot 0 = 0$ , in particular  $0|0$ );
- (4)  $a \in \mathbb{K}$  is divisible by each unit  $e \in \mathbb{K}$  and its  $a$ -multiple  $a \cdot e$  (this follows from the existence of  $e^{-1}$ ).

#### UNIQUE FACTORIZATION DOMAIN

An element  $a \in \mathbb{K}$  is said to be *irreducible* if and only if it is divisible only by units  $e \in \mathbb{K}$  and their  $a$ -multiples.

A ring  $\mathbb{K}$  is called a *unique factorization domain* if and only if the following conditions hold:

- For every non-zero element  $a \in \mathbb{K}$ , there are irreducible elements  $a_1, \dots, a_r \in \mathbb{K}$  such that  $a = a_1 \cdot a_2 \cdot \dots \cdot a_r$ . This is called *factorization* of  $a$ .
- If there are two factorizations of  $a$  into irreducible non-unit elements  $a = a_1 a_2 \dots a_r = b_1 b_2 \dots b_s$ , then  $r = s$  and, up to a permutation of the order of the factors  $b_j$ ,  $a_j = e_j b_j$  for suitable units  $e_j, j = 1, \dots, r$ .

$Z$  is a unique factorization domain. So is every field, since every non-zero element is a unit.

There are examples of integral domains without the unique factorization property. The construction is similar to polynomials. Instead of powers, consider conveniently combined roots of powers of the unknown variable  $x$ .

An integral domain  $\mathbb{K}$  consists of finite expressions of the form

$$a_0 + \sum_{i=1}^k a_i (x^{m_i})^{\frac{1}{2^{n_i}}},$$

where  $a_0, \dots, a_k \in Z, m_i, n \in Z_{>0}$ . The multiplication and addition is defined as with polynomials assuming the standard behaviour of rational powers of  $x$ . Then, the only units in  $\mathbb{K}$  are  $\pm 1$ , and all elements with  $a_0 = 0$  are reducible, but the expression  $x$ , for example, cannot be expressed as a product of irreducible elements. There are simply very few irreducible elements in  $\mathbb{K}$ .

#### 12.3.6. Euclidean division and roots of polynomials.

The fundamental tool for the discussion of divisibility, common divisors, etc. in the ring of integers  $Z$  is the procedure of division with remainder, and the Euclidean algorithm for the greatest common divisor. These procedures can be generalized.

Consider univariate polynomials  $a_k x^k + \dots + a_0$  over a general integral domain  $\mathbb{K}$ .  $a_k x^k$  is called the *leading monomial*, while  $a_k$  is the *leading coefficient*.

**Lemma** (An algorithm for division with remainder). Let  $\mathbb{K}$  be an integral domain and  $f, g \in \mathbb{K}[x]$  polynomials,  $g \neq 0$ .

**12.F.48.** For each of the following permutations, decide whether the subgroup it generates is normal in the corresponding group:

- $(1, 2, 3)$  in  $\mathbb{S}_3$ ,
- $(1, 2, 3, 4)$  in  $\mathbb{S}_4$ ,
- $(1, 2, 3)$  in  $\mathbb{A}_4$

For the last case, find the right cosets of  $\mathbb{A}_4$  by the considered subgroup. Find all  $n \geq 3$  for which the subset of all cycles of length  $n$  together with the identity is a subgroup of  $\mathbb{S}_n$ . Show that if this is so, then it is even a normal subgroup.

**Solution.**

- It is a normal subgroup of  $A_3$ .
- It is not a normal subgroup ( $(1, 2) \circ (1, 3) \circ (2, 4) \circ (1, 2) = (4, 1) \circ (2, 3)$ ).
- It is not a normal subgroup. The right cosets are

$$\begin{aligned} &\{(1, 2, 4), (2, 4, 3), (1, 3) \circ (2, 4)\}, \\ &\{(1, 4, 2), (1, 4, 3), (1, 4) \circ (2, 3)\}, \\ &\{(2, 3, 4), (1, 2) \circ (3, 4), (1, 3, 4)\}, \\ &\{\text{id}, (1, 2, 3), (1, 3, 2)\}. \end{aligned}$$

The mentioned subset is a subgroup only for  $n = 3$ . In this case, it is the alternating group  $A_3$  of all even permutations in  $\mathbb{S}_3$ , which is a normal subgroup. (For greater value of  $n$ , we can find two cycles of length  $n$  whose composition is neither a cycle of length  $n$  nor the identity.)  $\square$

**12.F.49.** Find the subgroup of  $\mathbb{S}_6$  that is generated by the permutations  $(1, 2) \circ (3, 4) \circ (5, 6)$ ,  $(1, 2, 3, 4)$ , and  $(5, 6)$ . Is this subgroup normal? If so, describe the set of (two-sided) cosets  $S_6/H$ .

**Solution.** First of all, note that all of the generating permutations lie in the subgroup  $\mathbb{S}_4 \times \mathbb{S}_2 \subseteq S_6$  (considering the natural inclusion of  $\mathbb{S}_4 \times \mathbb{S}_2$ , i. e., for  $s \in \mathbb{S}_4 \times \mathbb{S}_2$ , the restriction of  $s$  to  $\{1, 2, 3, 4\}$  is a permutation on this set and so is the restriction of  $s$  to  $\{5, 6\}$ ). This means that the group they generate is also a subgroup of  $\mathbb{S}_4 \times \mathbb{S}_2$ . Moreover, since there is  $(5, 6)$  among the generators, we can see that the subgroup is of the form  $H \times \mathbb{S}_2$ , where  $H \subseteq \mathbb{S}_4$ . Thus, it suffices to describe  $H$ . This group is generated by the elements  $(1, 2) \circ (3, 4)$  and  $(1, 2, 3, 4)$  (projection of the generators on  $\mathbb{S}_4$ ). We have

$$\begin{aligned} (1, 2, 3, 4)^2 &= (1, 3) \circ (2, 4), \\ (1, 2, 3, 4)^3 &= (4, 3, 2, 1), \\ (1, 2, 3, 4)^4 &= \text{id}, \\ [(1, 2) \circ (3, 4)]^2 &= \text{id}, \\ [(1, 2) \circ (3, 4)] \circ (1, 2, 3, 4) &= (2, 4), \\ (1, 2, 3, 4) \circ [(1, 2) \circ (3, 4)] &= (1, 3), \\ [(1, 2) \circ (3, 4)] \circ (4, 3, 2, 1) &= (1, 3), \\ (4, 3, 2, 1) \circ [(1, 2) \circ (3, 4)] &= (2, 4), \\ [(1, 2) \circ (3, 4)] \circ [(1, 3) \circ (2, 4)] &= (1, 4) \circ (2, 3), \\ [(1, 3) \circ (2, 4)] \circ [(1, 2) \circ (3, 4)] &= (1, 4) \circ (2, 3), \end{aligned}$$

Then, there exists an  $a \in \mathbb{K}$ ,  $a \neq 0$ , and polynomials  $q$  and  $r$  such that  $af = qg + r$ , where either  $r = 0$  or  $\deg r < \deg g$ . Moreover, if  $\mathbb{K}$  is a field or if the leading coefficient of  $g$  is one, and if the choice  $a = 1$  is made, then the polynomials  $q$  and  $r$  exist and they are unique.

**PROOF.** If  $\deg f < \deg g$  or  $f = 0$ , then the choice  $a = 1$ ,  $q = 0$ ,  $r = f$ , satisfies all the conditions. If  $g$  is constant, set  $a = g$ ,  $q = f$ ,  $r = 0$ . Continue by induction on the degree of  $f$ . Suppose  $\deg f \geq \deg g > 0$ , and write

$$f = a_0 + \dots + a_n x^n, \quad g = b_0 + \dots + b_m x^m.$$

Either  $b_m f - a_n x^{n-m} g = 0$  or  $\deg(b_m f - a_n x^{n-m} g) < \deg f$ . In the former case, the proof is finished. In the latter case, it follows by the induction hypothesis that there exist  $a', q', r'$  satisfying

$$a' (b_m f - a_n x^{n-m} g) = q' g + r'$$

and either  $r' = 0$  or  $\deg r' < \deg g$ . This means that

$$a' b_m f = (q' + a' a_n x^{n-m}) g + r'.$$

If  $b_m = 1$  or  $\mathbb{K}$  is a field, then the induction hypothesis can be used to choose  $a' = 1$  and then  $q', r'$  are unique. In this case,

$$b_m f = (q' + a_n x^{n-m}) g + r'.$$

If  $\mathbb{K}$  is a field, then this equation can be multiplied by  $b_m^{-1}$ .

Assume that there is another solution  $f = q_1 g + r_1$ . Then,  $0 = f - f = (q - q_1)g + (r - r_1)$  and either  $r = r_1$ , or  $\deg(r - r_1) < \deg g$ . In the former case, it follows that  $q = q_1$  as well, since there are no zero divisors in  $\mathbb{K}[x]$ . Let  $ax^s$  be the term of the highest degree in  $q - q_1 \neq 0$  (it must exist). Then, its product with the term of the highest degree in  $g$  must be zero (since the term of the highest degree is just the product of the terms of the highest degrees and there are no other terms of this degree there). However, this means that  $a = 0$ . Since  $ax^s$  is the non-zero term with the highest degree,  $q - q_1$  contains no non-zero monomials, so it equals zero. But then  $r = r_1$ .  $\square$

The procedure for the Euclidean division can be used to discuss the roots of a polynomial.

Consider a polynomial  $f \in \mathbb{K}[x]$ ,  $\deg f > 0$ , and divide it by the polynomial  $x - b$ ,  $b \in \mathbb{K}$ . Since the leading coefficient is one, the algorithm produces a unique result. It follows that there are unique polynomials  $q$  and  $r$  which satisfy  $f = q(x - b) + r$ , where  $r = 0$  or  $\deg r = 0$ , i.e.  $r \in \mathbb{K}$ . This means that the value of the polynomial  $f$  at  $b \in \mathbb{K}$  equals  $f(b) = r$ . It follows that the element  $b \in \mathbb{K}$  is a root of the polynomial  $f$  if and only if  $(x - b)|f$ . Since division by a polynomial of degree one decreases the degree of the original polynomial by at least one, the following proposition is proved:

**Corollary.** Every polynomial  $f \in \mathbb{K}[x]$  has at most  $\deg f$  roots, including multiplicities. In particular, polynomials over an infinite integral domain define the same mapping  $\mathbb{K} \rightarrow \mathbb{K}$  if and only if they are the same polynomial.

$$[(1, 2) \circ (3, 4)] \circ (4, 2) = (1, 2, 3, 4),$$

$$(1, 3) \circ (4, 2) = (1, 3) \circ (2, 4).$$

Now, we can note that the generating permutations  $(1, 2, 3, 4)$  and  $(1, 2) \circ (3, 4)$  are symmetries of a square on vertices  $1, 2, 3, 4$ . Therefore, they cannot generate more than 8-element  $D_4$ , which has already happened. This means that no more permutations can be obtained by further compositions. Thus, the subgroup  $H \subseteq S_4$  has 8 elements (which is possible by Lagrange's theorem, since 8 divides 24).

$$H = \{ \text{id}, (1, 2, 3, 4), (1, 3) \circ (2, 4), (4, 3, 2, 1), (1, 2) \circ (3, 4), (1, 3), (2, 4), (1, 4) \circ (2, 3) \}.$$

Altogether, the examined subgroup in  $S_6$  has 16 elements: for each  $h \in H$ , it contains  $(h, \text{id})$  and  $(h, (56))$ .

□

**12.F.50.** Find the subgroup in  $S_4$  that is generated by the permutations  $(1, 2) \circ (3, 4)$ ,  $(1, 2, 3)$ .

**Solution.** Since both the generating permutations are even, they can generate only even permutations. Thus, the examined group is a subgroup of the alternating group  $A_4$  of all even permutations. We have

$$[(1, 2) \circ (3, 4)]^2 = \text{id},$$

$$(1, 2, 3)^2 = (3, 2, 1),$$

$$[(1, 2) \circ (3, 4)] \circ (1, 2, 3) = (2, 4, 3),$$

$$(1, 2, 3) \circ [(1, 2) \circ (3, 4)] = (1, 3, 4),$$

$$[(1, 2) \circ (3, 4)] \circ (3, 2, 1) = (3, 1, 4),$$

$$(3, 2, 1) \circ [(1, 2) \circ (3, 4)] = (2, 3, 4),$$

and now, we already have seven elements of the examined subgroup of  $A_4$ , and since  $A_4$  has 12 elements and the order of a subgroup must divide that of the group, it is clear that the subgroup is the whole  $A_4$ . □

**12.F.51.** Find all subgroups of the group of invertible 2-by-2 matrices over  $\mathbb{Z}_2$  (with matrix multiplication). Is any of them normal?

**Solution.** In exercise 12.E.1, we built the table of the operation in this group. By Lagrange's theorem (12.4.10), the order of any subgroup must divide the order of the group, which is six. Thus, besides the trivial subgroup  $\{A\}$  and the entire group, each subgroup must have two or three elements. In a 2-element subgroup, the non-trivial element must be self-inverse, which is also sufficient for the subset to be a subgroup. We thus get the subgroups  $\{A, B\}$ ,  $\{A, C\}$ ,  $\{A, F\}$ , which are not normal, as can be easily verified. The identity is  $A$ . Since  $B, C, F$  have order 2, they cannot be in a 3-element subgroup. Thus, the only remaining possibility is  $P = \{A, D, E\}$ , which is indeed a subgroup. Moreover, checking the conjugations  $BDB = E$ ,  $CDC = E$ ,  $FD F = E$  (whence it follows that  $BEB = D$ ,  $CEC = D$ ,  $FEF = D$ ), we find out that this subgroup is normal. □

Indeed, if two polynomials over an integral domain define the same mapping  $\mathbb{K} \rightarrow \mathbb{K}$ , then their difference has any element of  $\mathbb{K}$  as a root. This means that if their difference is not the zero polynomial, then  $\mathbb{K}$  has at most as many elements as the maximum of the degrees of the polynomials in question.

**12.3.7. Multiple roots and derivatives.** In the continuous modelling, we mostly work over infinite integral domains  $\mathbb{K}$  and so we identify the algebraic expressions for the polynomials with the mappings. However the properties of differentiation on polynomials are of purely algebraic character, in general:

The differentiation of polynomials over real or complex numbers is an algebraic operation which make sense for all commutative rings  $\mathbb{K}$  and it still satisfies the Leibniz rule:

#### DERIVATIVE OF POLYNOMIALS

Consider polynomials  $f(x) = a_0 + a_1x + \dots + a_nx^n$ ,  $g(x) = b_0 + b_1x + \dots + b_mx^m$  be polynomials of orders  $n$  and  $m$  over an commutative ring  $\mathbb{K}$ . The derivative  $' : f(x) \mapsto f'(x) = a_1 + a_2x + \dots + na_nx^{n-1}$  respects the addition of polynomials and their multiplication by the elements in  $\mathbb{K}$ . Moreover it satisfies the *Leibniz rule*

$$(1) \quad (f(x)g(x))' = f'(x)g(x) + f(x)g'(x).$$

While claim on the additive structure is obvious, let us check the Leibniz rule:

$$f(x) \cdot g(x) = \sum_{k=0}^{m+n} c_k x^k, \quad c_k = \sum_{i+j=k} a_i b_j$$

and thus, expanding  $f'(x) \cdot g(x) + f(x) \cdot g'(x)$  yields exactly the expression for the derivative of the product  $\sum_{k=1}^{m+n} k c_k x^{k-1}$ .

In particular, the derivative is not a homomorphism  $\mathbb{K}[x] \rightarrow \mathbb{K}[x]$  of the ring of polynomials, in view of (1). In much more general context, the homomorphisms of the additive structure of a ring satisfying the Leibniz rule (1) are called *derivations*. For polynomial rings, we see inductively that the only derivation there is our operation  $'$ .

Differentiation can be exploited easily for discussing multiple roots of polynomials.

Consider a polynomial  $f(x) \in \mathbb{K}[x]$  over an integral domain  $\mathbb{K}$ , with root  $c \in \mathbb{K}$  of multiplicity  $k$ . Thus, in view of the division of polynomials discussed in the previous paragraph 12.3.6,

$$f(x) = (x - c)^k g(x),$$

with the unique polynomial  $g, g(c) \neq 0$ . Differentiating  $f(x)$  and applying the Leibniz rule we obtain

$$f'(x) = k(x - c)^{k-1} g(x) + (x - c)^k g'(x)$$

$$= (x - c)^{k-1} (k g(x) + (x - c) g'(x)).$$

Clearly the polynomial  $h(x) = k g(x) + (x - c) g'(x)$  does not admit  $c$  as root, i.e.  $h(c) = k g(c) \neq 0$ .

**12.F.52.** Find all subgroups of the group  $(\mathbb{Z}_{10}, +)$ .

**Solution.** The subgroups are isomorphic to  $(\mathbb{Z}_d, +)$ , Where  $d|10$ , i. e.,  $\{0\} \cong \mathbb{Z}_1$ ,  $\{0, 5\} \cong \mathbb{Z}_2$ ,  $\{0, 2, 4, 6, 8\} \cong \mathbb{Z}_5$ , and  $\mathbb{Z}_{10}$ .  $\square$

**12.F.53.** Find the orders of the elements 2, 4, 5 in  $(\mathbb{Z}_{35}^\times, \cdot)$  and in  $(\mathbb{Z}_{35}, +)$ .

**Solution.** By definition, the order of  $x$  in the group  $(\mathbb{Z}_{35}^\times, \cdot)$  is the least positive integer  $k$  such that  $x^k \equiv 1 \pmod{35}$ . By Euler's theorem, the order of  $x = 2$  and  $x = 4$  is  $k \leq \varphi(35) = 24$ . Computing the corresponding modular powers, we find out that the order of  $x = 2$  is 12. Hence it immediately follows that the order of  $x = 4$  is 6. The number  $x = 5$  does not lie in the group  $(\mathbb{Z}_{35}^\times, \cdot)$ . Specifically, we have (modulo 35):

$x$	$x^2$	$x^3$	$x^4$	$x^5$	$x^6$	$x^7$	$x^8$	$x^9$	$x^{10}$	$x^{11}$	$x^{12}$	
2	4	8	16	32	29	23	11	22	9	18	1	
4	16	29	11	9	1							

In the group  $(\mathbb{Z}_{35}, +)$ , the order of  $x$  is the least positive integer  $k$  such that  $k \cdot x \equiv 0 \pmod{35}$ . This can be calculated simply as  $k = \frac{35}{\gcd(35, x)}$ . Therefore, the order of 2 and 4 is 35, while the order of 5 is 7.  $\square$

**12.F.54.** Find all finite subgroups of the group  $(\mathbb{R}^*, \cdot)$ <sup>1</sup>

**Solution.** If a given subgroup of the group  $(\mathbb{R}^*, \cdot)$  contains an element  $a$ ,  $|a| \neq 1$ , then the elements  $a, a^2, a^3, \dots$  form an infinite geometric progression of pairwise distinct elements all of which must lie in the considered subgroup, so it is infinite. Thus, a finite subgroup may contain only the numbers 1 and  $-1$ , which means that there are two finite subgroups:  $\{1\}, \{-1, 1\}$ .  $\square$

**12.F.55.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism, and if so, find its kernel. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{Z}_4 \times \mathbb{Z}_3 \rightarrow \mathbb{Z}_{12}, \varphi([a]_4, [b]_3) = [a - b]_{12}$ ,
- ii)  $\varphi : \mathbb{Z}_4 \times \mathbb{Z}_3 \rightarrow \mathbb{Z}_{12}, \varphi([a]_4, [b]_3) = [6a + 4b]_{12}$ ,
- iii)  $\varphi : \mathbb{Z}_4 \times \mathbb{Z}_3 \rightarrow \mathbb{Z}_{12}, \varphi([a]_4, [b]_3) = [0]_{12}$ .

**Solution.**

- i) Not a mapping. For instance, if we take two representatives  $([6]_4, [1]_3) = ([2]_2, [1]_3)$  of the same element in  $\mathbb{Z}_4 \times \mathbb{Z}_3$ , then we get  $\varphi([6]_4, [1]_3) = [5]_{12}$  and  $\varphi([2]_4, [1]_3) = [1]_{12}$ , so this is not a correct definition of a mapping.
- ii) A homomorphism, neither injective, nor surjective. Its kernel  $\text{Ker}(\varphi)$  is the set  $\{([2]_4, [0]_3), ([0]_4, [0]_3)\}$ .
- iii) A homomorphism, neither injective, nor surjective. Its kernel is the entire group  $\mathbb{Z}_4 \times \mathbb{Z}_3$ .  $\square$

<sup>1</sup>The group of all invertible elements for  $\mathbb{R}$  and  $\mathbb{C}$  is denoted by  $\mathbb{R}^*$  and  $\mathbb{C}^*$ , respectively, and by  $\mathbb{Z}_n^\times$  for  $\mathbb{Z}_n$ .

On the contrary, if  $c$  is a joint root of  $f$  and its derivative, then, reading the previous computation backwards (with  $k = 1$ ), we see the  $c$  is also a root of  $g(x)$ , and thus a root with multiplicity at least two of  $f$ . Inductively, we arrive at the following very useful claim:

**Proposition.** A polynomial  $f(x)$  over an integral domain  $\mathbb{K}$  admits the root  $c \in \mathbb{K}$  of multiplicity  $k$ , if and only if  $c$  is the root of  $f'(x)$  of multiplicity  $k - 1$ .

**12.3.8. The greatest common divisor.** Consider a polynomial ring  $\mathbb{K}[x]$  over an integral domain  $\mathbb{K}$ . A polynomial  $h \in \mathbb{K}[x]$  is called the *greatest common divisor* of polynomials  $f$  and  $g \in \mathbb{K}[x]$  if and only if the following hold:

- $h|f$  and  $h|g$ ,
- for any  $k$ , if both  $k|f$  and  $k|g$ , then  $k|h$ .

As a direct corollary of the existence of an algorithm for unique division with remainder, there is the very important *Bezout's identity* (it is proved using the Euclidean division similarly as in the case of the integers in Chapter 11).

**Theorem.** Let  $\mathbb{K}$  be a field and  $f, g \in \mathbb{K}[x]$ . Then, there exists a greatest common divisor  $h$  of the polynomials  $f$  and  $g$ . The polynomial  $h$  is unique up to a multiple by a non-zero scalar. In addition, there exist polynomials  $A, B \in \mathbb{K}[x]$  such that  $h = Af + Bg$ .

**PROOF.** The polynomials  $h, A, B$  can be constructed directly using the Euclidean algorithm. Continue dividing with remainder (since  $\mathbb{K}$  is a field, there is always a unique way to do this; see the above lemma 12.3.6):

$$\begin{aligned} f &= q_1g + r_1, \\ g &= q_2r_1 + r_2, \\ r_1 &= q_3r_2 + r_3, \\ &\vdots \\ r_{p-1} &= q_{p+1}r_p + 0. \end{aligned}$$

In this procedure, the degrees of the polynomials  $r_i$  are strictly decreasing; hence the equality from the last line must occur (for some  $p$ ), and this says that  $r_p|r_{p-1}$ . It follows from the line above that  $r_p|r_{p-2}$  etc.. Continue sequentially up to the first and second lines, to obtain  $r_p|g$  and  $r_p|f$ .

If  $h|f$  and  $h|g$ , then the same equalities imply that  $h$  divides all the  $r_i$ . In particular, it divides  $r_p$ . In this way, the greatest common divisor  $h = r_p$  of the polynomials  $f$  and  $g$  is obtained.

Substitute upwards, starting with the last equation:

$$\begin{aligned} h &= r_p = r_{p-2} - q_p r_{p-1} = \\ &= r_{p-2} - q_p(r_{p-3} - q_{p-1}r_{p-2}) = \\ &= -q_p r_{p-3} + (1 + q_{p-1}q_p)r_{p-2} = \\ &= -q_p r_{p-3} + (1 + q_p q_{p-1})(r_{p-4} - q_{p-2}r_{p-3}) = \\ &\vdots \end{aligned}$$

**12.F.56.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism, and if so, find its kernel. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{Z}_4 \rightarrow \mathbb{C}^*, \varphi([a]_4) = i^a,$
- ii)  $\varphi : \mathbb{Z}_5 \rightarrow \mathbb{C}^*, \varphi([a]_5) = i^a,$
- iii)  $\varphi : \mathbb{Z}_4 \rightarrow \mathbb{C}^*, \varphi([a]_4) = (-1)^a,$
- iv)  $\varphi : \mathbb{Z} \rightarrow \mathbb{C}^*, \varphi(a) = i^a.$

**Solution.**

- i) We have  $\varphi([a]_4 + [b]_4) = i^{a+b} = i^a \cdot i^b = \varphi([a]) \cdot \varphi([b]),$  and  $\varphi([4]) = i^4 = 1,$  which means that if  $[c]_4 = [d]_4,$  i. e.,  $c = d + 4k, k \in \mathbb{Z},$  then  $\varphi([c]_4) = i^c = i^{d+4k} = i^d = \varphi([d]_4),$  so the mapping is a well-defined homomorphism. It is injective (which is equivalent to saying that  $\text{Ker}(\varphi) = \{[0]_4\}$ ), but it is clearly not surjective.
- ii) Not a mapping since we have  $[0]_5 = [5]_5$  and  $\varphi([0]_5) = i^0 = 1$  but  $\varphi([5]_5) = i^5 = i.$
- iii) Is a homomorphism, neither injective (we have  $-1 = \varphi(1) = \varphi(3) = (-1)^3 = -1$ ), nor surjective. The kernel is  $\text{Ker}(\varphi) = \{[0]_4, [2]_4\}.$
- iv) Is a homomorphism, neither injective nor surjective. The kernel is  $\text{Ker}(\varphi) = 4\mathbb{Z} = \{4k \mid k \in \mathbb{Z}\}.$

**12.F.57.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{Q}^* \rightarrow \mathbb{Q}^*, \varphi\left(\frac{p}{q}\right) = \frac{q}{p}$
- ii)  $\varphi : \mathbb{Q}^* \rightarrow \mathbb{Q}^*, \varphi\left(\frac{p}{q}\right) = \frac{p^2}{q^2}$
- iii)  $\varphi : \mathbb{Q}^* \rightarrow \mathbb{Q}^*, \varphi\left(\frac{p}{q}\right) = \frac{p^2+q^2}{pq}$

**12.F.58.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{C} \rightarrow \mathbb{R}, \varphi(a + bi) = a + b,$
- ii)  $\varphi : \mathbb{C} \rightarrow \mathbb{R}, \varphi(a + bi) = a,$
- iii)  $\varphi : \mathbb{C}^* \rightarrow \mathbb{R}^*, \varphi(a + bi) = a^2 + b^2,$
- iv)  $\varphi : \mathbb{C}^* \rightarrow \mathbb{R}^*, \varphi(c) = 2|c|,$
- v)  $\varphi : \mathbb{C}^* \rightarrow \mathbb{R}^*, \varphi(c) = |c|^3,$
- vi)  $\varphi : \mathbb{C}^* \rightarrow \mathbb{R}^*, \varphi(c) = 1/|c|.$

**12.F.59.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathcal{GL}_2(\mathbb{R}) \rightarrow \mathbb{R}^*, \varphi(A) = |A|$
- ii)  $\varphi : \mathcal{GL}_2(\mathbb{R}) \rightarrow \mathbb{R}^*, \varphi\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) = a^2 + b^2.$
- iii)  $\varphi : \mathcal{GL}_2(\mathbb{R}) \rightarrow \mathbb{R}^*, \varphi\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) = ac + bd.$

$$= Af + Bg. \quad \square$$

**12.3.9. Unique factorization.** Now follows a very useful (and elegant) statement, the proof of which is straightforward, yet it requires many technical details (and it also concerns the so called field of rational functions). It is recommended to read the following paragraph carefully. Then maybe, at the first reading, skip the technical lemmas of the proof.

**Theorem.** Let  $\mathbb{K}$  be a unique factorization domain. Then,  $\mathbb{K}[x]$  is also a unique factorization domain.

**PROOF.** The idea of the proof is very simple. Consider a polynomial  $f \in \mathbb{K}[x]$ . If  $f$  is reducible, then  $f = f_1 \cdot f_2,$  where neither of the polynomials  $f_1, f_2 \in \mathbb{K}[x]$  is a unit. Moreover, assume for a while that if  $f$  is divisible by an irreducible polynomial  $h,$  then so is  $f_1$  or  $f_2.$

If this is always the case, this procedure can be applied step by step to reach a unique factorization. If  $f_1$  is further reducible, then  $f_1 = g_1 \cdot g_2,$  where  $g_1, g_2$  are not units, and either both the polynomials  $g_1$  and  $g_2$  have degree less than that of  $f,$  or the number of irreducible factors in the leading terms of  $g_1$  and  $g_2$  decreases (for instance, over the integers  $\mathbb{Z}, 2x^2 + 2x + 2 = 2(x^2 + x + 1)$ ). After a finite number of steps, a factorization  $f = f_1 \dots f_r$  is obtained, where the polynomials  $f_1, \dots, f_r$  are irreducible.

It follows from the additional assumption that every irreducible polynomial  $h$  which divides  $f$  also divides one of  $f_1, \dots, f_r.$  Therefore, for every other factorization  $f = f'_1 f'_2 \dots f'_s,$  each factor  $f_i$  divides one of  $f'_j,$  and in this case,  $f'_j = e f_i$  for an appropriate unit  $e.$  Cancel such pairs step by step, to conclude that  $r = s$  and that the individual factors differ only by a unit multiple.  $\square$

To conclude, we have to deal with our assumption in the first paragraph of our above proof. This will require some technical preparation and we shall come back to it soon.

The direct consequence of the latter theorem for the multivariate polynomials can be formulated (due to their inductive definition):

**Corollary.** Let  $\mathbb{K}$  be a unique factorization domain. Then,  $\mathbb{K}[x_1, \dots, x_r]$  is also a unique factorization domain.

Every polynomial over a unique factorization domain can be factored in a similar way to the case of polynomials with real or complex coefficients.

In particular, this holds for polynomials over every field of scalars.

**12.3.10. Fields of fractions.** When dealing with integer calculations, it is often more advantageous to work with rational numbers and verify only at the end of the procedure that the result is an integer. This method is useful in the case of polynomials, too.

**12.F.60.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{Z}_3 \rightarrow \mathbb{A}_4, \varphi([a]_3) = (1, 2, 4) \circ (1, 3, 2)^a \circ (1, 4, 2)$
- ii)  $\varphi : \mathbb{Z}_3 \rightarrow \mathbb{A}_4, \varphi([a]_3) = (1, 2) \circ (1, 3, 2)^a$

**12.F.61.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{Z} \rightarrow \mathbb{Z}, \varphi(a) = 2a$
- ii)  $\varphi : \mathbb{Z} \rightarrow \mathbb{Z}, \varphi(a) = a + 1$
- iii)  $\varphi : \mathbb{Z} \rightarrow \mathbb{Z}, \varphi(a) = 3|a|$
- iv)  $\varphi : \mathbb{Z} \rightarrow \mathbb{Z}, \varphi(a) = 1$

**12.F.62.** For each of the following formulas, decide whether it correctly defines a mapping  $\varphi$ . If so, decide whether it is a homomorphism. Moreover, decide whether it is surjective and injective:

- i)  $\varphi : \mathbb{Z} \times \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{Q}^*, \varphi((a, b, c)) = 2^a 3^b 12^c$
- ii)  $\varphi : \mathbb{Z}_3^* \times \mathbb{Z}_5 \rightarrow \mathbb{Z}_5, \varphi((a, b)) = b^a$
- iii)  $\varphi : \mathbb{Z}_2 \times \mathbb{Z} \rightarrow \mathbb{Z}, \varphi(([a]_2, b)) = b$

**12.F.63.** Prove that there exists no isomorphism of the multiplicative group of non-zero complex numbers onto the multiplicative group of non-zero real numbers.

**Solution.** Every homomorphism must map the identity of the domain to the identity of the codomain (see 12.4.5). Thus, 1 must be mapped to itself. And what about  $-1$ ? We know that  $f(-1)^2 = f((-1)^2) = f(1) = 1$ . Therefore, the image of  $-1$  is a square root of 1. Since we are interested in bijective homomorphisms only, we must have  $f(-1) = -1$ . However, then  $f(i)^2 = f(i^2) = f(-1) = -1$ , so that  $f(i)$  is a square root of  $-1$  in  $\mathbb{R}$ ; however, no such real number exists. Therefore, no bijective homomorphism may exist.  $\square$

**Remark.** The mapping which assigns the absolute value to each non-zero complex number is a surjective homomorphism of  $\mathbb{C}^*$  onto  $\mathbb{R}^+$ .

**G. Burnside's lemma**

**12.G.1.** How many necklaces can be created from 3 black and 6 white beads? Beads of one color are indistinguishable, and two necklaces are considered the same if they can be transformed to each other by rotation and/or reflection.

Let  $\mathbb{K}$  be an integral domain. Its *field of fractions* is defined as the set of equivalence classes of the pairs  $(a, b) \in \mathbb{K} \times \mathbb{K}, b \neq 0$ . These classes are written  $\frac{a}{b}$ , and the equivalence is defined by

$$\frac{a}{b} = \frac{a'}{b'} \iff ab' = a'b.$$

Addition and multiplication is defined in terms of representatives:

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd},$$

$$\frac{a}{b} \frac{c}{d} = \frac{ac}{bd}.$$

It is easily verified that this definition is correct and that the resulting structure satisfies all field axioms. In particular,  $\frac{0}{1}$  is the additive identity, and  $\frac{1}{1}$  is the multiplicative identity. If  $a \neq 0, b \neq 0$ , then  $\frac{a}{b} \frac{b}{a} = \frac{1}{1}$ . All the details of the arguments are in fact identical with the discussion of rational numbers in 1.6.6.

The field of fractions of a ring  $\mathbb{K}[x_1, \dots, x_r]$  is called the *field of rational functions* (of  $r$  variables) and denoted  $\mathbb{K}(x_1, \dots, x_r)$ . In software systems like Sage, Maple or Mathematica, all algebraic operations with polynomials are performed in the corresponding field of fractions, i.e. in the field of rational functions, usually using  $\mathbb{K} = \mathbb{Q}$ .

**12.3.11. Completion of the proof.** It remains to prove that if a polynomial  $f = f_1 f_2$  is divisible by an irreducible polynomial  $h$ , then  $h$  divides either  $f_1$  or  $f_2$  or both.

This statement is proved in the following three lemmas.

**Lemma.** Let  $\mathbb{K}$  be a unique factorization domain. Then:

- (1) If  $a, b, c \in \mathbb{K}$ ,  $a$  is irreducible and  $a|bc$ , then either  $a|b$  or  $a|c$ .
- (2) If a constant polynomial  $a \in \mathbb{K}[x]$  divides  $f \in \mathbb{K}[x]$ , then  $a$  divides all coefficients of  $f$ .
- (3) If  $a$  is an irreducible constant polynomial in  $\mathbb{K}[x]$  and  $a|fg, f, g \in \mathbb{K}[x]$ , then  $a|f$  or  $a|g$ .

**PROOF.** (1) By the assumption,  $bc = ad$  for a suitable  $d \in \mathbb{K}$ . Let  $d = d_1 \dots d_r, b = b_1 \dots b_s, c = c_1 \dots c_q$  be the factorizations to irreducible factors. This means that

$$ad_1 \dots d_r = b_1 \dots b_s c_1 \dots c_q.$$

Since  $ad$  factors in a unique way, it follows that  $a = eb_j$  or  $a = ec_i$  for a suitable unit  $e$ .

(2) Let  $f = b_0 + b_1 x + \dots + b_n x^n$ . Since  $a|f$ , there must exist a polynomial  $g = c_0 + c_1 x + \dots + c_k x^k$  such that  $f = ag$ . Hence it immediately follows that  $k = n, ac_0 = b_0, \dots, ac_n = b_n$ .

(3) Consider  $f, g \in \mathbb{K}[x]$  as above and suppose that  $a$  divides neither  $f$  nor  $g$ . By the previous claim, there exists an  $i$  such that  $a$  does not divide  $b_i$ , and there exists a  $j$  such that  $a$  does not divide  $c_j$ . Choose the least such  $i$  and  $j$ . The coefficient at  $x^{i+j}$  of the polynomial  $fg$  is  $b_0 c_{i+j} + b_1 c_{i+j-1} + \dots + b_{i+j} c_0$ . By choice,  $a$  divides all of  $b_0 c_{i+j}, \dots, b_{i-1} c_{j+1}, b_{i+1} c_{j-1}, \dots, b_{i+j} c_0$ . At the same

**Solution.** Let us assume the necklace as coloring of the vertices of a regular 9-gon. Let  $S$  denote the set of all such colorings. Since each coloring is determined by the positions of the 3 black beads, we get that  $S$  has  $\binom{9}{3} = 84$  elements.

We know that the group of symmetries is  $D_9$ , which contains 9 rotations (including the identity) and 9 reflections. Two colorings are the same if they lie in the same orbit of the action of  $D_9$  on the set  $S$ . Thus, we are interested in the number of orbits (let us denote it  $N$ ). In order to find  $N$ , it suffices to compute the sizes of  $S_g$  for all elements  $g$  of  $D_9$ :

The identity is the only element of order 1, we have  $|S_{\text{id}}| = 84$ , so the contribution to the sum is 84.

There are 9 reflections  $g$ , each of order 2. Clearly, we have  $|S_g| = 4$ , so the total contribution is  $4 \cdot 9 = 36$ .

There are 2 rotations  $g$  by  $2\pi/3$  or  $4\pi/3$ , both of order 3, and  $|S_g| = 3$ . Their contribution is 6.

Finally, there are 6 rotations of order 9, and no coloring is kept unchanged by them, so they do not contribute to the sum.

Altogether, we get by the formula of Burnside's lemma that

$$N = \frac{1}{|D_9|} \sum_{g \in D_9} |S_g| = \frac{126}{18} = 7.$$

Draw the seven necklaces! □

**12.G.2.** Find the number of colorings of a 3-by-3 grid with three colors. Two colorings are considered the same if they can be transformed to each other by rotation and/or reflection.

**Solution.** The group of symmetries of the table is the same as for a square, i. e., it is the dihedral group  $D_4$ . Without any identification, there are clearly  $3^9$  colorings of the table. Now, the group  $G = D_4$  acts on these colorings. For each symmetry  $g \in G$ , we find the number of colorings that  $g$  keeps unchanged:

- $g = \text{Id}$ :  $|S_g| = 3^9$ .
- $g$  is a rotation by  $90^\circ$  or  $270^\circ (= -90^\circ)$ : In this rotation, every corner tile is sent to an adjacent corner tile. This means that if the coloring is to be unchanged, all the corner tiles must be of the same color. Similarly, all the edge tiles must be of the same color. Then, the center tile may be of any color. Altogether, we get that there are  $3^3$  which are not changed by the considered rotations.
- $g$  is a rotation by  $180^\circ$ : There are four pairs of tiles that are sent to each other by this symmetry, which means that the two tiles of each pair must be of the same color. Then, the center tile may be of any color. Altogether, we have  $|S_g| = 3^5$ .
- $g$  is one of the four reflections: There are three pairs of tiles that are sent to each other by the reflection, so again the tiles within each pair must be of one color. The three tiles that are fixed by the reflection may be each of an arbitrary color. Altogether, we get  $|S_g| = 3^6$ .

time, it does not divide  $b_i c_j$ . Therefore, it cannot divide the coefficient. □

**12.3.12. Lemma.** Consider the field of fractions  $\mathbb{L}$  of a unique factorization domain  $\mathbb{K}$ . If a polynomial  $f$  is irreducible in  $\mathbb{K}[x]$ , then it is irreducible in  $\mathbb{L}[x]$ , too.

**PROOF.** Each coefficient  $a \in \mathbb{K}$  can be considered as an element  $\frac{a}{1} \in \mathbb{L}$ . Therefore, every non-zero polynomial  $f \in \mathbb{K}[x]$  can be considered a polynomial in  $\mathbb{L}[x]$ .

Suppose that  $f = g'h'$  for some  $g', h' \in \mathbb{L}[x]$ , where the polynomials  $g', h'$  are not units in  $\mathbb{L}[x]$  (i.e. they are not constant polynomials, since  $\mathbb{L}$  is a field). Let  $a$  be a common multiple of the denominators of the coefficients in  $g'$  and  $b$  be a common multiple of the denominators of coefficients in  $h'$ . Then,  $bh', ag' \in \mathbb{K}[x]$ , and so  $abf = (bh')(ag')$ . Let  $c$  be an irreducible factor in the factorization of  $ab$ . Then,  $c$  divides  $(bh')(ag')$ , and hence  $c$  divides  $bh'$  or  $ag'$  (by the previous lemma). This means that  $c$  can be canceled out. After a finite number of such cancellations, the conclusion is that  $f = gh$  for polynomials  $g, h \in \mathbb{K}[x]$ . Since the degrees of the polynomials are not changed, neither  $g$  nor  $h$  is constant.

Thus if  $f$  is reducible in  $\mathbb{L}[x]$ , then it is also reducible in  $\mathbb{K}[x]$ , contradicting the implication to be proved. □

**12.3.13. Lemma.** Let  $\mathbb{K}$  be a unique factorization domain and  $f, g, h \in \mathbb{K}[x]$ . Suppose that  $f$  is irreducible and  $f|gh$ . Then, either  $f|g$  or  $f|h$ .

**PROOF.** This statement is already proved in one of the previous lemmas for the case that  $f$  is a constant polynomial (i.e. an element of  $\mathbb{K}$ ).

Suppose that  $\deg f > 0$ . Then  $f$  is irreducible in  $\mathbb{L}[x]$  as well, where  $\mathbb{L}$  is the field of fractions of the ring  $\mathbb{K}$ .

Suppose that  $\mathbb{K}$  itself is a field (and as such equals its field of fractions). Moreover, suppose that  $f|gh$  and  $f$  does not divide  $g$ . The greatest common divisor of the polynomials  $g$  and  $f$  must be a constant polynomial in  $\mathbb{K}$ . Therefore, there are  $A, B \in \mathbb{K}[x]$  such that  $1 = Af + Bg$ . Hence,  $h = Afh + Bgh$ . Since  $f|gh$ , it follows that  $f|h$  as well.

Return to the general case. It follows from the assumptions that  $f|g$  or  $f|h$  in the polynomial ring  $\mathbb{L}[x]$  over the field of fractions  $\mathbb{L}$  of the ring  $\mathbb{K}$ . For instance, let  $h = kf$  in  $\mathbb{L}[x]$ , and choose an  $a \in \mathbb{K}$  so that  $ak \in \mathbb{K}[x]$ . Then,  $ah = akf$  and it must hold for every irreducible factor  $c$  of  $a$  that  $c|ak$ , because  $f$  is irreducible and not constant.

It follows that  $c$  can be canceled. After a finite number of such cancellations,  $a$  becomes a unit, i.e.  $h = k'f$  for an appropriate  $k' \in \mathbb{K}[x]$ . □

The proof of this lemma completes the proof of theorem 12.3.9.

By Burnside's lemma, the wanted number of colorings is equal to

$$\frac{1}{8} (3^9 + 2 \cdot 3^3 + 3^5 + 4 \cdot 3^6) = 2862. \quad \square$$

**12.G.3.**

- a) Find all rotational symmetries of a regular octahedron.
- b) Find the number of colorings of its sides. Two colorings are considered the same they can be transformed to each other by rotation.

**Solution.**

- a) Placing the octahedron into the Cartesian coordinate system so that pairs of adjacent vertices are on the axes and the center of the octahedron lies in the origin, then every rotational symmetry is given by which of the six vertices is on the positive  $x$ -semi-axis and which of the four adjacent vertices is on the positive  $y$ -semi-axis. Thus, the group has 24 elements. These are (besides the identity) rotations by  $\pm 90^\circ$  and  $180^\circ$  around axes going through opposite vertices, rotations by  $180^\circ$  around axes going through the centers of opposite edges, and finally rotations around  $\pm 120^\circ$  around axes going through the centers of opposite sides.
- b) Without any identifications, there are  $3^8$  colorings. For each rotational symmetry  $g$ , we compute the number of colorings that are kept unchanged by it:
  - $g$  is a rotation by  $\pm 90^\circ$  around an axis going through opposite vertices. Then,  $g$  fixes  $3^2$  colorings, and there are 6 such rotations.
  - $g$  is a rotation by  $180^\circ$  around an axis going through opposite vertices or the centers of opposite edges. Then,  $g$  fixes  $3^4$  colorings. There are  $3 + 6 = 9$  of these.
  - $g$  is a rotation by  $\pm 120^\circ$ . Then,  $g$  also fixes  $3^4$  colorings, and there are 8 such rotations.

Together with  $3^8$  for the identity, we get that the number of colorings is

$$\frac{1}{24} (3^8 + 6 \cdot 3^2 + 17 \cdot 3^4) = 333. \quad \square$$

**12.G.4.** How many necklaces can be created from 9 white, 6 red, and 3 black beads? Beads of one color are indistinguishable, and two necklaces are considered the same if they can be transformed to each other by rotation and/or reflection.

**4. Groups, rings, and fields**

As an illustration of the most abstract approach to an algebraic theory, concepts enjoying just one operation only are considered. The focus is on objects and situations where equations of the form  $a \cdot x = b$  always have a unique solution (as usual with linear equations, the objects  $a$  and  $b$  are given, while  $x$  is what is sought for). This is group theory. Note that nothing is known about the "nature" of the objects, or even what the dot stands for. The only assumption is that two objects  $a$  and  $x$  are assigned an object  $a \cdot x$ .

In a previous part of this chapter, such operations are known as addition or multiplication in rings. The concepts and vocabulary concerning such operations are now extended. Among them, numbers and transformations of the plane and space, where such "group" objects are met. Then follows the foundations of a general theory.

**12.4.1. Examples and concepts.** Let  $A$  be a set. A *binary operation* on  $A$  is defined to be any mapping  $A \times A \rightarrow A$ . The result of such an operation is often denoted

$$(a, b) \mapsto a \cdot b$$

and called the product of  $a$  and  $b$ . A set together with a binary operation is called a *groupoid* or a *magma*.

Further assumed properties of the operations are needed in order to be able to say something interesting,

**BINARY OPERATIONS AND SEMIGROUPS**

A binary operation is said to be *associative*, if and only if  $a \cdot (b \cdot c) = (a \cdot b) \cdot c$  for all  $a, b, c \in A$ .

A groupoid where the operation is associative is called a *semigroup*.

A binary operation is said to be *commutative* if and only if  $a \cdot b = b \cdot a$  for all  $a, b \in A$ .

The natural numbers  $\mathbb{N} = \{0, 1, 2, \dots\}$  together with either addition or multiplication form a groupoid. These operations are both commutative and associative. The integers  $\mathbb{Z} = \{\dots, -2, -1, 0, 1, 2, \dots\}$  form a groupoid with any of addition, subtraction, and multiplication. Subtraction is neither associative, for example

$$(5 - 3) - 2 = 0 \neq 5 - (3 - 2) = 4,$$

nor commutative, since  $a - b = -(b - a)$ , which is in general different from  $b - a$ .

**Solution.** The group of symmetries of the necklace is the dihedral group  $D_{18}$ , which has 36 elements. It acts on the set of necklaces, where we can number each place (1 through 18), resulting in  $18!/(9!6!3!) = 4084080$  necklaces (without any identification). The only symmetries that fix a non-zero number of necklaces are rotations by  $120^\circ$  and  $240^\circ$ , reflections, and of course the identity. By Burnside's lemma, the wanted number of necklaces is equal to

$$\frac{1}{36} \left( 4084080 + 2 \cdot \binom{6}{3} \binom{3}{3} + 9 \cdot \binom{8}{4} \binom{4}{3} \right) = 113590.$$

□

**12.G.5.** How many necklaces can be created from 6 white, 6 red, and 6 black beads? Beads of one color are indistinguishable, and two necklaces are considered the same if they can be transformed to each other by rotation and/or reflection.

○

### H. Codes

**12.H.1.** Consider the  $(5, 3)$ -code over  $\mathbb{Z}_2$  generated by the polynomial  $x^2 + x + 1$ . Find all codewords as well as the generating matrix and the check matrix.

**Solution.**  $p(x) = x^2 + x + 1$ . The code words are precisely the multiples of the generating polynomial:

$$0 \cdot p, 1 \cdot p, x \cdot p, (x+1) \cdot p, x^2 \cdot p, (x^2+1) \cdot p, (x^2+x) \cdot p, (x^2+x+1) \cdot p$$

or

$$0, x^2 + x + 1, x^3 + x^2 + x, x^3 + 1, x^4 + x^3 + x^2, x^4 + x^3 + x + 1, x^4 + x, x^4 + x^2 + 1$$

### NEUTRAL ELEMENTS, INVERSES, AND GROUPS<sup>7</sup>

A *left identity* (or *left neutral element*) in a groupoid  $(A, \cdot)$  is an element  $e \in A$  such that  $e \cdot a = a$  for all  $a \in A$ . Similarly,  $e \in A$  is a *right identity* (*right neutral element*) iff for all  $a \in A$ ,  $a \cdot e = a$ . If  $e$  satisfies both these properties, it is called an *identity* (or a *neutral element*).

In a groupoid  $(A, \cdot)$  with identity  $e$ , an element  $b$  is a *left inverse* of an element  $a$  if and only if  $b \cdot a = e$ ; it is a *right inverse* of  $a$  if and only if  $a \cdot b = e$ . If  $b$  satisfies both these properties, it is called an *inverse* of  $a$ .

A *monoid*  $(M, \cdot)$  is a semigroup which has a neutral element. A *group*  $(G, \cdot)$  is a monoid where each element has an inverse.

A *commutative semigroup* is a semigroup where the operation is commutative, similarly for a *commutative monoid* or a *commutative group*. A commutative group is also often called an *Abelian group*.

Consider direct consequences of the definitions. A groupoid cannot have both a left identity and a different right identity (if it had, what would be their product equal to?). Thus, if a groupoid has a (two-sided) identity, then it is the only identity element, called *the* identity.

Similarly, in a monoid, an element  $x$  cannot have both a left inverse  $a$  and a different right inverse  $b$ , since if  $a \cdot x = x \cdot b = e$ , then also

$$a = a \cdot (x \cdot b) = (a \cdot x) \cdot b = b.$$

Note that associativity of the operation is needed here. It follows that if  $x$  has an inverse, then it is unique. It is usually denoted by  $x^{-1}$ .

As an example, consider again the subtraction on integers. This operation is not associative. There is a right identity (zero), i.e.  $a - 0 = a$  for any integer  $a$ , but it is not a left identity. There is no left identity for subtraction.

The integers are a semigroup with respect to either addition or multiplication. They form a group only with addition, since with respect to multiplication, only the integers  $\pm 1$  have an inverse.

If  $(A, \cdot)$  is a group, then any subset  $B \subseteq A$  which is closed with respect to the restriction of  $\cdot$  (i.e.  $a \cdot b \in B$  for any  $a, b \in B$ ) and forms a group with this operation is called a *subgroup*. Both conditions are essential. For instance, consider the integers as a subset of the rational numbers and the multiplication there.

Let  $G$  be a group and  $M \subset G$ . The *subgroup generated by  $M$*  is the smallest (with respect to set inclusion) subgroup of  $G$  which contains all the elements of  $M$ . Clearly, this is the intersection of all subgroups containing  $M$ .

<sup>7</sup>The name "Abelian" is in honour of a young mathematician Niels Henrik Abel. The adjective is so widely used that it is common to write it with a lower-case 'a', abelian, although it is derived from a surname.

or

00000, 11100, 01110, 10010, 00111, 11011, 01001, 10101.

The basis vectors multiplied by  $x^{5-3} = x^2$  yield mod ( $p$ ):

$$\begin{aligned} x^2 &\equiv x + 1, \\ x^3 &= x \cdot x^2 \equiv x(x + 1) = x^2 + x \equiv 1, \\ x^4 &\equiv x. \end{aligned}$$

This means that the basis vectors are encoded as follows:

$$\begin{array}{ll} 1 \mapsto x^2 + x + 1, & 100 \mapsto 11100, \\ x \mapsto x^3 + 1, & \text{i. e. } 010 \mapsto 10010, \\ x^2 \mapsto x^4 + x, & 001 \mapsto 01001. \end{array}$$

Thus, the generating matrix is

$$G = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

and the check matrix is

$$H = \begin{pmatrix} 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 & 1 \end{pmatrix}. \quad \square$$

**12.H.2.** Consider the (5, 3)-code over  $\mathbb{Z}_2$  generated by the polynomial  $x^2 + x + 1$ . Find the generating matrix and the check matrix of the (7, 4)-code over  $\mathbb{Z}_2$  generated by the polynomial  $x^3 + x + 1$ . ○

**12.H.3.** A 7-bit message  $a_0a_1 \dots a_6$ , considered as the polynomial  $a_0 + a_1x + \dots + a_6x^6$ , is encoded using the polynomial code generated by  $x^4 + x + 1$ .

- i) Encode the message 1100011.
- ii) You have received the word 10111010001. What was the message if you assume that at most one bit was flipped?
- iii) What was the message in ii) if you assume that exactly two bits were flipped?

**Solution.** i)

$$\begin{aligned} x^4 &\equiv x + 1, \\ x^5 &\equiv x^2 + x, \\ x^9 &\equiv x^3 + x, \\ x^{10} &\equiv x^2 + x + 1, \end{aligned}$$

whence

$$\begin{aligned} 1 + x + x^5 + x^6 &\mapsto x^4 + x^5 + x^9 + x^{10} + x + 1 + x^2 + x + \\ &= x^3 + x + x^2 + x + 1 = \\ &= x^3 + x^4 + x^5 + x^9 + x^{10}. \end{aligned}$$

Thus, the code is 00011100011.

Here are a few very well known examples of groups. The rational numbers  $\mathbb{Q}$  are a commutative group with respect to addition. The integers are one of their subgroups. The non-zero rational numbers are a commutative group.

For every positive integer  $k$ , the set of all  $k$ -th roots of unity, i.e. the set  $\{z \in \mathbb{C}; z^k = 1\}$  is a finite commutative group with respect to multiplication of complex numbers. For  $k = 2$ , this is the two-element group  $\{-1, 1\}$ , both of whose elements are self-inverse. For  $k = 4$ , this is the group  $G = \{1, i, -1, -i\}$ .

The set  $\text{Mat}_n$ ,  $n > 1$ , of all square matrices of order  $n$  is a (non-commutative) monoid with respect to multiplication and a commutative group with respect to addition (see subsections 2.1.2–2.1.5).

The set of all linear mappings  $\text{Hom}(V, V)$  on a vector space is a monoid with respect to mapping composition and a commutative group with respect to addition (see subsection 2.3.12).

In every monoid, the subset of all invertible elements forms a group. In the former of the above examples, it was the group of invertible matrices. In the latter case, it was the group of linear isomorphisms of the corresponding vector space.

In previous chapters, there are several (semi)group structures, sometimes met quite unexpectedly. For example, recall various subgroups of the group of matrices or the group structure on elliptic curves.

**12.4.2. Permutation groups.** Groups and semigroups often arise as sets of mappings on a fixed set  $M$ , which are closed with respect to mapping composition.

This is easily seen on finite non-empty sets  $M$ , where every subset of invertible mappings generates a group with respect to composition.

Such a set  $M$  consisting of  $m = |M| \in \mathbb{N}$  elements allows for  $m^m$  possible mappings (each of  $m$  elements can be sent to arbitrary element of  $M$ ), and all of these mappings can be composed. Since mapping composition is associative, it is a semigroup.

If a mapping  $\alpha : M \rightarrow M$  is required to have an inverse  $\alpha^{-1}$ , then  $\alpha$  must be a bijection. Composition of two bijections yields again a bijection; hence the set  $\Sigma_m$  of all bijections on an  $m$ -element set  $M$  is a group. This is called the *symmetric group* (on  $m$  elements). It is an example of a finite group.<sup>8</sup>

The name of the group  $\Sigma_m$  brings another connection: Instead of bijections on a finite set, permutations can be viewed as the rearranging of distinguished objects. Permutations are encountered in this sense when studying determinants, for example, see subsection 2.2.1 on page 96 for a few

<sup>8</sup>It can be proved that every finite group is a subgroup of an appropriate finite symmetric group. This can be interpreted so that the groups  $\Sigma_m$  are as non-commutative and complex as possible.

ii)  $1 + x^2 + x^3 + x^4 + x^6 + x^{10}$  divide by  $x^4 + x + 1$  gives remainder  $x^2 + 1 \equiv x^8$ . Thus, the ninth bit was flipped and the original message was 1010101.

iii) Either the first and third bits were flipped ( $x^2 + 1$ ), or the fifth and sixth were ( $x^4 + x^5 \equiv x^2 + 1$ ). In the first case, the message was 1010001, while in the second case, it was 0110001.  $\square$

**12.H.4.** A 7-bit message  $a_0a_1 \dots a_6$ , considered as the polynomial  $a_0 + a_1x + \dots + a_6x^6$ , is encoded using the polynomial code generated by  $x^4 + x^3 + 1$ .

- i) Encode the message 1101011.
- ii) You have received the word 01001011101. What was the message if you assume that at most one bit was flipped?
- iii) What was the message in ii) if you assume that exactly two bits were flipped?

**Solution.** i)

$$\begin{aligned} x^4 &\equiv x^3 + 1, \\ x^5 &\equiv x^3 + x + 1, \\ x^7 &\equiv x^2 + x + 1, \\ x^9 &\equiv x^2 + 1, \\ x^{10} &\equiv x^3 + x, \end{aligned}$$

thus we get

$$\begin{aligned} 1 + x + x^3 + x^5 + x^6 &\mapsto x^4 + x^5 + x^7 + x^9 + x^{10} + x^3 + \\ &+ 1 + x^3 + x + 1 + x^2 + x + 1 + x^2 + 1 + x^3 + x = \\ &= x^3 + x^4 + x^5 + x^7 + x^9 + x^{10} + x^3 + x. \end{aligned}$$

Therefore, the code is  $\underbrace{0101}_{\text{redundancy}} \underbrace{1101011}_{\text{message}}$ .

ii)  $x + x^4 + x^6 + x^7 + x^8 + x^{10}$  divided by  $x^4 + x^3 + 1$  gives remainder  $x^2 + x + 1 \equiv x^7$ . Thus, the eighth bit was flipped, and the original message was 1010101.

iii) Either the second and tenth bit were flipped ( $x + x^9 \equiv x^2 + x + 1$ ), or the fourth and seventh ( $x^3 + x^6 \equiv x^2 + x + 1$ ), or the fifth and ninth ( $x^4 + x^8 \equiv x^2 + x + 1$ ). The respective messages are 00001011111, 01011010101, and 01000011001.  $\square$

**12.H.5.** Consider the (15, 11)-code generated by the polynomial  $1 + x^3 + x^4$ . We have received the word 011101110111001. Find the original 11-bit message, provided exactly one bit was flipped.

**Solution.** The word is a codeword if and only if it is divisible by the generating polynomial  $1 + x^3 + x^4$ . The received word corresponds to the polynomial  $x + x^2 + x^3 + x^5 + x^6 + x^7 + x^9 + x^{10} + x^{11} + x^{14}$ . When divided by  $1 + x^3 + x^4$ , it leaves remainder  $x + 1$ . This means that an error has occurred. If we assume that only one bit was flipped, then there must be a power of  $x$  which is equal to this remainder modulo  $1 + x^3 + x^4$ . Thus, we compute  $x^4 \equiv x^3 + 1$ ,  $x^5 \equiv x^3 + x + 1$ ,  $\dots$ ,  $x^{12} \equiv x + 1$  and find out that the thirteenth bit was flipped, and the original message was 01110111101.

elementary results. Let us briefly recollect them now in view of the general concepts of groups and their homomorphisms.

What the operation in this group looks like needs more thought. In the case of a (small) finite group, build a complete table of the operation results for all pairs of operands. Considering the group  $\Sigma_3$  on numbers  $\{1, 2, 3\}$  and denoting the particular permutations by the ordering of the numbers (not to be confused with the notation for cycles!)

$$\begin{aligned} a &= (1, 2, 3), \quad b = (2, 3, 1), \quad c = (3, 1, 2), \\ d &= (1, 3, 2), \quad e = (3, 2, 1), \quad f = (2, 1, 3), \end{aligned}$$

then the composition is given by the following table:

$\cdot$	$a$	$b$	$c$	$d$	$e$	$f$
$a$	$a$	$b$	$c$	$d$	$e$	$f$
$b$	$b$	$c$	$a$	$f$	$d$	$e$
$c$	$c$	$a$	$b$	$e$	$f$	$d$
$d$	$d$	$e$	$f$	$a$	$b$	$c$
$e$	$e$	$f$	$d$	$c$	$a$	$b$
$f$	$f$	$d$	$e$	$b$	$c$	$a$

Note that there is a fundamental difference between the permutations  $a, b, c$  and the other three. The former three form a *cycle*, generated by either  $b$  or  $c$ :

$$b^2 = c, \quad b^3 = a, \quad c^2 = b, \quad c^3 = a.$$

It follows that these three permutations form a commutative subgroup. Here (as well as in the whole group),  $a$  is the neutral element and  $b$  and  $c$  are inverses of each other. Therefore, this subgroup is the same as the group  $\mathbb{Z}_3$  of residue classes modulo 3, or as the group of third roots of unity.

The other three permutations are self-inverse, which means that any one of them together with the identity  $a$  create a subgroup, the same one as  $\mathbb{Z}_2$ . Further,  $b$  and  $c$  are *elements of order 3*, i.e. the third power is the first one equal to the identity  $a$ , while  $d, e$ , and  $f$  are of order 2.

Since the table is not symmetric with respect to the main diagonal, the composition  $\cdot$  is not commutative.

Other permutation groups  $\Sigma_m$  of finite  $m$ -element sets behave similarly. Each permutation  $\sigma$  partitions the set  $M$  into a disjoint union of maximal invariant subsets, which are obtained by taking unprocessed elements  $x \in M$  step by step and putting all iteration results  $\sigma^k(x)$ ,  $k = 1, 2, \dots$ , into the class  $M_x$  until  $\sigma^k(x) = x$ .

Each permutation is obtained as a composition of the cycles, which behave as the identity outside  $M_x$  and as  $\sigma$  on  $M_x$ . If the elements of  $M_x$  are numbered as  $(1, 2, \dots, |M_x|)$  so that  $i$  corresponds to  $\sigma^i(x)$ , then the permutation is simply a one-place shift in the cycle (i.e. the last element is mapped back to the first one). Hence the name *cycle*. These cycles commute, so it does not matter in which order the permutation  $\sigma$  is composed from them. (Of course, if we pick arbitrary two cycles on  $M$ , they do not have to commute.)

The simplest cycles are one-element fixed points of  $\sigma$  and two-element subsets  $(x, \sigma(x))$ , where  $\sigma(\sigma(x)) = x$ . The latter are called *transpositions*. Since every cycle can be composed from transpositions of adjacent elements (just let the

Let us look at the exercise more thoroughly. Computing all powers of  $x$ , we obtain

$$\begin{aligned} x^4 &\equiv x^3 + 1, \\ x^5 &\equiv x^3 + x + 1, \\ x^6 &\equiv x^3 + x^2 + x + 1, \\ x^7 &\equiv x^2 + x + 1, \\ x^8 &\equiv x^3 + x^2 + x, \\ x^9 &\equiv x^2 + 1, \\ x^{10} &\equiv x^3 + x, \\ x^{11} &\equiv x^3 + x^2 + 1, \\ x^{12} &\equiv x + 1, \\ x^{13} &\equiv x^2 + x, \\ x^{14} &\equiv x^3 + x^2, \end{aligned}$$

so the generating matrix is

$$G = \begin{pmatrix} 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

We can verify that multiplication by 01110111101 yields the codeword 011101110111101, which differs from the received word 011101110111001 exactly in the thirteenth bit  $\square$

Now, we begin to efficiently use the check matrix.

**12.H.6.** Find the generating matrix and the check matrix of the  $(7, 2)$ -code (i. e., there are 2 bits of the message and 5 redundant bits) generated by the polynomial  $x^5 + x^4 + x^2 + 1$ . Decode the received word 0010111 (i. e., find the message that was sent) assuming that the least number of errors occurred.

**Solution.** The generating matrix of the code is

$$G = \begin{pmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 1 \\ 0 & 1 \\ 1 & 1 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

last element “bubble” back to the beginning), every permutation can be written as a composition of transpositions of adjacent elements.

Return to the case of  $\Sigma_3$ . Two elements,  $b, c$ , represent cycles which include all the three elements; each of them generates  $\{a, b, c\} = \mathbb{Z}_3$ . Besides those,  $d, e, f$  are composed of cycles of length 2 and 1; finally  $a$  is composed of three cycles of length one. There are no more possibilities. However, it is clear from the procedure that for more elements, there are very many possibilities.

In general, there are many ways of expressing a permutation as a composition of transpositions. However, for a given permutation, the parity of the number of transpositions is fixed and independent of the choice of particular transpositions. This can be seen from the number of inverses of a permutation, since each transposition changes the number of inverses by an odd number (see the discussion in subsection 2.2.2 on page 97).

It follows that there is a well-defined mapping

$$\text{sgn} : \Sigma_m \rightarrow \mathbb{Z}_2 = \{\pm 1\},$$

the *permutation parity*. This recovers the proposition crucial for building the determinants (see 2.2.1 and on):

**Theorem.** Every permutation of a finite set can be written as a composition of cycles. A cycle of length  $\ell$  can be expressed as a composition of  $\ell - 1$  transpositions. The parity of this cycle is  $(-1)^{\ell-1}$ .

The parity of the composition  $\sigma \circ \tau$  is equal to the product of the parities of the composed permutations  $\sigma$  and  $\tau$ .

The last proposition suggests that the mapping  $\text{sgn}$  transforms permutation composition  $\sigma \circ \tau$  to the product  $\text{sgn } \sigma \cdot \text{sgn } \tau$  in the commutative group  $\mathbb{Z}_2$ .

(SEMI)GROUP HOMOMORPHISMS

In general, a mapping  $f : G_1 \rightarrow G_2$  is a (semi)group homomorphism if and only if it respects the operation, i.e.

$$f(a \cdot b) = f(a) \cdot f(b).$$

In particular, the permutation parity is a homomorphism  $\text{sgn} : \Sigma_m \rightarrow \mathbb{Z}_2$ .

In a moment, we shall see that the group inversions and units are also preserved by homomorphisms. Before discussing the theory, let us look at more examples of groups.

**12.4.3. Symmetries of plane figures.** In the fifth part of chapter one, the connections between invertible 2-by-2 matrices and linear transformations in the plane are thoroughly considered.

A matrix in  $\text{Mat}_2(\mathbb{R})$  defines a linear mapping  $\mathbb{R}^2 \rightarrow \mathbb{R}^2$  that preserves standard distances if and only if its columns form an orthonormal basis of  $\mathbb{R}^2$  (which is a simple condition for the matrix entries, see subsection 1.5.7 on page 33). Combining the orthogonal linear mappings with translations, we arrive at the group of all Euclidean transformations of the plane.

The generating matrix is of the form  $G = \begin{pmatrix} P \\ \mathbb{I}_k \end{pmatrix}$ , where  $P =$

$\begin{pmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 1 \\ 0 & 1 \\ 1 & 1 \end{pmatrix}$ . The check matrix is of the form  $(\mathbb{I}_{n-k} \ P)$ , i. e., in our case

$$H = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 \end{pmatrix}.$$

Multiplying the received word by the check matrix, we get the syndrome (error) of the word:

$$H \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} = (0 \ 1 \ 1 \ 1 \ 1).$$

The syndrome corresponding to the received word is 01111. Now, we find all words corresponding to this syndrome. This can be done by adding all codewords to the received word. There are four codewords, corresponding to the four possible messages. They are obtained by multiplying the messages (00, 01, 10, 11) by the generating matrix. Thus, we get the codewords

$$0000000, 1111101, 1010110, 0101011.$$

The space of words corresponding to a given syndrome is an affine space whose direction is the vector space of all codewords (see 12.5.8). Thus, we get the words

$$0010111, 1101010, 1000001, 0111100.$$

The least number of errors is equal to the least number of ones in the obtained words. In our case, this is the word 1000001, which contains only two ones and thus is the so-called leading representative of the class of words with syndrome 01111. The original message can be obtained by subtracting (or adding – this is equivalent in  $\mathbb{Z}_2$ ) the received word and the leading representative of the class with the given syndrome. In our case, we get

$$0010111 - 1000001 = 1010110.$$

Therefore, assuming the least number of errors, the sent word was 1010110, where the last two bits are the original message, i. e., 10.  $\square$

**12.H.7.** Consider the (7, 3)-code generated by the polynomial  $x^4 + x^3 + x + 1$ . Find its generating matrix and check matrix. Using the method of leading representatives, decode the received word 1110010.  $\circ$

In fact, it is possible to prove that every mapping of the plane into itself which preserves distances is affine such a Euclidean transformation.<sup>9</sup>

As observed, the linear part of this mapping is orthogonal. Thus, all these mappings form a group of all orthogonal transformations (also called Euclidean transformations) in the plane. Moreover, it is shown that besides translations  $T_a$  by a vector  $a$ , these are only rotations  $R_\varphi$  around the origin by any angle  $\varphi$ , and reflection  $F_\ell$  with respect to any line that goes through the origin (also note that the central inversion is the same as the rotation by  $\pi$ ).

Now, general group concepts are illustrated on the problem of symmetries of plane figures. For example, consider tiles. First, consider them individually, in the form of a bounded diagram in the plane. Then consider with the condition of tiling in a band, and then in the entire plane.

As an example, consider a line segment and an equilateral triangle. It is of interest in how much these objects are symmetric; that is, with respect to which transformations (that preserve distances) they are invariant. In other words, we want the image of the figure to be identical to the original one (unless some significant points are labeled, for example the vertices of the triangle  $A, B, C$  or the endpoints of the line segment). It is clear that all symmetries of a fixed object form a group (usually with only one element, the identity).

In the case of the line segment, the situation is very simple – it is clear that the only non-trivial symmetries are rotation by  $\pi$  around the center of the segment, reflection  $F_H$  with respect to the axis of the segment, and reflection  $F_V$  with respect to the line itself. All these symmetries are self-inverse. Hence the group of symmetries has four elements. Its table looks as follows:

<sup>9</sup>If a mapping  $F : \mathbb{R}^2 \rightarrow \mathbb{R}^2$  preserves distances, then this must also hold for the mapped vectors of velocity, i.e. the Jacobi matrix  $DF(x, y)$  must be orthogonal at every point. Expanding this condition for the given mapping  $F = (f(x, y), g(x, y)) : \mathbb{R}^2 \rightarrow \mathbb{R}^2$  leads to a system of differential equations which has only affine solutions, since all second derivatives of  $F$  must be zero (and then, the proposition is an immediate consequence of Taylor's remainder theorem). Try to think out the details! The same procedure leads to the result for Euclidean spaces of arbitrary dimension. Note that the condition to be proved is independent of the choice of affine coordinates. Composing  $F$  with a linear mapping does not change the result. Hence, for a fixed point  $(x, y)$ , compose  $(DF)^{-1} \circ F$  and assume, without loss of generality, that  $DF(x, y)$  is the identity matrix. Differentiation of the equations then yields the desired proposition.

**12.H.8.** Consider the linear  $(7, 4)$ -code (i. e., the message has length 4) over  $\mathbb{Z}_2$  defined by the matrix

$$\begin{pmatrix} 0 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Decode the received word 1010001 (i. e., find the sent message) assuming that the least number of errors occurred.

**Solution.** There are  $2^4 = 16$  possible messages. All codewords can be obtained by multiplying the possible messages (0000, 0001, ..., 1111) by the generating matrix of the code. Thus, we get:

$$\begin{array}{cccc} 0110001, & 1010010, & 1100100, & 0111000 \\ 1100011, & 1010101, & 0001001, & 1011100 \\ 1101010, & 0110110, & 0001110, & 1101101 \\ 1011011, & 0000111, & 0111111, & 0000000. \end{array}$$

Now, we construct the check matrix of the given code:

$$H = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 1 & 1 \end{pmatrix}.$$

(we remove the block of the generating matrix that consists of the identity matrix and to the left of the remaining block, we write the identity matrix of fitting size). Now, multiplying the vector of the received word  $z^T = (1010001)$  by  $H$ , we get the syndrome  $s = Hz = (110)^T$ . One word with this syndrome is 1100000 (we fill the syndrome with zeros to the appropriate length). All words with syndrome 110 are obtained by adding this word to all codewords. Thus, we get the words

$$\begin{array}{cccc} 1000001, & 0110010, & 0000100, & 1011000, \\ 0000011, & 0110101, & 1101001, & 0111100, \\ 0001010, & 1010110, & 1101110, & 0001101, \\ 0111011, & 1100111, & 1011111, & 1100000 \end{array}$$

Out of these words with syndrome 110, only the word 0000100 contains a single one, so this is the leading representative of the class of words with syndrome 110. Subtracting the leading representative from the received word, we get the word that was sent, assuming the least number of bit flips (1 in this case), i. e., the word (101)0101, where the last four bits are the message, i. e. 0101.  $\square$

**12.H.9.** Consider the linear  $(7, 4)$ -code (i. e., the message has length 4) over  $\mathbb{Z}_2$  defined by the matrix

$$\begin{pmatrix} 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

$$\begin{array}{c|cccc} \cdot & R_0 & R_\pi & F_H & F_V \\ \hline R_0 & R_0 & R_\pi & F_H & F_V \\ R_\pi & R_\pi & R_0 & F_V & F_H \\ F_H & F_H & F_V & R_0 & R_\pi \\ F_V & F_V & F_H & R_\pi & R_0 \end{array}.$$

This group is commutative.

For the equilateral triangle, there are more symmetries: one can rotate by  $2\pi/3$  or one can mirror with respect to axes of the sides. In order to obtain the entire group, all compositions of these transformations must be added in. In 1.5.9 it is shown that the composition of two reflections is always a rotation. At the same time, it is clear that changing the order of composition of fixed two reflections leads to a rotation by the same angle but the other orientation. It follows that the reflections around two axes generate all the symmetries, of which there are six altogether. Placing the triangle as is shown in the diagram, the six transformations are given by the following matrices:

$$a = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad b = \begin{pmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}, \quad c = \begin{pmatrix} -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix},$$

$$d = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad e = \begin{pmatrix} \frac{1}{2} & -\frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}, \quad f = \begin{pmatrix} \frac{1}{2} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}.$$

A comparison of the table of the operation, with that of the permutation group  $\Sigma_3$ , shows that it is the same. For the sake of clarity, the vertices are labeled with numbers, so the corresponding permutations can be easily understood.

Similarly, there are groups of symmetries with  $k$  rotations and  $k$  reflections. It suffices to consider a regular  $k$ -gon. These groups are usually denoted  $D_k$  and are called the *dihedral groups* of order  $k$ . They are not commutative for  $k \geq 3$  ( $D_2$  is commutative). The name comes from the fact that  $D_2$  is the group of symmetries of the hydrogen molecule  $H_2$ , which contains two hydrogen atoms and can be imagined as a line segment.

Similarly, there are figures whose only symmetries are rotations, and hence the corresponding groups are commutative. They are denoted  $C_k$  and called *cyclic groups* of order  $k$ . For that, it suffices to consider a regular polygon whose sides are changed non-symmetrically, but in the same manner (see the extension of the triangle in the diagram). Note that the group  $C_2$  can be realized in two ways: either using the rotation by  $\pi$  or a single reflection.

As the first illustration of the power of abstraction, we prove the following theorem. A figure is said to have a *discrete group of symmetries* if and only if the set of images of an arbitrary point over all the symmetries is a discrete subset of the plane (i.e. each of its points has a neighbourhood where there is no other point of the set).

Note that every discrete group of symmetries of a bounded figure is necessarily finite.

**Theorem.** Let  $M$  be a bounded set in the plane  $\mathbb{R}^2$  with discrete group of symmetries  $G$ . Then,  $G$  is either trivial or one of the groups  $C_k, D_k$  for  $k > 1$ .

Decode the received word 1101001 (i. e., find the sent message) assuming that the least number of errors occurred.

**Solution.** Syndrome 101, leading representative 0001000, sent message (110)0001  $\square$

**12.H.10.** Consider the linear (7, 4)-code (i. e., the message has length 4) over  $\mathbb{Z}_2$  defined by the matrix

$$\begin{pmatrix} 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Decode the received word 0000011 (i. e., find the sent message) assuming that the least number of errors occurred.

**Solution.** Syndrome 011, leading representative 0000100, sent message (000)0111.  $\square$

**12.H.11.** Consider the linear (7, 4)-code (i. e., the message has length 4) over  $\mathbb{Z}_2$  defined by the matrix

$$\begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Decode the received word 0001100 (i. e., find the sent message) assuming that the least number of errors occurred.

**Solution.** Syndrome 110, leading representative 0000010, sent message (000)1110.  $\square$

**12.H.12.** We want to transfer one of four possible messages with a binary code which should be able to correct all single errors. What is the minimum possible length of the codewords (all codewords have to be of the same length)? Why?

**Solution.** Let us denote the desired length as  $n$ . The minimum Hamming distance of any two codewords must be at least three. This means that if we take two different codewords and flip one bit in each, the resulting words must also be different (and also different from each codeword). There are  $n + 1$  words that can be obtained from a given one by flipping at most one bit (this includes the original word itself as well). Thus, we must have at least  $4(n + 1)$  possible words. On the other hand, there are  $2^n$  words of length  $n$ , which means that  $4(n + 1) \leq 2^n$ . This inequality is satisfied only for  $n \geq 5$ . Thus, the codewords must be at least 5 bits long. And indeed, there are four codewords of length 5 with minimum Hamming distance 3, for instance 00111, 01001, 10100, 11010.  $\square$

**PROOF.** If there were a set  $M$  with translation as one of its symmetries, then it could not be bounded. If  $M$  had, as one of its symmetries, a rotation by angle which is an irrational multiple of  $2\pi$ , then iterating this rotation would lead to a dense subset of images on the corresponding circle.<sup>10</sup> It follows that the group is not discrete.

If  $M$  had non-trivial rotations with different centers as symmetries, then again it could not be bounded. To see this, write the corresponding rotations in the complex plane as

$$R : z \mapsto (z - a)\zeta + a, \quad Q : z \mapsto z\eta$$

for complex units  $\zeta = e^{2\pi i/k}$ ,  $\eta = e^{2\pi i/\ell}$  and an arbitrary  $a \neq 0 \in \mathbb{C}$ . Then, it is immediate (a straightforward computation with complex numbers) that

$$Q \circ R \circ Q^{-1} \circ R^{-1} : z \mapsto z + a(-1 + \zeta + \eta - \zeta\eta),$$

which is a translation by a non-trivial vector unless the angle of one of the rotations is zero. It follows that  $M$  is not bounded.

The same holds for the case of a rotation and a reflection with respect to a line which does not go through the center of the rotation. Check this case yourself!

The only symmetries available are rotations with a common center and reflections with respect to lines which pass through this center. It remains to prove that the entire group is composed either only from rotations, or from the same number of rotations and reflections.

Recall that the composition of two different reflections yields a rotation whose angle doubles the angle enclosed by the corresponding axes (see 1.5.9). Therefore, composing a reflection with respect to a line  $p$  with a rotation by angle  $\varphi$  is again a reflection with respect to the line which is at angle  $\varphi/2$  from  $p$  (draw a diagram!).

The proof is almost complete. Observe that the subgroup of all rotations in the group of symmetries contains a rotation by the smallest positive angle  $\varphi_0$  (there are only finite many of them there). But then it is impossible to allow a rotation  $R_\varphi$  where  $\varphi$  is not a multiple of  $\varphi_0$  (for then  $\varphi \in (k\varphi_0, (k + 1)\varphi_0)$  for some  $k$  and the composition  $R_{-k\varphi_0} \circ R_\varphi$  would have an smaller angle than  $\varphi_0$ ). This subgroup coincides with one of  $C_\ell$ . Next, adding one reflection produces exactly one different reflection for each nontrivial element in  $C_\ell$ , as seen above.  $\square$

**12.4.4. Symmetries of plane tilings.** There is more complicated behaviour in the case of plane figures in bands or in the entire plane (for example, symmetries of various tilings).

<sup>10</sup>The argument is subtle but straightforward: if there was an interval of length  $\varepsilon$  on the circle not hit by an orbit of a point under the rotation, all points in the orbit would have to be at distance at least  $\varepsilon$ . Thus there can be only finitely many of them and this contradicts the irrationality of the angle.

**12.H.13.** We want to transfer 4-bit messages with a binary code which should be able to correct all single and double errors. What is the minimum possible length of the codewords (all codewords have to be of the same length)? Why?

**Solution.** We proceed similarly as in the above exercise. If the code is to correct double errors as well, then the minimum Hamming distance of any two codewords must be at least three. This means that if we take two different codewords and flip up to two bits in each, the resulting words must also be different. Denoting by  $n$  the length of the words, we get the inequality

$$2^4 \left( 1 + n + \binom{n}{2} \right) \leq 2^n.$$

The least value of  $n$  for which it is satisfied is  $n = 12$ , so the codewords must be at least 12 bits long.  $\square$

### I. Extension of the stereographic projection

Let us try to extend the definition of the stereographic projection so that a circle would be parametrized by points of  $\mathbb{P}_1(\mathbb{R})$ . Let us look at the corresponding mapping  $\mathbb{P}_1(\mathbb{R}) \rightarrow \mathbb{P}_2(\mathbb{R}^2)$ . The points in projective extensions will be defined in the so-called *homogeneous coordinates*, which are given up to a multiple. For instance, the points in  $\mathbb{P}_2(\mathbb{R})$  will be  $(x : y : z)$ .

A circle in the plane  $z = 1$  is given as the intersection of the cone of directions defined by  $x^2 + y^2 - z^2 = 0$  with this plane. The inversion of the stereographic projection (i. e., our parametrization of the circle) can be described as:

$$(t : 1) \mapsto \left( \frac{2t}{1+t^2} : \frac{t^2-1}{t^2+1} : 1 \right) = (2t : t^2 - 1 : t^2 + 1).$$

For  $t \neq 0$ , we have  $(t : 1) = (2t^2 : 2t)$ , and the original stereographic projection (i. e., the inverse of the above mapping) can be written linearly as

$$(x : y : z) \mapsto (y + z : x),$$

which extends our parametrization to the improper point  $(0 : 1) \mapsto (0 : 1 : 1)$ . Then, the mapping of  $\mathbb{P}_1(\mathbb{R})$  onto the circle has the “linear” form

$$\mathbb{P}_1(\mathbb{R}) \ni (x : y) \mapsto (2x : x - y : x + y) \in \mathbb{P}_2(\mathbb{R}).$$

Now, let us look at how simple it is to calculate the formula for the stereographic projection in the projective extensions directly (see 4.4.1): We include  $\mathbb{P}_1(\mathbb{R})$  as points with homogeneous coordinates  $(t : 0 : 1)$ , and among the linear combinations of point  $(0 : 1 : -1)$  (i. e., the pole from which we project) and  $(x : y : z)$  (a general point of the circle), we must find the one whose coordinates are  $(u : 0 : v)$ . The only possibility is the point  $(x : 0 : z + y)$ , which is our previous formula.

Consider first the set containing the points that lie between two fixed parallel lines. Suppose that this band is covered with disjoint images of a bounded subset  $M$  by some translation. Of course, this translation is a symmetry of the chosen tiling of the band. So the group of symmetries is necessarily infinite.

Such a set allows for no other rotation symmetries than  $R_\pi$ , and the only possible reflections are either horizontal with respect to the axis of the band, or vertical with respect to any line which is perpendicular to the boundary lines. In addition, there are translations given by a vector which is parallel to the axis of the band.

A not-too-complicated discussion leads to description of all discrete groups of symmetries for these bands. Such a group is generated by some of the following symmetries: translation  $T$ , shifted reflection  $G$  (i.e. composition of horizontal reflection and translation), vertical reflection  $V$ , horizontal reflection  $H$  and rotation  $R$  by  $\pi$ .

**Theorem.** Every discrete group of symmetries of a band in the plane is isomorphic to one of the groups generated by the following symmetries:

- (1) a single translation  $T$ ,
- (2) a single shifted reflection  $G$ ,
- (3) a single translation  $T$  and a vertical reflection  $V$ ,
- (4) a single translation  $T$  and the rotation  $R$ ,
- (5) a single shifted reflection  $G$  and the rotation  $R$ ,
- (6) a single translation  $T$  and the horizontal reflection  $H$ ,
- (7) a single translation  $T$ , the horizontal reflection  $H$  and a vertical reflection  $V$ .

The proof is not presented here. The following diagram shows examples of schematic patterns with corresponding symmetries:

It is even more complicated with symmetries of tilings which cover the entire plane. There is insufficient space here to consider further details. It can be shown that there are 17 such groups of symmetries, known as the two-dimensional crystallographic groups.

A similar complete discussion is known even for three-dimensional discrete groups of symmetries. The rich theory was created namely in the 19th century in connection with studying symmetries of crystals and molecules of chemical elements.

**J. Elliptic curves**

A *singular point* of a hypersurface in  $P^n$ , defined by a homogeneous polynomial

$$F(x_0, x_1, \dots, x_n) = 0,$$

is such a point which satisfies  $\frac{\partial F}{\partial x_i} = 0$  for  $i = 1, \dots, n$ .

From the geometric point of view, “something weird” happens at the point. In the case of a curve in the projective space  $P^2(\mathbb{R})$ , the condition that the partial derivatives must be zero means that there is no tangent line to the curve at the given point. This means that the curve has the so-called *cusp* there or it intersects itself. A “nice” singularity can be seen in the “quatrefoil”, i. e., the variety given by the zero points of the polynomial  $(x^2 + y^2)^3 - 4x^2y^2 \in \mathbb{R}^2$ :

The cusp can be found on the curve in  $\mathbb{R}^2$  given by  $x^3 - y^2 = 0$ .

**12.4.5. Group homomorphisms.** Recall that a mapping  $f : G \rightarrow H$  from a group  $G$  to a group  $H$  is called a group homomorphism if and only if it respects the operation, i.e. for all  $a, b \in G$  that

$$f(a \cdot b) = f(a) \cdot f(b).$$

Note that the operation on the left-hand side is the operation in  $G$ , before  $f$  is applied, while the operation on the right-hand side is the operation in  $H$ , after  $f$  is applied.

The following properties of homomorphisms follow easily from the definition:

**Proposition.** Every group homomorphism  $f : G \rightarrow H$  satisfies:

- (1) the identity of  $G$  is mapped to the identity of  $H$ ,
- (2) the inverse of an element of  $G$  is mapped to the inverse of its image, i.e.

$$f(a^{-1}) = f(a)^{-1},$$

- (3) the image of a subgroup  $K \subseteq G$  is a subgroup  $f(K) \subseteq H$ ,
- (4) the preimage  $f^{-1}(K) \subseteq G$  of a subgroup  $K \subseteq H$  is again a subgroup,
- (5) if  $f$  is also a bijection, then the inverse mapping  $f^{-1}$  is also a homomorphism,
- (6)  $f$  is injective if and only if  $f^{-1}(e_H) = \{e_G\}$ .

**PROOF.** (3), (2), and (1). If  $K \subseteq G$  is a subgroup, then for each  $y = f(a), z = f(b)$  in  $H, a, b \in K, y \cdot z = f(a \cdot b)$  also lies in the image. In particular,  $f(b) = f(e \cdot b) = f(e) \cdot f(b)$  and similarly  $f(b) = f(b) \cdot f(e)$ . Thus  $f(e)$  is the unique unit in the image  $f(K)$ . Finally,  $f(e) = f(a \cdot a^{-1}) = f(a) \cdot f(a^{-1})$ , so that  $f(a^{-1})$  is the right inverse of  $f(a)$ . Similarly, it is a left inverse, too, and we have proved the first three claims.

Proceed similarly in the case of preimages: if  $a, b \in G$  satisfy  $f(a), f(b) \in K \subseteq H$ , then also  $f(a \cdot b) \in K$ .

Suppose there exists an inverse mapping  $g = f^{-1}$ . Fix arbitrarily  $y = f(a), z = f(b) \in H$ . Then,  $f(a \cdot b) = y \cdot z = f(a) \cdot f(b)$ , which is equivalent to the expression  $g(y) \cdot g(z) = a \cdot b = g(y \cdot z)$ . Thus the inverse mapping is also a homomorphism.

If  $f(a) = f(b)$ , then  $f(a \cdot b^{-1}) = e_H$ . Therefore, if the only element that is mapped to  $e_H$  is  $e_G$ , then  $a \cdot b^{-1} = e_G$ , i.e.  $a = b$ . The other implication is trivial.  $\square$

The subgroup  $f^{-1}(e_H)$  (the preimage of the identity in  $H$ ) is called the *kernel* of the homomorphism  $f$  and is denoted  $\ker f$ . A bijective group homomorphism is called a *group isomorphism*.

It follows directly from the above ideas that a homomorphism  $f : G \rightarrow H$  with a trivial kernel is an isomorphism onto the image  $f(G)$ .

An *elliptic curve*  $\mathcal{C}$  is the set of points in  $\mathbb{K}^2$ , where  $\mathbb{K}$  is a given field, which satisfy an equation of the form

$$y^2 = x^3 + ax + b,$$

where  $a, b \in \mathbb{K}$ . In addition, we require that there are no singularities, which means, over the field of real numbers, that

$$\Delta = -16(4a^3 + 27b^2) \neq 0.$$

This expression  $\Delta$  is called the discriminant of the equation. Note that the right-hand side contains a cubic polynomial without the quadratic term. This form of the equation is called the *Weierstrass equation* of an elliptic curve.

**12.J.1.** Prove that the curve  $y^2 = x^3 + ax + b$  in  $\mathbb{R}^2$  has a singularity if and only if  $4a^3 - 27b^2 = 0$ .

**Solution.** The equation of the curve in homogeneous coordinates (see 4.4.1) is  $F(x, y, z) = 0$ , where

$$(1) \quad F(x, y, z) = y^2z - x^3 - axz^2 - bz^3.$$

We have

$$\begin{aligned} \frac{\partial F}{\partial x} &= -3x^2 - az^2, \\ \frac{\partial F}{\partial y} &= 2yz, \\ \frac{\partial F}{\partial z} &= y^2 - 2axz - 3bz^2. \end{aligned}$$

Let  $[x, y, z]$  be a singular point of the given curve. If  $z = 0$ , then since the partial derivatives of  $F$  with respect to  $x$  and  $z$  must be zero, we get  $x = 0$  and  $y = 0$ , respectively. However, this is “out”, because the point  $[0, 0, 0]$  does not lie in the considered projective space  $P^2(\mathbb{R})$ . Thus, the singular points has  $z \neq 0$ , so that  $\frac{\partial F}{\partial y} = 0$  implies  $y = 0$ . Denoting  $\gamma = \frac{x}{z}$ , then  $-3x^2 - az^2 = 0$  implies  $3\gamma^2 = -a$ , and  $y^2 - 2axz - 3bz^2 = 0$  implies  $2a\gamma = -3b$ . We can see that the equality  $a = 0$  implies that  $b = 0$ , i. e., the equality  $4a^3 = 27b^2$  is satisfied trivially. If  $a \neq 0$ , then we can express  $\gamma$  from the two obtained equations. From the first one, we have  $\gamma = -\frac{3b}{2a}$ , and from the second one,  $\gamma^2 = -\frac{a}{3}$ . Altogether,

$$\gamma^2 = -\frac{a}{3} = \frac{9b^2}{4a^2} \implies 4a^3 + 27b^2 = 0.$$

Thus, we have proved one of the implications. On the other hand, if  $4a^3 + 27b^2 = 0$ , then defining  $\gamma = -\frac{3b}{2a}$ , we can see that the point  $[\gamma, 0, 1]$  satisfies the equation of the elliptic curve:

$$\begin{aligned} \gamma^2 + a\gamma + b &= \left(-\frac{3b}{2a}\right) \left(-\frac{a}{3}\right) + a \left(-\frac{3b}{2a}\right) + b = \\ &= \frac{b}{2} - \frac{3b}{2} = 0. \end{aligned}$$

Thanks to the choice of  $\gamma$ , all the three partial derivatives of  $F$  at the point  $[\gamma, 0, 1]$  are zero.  $\square$

In order to define a group operation on the points of an elliptic curve, it is useful to consider the curve in the projective extension of the plane (see 4.4.1), and we define a point

**12.4.6. Examples.** The additive group  $\mathbb{Z}_k$  of residue classes modulo  $k$  is isomorphic to the group of  $k$ -th roots of unity, and also to the group of rotations by integer multiples of  $2\pi/k$ . Draw a diagram, calculation with the complex units  $e^{2\pi i/k}$  is very efficient.

The mapping  $\exp : \mathbb{R} \rightarrow \mathbb{R}_+$  is an isomorphism of the additive group of the real numbers onto the multiplicative group of the positive real numbers.

This isomorphism extends naturally to a homomorphism  $\exp : \mathbb{C} \rightarrow \mathbb{C} \setminus \{0\}$  of the additive group of the complex numbers onto the multiplicative group of the non-zero complex numbers. However, this homomorphism has a non-trivial kernel. The restriction of  $\exp$  to purely imaginary numbers (which is a subgroup isomorphic to  $\mathbb{R}$ ) is a homomorphism

$$it \mapsto e^{it} = \cos t + i \sin t.$$

This means that the numbers  $2k\pi i$ ,  $k \in \mathbb{Z}$ , lie in the kernel. It can be shown that nothing else is in the kernel. If  $e^{s+it} = e^s \cdot e^{it} = 1$  for real numbers  $s$  and  $t$ , then  $e^s = 1$ , i.e.  $s = 0$ , and then  $t = 2k\pi$  for an integer  $k$ .

The determinant of a matrix is a mapping which assigns, to each square matrix of scalars in  $\mathbb{K}$ , a scalar in  $\mathbb{K}$  (the cases  $\mathbb{K} = \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C}$  have already been worked with). The Cauchy theorem about the determinant of the product of square matrices

$$\det(A \cdot B) = (\det A) \cdot (\det B)$$

can be also seen as the fact that for the group  $G = GL(n, \mathbb{K})$  of invertible matrices, the mapping  $\det : G \rightarrow \mathbb{K} \setminus \{0\}$  is a group homomorphism.

**12.4.7. Group product.** Given any two groups, a more complicated group can be constructed using the following construction:

#### GROUP PRODUCT

For any groups  $G, H$  the *group product*  $G \times H$  is defined as follows: The underlying set is the Cartesian product  $G \times H$  and the operation is defined componentwise. That is,

$$(a, x) \cdot (b, y) = (a \cdot b, x \cdot y),$$

where the left-hand operation is the one to be defined, while the right-hand operations are respectively those in  $G$  and  $H$ .

The projections onto the components  $G$  and  $H$  in the product:

$$p_G : G \times H \ni (a, b) \mapsto a \in G, \quad p_H : G \times H \ni (a, b) \mapsto b$$

are surjective homomorphisms, whose kernels are

$$\begin{aligned} \ker p_G &= \{(e_G, b); b \in H\} \simeq H, \\ \ker p_H &= \{(a, e_H); a \in G\} \simeq G. \end{aligned}$$

The group  $\mathbb{Z}_6$  is isomorphic to the product  $\mathbb{Z}_2 \times \mathbb{Z}_3$ . This can be seen easily in the multiplicative realization of the groups  $\mathbb{Z}_k$  as the complex  $k$ -th roots of unity.  $\mathbb{Z}_6$  consists of the points of the unit circle that form the vertices of a regular hexagon. Then,  $\mathbb{Z}_2$  corresponds to  $\pm 1$ , while  $\mathbb{Z}_3$  corresponds to the equilateral triangle, one of whose vertices is

$O \in \mathcal{C}$  as the direction  $(0, 1)$  (which is the point  $[0, 1, 0]$  in the homogeneous coordinates). Then, the addition of two points  $A, B \in \mathcal{C}$  is geometrically defined as the point  $-C$ , where  $C$  is the third intersection point of the line  $AB$  with the elliptic curve. If  $A = B$ , then the result is given by the other intersection point with the tangent line of the elliptic curve that goes through  $A$ .

**12.J.2.** Prove that the above definition correctly defines an operation on the points of an elliptic curve.

**Solution.** The intersections of the line with the elliptic curve are obtained as the roots of a cubic equation. If it has two real roots, corresponding to the points  $A$  and  $B$ , then it must have a third real root as well, i. e., the line  $AB$  must have another intersection point with the curve. In the case of a tangent line, the point  $A$  corresponds to a double root, so there also exists another intersection point. As for improper points (the last homogeneous coordinate is zero; they correspond to directions in the plane), the only improper point that belongs to the curve given by the equation (1) is the point  $O = [0, 1, 0]$ . Addition with the point  $O$  means looking for a second intersection of the elliptic curve (besides the point  $A$  itself) and the line which goes through  $A$  and is parallel to the  $y$ -axis. The improper line  $z = 0$  has triple intersection point  $O$  with the curve, i. e.,  $O + O = O$ .  $\square$

**Remark.** Thus, the operation is well-defined. Moreover, it follows directly from the definition that it is commutative. It even follows from the above that  $O$  is a neutral element of the operation. However, the proof of associativity is far from trivial.

**12.J.3.** Define the above operation algebraically.

**Solution.** For any point  $A \in \mathcal{C}$ , we define  $A + O = O + A = A$ .

For a point  $A \in \mathcal{C}$ ,  $A = (\alpha, \beta, 1)$ , we clearly have  $B \in \mathcal{C}$ , and we define  $A + B = 0$ , i. e.,  $A = -B$ .

For a point  $A \neq -B$ ,  $A = [\alpha, \beta, 1]$  and a point  $B \in \mathcal{C}$ ,  $B = [\gamma, \delta, 1]$ , we set

$$k = \begin{cases} \frac{\beta - \delta}{\alpha - \gamma} & \text{for } A \neq B, \\ [5pt] \frac{3\alpha^2 + a}{2\beta} & \text{for } A = B, \end{cases}$$

$$\sigma = k^2 - \alpha - \gamma,$$

$$\tau = -\beta + k(\alpha - \sigma).$$

the number 1. If each point is identified with the rotation that maps 1 to that point, then the composition of such rotations is always commutative. Composing a rotation from  $\mathbb{Z}_2$  with a rotation from  $\mathbb{Z}_3$  yields exactly all rotations from  $\mathbb{Z}_6$ . Draw a diagram! This leads to the following isomorphism (using additive notation, as is common for the residue classes):

$$\begin{aligned} [0]_6 &\mapsto ([0]_2, [0]_3), \\ [1]_6 &\mapsto ([1]_2, [2]_3), \\ [2]_6 &\mapsto ([0]_2, [1]_3), \\ [3]_6 &\mapsto ([1]_2, [0]_3), \\ [4]_6 &\mapsto ([0]_2, [2]_3), \\ [5]_6 &\mapsto ([1]_2, [1]_3). \end{aligned}$$

Similar constructions are available for finite commutative groups in complete generality.

**12.4.8. Commutative groups.** Any element  $a$  of a group

$G$  is contained in the minimal subgroup  $\{\dots, a^{-2}, a^{-1}, e, a, a^2, a^3, \dots\}$ , which contains it. It is clear that this subgroup is commutative. If  $G$  is finite, then it must once happen that  $a^k = e$ . The least positive integer  $k$  with this property is called the *order of the element  $a$*  in  $G$ . A *cyclic group*  $G$  is one which is generated by one of its elements  $a$  in the above manner. If the order  $k$  of the generator is finite, then it results in one of the groups  $C_k$ , known from the discussion of symmetries of plane figures.

It follows directly from the definition that every cyclic group is isomorphic either to the group of integers  $\mathbb{Z}$  (if it is infinite) or to one of the groups of residue classes  $\mathbb{Z}_k$  (if it is finite). These simple building stones are sufficient to create all finite commutative groups.

**Theorem.** Every finite commutative group  $G$  is isomorphic to a product of some cyclic groups  $C_k$ . The orders of the components  $C_k$  are always powers of the prime divisors of the number of elements  $n = |G|$ . This product decomposition is unique, up to order.

If  $n = p_1^{k_1} \dots p_r^{k_r}$  is the prime factorization of  $n$ , then the group  $C_n$  is isomorphic to the product

$$C_n = C_{p_1^{k_1}} \times \dots \times C_{p_r^{k_r}}.$$

**INCOMPLETE PROOF.** We are going to prove only the second claim now, and we return to the first claim later, see 12.4.12, 12.4.13.

For a simpler case, suppose  $n = pq$  with  $p$  coprime to  $q$ . Fix a generator  $a$  of the group  $C_n$ , a generator  $b$  of  $C_p$ , and a generator  $c$  of  $C_q$ . Define the mapping  $f : C_n \rightarrow C_p \times C_q$  by

$$f(a^k) = (b^k, c^k).$$

Since  $a^k \cdot a^\ell = a^{k+\ell}$  and similarly for  $b$  and  $c$ , it follows that

$$f(a^k \cdot a^\ell) = (b^{k+\ell}, c^{k+\ell}) = (b^k, c^k) \cdot (b^\ell, c^\ell),$$

so the mapping  $f$  is a homomorphism. If the image is the identity, then  $k$  must be a multiple of  $p$  as well as  $q$ . Since

Then, we define  $A + B = [\gamma, \tau, 1]$ . We leave it for the reader to verify that this is indeed the operation that we have defined geometrically.  $\square$

**K. Gröbner bases**

**12.K.1.** Is the basis  $g_1 = x^2, g_2 = xy + y^2$  a Gröbner basis for the lexicographic ordering  $x > y$ ? If not, find one.

**Solution.** Clearly, the leading monomials are  $LT(g_1) = x^2, LT(g_2) = xy$ , so the S-polynomial is equal to

$$S(g_1, g_2) = yg_1 - xg_2 = -xy^2.$$

By theorem 12.6.12,  $g_1, g_2$  is a Gröbner basis if and only if the remainder in the multivariate division of this S-polynomial by the basis polynomials is zero. Performing this division (see 12.6.6), we obtain

$$S(g_1, g_2) = yg_1 - xg_2 + yg_2 - y^3.$$

The remainder  $y^3$  shows that  $g_1, g_2$  do not form a Gröbner basis. By 12.6.13, in order to get one, we must add the remainder polynomial  $g_3 = y^3$  to  $g_1, g_2$ . Now, we calculate that

$$S(g_1, g_3) = y^3g_1 - x^2g_3 = 0$$

and

$$S(g_2, g_3) = y^2g_2 - xg_3 = y^4 = yg_3.$$

Hence it follows by theorem 12.6.12 that  $g_1, g_2, g_3$  is already a Gröbner basis.  $\square$

**12.K.2.** Is the basis  $g_1 = xy - 2y, g_2 = y^2 - x^2$  a Gröbner basis for the lexicographic ordering  $y > x$ ? If not, find one.

**Solution.** Since  $LT(g_1) = xy$  and  $LT(g_2) = y^2$ , the corresponding S-polynomials is  $S(g_1, g_2) = yg_1 - xg_2 = x^3 - 2y^2 = -2g_2 + x^3 - 2x^2$ . The leading term  $x^3$  is a multiple of neither  $xy$  nor  $y^2$ , which means that  $g_1, g_2$  do not form a Gröbner basis. We can obtain one by adding the polynomial  $g_3 = x^3 - 2x^2$ . Then, we have

$$S(g_1, g_3) = x^2g_1 - yg_3 = 0$$

and

$$S(g_2, g_3) = x^3g_2 - y^2g_3 = 2y^2x^2 - x^5 = (4y + 2xy)g_1 - (x^2 + 2x + 4)g_3 + 8g_2. \quad \square$$

**12.K.3.** Eliminate variables in the ideal

$$I = \langle x^2 + y^2 + z^2 - 1, x^2 + y^2 + z^2 - 2x, 2x - y - z \rangle.$$

**Solution.** The variable elimination is obtained by finding a Gröbner basis with respect to the lexicographic monomial ordering. Let us denote the generating polynomials of  $I$  as  $g_1, g_2, g_3$ , respectively. The reduction  $g_2 = g_1 + 1 - 2x$  yields the reduced polynomial  $f_1 = 2x - 1$ . Now, we use this polynomial to reduce  $g_3 = f_1 + 1 - y - z$  to  $f_2 = y + z - 1$ . Now, we reduce  $g_1$ , dividing it by  $f_1$  and  $f_2$ , which leads to

$$g_1 = \left(\frac{1}{2}x + \frac{1}{4}\right)f_1 + y^2 + z^2 - 1$$

and

$$y^2 + z^2 - 1 = (y - z + 1)f_2 + 2z^2 - 2z + \frac{1}{4}.$$

$p$  and  $q$  are coprime,  $k$  is a multiple of  $n$ , so  $f$  is injective. Moreover, the group  $C_n$  has the same number of elements as  $C_p \times C_q$ , so  $f$  is an isomorphism.

Finally, the proposition about the decomposition of cyclic groups of order  $k$  into smaller cyclic groups follows by induction on the number of different primes  $p_i$  in the factorization of  $n$ .  $\square$

Notice,  $C_{p^2}$  is never isomorphic to the product  $C_p \times C_p$ . While  $C_{p^2}$  is generated by an element of order  $p^2$ , the highest order of an element in  $C_p \times C_p$  is only  $p$ .

Since every finite commutative group is isomorphic to a product of cyclic groups, it is possible, for a given number of elements, to enumerate all commutative groups of that order up to isomorphism. For instance, there are only two groups of order 12:

$$C_{12} = C_4 \times C_3, \quad C_2 \times C_2 \times C_3 = C_2 \times C_6.$$

Notice similarly that if all elements (except the identity) of a finite commutative group  $G$  have order 2, then  $G$  has the form  $(C_2)^n$  for an integer  $n$ . In particular, such a group  $G$  has  $2^n$  elements. If the decomposition of  $G$  into cyclic groups contains a group  $C_p, p > 2$ , then the group contains elements of higher order.

**12.4.9. Subgroups and cosets.** Selecting any subgroup  $H$

of a group  $G$ , gives further information about the structure of the whole group. A binary relation  $\sim_H$  on  $G$  can be defined as follows:  $a \sim_H b$  if and only if  $b^{-1} \cdot a \in H$ . This relation expresses when two elements of  $G$  are “the same” up to multiplication by an element of  $H$  from the right. It is easily verified that this relation is an equivalence:

Clearly,  $a^{-1} \cdot a = e \in H$ , so it is reflexive. If  $b^{-1} \cdot a = h \in H$ , then  $a^{-1} \cdot b = (b^{-1} \cdot a)^{-1} = h^{-1} \in H$ , so it is symmetric as well. Finally, if  $c^{-1} \cdot b \in H$  and  $b^{-1} \cdot a \in H$ , then  $c^{-1} \cdot a = c^{-1} \cdot b \cdot b^{-1} \cdot a \in H$ , so it is transitive, too.

It follows that  $G$  partitions into the *left cosets* of mutually equivalent elements, with respect to the subgroup  $H$ . The coset corresponding to an element  $a$  is denoted  $a \cdot H$ , and

$$a \cdot H = \{a \cdot h; h \in H\},$$

since an element  $b$  is equivalent to  $a$  if and only if it can be expressed this way.

The corresponding partition of  $G$  (i.e. the set of all left cosets) with respect to  $H$  is denoted  $G/H$ .

Similarly, right cosets  $H \cdot a$  can be defined. The corresponding equivalence relation is given by  $a \sim b$  if and only if  $a \cdot b^{-1} \in H$ . Hence,

$$H \setminus G = \{H \cdot a; a \in G\}.$$

**Proposition.** Let  $G$  be a group and  $H$  a subgroup of  $G$ . Then:

(1) The left cosets with respect to  $H$  coincide with the right cosets with respect to  $H$  if and only if for each  $a \in G$ ,

Hence,  $f_3 = 8z^2 - 8z + 1$ . We can see that we could do with polynomial reduction and we did not have to add any other polynomials. The basis of  $I$  with eliminated variables is  $I = \langle 2x - 1, y + z - 1, 8z^2 - 8z + 1 \rangle$ .  $\square$

**12.K.4.** Solve the following system of polynomial equations:

$$\begin{aligned} x^2y - z^3 &= 0, \\ 2xy - 4z &= 1, \\ z - y^2 &= 0, \\ x^3 - 4yz &= 0. \end{aligned}$$

**Solution.** Using appropriate software, we can find out that the corresponding ideal

$$\langle x^2y - z^3, 2xy - 4z - 1, z - y^2, x^3 - 4yz \rangle$$

has Gröbner basis  $\langle 1 \rangle$  with respect to the lexicographic monomial ordering, which means that the system has no solution.  $\square$

**12.K.5.** Find the Gröbner basis of the variety in  $\mathbb{R}^3$  defined parametrically as

$$\begin{aligned} x &= 3u + 3uv^2 - u^3, \\ y &= 3v + 3u^2v - v^3, \\ z &= 3u^2 - 3v^2. \end{aligned}$$

This is the so-called Enneper surface, and it is depicted in the picture on page 1119.

**Solution.** Applying the elimination procedure (e. g. in the MAPLE system, using `gbasis` with `plex` ordering), we obtain the corresponding implicit representation, i. e., an equation with a single polynomial of degree nine:

$$\begin{aligned} &-59049z - 104976z^2 - 6561y^2 - 72900z^3 - 18954y^2z - \\ &-23328z^4 + 32805z^2x^2 + 14580z^3x^2 + 3645z^4x^2 - 1296y^4z - \\ &-16767y^2z^2 - 6156y^2z^3 - 783y^2z^4 + 39366zx^2 + 19683x^2z - \\ &-1296y^4 - 2430z^5 + 432z^6 + 108z^7 + 486z^5x^2 - 432y^4z^2 + \\ &+ 54y^2z^5 + 27z^6x^2 - 48y^4z^3 + 15y^2z^6 - 64y^6 - z^9. \end{aligned}$$

$\square$  As we illustrate on the following simple exercise, the Gröbner basis can be used for solving integer optimization problems.

**12.K.6.** What is the minimum number of banknotes that are necessary to pay 77700 CZK? Solve this problem for three scenarios: First, assume that the banknotes at disposal are of values 100 CZK, 200 CZK, 500 CZK, 1000 CZK. Then, assume that there are also banknotes of value 2000 CZK. Finally, assume that there are no banknotes of value 2000 CZK, but there are banknotes of value 5000 CZK.

**Solution.** Let us denote the respective banknotes by variables  $s, d, p, t, D, P$ . The banknotes to be used will be represented as a polynomial in these variables so that the exponent of each variable determines the number of the corresponding banknotes. For instance, if we decide to use only the 100 CZK banknotes, then the polynomial will be  $q = s^{777}$ . If we pay with ten 1000 CZK banknotes, ten 500 CZK banknotes,

$$h \in H$$

$$a \cdot h \cdot a^{-1} \in H.$$

(2) Each coset (left or right) has the same cardinality as the subgroup  $H$ .

**PROOF.** Both properties are direct consequences of the definition. In the first case, for any  $a \in G, h \in H$ , an element  $h' \in H$  is required so that  $h \cdot a = a \cdot h'$ . This occurs if and only if  $a^{-1} \cdot h \cdot a = h' \in H$ .

In the second case, if  $a \cdot h = a \cdot h'$ , then multiplication by  $a^{-1}$  from the left yields  $h = h'$ .  $\square$

As an immediate corollary of the above statement, there are the following extremely useful results:

**12.4.10. Theorem.** Let  $G$  be a finite group with  $n$  elements and  $H$  a subgroup of  $G$ . Then:

(1) the cardinality  $n = |G|$  is the product of the cardinality of  $H$  and the cardinality of  $G/H$ , i.e.

$$|G| = |G/H| \cdot |H|,$$

(2) the integer  $|H|$  divides  $n$ ,

(3) if  $a \in G$  is of order  $k$ , then  $k$  divides  $n$ ,

(4) for each  $a \in G, a^n = e$ ,

(5) if  $n$  is prime, then  $G$  is isomorphic to the cyclic group  $\mathbb{Z}_n$ .

The second proposition is called *Lagrange's theorem*. The fourth proposition is called *Fermat's little theorem*. Special cases are discussed in the previous chapter on number theory.

**PROOF.** Each left coset has exactly  $|H|$  elements. However, different cosets are disjoint. Hence the first proposition follows.

The second proposition is a direct corollary of the first one.

Each element  $a \in G$  generates the cyclic subgroup  $\{a, a^2, \dots, a^k = e\}$ , and the order of this subgroup is exactly the order of  $a$ . Therefore, the order of  $a$  must divide the number of elements of  $G$ .

Since the order  $k$  of any element  $a$  divides  $n$  and  $a^k = e$ , then also  $a^n = (a^k)^s = e$  for any integer  $s$ .

If  $n > 1$ , then there exists an element  $a \in G$  that is different from  $e$ . Its order  $k$  is an integer greater than one and it divides  $n$ . Therefore,  $k$  must be equal to  $n$ . This means that all the elements of  $G$  are of the form  $a^\ell$  for  $\ell = 1, \dots, n$ .  $\square$

**12.4.11. Normal subgroups and quotient groups.** A subgroup  $H$  which satisfies  $a \cdot h \cdot a^{-1} \in H$  for all  $a \in G, h \in H$ , is called a *normal subgroup*.

For normal subgroups, the operation on  $G/H$  can be defined by

$$(a \cdot H) \cdot (b \cdot H) = (a \cdot b) \cdot H.$$

Choosing other representatives  $a \cdot h, b \cdot h'$  leads to the same result:

$$(a \cdot h \cdot b \cdot h') \cdot H = ((a \cdot b) \cdot (h^{-1} \cdot h \cdot b) \cdot h') \cdot H = (a \cdot b) \cdot H.$$

and the remaining amount with 100 CZK banknotes, then the polynomial will be  $q = t^{10}p^{10}s^{627}$ . In the former case, the number of banknotes will be 777. In the latter case, it will be  $10 + 10 + 627 = 647$ .

If we have only the banknotes  $s, d, p, t$ , then the ideal that describes the relation of the individual banknotes is

$$I_1 = \langle s^2 - d, s^5 - p, s^{10} - t \rangle.$$

In order to minimize the number of used banknotes, we compute the Gröbner basis with respect to the graded reverse lexicographic ordering (we want to eliminate the small banknotes):

$$G_1 = (p^2 - t, s^2 - d, d^3 - sp, sd^2 - p).$$

Now, we take any polynomial that represents a given choice of banknotes. Reducing this polynomial with respect to the basis  $G_1$ , we get a polynomial whose degree is minimal for our monomial ordering, at it is easy to show that it is the polynomial corresponding to the optimal choice. For instance, take  $q = s^{777}$ . Reduction with respect to  $G_1$  yields  $t^{77}pd$ . This means that the optimal choice is seventy-seven 1000 CZK banknotes, one 500 CZK banknote, and one 200 CZK banknote. Altogether, it is 79 banknotes.

In the second scenario, when we also have the banknote  $D$ , the ideal is  $I_2 = \langle s^2 - d, s^5 - p, s^{10} - t, s^{20} - D \rangle$  and its Gröbner basis is

$$G_2 = (t^2 - D, p^2 - t, s^2 - d, d^3 - sp, sd^2 - p).$$

Reduction of  $q = s^{777}$  with respect to  $G_2$  gives  $D^{38}tpd$ , so this time we pay with 41 banknotes. In the third scenario, we have  $I_3 = \langle s^2 - d, s^5 - p, s^{10} - t, s^{50} - P \rangle$  and

$$G_3 = (t^5 - P, p^2 - t, s^2 - d, d^3 - sp, sd^2 - p),$$

and the reduction is equal to  $P^{15}t^2pd$ . In this case, we need only 19 banknotes.

Of course, this simple problem can be solved quickly with common sense. However, the presented method of Gröbner bases gives a universal algorithm which can be automatically used for higher amounts and other, more complicated cases.  $\square$

Gröbner bases have applications in robotics as well. In particular, it is in inversion kinematics, where one must find how to set individual joints of a robot so that it could reach a given position. This problem often leads to a system of non-linear equations which can be solved by finding a Gröbner basis, as in the following problem.

**12.K.7.** Consider a simple robot, as shown in the picture, which consists of three straight parts of length 1 which are connected with independent joints that enable arbitrary angles  $\alpha, \beta, \gamma$ . We want this robot to grasp, from above, an object which lies on the ground in distance  $x$ . What values should the angles  $\alpha, \beta, \gamma$  be set to? Draw the configuration of the robot for  $x = 1, 1.5a\sqrt{3}$ .

**Solution.** Consider a natural coordinate system, where the initial end of the robotic hand lies in the origin, and the

Moreover, cosets can be written as  $H \cdot a \cdot H$ , and the equation  $(H \cdot a) \cdot (b \cdot H) = H \cdot (a \cdot b) \cdot H$  is straightforward. On the other hand, the definition of the product on the cosets fails if  $H$  is not normal.

Clearly, this new operation on  $G/H$  satisfies all group axioms: the identity is the group  $H$  itself (formally it is the coset  $e \cdot H$  that corresponds to the identity  $e$  of  $G$ ), the inverse of  $a \cdot H$  is  $a^{-1} \cdot H$ , and the associativity is clear from the definition. This is called the *quotient group*  $G/H$  of  $G$  by the normal subgroup  $H$ .

Of course, in commutative groups, every subgroup is normal. The subset

$$n\mathbb{Z} = \{na; a \in \mathbb{Z}\} \subseteq \mathbb{Z}$$

is a subgroup of the integers, and the corresponding quotient group is the (additive) group  $\mathbb{Z}_n$  of residue classes.

It is clear from the definition that the kernel of every homomorphism is a normal subgroup. On the other hand, if a subgroup  $H \subseteq G$  is normal, then the mapping

$$p : G \rightarrow G/H, \quad a \mapsto a \cdot H$$

is a surjective homomorphism, whose kernel is  $H$ . It can be seen directly from the definition of the operation on  $G/H$  that  $p$  is a homomorphism, and it is clearly surjective. It follows that normal subgroups are precisely the kernels of homomorphisms.

Moreover, for any group homomorphism  $f : G \rightarrow K$  with kernel  $H = \ker f$ , there is a well-defined homomorphism

$$\tilde{f} : G/H \rightarrow K, \quad \tilde{f}(a \cdot H) = f(a),$$

which is injective. If  $H$  is any normal subgroup in  $G$  contained in  $\ker f$ , the latter homomorphism is still well defined, but not necessarily injective.

There is a seemingly paradoxical example of a group homomorphism  $\mathbb{C}^* \rightarrow \mathbb{C}^*$ , defined on the non-zero complex numbers by  $z \mapsto z^k$ , where  $k$  is a fixed positive integer. Clearly, this is a surjective homomorphism, and its kernel is the set of  $k$ -th roots of unity, i.e. the cyclic subgroup  $\mathbb{Z}_k$ . Reasoning as above, there is an isomorphism

$$\tilde{f} : \mathbb{C}^*/\mathbb{Z}_k \rightarrow \mathbb{C}^*$$

for any positive integer  $k$ . This example illustrates that in the case of infinite groups, the calculations with cardinalities are not so intuitive as in the case of finite groups and theorem 12.4.10.

**12.4.12. Exact sequences.** A normal subgroup  $H$  of a group  $G$  yields the *short exact sequence of groups*

$$e \rightarrow H \rightarrow G \rightarrow G/H \rightarrow e,$$

where the arrows respectively correspond to the only homomorphism of the trivial group  $\{e\}$  into the group  $H$ , the inclusion  $\iota$  of the subgroup  $H \subseteq G$ , the projection  $\nu$  onto the quotient group  $G/H$ , and the only homomorphism of the group  $G/H$  onto the trivial group  $\{e\}$ . In each case, the image of one arrow is precisely the kernel of the following one. This is the definition of *exactness* of a sequence of homomorphisms.

ground corresponds to the  $x$ -axis. It follows from elementary trigonometry that the total  $x$ -range of the robot at angles  $\alpha, \beta, \gamma$  is equal to

$$x = \sin \alpha + \sin(\alpha + \beta) + \sin(\alpha + \beta + \gamma).$$

Similarly, the range of the robot in the vertical direction is

$$y = \cos \alpha + \cos(\alpha + \beta) + \cos(\alpha + \beta + \gamma).$$

The condition of grasping the object from above is clearly equivalent to the condition  $\alpha + \beta + \gamma = \pi$ , so the statement of the problem leads to the system

$$\begin{aligned} \sin \alpha + \sin(\alpha + \beta) &= x, \\ \cos \alpha + \cos(\alpha + \beta) - 1 &= 0. \end{aligned}$$

In order to transform this system to a system of polynomial equations, we introduce new variables  $s_1 = \sin \alpha$ ,  $c_1 = \cos \alpha$ ,  $s_2 = \sin \beta$ ,  $c_2 = \cos \beta$ , which of course satisfy  $s_1^2 + c_1^2 = 1$  and  $s_2^2 + c_2^2 = 1$ . Using basic trigonometric equalities for sums in arguments, we obtain the following, equivalent system of polynomial equations:

$$\begin{aligned} s_1 + s_1 c_2 + c_1 s_2 - x &= 0, \\ c_1 + c_1 c_2 - s_1 s_2 - 1 &= 0, \\ s_1^2 + c_1^2 - 1 &= 0, \\ s_2^2 + c_2^2 - 1 &= 0. \end{aligned}$$

The Gröbner basis of the corresponding ideal can be found in a while using appropriate software. For the graded reverse lexicographic ordering  $s_1 > c_1 > s_2 > c_2$ , we get the basis

$$\begin{aligned} (2c_2 + 1 - x^2, 2c_1(1 + x^2) - 2s_2x - 1 - x^2, 2s_1(1 + x^2) + \\ + 2s_2 - x - x^3, 4s_2^2 - 3 - 2x^2 + x^4), \end{aligned}$$

and hence it is easy to calculate the values of the variables in dependence on  $x$ . For example, we can immediately see that  $c_2 = \frac{x^2-1}{2}$ , i. e.,  $\beta = \arccos(\frac{x^2-1}{2})$ . In particular, it is clear that the problem has no solution for  $|x| > \sqrt{3}$ . Specifically, for  $|x| < \sqrt{3}$ , there are 2 solutions, and for  $|x| = \sqrt{3}$ , there is one solution ( $\alpha = \frac{\pi}{3}, \beta = 0, \gamma = \frac{2\pi}{3}$  for positive  $x$ ;  $\alpha = -\frac{\pi}{3}, \beta = 0, \gamma = \frac{4\pi}{3}$  for negative  $x$ ). For  $x = 1$ , we get the solution  $\alpha = 0, \beta = \frac{\pi}{2}, \gamma = \frac{\pi}{2}$  and the degenerated solution  $\alpha = \frac{\pi}{2}, \beta = -\frac{\pi}{2}, \gamma = \pi$ . The case  $x = -1$  is similar. It is good to realize that for  $|x| < 1$ , one of the solutions will always correspond to a configuration of the robot where some parts will intersect. For these values of  $x$ , there will be only one realizable configuration.

If there exists a homomorphism  $\sigma : G/H \rightarrow G$  such that  $\nu \circ \sigma = \text{id}_{G/H}$ , it is said that the exact sequence *splits*.

**Lemma.** *Every split short exact sequence of commutative groups defines an isomorphism  $G \rightarrow H \times G/H$ .*

**PROOF.** Define a mapping  $f : H \times G/H \rightarrow G$  by

$$f(a, b) = a \cdot \sigma(b).$$

Since the groups are commutative,  $f$  is a homomorphism:

$$f(aa', bb') = aa' \sigma(b) \sigma(b') = (a \sigma(b)) (a' \sigma(b')).$$

If  $f(a, b) = e$ , then  $\sigma(b) = a^{-1} \in H$ , i.e.  $b = \nu(\sigma(b))$  is the identity in  $G/H$ . However, its image is then  $\sigma(b) = e$ , so  $a = e$ . Since the left and right cosets of commutative groups coincide, the mapping  $f$  is surjective. Hence  $f$  is an isomorphism.  $\square$

Now, the main idea of the proof of theorem 12.4.8 can be indicated. If it is known that every short exact sequence created by choosing cyclic subgroups  $H$  of a finite commutative group  $G$  splits, then it is easy to proceed with the proof by induction. If  $G$  is a group of order  $n$  which is not cyclic, then an element  $a$  of order  $p$ ,  $p < n$ , can be selected. The cyclic subgroup  $H$  generated by  $a$  can be found as well as the splitting of the corresponding short exact sequence. This expresses the group  $G$  as the product of the selected cyclic subgroup  $H$  and the group  $G/H$  of order  $n/p$ .

The main technical point of the proof is the verification that in each finite commutative group, there are elements of order  $p^r$  with appropriate powers of the primes  $p$  and that the short exact sequences for these groups really split.

**12.4.13. Return to finite Abelian groups.** Below is a brief exposition of the complete proof of the classification theorem, broken into several steps.

The following lemma suggests that cyclic subgroups with prime orders are required.

**Lemma (Claim 1).** *Let  $G$  be a finite Abelian group with  $n$  elements. If  $p$  is a prime which divides  $n$ , then there is an element  $g \in G$  of order  $p$ .*<sup>11</sup>

**PROOF.** The claim is obvious if  $n$  is prime, i.e.  $G = \mathbb{Z}_p$  (as proved above). If  $n$  is not prime, proceed by induction on  $n$ . Clearly  $G$  must have a proper subgroup  $H$  if  $n$  is not prime,  $|H| = m < n$ . Either  $p|m$  or  $p|(n/m)$ . In the former case, the claim follows from the induction hypothesis directly.

Otherwise assume  $p|(n/m)$  (remind  $n/m$  is the order of  $G/H$ ). Then there is an element  $g \in G$  such that the order of  $g \cdot H$  in the quotient group  $G/H$  is  $p$ . Thus  $g^p \in H$ , and therefore the order of  $g$  in  $G$  divides  $p|H|$ . Since  $p$  is a prime, the order of  $g$  is  $\ell p$  for some integer  $\ell$ . Hence the element  $g^\ell$  has the required order  $p$ .  $\square$

<sup>11</sup>This is a special version of the more general result valid for all finite groups, called the Cauchy theorem. The formulation remains the same, with the word Abelian omitted.

Gröbner bases can also be used in software engineering when looking for loop invariants, which are needed for verification of algorithms, as in the following problem.

**12.K.8.** Verify the correctness of the algorithm for the product of two integers  $a, b$ .

```

(x, y, z) := (a, b, 0);
while not (y = 0) do
  if y mod 2 = 0
  then (x, y, z) := (2*x, y/2, z)
  else (x, y, z) := (2*x, (y-1)/2, x+z)
  end if
end while
return z
    
```

**Solution.** Let  $X, Y, Z$  denote the initial values of the variables  $x, y, z$ , respectively. Then, by definition, a polynomial  $p$  is an invariant of the loop if and only if we have  $p(x, y, z, X, Y, Z) = 0$  after each iteration. Such a polynomial can be found using Gröbner basis as follows:

Let  $f_1, f_2$  denote the assignments of the then- and else-branches, respectively, i. e.,

$$f_1(x, y, z) = (2x, \frac{1}{2}y, z) \text{ and } f_2(x, y, z) = (2x, \frac{y-1}{2}, x+z).$$

For  $n$  iterations of the first one, we immediately obtain the explicit formula  $f_1^n(x, y, z) = (2^n x, \frac{1}{2^n} y, z)$ . In order to transform this iterated function to a polynomial mapping, we introduce new variables  $u := 2^n, v := \frac{1}{2^n}$ . Then,  $f_1^n$  is given by the polynomial function

$$F_1: x \mapsto ux \quad y \mapsto vy \quad z \mapsto z,$$

For any prime number  $p$ ,  $G$  is called a  $p$ -group if each of its elements has order  $p^k$  for some power  $k$ . Claim 1 has an obvious corollary:

**Lemma (Claim 2).** A finite Abelian group  $G$  is a  $p$ -group if and only if its number of elements  $n$  is a power of  $p$ .

**PROOF.** One implication follows straight from the Lagrange's theorem since all proper divisors of a power of a prime  $p$  are just smaller powers of  $p$ .

On the other hand, if  $n$  is not a power of prime, it has another prime divisor  $q$  and so there is an element of order  $q$  by Claim 1.  $\square$

Now it can be shown that a given finite Abelian group  $G$  can always be decomposed into a product of  $p$ -groups.

**Lemma (Claim 3).** If  $G$  is a finite Abelian group then it is isomorphic to a product of  $p$ -groups. This decomposition is unique up to order.

**PROOF.** Consider a prime  $p$  dividing  $n = |G|$ . Define  $G_p$  to be the subgroup of all elements whose orders are powers of  $p$ , while  $G'_p$  is the subgroup of all elements whose orders are not divisible by  $p$  (check yourself that subgroups are obtained in this way). By the above Claim 1, the subgroup  $G_p$  is not trivial.

Next, consider an element  $g$  of order  $qp^\ell$  with  $q$  not divisible by  $p$ . Then  $g^{p^\ell}$  has order  $q$ , so this element belongs to  $G'_p$ , while  $g^q \in G_p$ . The Bezout equality guarantees there are integers  $r$  and  $s$  such that  $rp^\ell + sq = 1$ . Hence

$$g = g^{rp^\ell} \cdot g^{sq}$$

is a decomposition of  $g$  into product of elements in  $G_p$  and  $G'_p$ . This verifies  $G \simeq G_p \times G'_p$  and  $G_p$  is a  $p$ -group.

This process can be repeated for the subgroup  $G'_p$  and the remaining primes in the decomposition in order to complete the proof.

The uniqueness claim is obvious.  $\square$

It remains to consider the  $p$ -groups only. The next claim shows that the  $p$ -groups which are not cyclic must have more than one subgroup of order  $p$ .

**Lemma (Claim 4).** If a finite Abelian  $p$ -group  $G$  has just one subgroup  $H$  with  $|H| = p$ , then it is cyclic.

**PROOF.** The case  $p = n = |G|$  is obvious. Proceed by induction on  $n$ . Assume  $H$  is the only subgroup of order  $p$  and consider  $\sigma : G \rightarrow G, \sigma(g) = g^p$  and write  $K = \ker(\sigma)$ . Then  $H \subset K$  and since  $p$  is prime, all elements in  $K$  have order  $p$ . For any  $g \in K$ , the cyclic group generated by  $g$  has order  $p$  and so coincides with  $H$  and consequently  $H = K$ . If  $G \neq K$ , then  $\sigma(G)$  is a non-trivial subgroup in  $G$  which must be isomorphic to  $G/K$ . By Claims 1 and 2, there is a subgroup in  $\sigma(G)$  of order  $p$ . This yields a subgroup in  $G$  and by assumption it is again  $H$ . Finally, apply the induction hypothesis on the group  $\sigma(G) \simeq G/H$ , which has to be cyclic. Choosing a generator  $g \cdot H$  of the latter group, even in  $G$  the

where the new variables satisfy  $uv = 1$ . Clearly, the invariant polynomial must lie in the ideal

$$I_1 = \langle ux - X, vy - Y, z - Z, uv - 1 \rangle.$$

In order to find such polynomial, it suffices to eliminate the variables  $u$  and  $v$ , which can be done just with the Gröbner basis with respect to the graded reverse lexicographic ordering with  $u > v > x > y > z$ . This basis is equal to

$$(xy - XY, z - Z, x - vX, y - uY).$$

Hence  $F_1(xy - XY) = xy - XY$  and  $F_1(z - Z) = z - Z$ , and all other polynomials are invariant with respect to any number  $n$  of applications of  $f_1$  and are given by a polynomial in (polynomials)  $xy - XY$  and  $z - Z$ .

Now, we proceed similarly for  $f_2$ . For  $n$  iterations, we derive the formula

$$f_2^n(x, y, z) = (2^n x, \frac{1}{2^n}(y + 1) - 1, (2^n - 1)x + z),$$

and introducing the variables  $u$  and  $v$ , we get an equivalent polynomial function

$$F_2: \quad x \mapsto ux \quad y \mapsto v(y + 1) - 1 \quad z \mapsto (u - 1)x + z.$$

The invariant polynomial for  $F_2$  can be obtained similarly as above, thanks to the Gröbner basis of the corresponding ideal. However, we are interested in those polynomials which are invariant for both  $F_1$  and  $F_2$ . Clearly, these must lie in the ideal

$$I_2 = \langle F_2(xy - XY), F_2(z - Z), uv - 1 \rangle.$$

Substituting for  $F_2$ , we obtain

$$I_2 = \langle u xv(y + 1) - ux - XY, (u - 1)x + z - Z, uv - 1 \rangle$$

and with the Gröbner basis of this ideal, we eliminate the variables  $u$  and  $v$  and thus find the polynomial  $xy - XY + z - Z$ , which is invariant for both  $F_1$  and  $F_2$ , so it is an invariant of the given cycle. Since at the beginning we have  $X = a, Y = b, Z = 0$ , we can see that it holds in every step of the algorithm that  $xy - ab + z = 0$ . Since the loop terminates only if  $y = 0$ , we get that indeed  $z = ab$ .  $\square$

Now, we present several exercises where we use Gröbner bases to solve various polynomial systems. The primary goal will not be to find the Gröbner basis, but rather to solve the given system.

**12.K.9.** Using Gröbner basis, solve the polynomial system

$$\begin{aligned} x^3 - 2xy &= 0, \\ x^2y + x - 2y^2 &= 0. \end{aligned}$$

**Solution.** Let us denote  $f_1 := x^3 - 2xy, f_2 := x^2y + x - 2y^2$ . The basis  $(f_1, f_2)$  is not a Gröbner basis since, e. g.,  $LM(yf_1 - xf_2) = x^2 \notin (x^3, x^2y) = (LM(f_1), LM(f_2))$ . Thus, we have to add the polynomial

$$yf_1 - xf_2 = -x^2.$$

cyclic subgroup generated by  $g$  must have a subgroup of order  $p$  (again Claim 1). The uniqueness assumption ensures that this is again the subgroup  $H$ .

Clearly,  $|G/H| = |G|/p$  is the smallest exponent with  $g^{|G|/p} \in H$ . At the same time the latter power is not equal to the unit since  $H \subset \langle g \rangle$ . Consequently, the order of  $g$  in  $G$  is bigger than  $|G|/p$  and so the group  $G$  is cyclic.  $\square$

Finally, a splitting condition for the  $p$ -groups is proved, which provides the property discussed in the end of the previous paragraph on the exact sequences. This completes the entire proof of the classification theorem.

**Lemma (Claim 5).** *Let  $G$  be a finite Abelian  $p$ -group and let  $C$  be a cyclic subgroup of maximal order in  $G$ . Then  $G = C \times L$  for some subgroup  $L$ .*

**PROOF.** If  $G$  is cyclic, set  $G = C$  and of course  $G = C \times L$  with  $L = \{e\}$ . Proceed by induction on  $n = |G|$ . Assume  $G$  is not cyclic. Then it contains more than one cyclic subgroup of order  $p$ . Of course the subgroup  $C$  is one such subgroup. Choose  $H$  to be another subgroup of order  $p$  which is not a subgroup in  $C$ . Since  $p$  is prime, the intersection of  $H$  and  $C$  is trivial. Consequently the quotient group  $(C \times H)/H \subset G/H$  is isomorphic to  $C$ .

Now consider the induction step. The order of the cyclic subgroup  $(C \times H)/H$  in  $G/H$  must be maximal, since the orders of the elements  $g \cdot H$  in the quotient group are divisors of the orders of the generators  $g$  in the group  $G$ . By the induction hypothesis,

$$G/H = (C \times H)/H \times K$$

for some subgroup  $K \subset G/H$ . Clearly the preimage of  $K$  under the quotient projection is a group  $L$  satisfying  $H \subset L \subset G$ . Now, the latter identification of  $G/H$  with the product implies

$$G = (C \cdot H) \cdot L = C \cdot (H \cdot L) = C \cdot L.$$

At the same time,  $L \cap (C \cdot H) = H$  and so  $L \cap C = \{e\}$ . So  $G = C \times L$ .  $\square$

The proof is complete up to the uniqueness claim. It is known already that the decomposition into  $p$ -groups is unique. Assume that a  $p$ -group  $G$  decomposes into two products of cyclic groups  $H_1 \times \dots \times H_k$  and  $H'_1 \times \dots \times H'_\ell$  with non-increasing orders of  $H_i$  or  $H'_j$ . Then the orders of  $H_1$  and  $H'_1$  coincide, since these are the maximal orders in  $G$ . By induction all the orders coincide and the work is complete.

The classification theorem is a special case of a more general result on finitely generated Abelian groups. In additive notation, if  $g_1, \dots, g_t$  are generators of the entire  $G$ , then all elements of  $G$  are of the form  $a_1g_1 + \dots + a_tg_t$  with integer coefficients  $a_i$ . The general theorem provides a severe restriction for possible relations between such combinations. In fact it says that all finitely generated Abelian groups are products of cyclic groups, hence  $G = \mathbb{Z}^\ell \oplus \mathbb{Z}_{p_1} \times \dots \times \mathbb{Z}_{p_k}$ . This means there is always a finite number of completely independent generators of  $G$  and each of them generates a cyclic subgroup in

The resulting basis can be reduced using division of the polynomials  $f_1, f_2$  by  $x^2$ . This leads to the basis

$$(xy, x - 2y^2, x^2).$$

Now, we can divide the first polynomial by the second one, with remainder  $2y^3$ , and the third one by the second one, with remainder  $4y^4$ . Thus, we get the basis

$$(x - 2y^2, y^3),$$

and this is a Gröbner basis: by the naive algorithm (see 12.6.13), it suffices to verify that the polynomial

$$S(x - 2y^2, y^3) = y^3(x - 2y^2) - xy^3 = -2y^5$$

gives zero remainder with respect to the basis  $(x - 2y^2, y^3)$ , even for any polynomial ordering. Clearly, the solution of the system is the point  $(0, 0)$ .  $\square$

**12.K.10.** Consider the following system of polynomial equations:

$$\begin{aligned} x^2yz^2 + x^2y^2 + yz - xyz^2 - z^2 &= 0, \\ x^2y + z &= 0, \\ xyz + z + 1 &= 0. \end{aligned}$$

Sort the monomials of the polynomials with respect to the lexicographic ordering with  $x > y > z$ , then divide the first polynomial by the second one and the third one, and use the result in order to solve the system in the real numbers.

**Solution.**

$$\begin{aligned} x^2y^2 + x^2yz^2 - xyz^2 + yz - z^2 &= (y + z^2)(x^2y + z) - \\ &\quad - y(xyz + z + 1) - z^3 + z. \end{aligned}$$

Hence  $z = 0, \pm 1$ . Then, e. g.,

$$\begin{aligned} 0 &= z(x^2y + z) - x(xyz + z + 1) = \\ &= z^2 - zx - x. \end{aligned}$$

Hence,  $x = \frac{z^2}{z+1}$ , and we get from the third equation that  $y = -\frac{(1+z)^2}{z^3}$ . This is satisfied by the sole point  $(\frac{1}{2}, -4, 1)$ .  $\square$

**12.K.11.** Using Gröbner basis, solve the polynomial system

$$\begin{aligned} x^2 + y + z &= 1, \\ x + y^2 + z &= 1, \\ x + y + z^2 &= 1. \end{aligned}$$

**Solution.** Let us denote  $f_1 := x + y + z^2 - 1$ . The division of  $x + y^2 + z - 1$  by  $f_1$  gives

$$f_2 = y^2 - y - z^2 + z.$$

The division of  $x^2 + y + z - 1$  by  $f_1$  yields  $y^2 + 2yz^2 - y + z^4 - 2z^2 + z$ , and further division by  $f_2$  produces the remainder.

$$f_3 = 2yz^2 + z^4 - z^2.$$

$G$ . (Compare this to the description of finite dimensional vector spaces via their basis, as discussed in chapter 2.)

**12.4.14. Group actions.** Groups can be considered as sets

of transformations of a fixed set. All the transformations are invertible, and the set of transformations must be closed under composition. The idea is to work with a fixed group whose elements are represented as mappings on a fixed set, but the mappings corresponding to different elements of the group need not be different. For instance, the rotations around the origin over all possible angles correspond to the group of real numbers. On the other hand, the rotation by  $2\pi$  is the identity as a mapping.

Formally, this situation can be described as follows:

#### GROUP ACTIONS

A *left action of a group  $G$  on a set  $S$*  is a homomorphism of the group  $G$  to the subgroup of invertible mappings in the monoid  $S^S$  of all mappings  $S \rightarrow S$ . Such a homomorphism can be viewed as a mapping  $\varphi : G \times S \rightarrow S$  which satisfies

$$\varphi(a \cdot b, x) = \varphi(a, \varphi(b, x)),$$

hence the name “left action”. Often, the notation  $a \cdot x$  is used to refer to the result of an  $a \in G$  applied to a point  $x \in S$  (although this is a different dot than the operation inside the group). Then, the definition property can be expressed as

$$(a \cdot b) \cdot x = a \cdot (b \cdot x).$$

The image of a point  $x \in S$  in the action of the entire group  $G$  is called the *orbit*  $S_x$  of  $x$ , i.e.

$$S_x = \{y = \varphi(a, x); a \in G\}.$$

For each point  $x \in S$ , define the *isotropy subgroup*  $G_x \subseteq G$  of the action  $\varphi$  (also called the *stabilizer subgroup*):

$$G_x = \{a \in G; \varphi(a, x) = x\}.$$

If for every two points  $x, y \in S$ , there is an  $a \in G$  such that  $\varphi(a, x) = y$ , then the action  $\varphi$  is said to be *transitive*.

Choosing any two points  $x, y \in S$  and a  $g \in G$  which maps  $x$  to  $y = g \cdot x$ , then the set  $\{ghg^{-1}; h \in G_x\}$  is clearly the isotropy subgroup  $G_y$ . In addition, the mapping  $h \mapsto ghg^{-1}$  is a group homomorphism  $G_x \rightarrow G_y$ .

In the case of transitive actions, the entire space forms a single orbit and all isotropy subgroups have the same cardinality.

As an example of a transitive action of a finite group, consider the apparent action of the symmetric group of a fixed set  $X$  on  $X$  itself. The natural action of all invertible linear transformations on the non-zero elements of a vector space  $V$  is also transitive. However, if the entire space  $V$  is selected, then the zero vector forms its own orbit.

The mentioned example of the action of the additive group of real numbers that acts as rotations around a fixed center  $O$  in the plane is not transitive. The orbit of each point  $M$  is the circle which is centered at  $O$  and goes through  $M$ .

However,  $(f_1, f_2, f_3)$  is not a Gröbner basis yet. That will be constructed by the choice  $g_1 := f_1, g_2 := f_2$  and replacing  $f_3$  with the  $S$ -polynomial

$$2z^2 f_2 - y f_3 = -yz^4 - yz^2 - 2z^4 + 2z^3.$$

Then, the division by the polynomial  $f_3$  leads to

$$\begin{aligned} g_4 &= z^6 - 4z^4 + 4z^3 - z^2 = \\ &= z^2(z-1)^2(z^2 + 2z - 1). \end{aligned}$$

Now,  $(g_1, g_2, g_3)$  is a Gröbner basis, so we can solve the system by elimination. We get from  $g_4 = 0$  that  $z = 0, 1, -1 \pm \sqrt{2}$ . Substituting this to  $g_2 = 0$  and  $g_1 = 0$  gives the solutions  $(1, 0, 0), (0, 1, 0), (0, 0, 1), (-1 + \sqrt{2}, -1 + \sqrt{2}, -1 + \sqrt{2}), (-1 - \sqrt{2}, -1 - \sqrt{2}, -1 - \sqrt{2})$ .  $\square$

**12.K.12.** Solve the following system of polynomial equations in  $\mathbb{R}$ :

$$\begin{aligned} x^2 - 2xz - 4, \\ x^2 y^2 z + yz^3, \\ 2xy^2 - 3z^3. \end{aligned}$$

**Solution.** The basis suitable for variable elimination is the Gröbner basis for the lexicographic monomial ordering with  $x > y > z$ . Using Maple, we can find the basis

$$\begin{aligned} 144z^5 + 35z^7 + 12z^9, \\ 23z^6 + 12z^8 + 44yz^4, \\ yz^3 + 3z^5 + 4zy^2, 9z^4 + 4y^3, \\ -8y^2 - 6z^4 + 3xz^3, 2xy^2 - 3z^3, \\ x^2 - 2xz - 4. \end{aligned}$$

Since the discriminant of the first polynomial of the basis (divided by  $z^5$ ) satisfies  $35^2 - 4 \cdot 144 \cdot 7 < 0$ , we must have  $z = 0$ . Substituting this into the other polynomials, we immediately obtain  $y = 0, x = \pm 2$ .  $\square$

**12.K.13.** Solve the following system of polynomial equations in  $\mathbb{R}$ :

$$\begin{aligned} xy + yz - 1, \\ yz + zw - 1, \\ zw + wx - 1, \\ wx + xy - 1. \end{aligned}$$

**Solution.** In this case, it is a good idea to take the graded lexicographic ordering with  $w > x > y > z$ . Using the algorithm 12.6.13 or appropriate software, we find the corresponding Gröbner basis

$$(x - z, w - y, 2yz - 1).$$

Thus, the system is satisfied by exactly the points  $(\frac{1}{2t}, t, \frac{1}{2t}, t)$  for an arbitrary  $t \in \mathbb{R}$  except zero.  $\square$

A typical example of a transitive action of a group  $G$  is the natural action on the set  $G/H$  of left cosets for any subgroup  $H$ . It is defined by

$$g \cdot (aH) = (ga)H.$$

This is the form of every transitive group action. For any transitive action  $G \times S \rightarrow S$  and a fixed point  $x \in G, S$  can be identified with the set  $G/G_x$  of left cosets by  $gG_x \mapsto g \cdot x$ . Clearly, this mapping is surjective, and the images  $g \cdot x = h \cdot x$  coincide if and only if  $h^{-1}g \in G_x$ , which is equivalent to  $gG_x = hG_x$ . Finally, note that this identification transforms the original action of  $G$  on  $S$  just to the mentioned action of  $G$  on  $G/G_x$ .

**12.4.15. Theorem.** Let an action of a finite group  $G$  on a finite set  $S$  be given. Then:

(1) for each point  $x \in S$ ,

$$|G| = |G_x| \cdot |S_x|,$$

(2) (Burnside's lemma) if  $N$  denotes the number of orbits, then

$$|G| = \frac{1}{N} \sum_{g \in G} |S^g|,$$

where  $S^g = \{x \in S; g \cdot x = x\}$  denotes the set of fixed points of the action corresponding to an element  $g$ .

**PROOF.** Consider any point  $x \in S$  and its isotropy subgroup  $G_x \subseteq G$ . The same argument as the one at the end of the previous paragraph for transitive group actions can be applied to each action of the group  $G$ . This gives the mapping  $G/G_x \rightarrow S_x, g \cdot G_x \mapsto g \cdot x$ . If  $g \cdot x = h \cdot x$ , then clearly  $g^{-1}h \in G_x$ , so this mapping is injective. Clearly, it is also surjective, which means that the cardinalities of the finite sets must satisfy  $|G/G_x| = |S_x|$ . The first proposition follows, because  $|G| = |G/G_x| \cdot |G_x|$ .

The second proposition is proved by counting the cardinality of the set of fixed points of individual group elements in two different ways:

$$F = \{(x, g) \in S \times G; g \cdot x = x\} \subseteq S \times G.$$

Since these are finite sets, the elements of the Cartesian product  $S \times G$  can be considered as entries of a matrix (columns are indexed by elements of  $S$ , rows are indexed by elements of  $G$ ). Summing this matrix up, either by rows or by columns, yields

$$|F| = \sum_{g \in G} |S^g| = \sum_{x \in S} |G_x|.$$

For the sake of clarity, choose one representative for each orbit (denote them  $x_1, \dots, x_N$ ), and recall that the cardinalities of the isotropy groups for points that lie in the same orbit are the same. Using the proved statement (1), it is obtained easily that

$$|F| = \sum_{g \in G} |S^g| = \sum_{i=1}^N \sum_{x \in S_{x_i}} |G_x| = \sum_{i=1}^N |S_{x_i}| |G_{x_i}| = N \cdot |G|,$$

which completes the proof.  $\square$

**12.K.14.** Solve the following system of polynomial equations in  $\mathbb{R}$ :

$$\begin{aligned} x^2 + yz + x, \\ z^2 + xy + z, \\ y^2 + xz + y. \end{aligned}$$

**Solution.** Using the algorithm 12.6.13 or appropriate software, we find the corresponding Gröbner basis for the lexicographic monomial ordering with  $x > y > z$ , consisting of six polynomials:

$$\begin{aligned} z^2 + 3z^3 + 2z^4, \\ z^2 + z^3 + 2yz^2 + 2yz^3, \\ y - yz - z - z^2 - 2yz^2 + y^2, \\ yz + z + z^2 + 2yz^2 + xz, \\ z^2 + xy + z, x^2 + yz + x. \end{aligned}$$

The roots of the first polynomial are  $z = 0, -1, -\frac{1}{2}$ . Discussing the individual cases, we find out that the system is satisfied exactly by the points  $(0, 0, 0), (-1, 0, 0), (0, -1, 0), (0, 0, -1)$  and  $(-\frac{1}{2}, -\frac{1}{2}, -\frac{1}{2})$ .  $\square$

It is recommended to think out thoroughly how useful these propositions are for solving combinatorial problems, c.f. 12.G.1 through 12.G.7.

Next, we shall come back to fields and after knowing the complete classification of finite Boolean algebras and finite abelian groups, we focus on finite fields.

As first step, we have to draw some elementary results on rings and univariate polynomial rings.

**12.4.16. Rings, ideals, quotients.** We are meeting rings on our journey permanently since the very beginning. Now we shall add some structural understanding of objects and homomorphisms in this category.

Similarly to groups, the inclusion of a subring  $K \subset L$  allows us to construct the residue class space  $L/K = \{a + K; a \in L\}$ , i.e., we consider the (commutative) additive group structure only. If we want to equip  $L/K$  by a ring structure applying the operations to representatives, we do not face problems with the addition (since all subgroups are normal in the abelian case), but we need the properties  $a \cdot K \subset K$  and  $K \cdot a \subset K$  for all  $a \in L$  to get the multiplication right, too. Indeed,  $(a+K) \cdot (b+K) = a \cdot b + a \cdot K + K \cdot b + K = a \cdot b + K$  under this assumption. Such a subring  $K \subset L$  is called an *ideal* in  $L$ , and we call  $L/K$  the *residue class ring*, or *quotient ring*. The verification of all ring properties for the addition and multiplication defined by means of the representatives is straightforward.

For all homomorphisms of rings,  $f : K \rightarrow L$ , the kernel  $\ker f = \{a \in K; f(a) = 0\}$  is clearly an ideal, since all multiples of zero are zero. Similarly to groups, the ideals  $K \subset L$  come with the short exact sequences of rings

$$(1) \quad 0 \rightarrow K \rightarrow L \rightarrow L/K \rightarrow 0.$$

By the very definition, an intersection of ideals is an ideal again. Thus we may talk about ideals generated by subsets in  $L$ . In commutative rings  $L$ , we distinguish the ideals generated by a single element and call them the *principal ideals*,  $\langle a \rangle = \{b \cdot a; b \in L\}$ . If there are no proper ideals (i.e. different from the trivial ones) except of the principal ones, we call  $L$  a *principal ideal domain*.

The integer ring  $\mathbb{Z}$  is a principal ideal domain. Indeed, if  $K \subset \mathbb{Z}$  and  $n$  is the smallest positive integer in  $K$ , then for any  $m \in K$ , the division yields  $m = qn + r$  with the remainder again in  $K$ . Thus  $r = 0$  (it cannot be smaller than  $n$ ) and we have proved  $K = \langle n \rangle$ . If  $n = 1$ , then  $K = \mathbb{Z}$ . The quotient ring  $\mathbb{Z}/\langle n \rangle$  is the ring of residue classes  $\mathbb{Z}_n$ .

Notice, there are no proper ideals in any field  $\mathbb{K}$ .

**12.4.17. Characteristic of rings and fields.** Consider a ring  $K$ . Its additive structure provides the cyclic subgroups generated by single elements  $a \in K$ ,  $G_a = \{a, a + a, 3a, \dots\}$ . If there is the minimal positive integer  $n$ , such that  $na = 0$ , then we say that the order of  $a$  is  $n$ . If there is such a (minimal)  $n$  valid for all  $a \in K$ , we say that the *characteristic* of the ring  $K$  is  $n$ . If there are elements of infinite order, or their

orders are not bounded, we say that the characteristic of  $K$  is infinity.

Clearly, the characteristic of  $\mathbb{Z}_n$  is  $n$ , while the scalars  $\mathbb{Z}$ ,  $\mathbb{Q}$ ,  $\mathbb{R}$ ,  $\mathbb{C}$  all have characteristic  $\infty$ .

**Lemma.** *If  $K$  is a finite ring with  $|K| = m$  elements, then the characteristic of  $K$  is a divisor of  $m$ .*

**PROOF.** The orders of the cyclic subgroups  $G_a$  must be finite (if  $ka = \ell a$ , then  $(k - \ell)a = 0$ , and there are only finitely many elements in  $K$ ) and they must be divisors of  $m$  (as known for all finite abelian groups).  $\square$

Another nice observation says, that finite integral domains are actually fields:

**Theorem.** *If  $K$  is a finite commutative ring without divisors of zero, then  $K$  is a field. Moreover the number of elements  $|K| = m$  is a power of a prime number,  $m = p^n$ , where  $p$  is the characteristic of  $K$ .*

**PROOF.** Let  $p$  be the characteristic of  $K$ . Suppose,  $p = k\ell$  is not a prime (clearly,  $1 < k \leq \ell < p$ ). Then looking at  $1 \in K$ ,  $0 = p \cdot 1 = (k\ell) \cdot 1 = (k \cdot 1) \cdot (\ell \cdot 1)$  and this is impossible without divisors of zero. Thus the characteristic of  $K$  is a prime  $p$ .

Next, for any  $0 \neq a \in K$ , all the elements  $a \cdot b$ ,  $b \in K$  must be different, since  $a \cdot b_1 = a \cdot b_2$  would imply  $a \cdot (b_1 - b_2) = 0$ , i.e.,  $b_1 = b_2$ . In particular, the unit 1 is expressed as  $1 = a \cdot b$  for some  $b$  and so  $b$  is the inverse to  $a$ . Thus  $K$  is a finite field.

Finally, the additive subgroup  $G_1 = \{1, 2 \cdot 1, \dots, p \cdot 1\}$  is closed under the multiplication, too (and is isomorphic to the field  $\mathbb{Z}_p$ ). Now,  $K$  can be viewed as a vector space over  $G_1$  and it must be generated by finite number of elements  $a_1, \dots, a_n$  (with big freedom in the choices, but always the same number, as known from the elementary linear algebra). But then it is clear that  $|K| = p^n$ , as requested.  $\square$

The theorem suggests that all finite fields are built from the simplest bricks — the so called *Galois fields*  $GF(p)$  isomorphic to  $\mathbb{Z}_p$  with prime  $p$ . They are often denoted  $\mathbb{F}_p$  in literature.

**12.4.18. Univariate polynomials over fields.** The ring of univariate polynomials  $K[x]$  over any field  $K$  is a principal ideal domain. Indeed, the same argument as for integers applies. Given a non-zero ideal  $J$ , there must be a polynomial  $f$  of lowest degree in  $J$ . If the degree is zero,  $J = K[x]$ . Otherwise, each  $g \in J$  is expressed as  $g = qf + r$  applying the division with remainder (cf. 12.3.6). Then  $r \in J$  and it must be of lower degree than  $f$  (which is impossible) or zero. Thus,  $J = \langle f \rangle$ .

Recall that each ideal  $J = \langle f \rangle \subset K[x]$ ,  $\deg f > 0$ , provides the quotient ring  $L = K[x]/J$ .

**Lemma.** *The ring  $L = K[x]/\langle f \rangle$ ,  $d = \deg f > 0$  contains  $K$  as subfield, and  $L$  is a vector space over  $\mathbb{K}$  of dimension at most  $d$ .*

PROOF. Since  $d = \deg f > 0$ , no constant polynomial can appear in  $\langle f \rangle$ . Thus  $a \mapsto a + J$  embeds  $K$  into  $L$  as a subring. Finally, the elements  $1 + J, x + J, \dots, x^{d-1} + J$  must generate  $L$  (remind we deal with univariate polynomials).  $\square$

**Proposition.** *The ring  $L = K[x]/\langle f \rangle$ ,  $\deg f > 0$  is a field if and only if the polynomial  $f$  does not have any roots in  $K$ . If  $K$  is finite, then  $|L| = p^{nm}$ , where  $p^n = |K|$  and  $m$  is the dimension of the vector space  $L$  over  $K$ .*

PROOF.  $\square$

In the situation of the proposition, we call  $L$  the *algebraic extension of the field  $K$*  with respect to the polynomial  $f$ . Clearly, the polynomial  $f$  becomes completely reducible,  $f = a(x - \alpha_1) \dots (x - \alpha_d)$ , over  $L$ . Thus the construction adds all the missing roots  $\alpha_i$  to  $\mathbb{K}$  and extends the field this way.

Considering a polynomial

**12.4.19. Theorem** (Classification of finite fields). *For each prime number  $p$  and power  $n \in \mathbb{N}$ , there is a field with  $p^n$  elements. Such field  $F$  is obtained as extension. All fields with the same number of elements are isomorphic.*

PROOF.  $\square$

**12.4.20. The fundamental theorem of algebra.** While it may happen that a polynomial over the real numbers has no roots, every polynomial over the complex numbers has a root. This is the statement of the so called *fundamental theorem of algebra*, which is presented here with an (essentially) complete proof. By this result, every polynomial in  $\mathbb{C}[x]$  has as many roots (including multiplicity) as its degree  $\deg f = k$ . Hence it always admits a factorization of the form

$$f(x) = b(x - a_1) \cdot (x - a_2) \dots (x - a_k)$$

for the complex roots  $a_i$  and the appropriate leading coefficient  $b$ .

**Theorem.** *The field  $\mathbb{C}$  is algebraically closed, i.e. every polynomial of degree at least one has a root.*

PROOF. We are going to provide an elementary proof based on simple real analysis, in particular the concept of continuity (the readers should be familiar with the techniques developed in Chapters 5 and 6).

Suppose that  $f \in \mathbb{C}[z]$  is a non-zero polynomial with no root, i.e.  $f(z) \neq 0$  for all  $z \in \mathbb{C}$ . Consider the mapping defined by

$$\varphi : \mathbb{C} \rightarrow \mathbb{C}, \quad z \mapsto \frac{f(z)}{|f(z)|}.$$

Then  $\varphi$  maps the entire  $\mathbb{C}$  into the unit circle

$$K_1 = \{e^{it}, t \in \mathbb{R}\} \subseteq \mathbb{C}.$$

By the assumption that  $f(z)$  is never zero, this mapping is well-defined. Next, we shall consider the restrictions of  $\varphi$  to the individual circles  $K_r \subseteq \mathbb{C}$  with center at zero and radius  $r \geq 0$

We can parameterize these circles by the mappings

$$\psi_r : \mathbb{R} \rightarrow K_r, \quad t \mapsto \psi_r(t) = r e^{it}.$$

For all  $r$ , the composition  $\kappa : (0, \infty) \times \mathbb{R} \rightarrow K_1$ ,  $\kappa(r, t) = \varphi \circ \psi_r(t)$ , is continuous in both  $t$  and  $r$ . Thus, for each  $r$ , there exists a mapping  $\alpha_r : \mathbb{R} \rightarrow \mathbb{R}$  which is uniquely given by the conditions  $0 \leq \alpha_r(0) < 2\pi$  and  $\kappa(r, t) = e^{i\alpha_r(t)}$ . Again, the obtained mapping  $\alpha_r$  continuously depends on  $r$ . Altogether, there is a continuous mapping

$$\alpha : \mathbb{R} \times (0, \infty) \rightarrow \mathbb{R}, \quad (t, r) \mapsto \alpha_r(t).$$

It follows from its construction that for every  $r$ ,  $\frac{1}{2\pi}(\alpha_r(2\pi) - \alpha_r(0)) = n_r \in \mathbb{Z}$ . Since  $\alpha$  is continuous in  $r$ , it means that  $n_r$  is an integer constant which is independent of  $r$ .

In order to complete the proof, it suffices to note that if  $f = a_0 + \dots + a_d z^d$  and  $a_d \neq 0$ , then for small values of  $r$ ,  $\alpha_r$  behaves nearly as a constant mapping, while for large values of  $r$ , it behaves almost as if  $f = z^d$ . First, calculate  $n_r$  for  $f = z^d$ , then make this statement more precise. This completes the proof.

The complex functions  $z \mapsto z^d$ ,  $z \mapsto \frac{z^d}{|z^d|}$  can be expressed easily using the trigonometric form of the complex numbers  $z = r(\cos \theta + i \sin \theta)$ :

$$\begin{aligned} z^d &= r^d (\cos d\theta + i \sin d\theta) = r^d e^{id\theta}, \\ \frac{z^d}{|z^d|} &= 1(\cos d\theta + i \sin d\theta) = e^{id\theta}. \end{aligned}$$

In this case, the mapping  $\varphi$  is simply a rotation of the complex plane, followed by the central projection onto the unit circle.

Then,  $\kappa_r(t) = e^{idt}$ , and so  $\alpha_r(t) = dt$ , regardless of  $r$ . It follows that  $n_r = d$  for the choice  $f = z^d$ . If  $f = az^d$  is chosen,  $a \neq 0$ , then there is no impact on the above result (verify this yourselves!).

Consider a general polynomial  $f = a_0 + \dots + a_d z^d$  with no root. Then  $a_0 \neq 0$  ( $a_0 = 0$ , implies that 0 is a root). For  $z \neq 0$ ,

$$\frac{f(z)}{a_d z^d} = 1 + \frac{1}{a_d} (a_0 z^{-d} + \dots + a_{d-1} z^{-1}).$$

Hence,  $\lim_{|z| \rightarrow \infty} \frac{f(z)}{a_d z^d} = 1$ . Knowing this, calculate

$$\begin{aligned} \lim_{|z| \rightarrow \infty} \left| \frac{f(z)}{|f(z)|} - \frac{a_d z^d}{|a_d z^d|} \right| &= \\ &= \lim_{|z| \rightarrow \infty} \left| \frac{f(z)}{a_d z^d} \frac{a_d z^d}{|a_d z^d|} \frac{|a_d z^d|}{|f(z)|} - \frac{a_d z^d}{|a_d z^d|} \right| = 0. \end{aligned}$$

Hence,  $n_r = d$  for large values of  $r$ .

A similar computation can be done for small values of  $r$ . Recall that  $a_0 \neq 0$ :

$$\frac{f(z)}{a_0} = 1 + \frac{1}{a_0}(a_1 z + \cdots + a_d z^d).$$

Thus,  $\lim_{|z| \rightarrow 0} \frac{f(z)}{a_0} = 1$ . In addition,  $\frac{f(z)}{|f(z)|} = \frac{f(z)}{a_0} \frac{a_0}{|a_0|} \frac{|a_0|}{|f(z)|}$ . Hence,  $\lim_{|z| \rightarrow 0} \frac{f(z)}{|f(z)|} = \lim_{|z| \rightarrow 0} \frac{a_0}{|a_0|}$ , i.e.  $n_r = 0$  for small values of  $r$ . Altogether, the degree of the polynomial is  $d = 0$ .  $\square$

## 5. Coding theory

It is often needed to transfer data while guaranteeing that they are transferred correctly. In some cases, it suffices to recognize whether the data is unchanged. In some cases, it can be transferred again. In other cases, this might not be reasonable, so that the data is needed to be recovered after a small number of errors in the transfer. This is the goal of coding theory. Some of the algorithms are explored now.

Notice that coding is quite different from encrypting. If no one but the addressee is meant to be able to read the message, then it should be encrypted. This topic is discussed briefly at the end of the previous chapter.

**12.5.1. Codes.** Data transfer is usually prone to errors. Since any information may be encoded as a sequence of *bits* (zeros or ones), the work is with  $\mathbb{Z}_2$  although the theory may be developed even for a general finite field. Furthermore, the length of the message to be transferred is assumed to be known in advance. Thus, one transfers  $k$ -bit words, where  $k \in \mathbb{N}$  is fixed.

It is desired to detect potential errors, and if possible, recover the original data. For this reason, further  $(n-k)$  bits are added to the  $k$ -bit word, where  $n$  is also fixed (and of course  $n > k$ ). These are called  $(n, k)$ -codes.

There are  $2^k$  binary words of length  $k$  and each should be mapped to one of the  $2^n$  possible *codewords*. For an  $(n, k)$ -code, there remain

$$2^n - 2^k = 2^k(2^{n-k} - 1)$$

words which are not codewords (if such a word is received, then an error has occurred). Thus, even for a large value of  $k$ , only a few bits added provide much redundant information.

The simplest example is the *parity check code*. Having a message of length  $k$ , the codeword is created by adding a bit whose value is determined so that the total number ones would be even. This is an example of a  $(k+1, k)$ -code.

If there occur an odd number of errors during the transfer, then it can be detected with this simple code. Every two

codewords differ in at least two bits, but an error word differs from at least two codewords in only one bit. Therefore, this code is unable to recover the original message, even with the assumption that only one bit was changed.

The following diagram illustrates all 2-bit words with the parity bit added. The codewords are marked with a bold dot.

Moreover, the parity check code is unable to detect the error of interchanging a pair of adjacent bits, which often happens.

**12.5.2. Word distance.** In the diagram of the parity check (3, 2)-code, each error word is at the “same” distance from three codewords – those which differ in exactly bits. The other words are farther. Formally, this observation can be described by the following definition of distance:

WORD DISTANCE

The *Hamming distance* of a pair of words (of equal length) is the number of bits in which they differ.

Consider words  $x, y, z$  such that  $x$  and  $y$  differ in  $r$  bits, and  $y$  and  $z$  differ in  $s$  bits. Then,  $x$  and  $z$  differ in at most  $r + s$ , which verifies the triangle inequality for distances.

If the code is to detect errors in  $r$  bits, then the minimum distance between each pair of codewords must be at least  $r + 1$ . If the code is to recover errors in  $r$  bits, then there exists only one codeword whose distance from the received word is at most  $r$ . Thus, the following propositions are verified:

- Theorem.** (1) A code reliably detects at most  $r$  errors if and only if the minimum Hamming distance of the codewords is  $r + 1$ .
- (2) A code reliably detects and recovers at most  $r$  errors if and only if the minimum Hamming distance of the codewords is  $2r + 1$ .

**12.5.3. Construction of polynomial codes.** For practical applications, the codewords should be constructed efficiently so that they can be easily recognized among all the words. The parity check code is one example; another trivial possibility is to simply repeat the bits. For instance, the (3, 1)-code can be considered which triplicates each bit.

A systematic way for code construction is to use division of polynomials. A message  $b_0b_1 \dots b_{k-1}$  is understood as the polynomial

$$m(x) = b_0 + b_1x + \dots + b_{k-1}x^{k-1}$$

over the field  $\mathbb{Z}_2$ . The encoded message should be another polynomial  $v(x)$  of degree at most  $n - 1$ .

POLYNOMIAL CODES

Let  $p(x) = a_0 + \dots + a_{n-k}x^{n-k} \in \mathbb{Z}_2[x]$  be a polynomial with coefficients  $a_0 = 1, a_{n-k} = 1$ . The *polynomial code generated by a polynomial  $p(x)$*  is the  $(n, k)$ -code whose codewords are polynomial of degree less than  $n$  divisible by  $p(x)$ . A message  $m(x)$  is encoded as

$$v(x) = r(x) + x^{n-k}m(x),$$

where  $r(x)$  is the remainder in the division of the polynomial  $x^{n-k}m(x)$  by  $p(x)$ .

Check the claimed properties first. By the very definition of the codeword  $v(x)$  of a message  $m(x)$ :

$$\begin{aligned} v(x) &= r(x) + x^{n-k}m(x) = \\ &= r(x) + q(x)p(x) + r(x) = q(x)p(x), \end{aligned}$$

since the sum of two identical polynomials is always zero over  $\mathbb{Z}_2$ . Therefore, all codewords are divisible by  $p(x)$ .

On the other hand, if  $v(x)$  is divisible by  $p(x)$ , the above calculation can be read from right to left (setting  $r(x) = x^{n-k}m(x) - q(x)p(x)$ ), and so it is a codeword created by the above procedure.

From the definition, the codeword is created by adding  $n - k$  bits given by  $r(x)$  at the beginning of the word (and simply shifting the message to the right by that). It follows that the original message is contained in the polynomial  $v(x)$  and the decoding is easy.

Consider the two simple examples, already mentioned. First, note that  $p(x) = 1 + x$  divides  $v(x)$  if and only if  $v(1) = 0$ . This occurs if and only if  $v(x)$  has an even number of non-zero coefficients. So the polynomial  $p(x) = 1 + x$  generates the parity check  $(n, n - 1)$ -code for any  $n \geq 2$ .

Similarly, it is easily verified that the polynomial

$$p(x) = 1 + x + \dots + x^{n-1}$$

generates the  $(n, 1)$ -code of  $n$ -fold bit repetition. Dividing the polynomial  $b_0x^{n-1}$  by  $p(x)$ , gives the remainder  $b_0(1 + \dots + x^{n-2})$ , so the corresponding codeword is  $b_0p(x)$ .

**12.5.4. Error detection.** Let  $e(x)$  denote the *error vector*.

This is, the difference between the original message  $v \in (\mathbb{Z}_2)^n$  and the received data  $u$ :

$$u(x) = v(x) + e(x).$$

The error is detected if and only if the generator of the code (i.e. the polynomial  $p(x)$ ) does not divide  $e(x)$ . Therefore, polynomials over  $\mathbb{Z}_2[x]$  which do not happen to be divisors too often are of interest.

**Definition.** An irreducible polynomial  $p(x) \in \mathbb{Z}_2[x]$  of degree  $m$  is said to be *primitive* if and only if  $p(x)$  divides  $(1 + x^k)$  for  $k = 2^m - 1$ , but not for any smaller value of  $k$ .

**Theorem.** Let  $p(x)$  be a primitive polynomial of degree  $m$  and  $n \leq 2^m - 1$ . Then the polynomial  $(n, n - m)$ -code generated by  $p(x)$  detects all simple and double errors.

**PROOF.** If exactly one error occurs, then  $e(x) = x^i$  for some  $i, 0 \leq i < n$ . Since  $p(x)$  is irreducible, it cannot have a root in  $\mathbb{Z}_2$ . In particular, it cannot divide  $x^i$  since the factorization of  $x^i$  is unique. It follows that every simple error is detected.

If exactly two errors occur, then

$$e(x) = x^i + x^j = x^i (1 + x^{j-i})$$

for some  $0 \leq i < j < n$ .  $p(x)$  does not divide any  $x^i$ , and since it is primitive, it does not divide  $1 + x^{j-i}$  either, provided  $j-i < 2^m - 1$ . At the same time,  $p(x)$  is irreducible, which means that it does not divide the product  $e(x) = x^i(1 + x^{j-i})$ , which completes the proof.  $\square$

**12.5.5. Corollary.** Let  $q(x)$  be a primitive polynomial of degree  $m$  and  $n \leq 2^m - 1$ . Then the polynomial  $(n, n - m - 1)$ -code generated by the polynomial  $p(x) = q(x)(1 + x)$  detects all double errors as well as all errors with an odd number of bit flips.

**PROOF.** The codewords generated by the chosen polynomial  $p(x)$  are divisible by both  $x + 1$  and the primitive polynomial  $q(x)$ . As verified, the factor  $x + 1$  is responsible for parity checking, i.e. all codewords have an even number of non-zero bits. This detects any odd number of errors. By the above theorem, the second factor is able to detect all double errors.  $\square$

The following table illustrates the power of the above theorems for several primitive polynomials of low degrees. For instance, the last row says that by adding only 11 redundant bits to a message of length 1012, and employing the polynomial  $(x+1)p(x)$ , all single, double, triple, and odd-numbered errors in the transfer can be detected. These are already quite large numbers, with over 300 decimal digits.

primitive polynomial $p(x)$	redundant bits	codeword length
$1 + x$	1	1
$1 + x + x^2$	2	3
$1 + x + x^3$	3	7
$1 + x + x^4$	4	15
$1 + x^2 + x^5$	5	31
$1 + x + x^6$	6	63
$1 + x^3 + x^7$	7	127
$1 + x^2 + x^3 + x^4 + x^8$	8	255
$1 + x^4 + x^9$	9	511
$1 + x^3 + x^{10}$	10	1023

Note that quite strong results on the divisibility are used for the decomposition of polynomials derived in the second part of this chapter. But tools which would assist in constructing primitive polynomials are not mentioned.

Such tools come from the theory of finite fields. The name "primitive" reflects the connection to the primitive elements in the Galois fields  $G(2^m)$ . This theory also provides a convenient way of applying the Euclidean division, that is, of verifying whether or not the received word is a codeword, using the delayed registers. This is a simple circuit with as many elements as is the degree of the polynomial.<sup>12</sup>

**12.5.6. Linear codes.** Polynomial codes can also be described using elementary matrix calculus.

Recall that when working over the field  $\mathbb{Z}_2$ , caution is required when applying the results of elementary linear algebra, since then the property that  $v = -v$  implies  $v = 0$  is often used. This is not the case now.

However, the basic definition of vector spaces, existence of bases and descriptions of linear mappings by matrices are still valid. It is useful to recall the general theory and its applicability.

Start with a more general definition of codes, which only requires linear dependency of the codeword on the original message:

LINEAR CODES

Any injective linear mapping  $g : (\mathbb{Z}_2)^k \rightarrow (\mathbb{Z}_2)^n$  is a *linear code*. The  $k$ -by- $n$  matrix  $G$  that corresponds to this mapping (in the canonical bases) is called the *generating matrix* of the code.

For each message  $v$ , the corresponding codeword is given by

$$u = G \cdot v.$$

**Theorem.** *Every polynomial  $(n, k)$ -code is a linear code.*

**PROOF.** Use elementary properties of Euclidean division. Apply the assignment of the polynomial  $v(x) = r(x) + x^{n-k}m(x)$  determined by the original message  $m(x)$  to the sum of two messages  $m(x) = m_1(x) + m_2(x)$ . The remainder in the division  $x^{n-k}(m_1(x) + m_2(x))$  is, by uniqueness, given as the sum  $r_1(x) + r_2(x)$  of the remainders for the individual messages. It follows that

$$v(x) = r_1(x) + r_2(x) + x^{n-k}(m_1(x) + m_2(x)),$$

which is the desired additivity. Since the only non-zero scalar in  $\mathbb{Z}_2$  is 1, the linearity of the mapping of the message  $m(x)$  to the longer codeword  $v(x)$  is proved. Moreover, this mapping is clearly injective, since the original message  $m(x)$  is simply copied beyond the redundant bits.  $\square$

For instance, consider the  $(6, 3)$ -code generated by the polynomial  $p(x) = 1 + x + x^3$ , for encoding 3-bit words.

<sup>12</sup>More about the beautiful theory and its connection with codes can be found in the book Gilbert, W., Nicholson, K., Modern Algebra and its applications, John Wiley & Sons, 2nd edition, 2003, 330+xvii pp., ISBN 0-471-41451-4.

Evaluate it on the individual basis vectors  $m_i(x) = x^{i-1}$ ,  $i = 1, 2, 3$ , to get

$$\begin{aligned}v_0 &= (1 + x) + x^3, \\v_1 &= (x + x^2) + x^4, \\v_2 &= (1 + x + x^2) + x^5.\end{aligned}$$

It follows that the generating matrix of this  $(6, 3)$ -code is

$$G = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Polynomial codes always copy the original message beyond the redundant bits. So the generating matrix can be split into two blocks  $P$  and  $Q$  consisting respectively of  $n - k$  and  $k$  rows. Then  $Q$  equals the identity matrix  $\mathbb{I}_k$ .

**12.5.7. Theorem.** *Let  $g : (\mathbb{Z}_2)^k \rightarrow (\mathbb{Z}_2)^n$  be a linear code with generating matrix  $G$ , written in blocks as*

$$G = \begin{pmatrix} P \\ \mathbb{I}_k \end{pmatrix}.$$

*Then, the mapping  $h : (\mathbb{Z}_2)^n \rightarrow (\mathbb{Z}_2)^{n-k}$  with the matrix*

$$H = (\mathbb{I}_{n-k} \quad P)$$

*has the following properties:*

- (1)  $\text{Ker } h = \text{Im } g$ ,
- (2) *a received word  $u$  is a codeword if and only if  $H \cdot u = 0$ .*

**PROOF.** The composition  $h \circ g : (\mathbb{Z}_2)^k \rightarrow (\mathbb{Z}_2)^{n-k}$  is given by the product of matrices (computing over  $\mathbb{Z}_2$ ):

$$H \cdot G = (\mathbb{I}_{n-k} \quad P) \cdot \begin{pmatrix} P \\ \mathbb{I}_k \end{pmatrix} = P + P = 0.$$

Hence it is proved that  $\text{Im } g \subseteq \text{Ker } h$ . Since the first  $n - k$  columns of  $H$  are basis vectors of  $(\mathbb{Z}_2)^{n-k}$ , the image  $\text{Im } h$  has the maximum dimension  $n - k$ , which means that this image contains  $2^{n-k}$  vectors. Vector spaces over  $\mathbb{Z}_2$  are finite commutative groups, so the formula relating the orders of subgroups and quotient groups from subsection 12.4.10 can be used, thus obtaining

$$|\text{Ker } h| \cdot |\text{Im } h| = |(\mathbb{Z}_2)^n| = 2^n.$$

Therefore, the number of vectors in  $\text{Ker } h$  is equal to  $2^n \cdot 2^{k-n} = 2^k$ . In order to complete the proof of the first proposition, it suffices to note that the image  $\text{Im } g$  also has  $2^k$  elements.

The second proposition is a trivial corollary of the first one.  $\square$

The matrix  $H$  from the theorem is called the *parity check matrix* of the corresponding linear  $(n, k)$ -code.

For instance, the matrix  $H = (1\ 1\ 1)$  is the parity check matrix for the parity check  $(3, 2)$ -code, encoding 2-bit words. It is easily obtained from the matrix

$$G = \begin{pmatrix} 1 & 1 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$$

that generates this code.

For the  $(6, 3)$ -code mentioned above, the parity check matrix is

$$H = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 & 1 & 1 \end{pmatrix}.$$

**12.5.8. Error-correcting codes.** As seen, transferring a message  $u$  gives the result

$$v = u + e.$$

Over  $\mathbb{Z}_2$ , this is equivalent to  $e = u + v$ .

It follows that if the error  $e$  to be detected fixed, all the received words determined by the correct codewords  $u$  fill one of the cosets in the quotient space  $(\mathbb{Z}_2)^n/V$ , where  $V$  is the vector subspace  $V \subseteq (\mathbb{Z}_2)^n$  of the codewords.

The mapping  $h : (\mathbb{Z}_2)^n \rightarrow (\mathbb{Z}_2)^{n-k}$  corresponding to the parity check matrix has  $V$  as its kernel. Therefore, it induces the injective linear mapping  $\tilde{h} : (\mathbb{Z}_2)^n/V \rightarrow (\mathbb{Z}_2)^{n-k}$ . Clearly, the value  $\tilde{h}(v + V)$  on the coset generated by  $v$  is determined uniquely by the value  $H \cdot v$ .

#### SYNDROMES

The expression  $H \cdot v$ , where  $H$  is the parity check matrix for the considered linear code, is called the *syndrome* of  $v$ .

The following claim is a direct corollary of the construction and the above observations:

**Theorem.** *Two words are in the same class  $u + V$  if and only if they have the same syndromes.*

It follows that self-correcting codes can be constructed by choosing, for every syndrome, the element of the corresponding coset which is most likely to be the sent codeword. Naturally, when choosing the code, it is desirable to maximize the probability that it can correct single errors (and possibly even more errors).

Try it on the example of the  $(6, 3)$ -code for which the matrices  $G$  and  $H$  are already computed. Build the table of all syndromes and the corresponding words.

The syndrome 000 is possessed exactly by the codewords. All words with a given different syndrome are obtained by choosing one of them and adding all the proper codewords.

The following two tables display the syndromes in the first rows; the second rows then display the vector which has the least number of ones among the vectors of the corresponding coset. In almost all cases, this is just one value one there; only in the last column, there are two ones, and the element

is chosen where the ones are adjacent (because, for instance, multiple errors are more likely to be adjacent).

000	100	010	001
<b>000000</b>	<b>100000</b>	<b>010000</b>	<b>001000</b>
110100	010100	100100	111100
011010	111010	001010	010010
111001	011001	101001	110001
101110	001110	111110	100110
001101	101101	011101	000101
100011	000011	110011	101011
010111	110111	000111	011111

110	011	111	101
<b>000100</b>	<b>000010</b>	<b>000001</b>	<b>000110</b>
110000	110110	110101	110010
011110	011000	011011	011100
111101	111011	111000	111111
101010	101100	101111	101000
001001	001111	001100	001011
100111	100001	100010	100101
010011	010101	010110	010001

All the columns in the tables are affine subspaces whose modelling vector spaces are always the first column of the first table. This is because the code is linear, so that the set of all codewords forms a vector space, and the individual cosets of the quotient space are consequently affine subspaces.

In particular, the difference of each pair of words in the same column is a codeword. The words in bold are the leading representatives of the coset (affine space) that correspond to the given syndromes. These are the words with the least number of ones in their column. They correspond to the least number of bit flips which must be made to any word in the given column in order to get a codeword.

For instance, if a word 111101 is received, compute that its syndrome is 110. The leading representative of the coset of this syndrome is 000100. Subtract it from the received word, to obtain the codeword 111001. This is the codeword with the least Hamming distance from the received word. So the original message is most likely to be 001.

### 6. Systems of polynomial equations

In practical problems, objects or actions are often encountered which are described in terms of polynomials or systems of polynomial equations. For instance, the set of points in  $\mathbb{R}^3$  defined by two equations  $x^2 + y^2 - 1 = 0$  and  $z = 0$  is the circle which is centered at  $(0, 0, 0)$ , has radius 1 and lies in the plane  $xy$ .

Similarly, equations  $xz = 0$  and  $yz = 0$  considered in  $\mathbb{R}^3$  define the union of the line  $x = 0, y = 0$  and the plane  $z = 0$ . Notice we have to specify the space carefully, since  $x^2 + y^2 = 0$  defines a circle in  $\mathbb{R}^2$ , but it is a cylinder if viewed in  $\mathbb{R}^3$ .

Deciding whether or not a given point lies within a given body, finding extrema of algebraically defined subsets of multidimensional spaces, analyzing movements of parts of some machine, etc. are examples of such problems.

**12.6.1. Affine varieties.** For the sake of simplicity (existence of roots of polynomials), the work is mainly with the field of complex numbers. Some ideas are extended to the case of a general field  $\mathbb{K}$ .

An affine  $n$ -dimensional space over a field  $\mathbb{K}$  is understood to be  $\mathbb{K}^n = \underbrace{\mathbb{K} \times \cdots \times \mathbb{K}}_n$  with the standard affine structure (see the beginning of Chapter 4).

As seen, a polynomial  $f = \sum_{\alpha} a_{\alpha} x^{\alpha} \in \mathbb{K}[x_1, \dots, x_n]$  can be viewed naturally as a mapping  $f: \mathbb{K}^n \rightarrow \mathbb{K}$ , defined by

$$f(u_1, \dots, u_n) := \sum_{\alpha} a_{\alpha} u^{\alpha}, \text{ where } u^{\alpha} = u_1^{\alpha_1} \cdots u_n^{\alpha_n}.$$

In dimension  $n = 1$ , the equality  $f(x) = 0$  describes only finitely many points of  $\mathbb{K}$ . In higher dimension, the similar equality  $f(x_1, \dots, x_n) = 0$  describes subsets similar to curves in the plane or surfaces in the space. However, they may be of quite complicated and self-intersecting shapes.

For instance, the set given by the equation  $(x^2 + y^2)^3 - 4x^2y^2 = 0$  look as a *quatrefoil* (see the illustration in the beginning of the part J in the other column). Another illustration of a two-dimensional surface is given by *Whitney's umbrella*  $x^2 - y^2z = 0$ , which, besides the part shown in the diagram, also includes the line  $\{x = 0, y = 0\}$ .

The diagram was drawn using the parametric description  $x = uv, y = v, z = u^2$ , whence the implicit description  $x^2 - y^2z = 0$  is easily guessed.

In the following illustration, there is the *Enneper surface* with parametrization  $x = 3u + 3uv^2 - u^3$ ,  $y = 3v + 3u^2v - v^3$ ,  $z = 3u^2 - 3v^2$ .

It is hard to imagine how to obtain the implicit description from this parametrization in hand. Nevertheless, there is an algorithm to eliminate the variables  $u$  and  $v$  from these three equations.

Quite a complex theory is needed to be developed for that. As usual, begin by formalization of the objects of interest.

#### AFFINE VARIETIES

Let  $f_1, \dots, f_s \in \mathbb{K}[x_1, \dots, x_n]$ . The *affine variety* in  $\mathbb{K}^n$  corresponding to the set of polynomials  $f_1, \dots, f_s$  is the set

$$\mathfrak{V}(f_1, \dots, f_s) = \{(a_1, \dots, a_n) \in \mathbb{K}^n; \\ f_i(a_1, \dots, a_n) = 0, i = 1, \dots, s\}$$

5

Affine varieties include conic sections, quadrics, and hyperquadrics, both singular and regular. Many curves and surfaces can be easily described as affine varieties.

The variety corresponding to a set of polynomials is the intersection of the varieties corresponding to the individual polynomials. For instance,  $\mathfrak{V}(x^2 + y^2 - 1, z) \subset \mathbb{R}^3$  is the circle which is centered at  $(0, 0, 0)$ , has radius 1 and lies in the plane  $xy$ .

Similarly,  $\mathfrak{V}(xz, yz) \subset \mathbb{R}^3$  is the union of the line  $x = 0$ ,  $y = 0$  and the plane  $z = 0$ , since it is exactly the points of these two objects where both the polynomials  $xz, yz$  are zero.

These examples illustrate that it is not easy to deal with the concept of dimension. Is the mentioned line, added to the plane, enough for the variety to be considered three-dimensional, or should one keep considering it two-dimensional with a certain anomaly?

Verify the following straightforward proposition:

**Theorem.** Let  $V = \mathfrak{V}(f_1, \dots, f_s)$  and  $W = \mathfrak{V}(g_1, \dots, g_t) \subseteq \mathbb{K}^n$  be affine varieties. Then,  $V \cup W$  and  $V \cap W$  are also affine varieties, where

$$V \cap W = \mathfrak{V}(f_1, \dots, f_s, g_1, \dots, g_t),$$

$$V \cup W = \mathfrak{V}(f_i g_j) \quad \text{for } 1 \leq i \leq s, 1 \leq j \leq t.$$

In the following subsections, some questions which arise in the context of varieties are answered:

Q1. Is the set  $\mathfrak{V}(f_1, \dots, f_s)$  empty?

Q2. Is the set  $\mathfrak{V}(f_1, \dots, f_s)$  finite?

Q3. How to understand the concept of dimension for varieties?

All of these problems can be “reasonably” solved for varieties over the complex numbers (as well as over any algebraically closed field); it is more difficult for the real numbers and nearly impossible for general fields. For instance, over the rational numbers, the question whether  $\mathfrak{V}(x^n + y^n - z^n) = \emptyset$  leads to the well-known Fermat’s last theorem, many times mentioned in Chapter 11.

**12.6.2. Parametrization.** For some purely practical operations with varieties, it is convenient to use the implicit representation (the one used so far). For instance, deciding whether a given point lies in a given variety, or inside the space enclosed by it, is quite easy using the implicit description. On the other hand, the parametric description may also come in handy in many situations (for example, it was used to draw the diagram).

The variety  $\mathfrak{V}(x + y + z - 1, x + 2y - z - 3)$  is a line (the intersection of two planes). If the system

$$\begin{aligned} x + y + z - 1 &= 0, \\ x + 2y - z - 3 &= 0, \end{aligned}$$

is solved, the parametric description of this line is immediate:

$$\begin{aligned} x &= -1 - 3t, \\ y &= 2 - 2t, \\ z &= t \end{aligned}$$

as known from the affine geometry. One needs to be more careful in general:

#### RATIONAL PARAMETRIZATION

**Definition.** A *rational parametric representation* of a variety  $\mathfrak{V}(f_1, \dots, f_r) \subseteq \mathbb{K}^n$  is a set of rational functions  $r_1, \dots, r_n \in \mathbb{K}(t_1, \dots, t_s)$  such that:

- the entire image of the mapping  $r = (r_1, \dots, r_n)$  is contained in  $\mathfrak{V}(f_1, \dots, f_r)$ ;
- $\mathfrak{V}(f_1, \dots, f_r)$  is the minimal affine variety which contains these points  $(x_1, \dots, x_n)$ .

Note that the parametrization is not required to describe all the points of the variety. This is important, as seen by a simple example of parametrization of a circle in the plane:

$$x = \frac{2t}{1+t^2}, \quad y = \frac{-1+t^2}{1+t^2},$$

which can be obtained using the stereographic projection. (Verify this in detail!) Note that this parametrization describes all points except for the point  $(0, 1)$ , from which we project, since this point is not reachable for any value of the parameter  $t$ . This is nobody's fault; it follows from the different topological properties of the circle and the line that there exists no global bijective rational parametrization.

In this connection, two more questions arise:

- Q4. *Does there exist a parametrization of a given variety and how to find it?*  
 Q5. *Is there an implicit description of a parametrically defined variety?*

The general answer to question 4 is negative. In fact, most affine varieties cannot be parametrized; or at least there is no algorithm for parametrization of the implicit description.

It is clear at first sight that a given variety may admit many implicit and parametric descriptions. In the case of implicit descriptions, it is given by representation in terms of several "generating" polynomials, and there is clearly much freedom in their choice. Once a parametrization is found, it can be composed with any rational bijection on the parameters in order to obtain another one.

**12.6.3. Ideals.** In order to avoid the dependence on the chosen equations that define a variety, consider all consequences of the given equations. This leads to the following algebraic concept of subsets in rings (which is similar to normal subgroups):

IDEALS

**Definition.** Let  $\mathbb{K}$  be a commutative ring. A subset  $I \subseteq \mathbb{K}$  is called an *ideal* if and only if  $0 \in I$  and

$$\begin{aligned} f, g \in I &\implies f + g \in I, \\ f \in I, h \in \mathbb{K} &\implies f \cdot h \in I. \end{aligned}$$

Since the definition contains only universal quantifiers (the properties are required for all elements in  $\mathbb{K}$  or  $I$ ), the intersection of two ideals is also an ideal. Consequently, ideals can be considered *generated* by subsets. Use the notation  $I = \langle a_1, \dots, a_n \rangle$ . It is easy to prove that such an ideal is

$$I = \left\{ \sum_i a_i b_i, b_i \in \mathbb{K} \right\},$$

where only finite sums are considered. (Check that this is the intersection of all ideals containing the set of the generators!) The set of generators may be infinite, too. If there are only finitely many generators, the ideal is said to be *finitely generated*.

It is easy to verify that each variety defines an ideal in the ring of polynomials in the following way:

## THE IDEAL OF A VARIETY

For a variety  $V = \mathfrak{V}(f_1, \dots, f_s)$ , set

$$\mathfrak{I}(V) := \{f \in \mathbb{K}[x_1, \dots, x_n]; \\ f(a_1, \dots, a_n) = 0, \forall (a_1, \dots, a_n) \in V\}.$$

**Lemma.** Let  $f_1, \dots, f_s, g_1, \dots, g_t \in \mathbb{K}[x_1, \dots, x_n]$  be polynomials. Then:

(1) if  $\langle f_1, \dots, f_s \rangle = \langle g_1, \dots, g_t \rangle$ , then

$$V = \mathfrak{V}(f_1, \dots, f_s) = \mathfrak{V}(g_1, \dots, g_t);$$

(2)  $\mathfrak{I}(V)$  is an ideal, and  $\langle f_1, \dots, f_s \rangle \subseteq \mathfrak{I}(V)$ .

**PROOF.** If a point  $a = (a_1, \dots, a_n)$  lies in a variety  $\mathfrak{V}(f_1, \dots, f_s)$ , then any polynomial of the form

$$f = h_1 f_1 + \dots + h_s f_s$$

(i.e. any member of the ideal  $I = \langle f_1, \dots, f_s \rangle$ ) takes zero at  $a$ . In particular, this means that all the polynomials  $g_i$  take zero at  $a$ . Hence

$$\mathfrak{V}(f_1, \dots, f_s) \subseteq \mathfrak{V}(g_1, \dots, g_t).$$

The other inclusion can be proved similarly.

In order to verify the second proposition, choose  $g, g' \in \mathfrak{I}(V)$ ,  $h \in \mathbb{K}[x_1, \dots, x_n]$ . Then, for any point  $a \in V$  that

$$(gh)(a) = 0 \Rightarrow gh \in \mathfrak{I}(V),$$

$$(g + g')(a) = 0 \Rightarrow g + g' \in \mathfrak{I}(V).$$

Hence  $\mathfrak{I}(V)$  is an ideal in  $\mathbb{K}[x_1, \dots, x_n]$ .

For any polynomial  $f = h_1 f_1 + \dots + h_s f_s \in \langle f_1, \dots, f_s \rangle$  and a point  $a \in V$ ,  $f(a) = 0$ , which proves the desired inclusion.  $\square$

The simplest examples are trivial varieties – a single point and the entire affine space:

$$\mathfrak{I}(\{(0, 0, \dots, 0)\}) = \langle x_1, \dots, x_n \rangle,$$

$$\mathfrak{I}(\mathbb{K}^n) = \{0\} \quad \text{for any infinite field } \mathbb{K}.$$

The other inclusion of the second part of the lemma does not hold in general. For instance, the variety  $\mathfrak{V}(x^2, y^2)$  contains only the single point –  $(0, 0)$ . This means that  $\mathfrak{I}(V) = \langle x, y \rangle \supset \langle x^2, y^2 \rangle$ .

If  $V, W \subseteq \mathbb{K}^n$  are varieties, then

$$V \subseteq W \implies \mathfrak{I}(V) \supseteq \mathfrak{I}(W).$$

In other words, a polynomial which takes zero at each point of a given variety clearly takes zero at each point of any of the variety's subsets.

Now, further natural problems can be formulated:

Q6. Is every ideal  $I \in \mathbb{K}[x_1, \dots, x_n]$  finitely generated?

Q7. Is there an algorithm which decides whether  $f \in \langle f_1, \dots, f_s \rangle$ ?

Q8. What is the precise relation between  $\langle f_1, \dots, f_s \rangle$  and  $\mathfrak{I}(\mathfrak{V}(f_1, \dots, f_s))$ ?

**12.6.4. Dimension 1.** Consider univariate polynomials first

$$f = a_0x^n + a_1x^{n-1} + \cdots + a_n, \quad \text{where } a_0 \neq 0.$$

The leading term of a polynomial is defined to be  $LT(f) := a_0x^n$ . Clearly,

$$\deg f \leq \deg g \iff LT(f)|LT(g).$$

Let  $\mathbb{K}$  be a field and  $g$  a non-zero polynomial. Every polynomial  $f \in \mathbb{K}[x]$  can be written in a unique way as

$$f = q \cdot g + r, \quad \text{where } r = 0 \text{ or } \deg r < \deg g.$$

In fact, the quotient  $q$  and the remainder  $r$  can be computed by the following algorithm:

- (1)  $q := 0, r := f$
- (2) while  $r \neq 0 \wedge LT(g)|LT(r)$ 
  - (a)  $q := q + LT(r)/LT(g)$
  - (b)  $r := r - LT(r)/LT(g) \cdot g$

When checking the loop condition, the invariant  $f = q \cdot g + r$  holds, so the algorithm answers correctly as soon as the loop condition becomes "false". Since the degree of  $r$  is decreasing, the algorithm eventually terminates.

**Corollary.** *Let  $\mathbb{K}$  be a field. Then, every ideal in the polynomial ring  $\mathbb{K}[x]$  is of the form  $\langle f \rangle$ .*

**PROOF.** Consider an ideal  $I \subseteq \mathbb{K}[x]$ . If  $I = \{0\}$ , then the ideal is generated by the zero polynomial. If  $I$  contains a non-zero polynomial  $f$ , then choose any with the lowest degree. Clearly  $\langle f \rangle \subseteq I$ .

For any polynomial  $g \in I$ , consider the Euclidean division of  $g$  by  $f$ , i.e.  $g = qf + r$ . Clearly,  $qf \in I$ , which means that  $r \in I$  as well. However, the degree of  $f$  is as small as possible, so  $r = 0$ . Therefore,  $g$  is a multiple of  $f$ , and  $I = \langle f \rangle$ .  $\square$

An ideal which is generated by a single element is called a *principal ideal*. A ring which has the property of the last lemma is called a *principal ideal domain*.

Recall the Euclidean algorithm for the greatest common divisor  $h = GCD(f, g)$  of polynomials  $f$  and  $g$  (the variable  $h$  contains the desired greatest common divisor when the algorithm terminates):

- (1)  $h := f, s := g$
- (2) while  $s \neq 0$ 
  - (a)  $r := h \bmod s$
  - (b)  $h := s$
  - (c)  $s := r$

Let  $f = q \cdot g + r$  and  $h = GCD(f, g)$ . Then,  $h|r, g$  and

$$\forall p \in \mathbb{K}[x]: p|r, g, \quad \text{so } p|f \text{ and } p|h.$$

Hence,  $h$  is  $GCD(r, g)$ . Trivially,  $GCD(h, 0) = h$ , so the algorithm computes  $GCD(f, g)$  correctly. Since the degree of  $r$  is strictly decreasing, the algorithm eventually terminates.

It follows that each pair of polynomials has a greatest common divisor. It is unique up to multiplication by a scalar. Indeed, if two polynomials are greatest common divisors of a given pair of polynomials, then they must divide each other,

which is, for polynomials, possible only in the case mentioned.

The greatest common divisor of more polynomials is defined as follows: If  $s > 2$ , then

$$GCD(f_1, \dots, f_s) := GCD(f_1, GCD(f_2, \dots, f_s)).$$

**Lemma.** *Let  $f_1, \dots, f_s$  be polynomials. Then,  $\langle GCD(f_1, \dots, f_s) \rangle = \langle f_1, \dots, f_s \rangle$ .*

**PROOF.**  $GCD(f_1, \dots, f_s)$  divides all the polynomials  $f_i$ . Hence the principal ideal  $\langle GCD(f_1, \dots, f_s) \rangle$  contains the ideal  $\langle f_1, \dots, f_s \rangle$ . The other inclusion follows immediately from Bezout's identity.  $\square$

Earlier, eight questions were formulated. Here are some answers for dimension 1:

- Since  $\mathfrak{V}(f_1, \dots, f_s) = \mathfrak{V}(GCD(f_1, \dots, f_s))$ , the problem of emptiness of a given variety reduces to the problem of existence of a root of a single polynomial.
- For the same reason, each variety is a finite set of isolated points – the roots of the polynomial  $GCD(f_1, \dots, f_s)$ , except for the case when  $GCD(f_1, \dots, f_s) = 0$ . This can happen only if  $f_1 = f_2 = \dots = f_s = 0$ , and then the variety is the entire  $\mathbb{K}$ .
- The concept of dimension is not of much interest in this case; each variety has dimension zero, being a discrete set of points.
- Each ideal can be generated by a single polynomial.
- $f \in \langle f_1, \dots, f_s \rangle \iff GCD(f_1, \dots, f_s) | f$ .
- Denoting  $\langle f \rangle := \mathfrak{I}(\mathfrak{V}(f_1, \dots, f_s))$ , then  $f$  and  $GCD(f_1, \dots, f_s)$  may differ only in root multiplicities.

**12.6.5. Monomial ordering.** In order to generalize the Euclidean division of polynomials for more variables, one must first find an appropriate analogy for the degree of a polynomial and its leading term.

The Euclidean division of a polynomial  $f \in \mathbb{K}[x_1, \dots, x_n]$  by polynomials  $g_1, \dots, g_s$  is to be an expression of the form

$$f = a_1 g_1 + \dots + a_s g_s + r$$

where no term of the remainder  $r$  is divisible by the leading term of any of the polynomials  $g_i$ .

Try this with  $f = x^2 y + x y^2 + y^2$ ,  $g_1 = xy - 1$ , and  $g_2 = y^2 - 1$ . The first division yields

$$f = (x + y) \cdot g_1 + (x + y^2 + y).$$

$LT(y^2 - 1)$  does not divide  $x$  (the leading term of the remainder), so, theoretically, continuation is not possible.

However,  $x$  can be moved into the remainder, thus obtaining the result

$$f = (x + y) \cdot g_1 + g_2 + (x + y + 1).$$

No term of the remainder is divisible by either  $LT(g_1)$  or  $LT(g_2)$ . How are the leading terms determined?

MONOMIAL ORDERING

A *monomial ordering* on  $\mathbb{K}[x_1, \dots, x_n]$  is a well-ordering (every non-empty subset has a least element)  $<$  on  $\mathbb{N}^n$  which satisfies

$$\forall \alpha, \beta, \gamma \in \mathbb{Z}^n : \alpha < \beta \implies \alpha + \gamma < \beta + \gamma.$$

An ordering on  $\mathbb{N}^n$  induces an ordering on monomials as soon as the order of the variables  $x_1 < x_2 < \dots < x_n$  is fixed.

Each polynomial can be rearranged as a decreasing sequence of monomials (ignoring the coefficients for now).

The following three definitions introduce the most common monomial orderings. Each ordering assumes that the order of the variables is fixed, usually  $x_1 > x_2 > \dots > x_n$ .

**Definition.** Let  $\alpha, \beta \in \mathbb{N}^n$ . The *lexicographic ordering*  $<_{\text{lex}}$  is defined by

$$\alpha >_{\text{lex}} \beta \iff \text{the left-most non-zero term of } \alpha - \beta \text{ is positive.}$$

The *graded lexicographic ordering*  $<_{\text{glex}}$  is defined by

$$\alpha >_{\text{glex}} \beta \iff |\alpha| > |\beta| \quad \text{or} \\ |\alpha| = |\beta| \quad \text{and } \alpha >_{\text{lex}} \beta.$$

The *graded reverse lexicographic ordering*  $<_{\text{grevlex}}$  is defined by

$$\alpha >_{\text{grevlex}} \beta \iff |\alpha| > |\beta| \quad \text{or} \\ |\alpha| = |\beta| \quad \text{and the right-most nonzero} \\ \text{term of } \alpha - \beta \text{ is negative.}$$

If  $x > y > z$ , then  $x >_{\text{grevlex}} y >_{\text{grevlex}} z$ , but  $x^2yz^2 >_{\text{glex}} xy^3z$ , yet  $x^2yz^2 <_{\text{grevlex}} xy^3z$ .

Verify in detail that  $>_{\text{lex}}, >_{\text{glex}}, >_{\text{grevlex}}$  are monomial orderings!

**12.6.6. Multivariate division with remainder.** Consider a non-zero polynomial  $f = \sum_{\alpha \in \mathbb{N}^n} a_{\alpha} x^{\alpha}$  in  $\mathbb{K}[x_1, \dots, x_n]$  and  $<$  a monomial ordering. Then define the *degree*, *leading coefficient*, *leading monomial*, and *leading term* of  $f$  as follows:

- $\text{multideg } f := \max\{\alpha \in \mathbb{N}^n, a_{\alpha} \neq 0\}$ ,
- $LC f := a_{\text{multideg } f}$ ,
- $LM f := x^{\text{multideg } f}$ ,
- $LT f := LC f \cdot LM f$ .

Of course, these concepts depend on the underlying monomial ordering.

**Lemma.** Let  $f, g \in \mathbb{K}[x_1, \dots, x_n]$  and  $<$  be a monomial ordering. Then,

- (1)  $\text{multideg}(f \cdot g) = \text{multideg } f + \text{multideg } g$ ,
- (2)  $f + g \neq 0 \implies \text{multideg}(f + g) \leq \max\{\text{multideg } f, \text{multideg } g\}$ .

PROOF. Both claims are straightforward corollaries of the definitions.  $\square$

**Theorem.** Let  $<$  be a monomial ordering and  $F = (f_1, \dots, f_s)$  be an  $s$ -tuple of polynomials in  $\mathbb{K}[x_1, \dots, x_n]$ . Then, every polynomial  $f \in \mathbb{K}[x_1, \dots, x_n]$  can be expressed as

$$f = a_1 f_1 + \dots + a_s f_s + r,$$

where  $a_i, r \in \mathbb{K}[x_1, \dots, x_n]$  for all  $i = 1, 2, \dots, s$ . Moreover, either  $r = 0$  or  $r$  is a linear combination of monomials none of which is divisible by any of  $LT f_1, \dots, LT f_s$ , and if  $a_i f_i \neq 0$ , then  $\text{multideg } f \geq \text{multideg } a_i f_i$  for each  $i$ .

The polynomial  $r$  is called the remainder of the multivariate division  $f/F$ .

**PROOF.** The theorem says nothing about uniqueness of the result. The following algorithm produces a possible solution and thus proves the theorem.

In the sequel, consider the output of this algorithm to be the result of the division.

- (1)  $a_1 := 0, \dots, a_s := 0, r := 0, p := f$
- (2) while  $p \neq 0$ 
  - (a)  $i := 1$
  - (b)  $d := \text{false}$
  - (c) while  $i \leq s \wedge \text{not } d$ 
    - (i) if  $LT f_i | LT p$ 

$$a_i := a_i + LT p / LT f_i$$

$$p := p - (LT p / LT f_i) \cdot f_i$$

$$d := \text{true}$$
    - (ii) else  $i := i + 1$
  - (d) if not  $d$ 
    - (i)  $r := r + LT p$
    - (ii)  $p := p - LT p$

In every iteration of the outer loop, exactly one of the commands 2(c)i, 2(d)ii is executed, so the degree of  $p$  decreases. Therefore, the algorithm eventually terminates.

When checking the loop condition, the invariant  $f = a_1 f_1 + \dots + p + r$  holds, and each term of each  $a_i$  is the quotient  $LT p / LT f_i$  from some moment. The degrees of these terms are less than the current degree of  $p$ , which is at most the degree of  $f$ . Altogether, the degree of each  $a_i f_i$  is at most the degree of  $f$ .  $\square$

In the ring  $\mathbb{K}[x_1, \dots, x_n]$ , the following implication clearly holds:

$$f = a_1 f_1 + \dots + a_s f_s + 0 \implies f \in \langle f_1, \dots, f_s \rangle.$$

However, the converse is generally not true for multivariate division:

Consider  $f = xy^2 - x$ ,  $f_1 = xy + 1$ ,  $f_2 = y^2 - 1$ . The algorithm outputs

$$f = y(xy + 1) + 0(y^2 - 1) + (-x - y),$$

but  $f = x(y^2 - 1)$ , so that  $f \in \langle f_1, f_2 \rangle$ .

The next goal is to find some distinguished generators of the ideals  $I = \langle f_1, \dots, f_s \rangle$  which would behave better. In a certain sense, this is a similar procedure to the Gaussian elimination of variables for systems of linear equations. Begin with some special assumptions about the ideals.

**12.6.7. Monomial ideals.** An ideal  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  is called *monomial* if and only if there is a set of multi-indices  $A \subseteq \mathbb{N}^n$  such that  $I$  is generated by the monomials  $x^\alpha$  with  $\alpha \in A$ .

This means that all polynomials in  $I$  are of the form  $\sum_{\alpha \in A} h_\alpha x^\alpha$ , where  $h_\alpha \in \mathbb{K}[x_1, \dots, x_n]$ .

Clearly, for a monomial ideal  $I$   $x^\beta \in I$  if and only if there exists an  $\alpha \in A$  such that  $x^\alpha$  divides  $x^\beta$ .

**Lemma.** Let  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  be a monomial ideal and  $f \in \mathbb{K}[x_1, \dots, x_n]$  a polynomial. Then, the following propositions are equivalent:

- (1)  $f \in I$ ,
- (2) each term of  $f$  lies in  $I$ ;
- (3) the polynomial  $f$  is a linear combination of monomials from  $I$  with coefficients from  $\mathbb{K}$ .

**PROOF.** The implications (3)  $\implies$  (2)  $\implies$  (1) are obvious. It remains to prove (1)  $\implies$  (3).

Write the polynomial  $f$  as  $f = \sum_{\alpha} a_\alpha x^\alpha$ , where  $a_\alpha \in \mathbb{K}$ . It follows from the assumption  $f \in I$  that  $f = \sum_{\beta \in A} h_\beta x^\beta$ , where  $x^\beta \in I$  and  $h_\beta \in \mathbb{K}[x_1, \dots, x_n]$ . Each term  $a_\alpha x^\alpha$  must equal some term of the other equality. Hence each term  $a_\alpha x^\alpha$  of the polynomial  $f$  can be expressed as the sum of expressions  $d x^{\beta+\delta}$ , where  $d \in \mathbb{K}$ ,  $x^\beta \in I$ . However, this means that  $x^\alpha \in I$ , so that (3) holds.  $\square$

**Corollary.** Two monomial ideals coincide if and only if they contain the same monomials.

The following theorem goes much further. It says that every monomial ideal is finitely generated and, moreover, the finite set of generators may be chosen from any given set of generators.

**12.6.8. Theorem** (Dickson's lemma). Every monomial ideal  $I = \langle x^\alpha, \alpha \in A \rangle \subseteq \mathbb{K}[x_1, \dots, x_n]$  can be written in the form  $I = \langle x^{\alpha_1}, \dots, x^{\alpha_s} \rangle$ , where  $\alpha_1, \dots, \alpha_s \in A$ .

**PROOF.** Proceed by induction on the number of variables. If  $n = 1$ , then  $I \subseteq \mathbb{K}[x]$ ,  $I = \langle x^\alpha, \alpha \in A \subseteq \mathbb{N} \rangle$ . The set of exponents in  $A$  has a minimum, so denote it by  $\beta := \min A$ . Then,  $x^\beta$  divides each monomial  $x^\alpha$  with  $\alpha \in A$ , so  $I = \langle x^\beta \rangle$ .

Now suppose  $n > 1$  and assume that the proposition is true for fewer variables. Denote the variables  $x_1, \dots, x_{n-1}, y$ , and write monomials in the form  $x^\alpha y^m$  where  $\alpha \in \mathbb{N}^{n-1}$ ,  $m \in \mathbb{N}$ . Suppose that  $I \subseteq \mathbb{K}[x_1, \dots, x_{n-1}, y]$  is monomial, and define  $J \subseteq \mathbb{K}[x_1, \dots, x_{n-1}]$  by

$$J := \langle x^\alpha, \exists m \in \mathbb{N}, x^\alpha y^m \in I \rangle.$$

Clearly,  $J$  is a monomial ideal in  $n - 1$  variables, so by the induction hypothesis,  $J = \langle x^{\alpha_1}, \dots, x^{\alpha_s} \rangle$ . It follows from the definition of  $J$  that there are minimal integers  $m_i \in \mathbb{N}$  such that  $x^{\alpha_i} y^{m_i} \in I_A$ . Denote  $m := \max\{m_i\}$  and define an analogous system of ideals  $J_k \subseteq \mathbb{K}[x_1, \dots, x_{n-1}]$  for  $0 \leq k \leq m - 1$

$$J_k := \langle x^\beta; x^\beta y^k \in I_A \rangle.$$

Again, all the ideals  $J_k$  satisfy the induction hypothesis, so they can be expressed as

$$J_k = \langle x^{\alpha_{k,1}}, \dots, x^{\alpha_{k,s_k}} \rangle.$$

It remains to show that  $I$  is generated by the following finite set of monomials:

$$\begin{aligned} & x^{\alpha_1} y^m, \dots, x^{\alpha_s} y^m, \\ & x^{\alpha_{0,1}} y^0, \dots, x^{\alpha_{0,s_0}} y^0, \\ & \vdots \\ & x^{\alpha_{m-1,1}} y^{m-1}, \dots, x^{\alpha_{m-1,s_{m-1}}} y^{m-1}. \end{aligned}$$

Consider a monomial  $x^\alpha y^p \in I$ . Either of the following cases occurs:

- $p \geq m$ . Then,  $x^\alpha \in J$ ,  $k = p$ , so one of  $x^{\alpha_1} y^m, \dots, x^{\alpha_s} y^m$  divides  $x^\alpha y^p$ .
- $p < m$ . Then, analogously,  $x^\alpha \in J_k$ , and one of  $x^{\alpha_{k,1}} y^k, \dots, x^{\alpha_{k,s_k}} y^k$  divides  $x^\alpha y^p$ .

By the previous lemma, each polynomial  $f \in I$  can be expressed as a linear combination of monomials from  $I$ . Each of these is divisible by one of the generators; hence  $f$  lies in the ideal generated by them. Therefore,  $I$  is a subset of that. The other inclusion is trivial, which completes the proof of Dickson's lemma.  $\square$

**12.6.9. Hilbert's theorem.** Everything is now at hand for the discussion of ideal bases in polynomial rings. The main idea is the maximal utilization of the information about the leading terms among the generating polynomials and in the ideal. For a non-zero ideal  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$ , denote

$$LT I := \{ax^\alpha; \exists f \in I: LT f = ax^\alpha\}.$$

Clearly,  $\langle LT I \rangle$  is a monomial ideal, so by Dickson's lemma,  $\langle LT I \rangle = \langle LT g_1, \dots, LT g_s \rangle$  for appropriate  $g_1, \dots, g_s \in I$ .

**Theorem.** Every ideal  $I \in \mathbb{K}[x_1, \dots, x_n]$  is finitely generated.

**PROOF.** The statement is trivial for  $I = \{0\}$ . So suppose  $I \neq \{0\}$ . By Dickson's lemma and the above note, there are  $g_1, \dots, g_s \in I$  such that  $\langle LT I \rangle = \langle LT g_1, \dots, LT g_s \rangle$ .

Clearly,  $\langle g_1, \dots, g_s \rangle \subseteq I$ . Choose any polynomial  $f \in I$  and divide it by the  $s$ -tuple  $g_1, \dots, g_s$ .

$$f = a_1 g_1 + \dots + a_s g_s + r,$$

is obtained where no term of  $r$  is divisible by any of  $LT g_1, \dots, LT g_s$ .

Since  $r = f - a_1 g_1 - \dots - a_s g_s$ ,  $r \in I$ , and also  $LT r \in LT I$ . This means that  $LT r \in \langle LT I \rangle$ . Admit that  $r \neq 0$ . Since  $\langle LT I \rangle$  is monomial,  $LT r$  must be divisible by one of its generators, i.e.  $LT g_1, \dots, LT g_s$ . This contradicts the result of the multivariate division algorithm. Therefore,  $r = 0$  and  $I$  is generated by  $g_1, \dots, g_s$ .  $\square$

**12.6.10. Gröbner bases.** The basis used in the proof of Hilbert's theorem has the properties stated in the following definition:

GRÖBNER BASES OF IDEALS

**Definition.** A finite set of generators  $g_1, \dots, g_s$  of an ideal  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  is called *Gröbner basis* if and only if  $\langle LT I \rangle = \langle LT g_1, \dots, LT g_s \rangle$ .

**Corollary.** Every ideal  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  has a Gröbner basis. Every set of polynomials  $g_1, \dots, g_s \in I$  such that  $\langle LT I \rangle = \langle LT g_1, \dots, LT g_s \rangle$  is a Gröbner basis of  $I$ .

**Example.** Return to the remark on similarity with the Gaussian variable elimination for systems of linear equations. That is, illustrate the general results above on the simplest case of polynomials of degree one with the lexicographic ordering.

Denote the generators  $f_i = \sum_j a_{ij}x_j + a_{i0}$ . Consider the matrix  $A = (a_{ij})$ , where  $i = 1, \dots, s$  and  $j = 0, \dots, n$ , and apply the Gaussian elimination to it. This gives a matrix  $B = (b_{ij})$  in echelon form. Zero rows can be omitted from it. Hence there is a new basis  $g_1, \dots, g_t$ , where  $t \leq s$ .

Due to the performed steps, each  $f_i$  can be expressed as a linear combination  $g_1, \dots, g_t$ , which means that

$$\langle f_1, \dots, f_s \rangle = \langle g_1, \dots, g_t \rangle.$$

Now, verify that these polynomials  $g_1, \dots, g_t$  form a Gröbner basis. Without loss of generality, assume that the variables are labeled so that  $LM g_i = x_i$  for  $i = 1, \dots, t$ . Any polynomial  $f \in I$  can be written as

$$f = h_1 f_1 + \dots + h_s f_s = h'_1 g_1 + \dots + h'_t g_t.$$

It is required that  $LT f \in \langle LT g_1, \dots, LT g_t \rangle$ . That is,  $LT f$  is divisible by one of  $x_1, \dots, x_t$ . Suppose that  $f$  contains only the variables  $x_{t+1}, \dots, x_n$ . However, then  $h'_1 = 0$ , since  $x_1$  is only in  $g_1$  by the echelon form of  $B$ . Analogously,  $h'_2 = \dots = h'_t = 0$ , and so  $f = 0$ .

The existence of the very special bases is now proved.

However, they cannot yet be constructed algorithmically. This is the goal of the following subsections.

**12.6.11. Theorem.** Let  $G = \{g_1, \dots, g_t\}$  be a Gröbner basis of an ideal  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  and  $f$  a polynomial in  $\mathbb{K}[x_1, \dots, x_n]$ . Then, there is a unique  $r = \sum_{\alpha} a_{\alpha} x^{\alpha} \in \mathbb{K}[x_1, \dots, x_n]$  such that:

- (1) no term of  $r$  is divisible by any of  $LT g_1, \dots, LT g_t$ , i.e.  $\forall \alpha \forall i: LT g_i \nmid a_{\alpha} x^{\alpha}$ ;
- (2)  $\exists g \in I: f = g + r$ .

**PROOF.** The algorithm for multivariate division produces

$$f = a_1 g_1 + \dots + a_t g_t + r,$$

where  $r$  satisfies the condition (1). Select  $g$  as  $a_1 g_1 + \dots + a_t g_t$ , which of course lies in  $I$ .

It remains to prove uniqueness. Suppose that

$$f = g + r = g' + r',$$

where  $r \neq r'$ . Clearly,  $r - r' = g' - g \in I$ . Since  $G$  is a Gröbner basis,  $LT(r - r')$  is divisible by one of  $LT g_1, \dots, LT g_t$ . There are two possibilities:

- $LM r \neq LM r'$ . The one with the higher degree must be divisible by one of  $LT g_1, \dots, LT g_t$ , which contradicts condition (1).
- $LM r = LM r'$  and  $LC r \neq LC r'$ . Then both the monomials  $LM r$  and  $LM r'$  must be divisible by one of  $LT g_1, \dots, LT g_t$ , which is again a contradiction.

It follows that  $LT r = LT r'$  and the inductive argument shows that  $r = r'$ .  $\square$

The previous theorem generalizes the Euclidean division, with an ideal instead of a divisor. In the univariate case, this is no generalization, since every ideal is generated by a single polynomial. If it is only the remainder which is of interest, the order of polynomials in the Gröbner basis does not matter. Hence it makes sense to define the notation  $\bar{f}^G$  for the remainder in the division  $f/G$ , provided  $G = (g_1, \dots, g_s)$  is a Gröbner basis.

**Corollary.** *Let  $G = \{g_1, \dots, g_t\}$  be a Gröbner basis of an ideal  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  and  $f$  a polynomial in  $\mathbb{K}[x_1, \dots, x_n]$ . Then,  $f \in I$  if and only if the remainder  $\bar{f}^G$  is zero.*

**12.6.12. Syzygies.** The next step is to find a sufficient “testing set” of polynomials of a given ideal which allows us to verify whether the considered system is a Gröbner basis. Again, we wish to test this by means of multivariate division only.

For  $\alpha = \text{multideg } f$  and  $\beta = \text{multideg } g$ , consider

$$\gamma := (\gamma_1, \dots, \gamma_n), \quad \text{where } \gamma_i = \max\{\alpha_i, \beta_i\}.$$

The monomial  $x^\gamma$  is called the *least common multiple* of the monomials  $LM f$  and  $LM g$  and is denoted  $LCM(LM f, LM g) := x^\gamma$ . The expression

$$S(f, g) := \frac{x^\gamma}{LT f} \cdot f - \frac{x^\gamma}{LT g} \cdot g$$

is called the *S-polynomial* (also *syzygy*, or pair) of the polynomials  $f, g$ .

This is a tool for the elimination of leading terms. The Gaussian elimination is a special case of this procedure for polynomials of degree one. However, during the general procedure, it may happen that the degrees of the resulting polynomials are higher even though the original leading terms are removed.

For instance, consider the polynomials

$$f = x^3y^2 - x^2y^3 + x, \quad g = 3x^4y + y^2$$

of degree 5 in  $\mathbb{R}[x, y]$  with the  $<_{\text{grlex}}$  ordering. Then,  $\gamma = (4, 2)$  and

$$S(f, g) = \frac{x^4 y^2}{x^3 y^2} f - \frac{x^4 y^2}{3x^4 y} g = x f - \frac{1}{3} y g = -x^3 y^3 + x^2 - \frac{1}{3} y^3,$$

which is a polynomial of degree 6.

**Theorem.** Let  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  be an ideal. Then,  $G = \{g_1, \dots, g_t\}$  is a Gröbner basis of  $I$  if and only if for each  $i \neq j$ , the remainder of the division  $S(g_i, g_j)/G$  is zero.

**PROOF.** Begin with a technical lemma which describes which cancellations may occur when expressing polynomials in terms of generators. More precisely, they can always be expressed in terms of S-polynomials.

**Lemma.** Consider a polynomial  $f = \sum_{i=1}^t c_i x^{\alpha_i} g_i$ , where  $c_1, \dots, c_t \in \mathbb{K}$  and  $\alpha_i + \text{multideg } g_i = \delta$  for a fixed  $\delta$  whenever  $c_i \neq 0$ . If  $\text{multideg } f < \delta$ , then there are  $c_{jk} \in \mathbb{K}$  such that

$$\sum_{i=1}^t c_i x^{\alpha_i} g_i = \sum_{j,k=1}^t c_{jk} x^{\delta - \gamma_{jk}} S(g_j, g_k),$$

where  $x^{\gamma_{jk}} = \text{LCM}(\text{LM } g_j, \text{LM } g_k)$ , and the degree of each monomial  $x^{\delta - \gamma_{jk}} S(g_j, g_k)$  is less than  $\delta$ .

**PROOF.** Let  $d_i := \text{LC } g_i$  and  $p_i = x^{\alpha_i} g_i / d_i$ . Clearly,  $c_i d_i = \text{LC}(c_i x^{\alpha_i} g_i)$  and  $\text{LC } p_i = 1$ . Since  $\text{multideg}(c_i x^{\alpha_i} g_i) = \delta$  and  $\text{multideg } f < \delta$ , it follows that  $\sum_{i=1}^t c_i d_i = 0$ . Express  $f$  as a combination of S-polynomials:

$$\begin{aligned} f &= \sum_{i=1}^t c_i d_i p_i = c_1 d_1 (p_1 - p_2) + (c_1 d_1 + c_2 d_2) (p_2 - p_3) + \\ &+ \dots + (c_1 d_1 + \dots + c_{t-1} d_{t-1}) (p_{t-1} - p_t) + \\ &+ \underbrace{(c_1 d_1 + \dots + c_t d_t)}_0 p_t. \end{aligned}$$

Each difference  $p_j - p_k$  can be expressed in terms of S-polynomials

$$\begin{aligned} \frac{x^\delta}{d_j x^{\delta - \alpha_j}} g_j - \frac{x^\delta}{d_k x^{\delta - \alpha_k}} g_k &= x^{\delta - \gamma_{jk}} \left( \frac{x^{\gamma_{jk}}}{\text{LT } g_j} g_j - \frac{x^{\gamma_{jk}}}{\text{LT } g_k} g_k \right) = \\ &= x^{\delta - \gamma_{jk}} S(g_j, g_k) \end{aligned}$$

Now the individual coefficients  $c_{jk}$  can be derived easily from these equalities.  $\square$

Now follows the proof of the theorem. The “ $\implies$ ” implication follows directly from the corollary of subsection 12.6.11.

For the reverse implication, consider a non-zero polynomial  $f \in I$ . It must be shown that under the implication assumption,  $\text{LT } f \in \langle \text{LT } g_1, \dots, \text{LT } g_t \rangle$ . If it is known that the polynomial can be expressed as  $f = \sum_{i=1}^t h_i g_i$  with the property that

$$\text{multideg } f = \max\{\text{multideg}(h_i g_i)\},$$

then  $LT f$  is necessarily divisible by one of the leading terms  $LT g_i$ , which means that  $G$  is a Gröbner basis.

Denote  $m_i := \text{multideg}(h_i g_i)$ ,  $\delta := \max\{m_1, \dots, m_t\}$ . Clearly,  $\text{multideg } f \leq \delta$ . Let polynomials  $h_1, \dots, h_t$  be chosen so that  $\delta$  is as small as possible. Since this is a monomial ordering, which, in particular, is a well-ordering, such a  $\delta$  exists.

It is necessary to prove that  $\text{multideg } f = \delta$ . Write

$$\begin{aligned} f &= \sum_{m_i=\delta} h_i g_i + \sum_{m_i<\delta} h_i g_i = \\ &= \sum_{m_i=\delta} (LT h_i) g_i + \sum_{m_i=\delta} (h_i - LT h_i) g_i + \sum_{m_i<\delta} h_i g_i. \end{aligned}$$

Clearly, the degrees of all the terms of the second and third sums are less than  $\delta$ . Admitting that  $\text{multideg } f < \delta$ , it follows that

$$\text{multideg} \left( \sum_{m_i=\delta} (LT h_i) g_i \right) < \delta.$$

Denote  $c_i x^{\alpha_i} := LT h_i$  and apply the lemma:

$$\sum_{m_i=\delta} (LT h_i) g_i = \sum_{m_i=\delta} c_i x^{\alpha_i} g_i = \sum_{j,k} c_{jk} x^{\delta-\gamma_{jk}} S(g_j, g_k).$$

It follows from the assumption of the theorem and the multivariate division algorithm that

$$S(g_j, g_k) = \sum_{i=1}^t p_{ijk} g_i$$

and, moreover,  $\text{multideg}(p_{ijk} g_i) \leq \text{multideg } S(g_j, g_k)$ . Denote  $q_{ijk} := x^{\delta-\gamma_{jk}} p_{ijk}$ , to obtain

$$x^{\delta-\gamma_{jk}} S(g_j, g_k) = \sum_{i=1}^t q_{ijk} g_i.$$

By the second part of the lemma,

$$\text{multideg}(q_{ijk} g_i) \leq \text{multideg}(x^{\delta-\gamma_{jk}} S(g_j, g_k)) < \delta.$$

Substitution yields

$$\begin{aligned} \sum_{m_i=\delta} (LT h_i) g_i &= \sum_{j,k} c_{jk} \left( \sum_{i=1}^t q_{ijk} g_i \right) = \\ &= \sum_{i=1}^t \left( \sum_{j,k} c_{jk} q_{ijk} \right) g_i. \end{aligned}$$

At the same time,

$$\text{multideg} \left( \sum_{j,k} c_{jk} q_{ijk} g_i \right) < \delta \quad \text{for } i = 1, \dots, t.$$

Substitute this into the original equality, to get  $f$  expressed as a combination of  $g_1, \dots, g_t$ , where the degrees of all terms are less than  $\delta$ . This contradicts the minimality of  $\delta$ , and so  $\text{multideg } f = \delta$ , whence  $LT f \in \langle LT g_1, \dots, LT g_t \rangle$ . So  $G$  is a Gröbner basis.  $\square$

**12.6.13. A naive algorithm for Gröbner bases.** The theorem just proved provides an efficient method for deciding whether a given basis is a Gröbner basis. For example, consider  $I = \langle x + y, y - z \rangle$ . The only relevant  $S$ -polynomial is

$$S(x + y, y - z) = \frac{xy}{x}(x + y) - \frac{xy}{y}(y - z) = xz + y^2.$$

The division yields  $xz + y^2 = z(x + y) + y(y - z)$ , so it is a Gröbner basis.

The following algorithm utilizes just this method to find a Gröbner basis of an ideal that is generated by a given  $s$ -tuple of polynomials  $F = (f_1, \dots, f_s)$ .

- (1)  $G := F, G' := \emptyset$
- (2) while  $G \neq G'$ 
  - (a)  $G' := G$
  - (b)  $\forall p, q \in G' : p \neq q$  do
    - (i)  $s := \overline{S(p, q)}^{G'}$
    - (ii) if  $s \neq 0$ 

$$G := G \cup \{s\}$$

If the algorithm ever terminates, then  $G$  contains a Gröbner basis. Thus, it suffices to verify that it terminates. However, in each iteration of the inner loop (2), i.e. when a non-trivial remainder is added, either the monomial ideal generated by  $LT G$  extends or it remains unchanged. Consequently, there is a non-decreasing chain of (monomial) ideals  $I_1 = LT(F) \subseteq I_2 \subseteq \dots \subseteq I_k \subseteq \dots$ . Denoting  $I = \cup_{k=1}^{\infty} I_k$ , then  $I$  is an ideal, and by Hilbert's theorem, it is finitely generated. However, this means that all generators of  $I$  already lie in one of the  $I_k$ . Therefore, from this  $k$  onwards,  $I_k = I_{k+1} = \dots$ <sup>13</sup>

Clearly, the stabilization of this chain of monomial ideals of the leading terms is equivalent to termination of the algorithm.

This algorithm is far from ideal. There are quite trivial inputs for which it returns wild results. Moreover, the output basis directly depends on the input, so the outputs for the same ideal defined by different bases may vary.

**12.6.14. Reduction of bases.** In order to recognize the generators which are needed in a Gröbner basis, it suffices to follow the leading terms. The first step of the discussion is simply to remove all elements which are not needed in this sense.

**Lemma.** Let  $G$  be a Gröbner basis of an ideal  $I$  and  $p \in G$  such that  $LT p \in \langle LT(G \setminus \{p\}) \rangle$ . Then,  $G - \{p\}$  is also a Gröbner basis of  $I$ .

**PROOF.** From the definition of the Gröbner basis,  $\langle LT I \rangle = \langle LT G \rangle$ . But  $LT p \in \langle LT(G \setminus \{p\}) \rangle$ , so

<sup>13</sup>The condition of stabilization of every non-decreasing chain of ideals is called the "ascending chain condition". Rings which satisfy ACC are called Noetherian (in honour of Emy Noether). Hilbert's theorem can also be formulated as "a polynomial ring over a Noetherian ring is again Noetherian".

$\langle LT(G \setminus \{p\}) \rangle = \langle LT G \rangle$ . Hence the proposition follows immediately.  $\square$

**Definition.** A Gröbner basis  $G$  of an ideal  $I$  is said to be *minimal* if and only if  $LC p = 1$  and  $LT p \notin \langle LT(G - \{p\}) \rangle$  for all  $p \in G$ .

For instance, consider  $\mathbb{K}[x, y]$  and  $\langle_{\text{grlex}}, I = \langle f_1, f_2 \rangle = \langle x^3 - 2xy, x^2y - 2y^2 + x \rangle$ . The mentioned algorithm produces the following five polynomials  $F = (f_1, \dots, f_5)$ :

$$F = (x^3 - 2xy, x^2y - 2y^2 + x, -x^2, -2xy, -2y^2 + x).$$

Nevertheless,  $LT f_1 = x^3 = -x LT f_3$  and  $LT f_2 = -\frac{1}{2}x LT f_4$ , so neither  $f_1$  nor  $f_2$  is needed.

However, this reduction is still insufficient, since redundancy may occur at the level of individual terms of the basis elements. For example, for every  $a$ , the set  $\{x^2 + axy, xy, y^2 - 1/2x\}$  is a minimal Gröbner basis of the considered ideal.

That is why the following concept is introduced:

**REDUCED GRÖBNER BASIS**

Let  $G$  be a Gröbner basis of an ideal  $I$ . A polynomial  $g \in G$  is said to be *reduced* for the basis  $G$  if and only if none of its monomials lies in  $\langle LT(G \setminus \{g\}) \rangle$ .  $G$  is said to be *reduced* if and only if for all  $p \in G$ ,  $LC p = 1$  and  $p$  is reduced for  $G$ .

Clearly, every reduced Gröbner basis is minimal. Moreover:

**Proposition.** *If a polynomial  $g$  is reduced for a minimal Gröbner basis  $G$  of an ideal  $I$ , then it is reduced for every minimal Gröbner basis  $G'$  of  $I$  which contains it.*

**PROOF.** In order to arrive at a contradiction, let  $G = \{g_1, \dots, g_s\}$ ,  $G' = \{g'_1, \dots, g'_t\}$  be two minimal Gröbner bases. Choose a term  $m$  of a polynomial  $g$  where  $m \in \langle LT(G' - \{g\}) \rangle$  (i.e.  $g$  is not reduced for  $G'$ ). Then,  $m = a_1 LT g'_1 + \dots + a_t LT g'_t$  for appropriate polynomials  $a_1, \dots, a_t$ . Since both  $G$  and  $G'$  are Gröbner bases of the same ideal,  $\langle LT G \rangle = \langle LT G' \rangle$ , which means that each  $LT g'_i$  can be expressed as a multiple of one of the  $LT g_1, \dots, LT g_s$ , except  $LT g$  (since  $G'$  is minimal). Hence  $m \in \langle LT(G \setminus \{g\}) \rangle$ , which contradicts the assumption that  $g$  is reduced for  $G$ .  $\square$

Everything is now available to prove the main result about the existence and uniqueness of a reduced Gröbner basis. This is the main achievement of this part of the chapter on algebra. It allows for a straightforward algorithm to eliminate variables in systems of polynomial equations.

**12.6.15. Theorem.** *Let  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  be a non-zero ideal. Then, for every monomial ordering, there is a unique reduced Gröbner basis of  $I$ . Moreover, every Gröbner basis can be reduced algorithmically.*

**PROOF.** Assume that  $G$  is a Gröbner basis of an  $I$ . By the lemma of the previous subsection, it can be assumed that  $G$  is minimal. (The minimizing algorithm is clear: it suffices to

check for divisibility of leading monomials in any order and to omit redundant elements of the basis.)

Assume that a polynomial  $g \in G$  is not reduced. Then in the division  $g/(G \setminus \{g\})$ , the leading term of  $g$  stays in the remainder, since it is not divisible by anything (the basis is minimal). Therefore,  $LT(\overline{g}^{G \setminus \{g\}}) = LT g$ , since nothing else can be the leading term of the remainder. Now, denote

$$g' := \overline{g}^{G \setminus \{g\}}, \quad G' := (G \setminus \{g\}) \cup \{g'\}.$$

This new system of generators  $G'$  is again a minimal Gröbner basis of  $I$ , because  $\langle LT G' \rangle = \langle LT G \rangle$ . That is,  $\langle LT G' \rangle = \langle LT I \rangle$ . By properties of the multivariate division algorithm, the polynomial  $g'$  is reduced for  $G'$ . If a polynomial  $h \neq g$  is reduced for  $G$ , then it is also reduced for  $G'$  by the above proposition.

With every reduction of one of the elements, the total number of terms in all polynomials of the reduced Gröbner basis decreases. Therefore, the algorithm terminates as soon as each element is reduced. Hence there is an algorithm for the construction of the reduced Gröbner basis.

It remains to prove uniqueness. Let there be two reduced Gröbner bases  $G, \tilde{G}$  of a non-zero ideal  $I$ . Then  $\langle LT G \rangle = \langle LT I \rangle = \langle LT \tilde{G} \rangle$ . Since this ideal is monomial, Dickson's lemma can be applied.

Recalling the construction of the basis in the proof of Dickson's lemma, there exists a unique monomial basis of a monomial ideal such that the coefficients of its elements equal 1, and no element of the basis divides another one.

By the definition of minimality, both  $LT G$  and  $LT \tilde{G}$  must be such. This means that  $LT G = LT \tilde{G}$ . Consequently for each  $g \in G$ , there is a unique  $\tilde{g} \in \tilde{G}$  such that  $LT g = LT \tilde{g}$ .

$g - \tilde{g} \in I$ . Since  $G$  is a Gröbner basis,  $\overline{g - \tilde{g}}^G = 0$ . The terms  $LT g, LT \tilde{g}$  cancel out in  $g - \tilde{g}$ . Since both the bases are reduced, none of the remaining terms of  $g - \tilde{g}$  may be divisible by any of  $LT G = LT \tilde{G}$ . Therefore, it must be in the remainder, which means that

$$g - \tilde{g} = \overline{g - \tilde{g}}^G = 0.$$

This proves the uniqueness. □

**12.6.16. Remarks.** Several of the previous questions are now answered: It can be decided efficiently whether or not a given polynomial

lies in a given ideal by means of the multivariate division and the Gröbner basis.

Because of the reduced Gröbner bases, it can be decided whether or not two ideals coincide – they simply need to have the same reduced Gröbner basis.

This means that it can be decided whether or not a polynomial equation lies in the ideal generated by a given system. Moreover, it can be decided efficiently whether or not two given systems generate the same ideal of consequences.

The above algorithmic construction depends on an appropriate monomial ordering. The answers to the questions are, of course, independent of such ordering.

As mentioned at the beginning of this chapter, the technique of Gröbner bases is one of the fundamentals of computer algebra. Of course, this algorithm is usually implemented using various tricks to make it faster. One can use the reduction technique as early as when creating the Gröbner basis in the fundamental algorithm from subsection 12.6.13, etc.

In the literature, one may find miscellaneous variations for non-commutative algebraic objects (e.g. for formal manipulations with differential operators). The algorithm for finding a Gröbner basis can be viewed as a special case of the Knuth-Bendix algorithm for rewriting some rules. This solves the problem of word equivalence in monoids that are given by generators and a set of equalities.

Last, but not least, the technique of Gröbner bases can be used in a much more sophisticated way in commutative algebra. In the algorithm, the syzygies of all pairs of generators of a finite basis can be found sequentially. These syzygies are a basis of the submodule of all relations between  $k$  elements  $g_1, \dots, g_k$  of the basis, that is, subsets  $S$  in the space  $(\mathbb{K}[x_1, \dots, x_n])^k$ . The algorithm can be extended to these subsets, to find distinguished generators of all relations between generators. As long as there are some non-trivial relations the procedure can continue. It can be proved that after at most  $n$  such steps, there exist no non-trivial relations. The number of generators of relations in each step provides detailed information about the topological properties of the corresponding affine variety  $\mathfrak{V}(g_1, \dots, g_k)$ .

**12.6.17. Elimination of variables.** We finish this chapter by an application of the above algorithms.

Consider the ring  $\mathbb{K}[x_{p+1}, \dots, x_n]$  to be a subring of  $\mathbb{K}[x_1, \dots, x_n]$ . These are polynomials with no occurrence of the variables  $x_1, \dots, x_p$ . It is a subring, but not an ideal.

ELIMINATION IDEALS

Let  $I = \langle f_1, \dots, f_s \rangle \subseteq \mathbb{K}[x_1, \dots, x_n]$ . For  $p = 1, \dots, n$ , define

$$I_p := I \cap \mathbb{K}[x_{p+1}, \dots, x_n].$$

This set is called the *p-th elimination ideal*. Note that  $I_p$  is an ideal only in  $\mathbb{K}[x_{p+1}, \dots, x_n]$ .

On the level of polynomial equations,  $I_p$  contains all equations which are consequences of the system  $f_1 = 0, \dots, f_s = 0$  and which contain only the variables  $x_{p+1}, \dots, x_n$ .

**Theorem (Elimination theorem).** *Let  $I \subseteq \mathbb{K}[x_1, \dots, x_n]$  be an ideal and  $G = \{g_1, \dots, g_m\}$  a Gröbner basis of  $I$  with respect to  $<_{lex}$ . Let the variables be ordered as  $x_1 >_{lex} x_2 >_{lex} \dots$ . Then, for each  $p = 0, \dots, n$ ,  $G_p := G \cap \mathbb{K}[x_{p+1}, \dots, x_n]$  is a Gröbner basis for the ideal  $I_p$ .*

*If  $G$  is minimal or reduced, then  $G_p$  is again minimal or reduced, respectively.*

PROOF. Without loss of generality, assume that  $G_p = \{g_1, \dots, g_r\}$ . Since  $G \subseteq I$ , it follows that  $G_p \subseteq I_p$ . The inclusion  $\langle G_p \rangle \subseteq I_p$  is trivial.

It needs to be verified for each polynomial  $f \in I_p$  that

$$f = h_1 g_1 + \dots + h_r g_r.$$

To do this, perform multivariate division by the original Gröbner basis  $G$ . Since  $f \in I$ , it follows that  $\bar{f}^G = 0$ , i.e.

$$f = h_1 g_1 + \dots + h_r g_r + h_{r+1} g_{r+1} \dots + h_m g_m.$$

Each of the polynomials  $g_{r+1}, \dots, g_m$  must contain at least one of the variables  $x_1, \dots, x_p$ , otherwise it would lie in  $G_p$ . By the properties of the lexicographic ordering, this variable must also be contained in  $LT g_{r+1}, \dots, LT g_m$ .

Recall the individual steps of the algorithm for multivariate division and the fact that  $f$  contains no monomial with any of  $x_1, \dots, x_p$ . Then  $h_{r+1} = \dots = h_m = 0$ , thus verifying that  $f \in \langle G_p \rangle$ .

Not only the desired inclusion but also the fact that the division  $f/G$  on  $I_p$  gives the same result as  $f/G_p$  is proved. For  $1 \leq i < j \leq r$ , consider the  $S$ -polynomials  $S(g_i, g_j)$ .

$$\overline{S(g_i, g_j)}^{G_p} = \overline{S(g_i, g_j)}^G = 0,$$

so  $G_p$  is a Gröbner basis of  $I_p$ .

It is clear that the property, for the basis, of being either minimal or reduced, is preserved.  $\square$

The only property of the lexicographic ordering used in the proof is that if a variable occurs in the polynomial  $f$ , then it occurs in its leading term as well. However, this condition is much weaker than that of the lexicographic ordering. Therefore, in actual implementations, one may use any ordering with the mentioned property. This usually leads to more efficient computations, since the pure lexicographic ordering usually leads to an unpleasant increase of the polynomials' degrees.

**12.6.18. Back to parametrized varieties.** The above theorem suggests an algorithm for finding an implicit representation of a variety defined in terms of polynomial parametrization. Tools necessary for work with the smallest varieties that contain the points defined by parametrization, are not here available, so a detailed discussion is omitted.

When the parametrization of a variety is given by polynomial relations

$$x_1 = f_1(u_1, \dots, u_k), \dots, x_n = f_n(u_1, \dots, u_k),$$

the reduced Gröbner basis of the ideal

$$\langle x_1 - f_1, \dots, x_n - f_n \rangle$$

can be computed in the lexicographic ordering where  $u_i < x_j$  for all  $i, j$ . From this basis, the reduced Gröbner basis of the elimination ideal  $I_k$  is obtained. This is precisely the required ideal and its implicit representation.

It suffices to use an ordering which guarantees that each  $u_i$  is before each  $x_j$ , so that the computation of the Gröbner

basis would eliminate  $u_i$ ; otherwise the ordering may be arbitrary. There is a chance that there is a more efficient computation than with the pure lexicographic ordering.

When the parametrization is rational, i.e.

$$x_i = \frac{f_i(t_1, \dots, t_m)}{g_i(t_1, \dots, t_m)},$$

it is perhaps natural to think of substituting the ideal

$$\langle x_1 g_1 - f_1, \dots, x_n g_n - f_n \rangle$$

into the above theorem. However, the result of this is usually not good. For instance, consider

$$x = \frac{u^2}{v}, \quad y = \frac{v^2}{u}, \quad z = u.$$

Here,  $I = \langle vx - u^2, uy - v^2, z - u \rangle$ , and the elimination yields  $I_2 = \langle z(x^2y - z^3) \rangle$ . However, the correct result is  $\mathfrak{V}(x^2y - z^3)$ . The computation has added an entire plane.

The problem is that the entire variety of zero points of the denominators in the parametrizations of individual variables is included in  $W = \mathfrak{V}(g_1, \dots, g_n)$ . Instead, perceive the parametrization  $F$  as a mapping  $F : (\mathbb{K}^k - W) \rightarrow \mathbb{K}^n$ . For the implicit situation, use the ideal

$$\begin{aligned} I &= \langle g_1 x_1 - f_1, \dots, g_n x_n - f_n, 1 - g_1 \cdots g_n y \rangle \subseteq \\ &\subseteq \mathbb{K}[y, t_1, \dots, t_m, x_1, \dots, x_n], \end{aligned}$$

where the additional variable  $y$  enables avoidance of the zero spaces of the denominators. It can be shown that  $V(I_{k+1})$  is the minimal affine variety which contains  $F(\mathbb{K}^m - W)$ .

**Key to the exercises**

## Combinatorial methods, graphs, and algorithms

*Do we often prefer thinking in pictures?  
– yes, but we can compute discrete things only...*

### A. Fundamental concepts

One of the motives for creating graph theory was visualization of certain problems concerning relations. A human brain like thinking about entities it can imagine. Therefore, we like representing a binary relation with a graph whose vertices correspond to the elements and edges (lines between the elements) correspond to the fact that the given pair is related. Optionally, we can encode a relation in a more complicated way—use Hasse diagram (see 12.1.8), for instance. Partially ordered sets are almost always depicted this way. The relation of friendship or acquaintance between people can also be translated to graphs. This gives rise to a good deal of “relaxing” problems.

**13.A.1.** Prove that the number of odd-degree vertices in an undirected graph is always even.

**Solution.** Let  $G = (V, E)$  be an arbitrary undirected graph with degree  $d(v)$  at every  $v \in V$ . Adding the numbers of all degrees at the vertices we count all edges twice, and, therefore,  $\sum_{v \in V} d(v) = 2|E|$ . Let  $V_1 \subset V$  be the set of vertices

In this chapter, we return to problems concerning properties or mutual relations of (mainly) finite sets of objects. Combinatorial problems are already introduced in the second and third parts of chapter one.

Like number theory, combinatorics is a field of mathematics where the problems can often be formulated very easily. On the other hand, solutions can be much more difficult to find.

We begin with graph theory, and display a collection of useful algorithms based on this theory. At the end of the chapter methods of combinatorial computations are considered.

### 1. Elements of Graph theory

**13.1.1. Two examples.** Several people come to a party; some pairs of people know each other, while other people know nobody. (Acquaintance is assumed to be symmetric). How many people must be there in order to guarantee that there are either three people who all know each other, or there are three people with no mutual acquaintance?

Such situations can be aptly illustrated by a diagram. The points (or vertices) stand for the particular people of the party, the full lines represent pairs who know one another, while the dashed lines stand for pairs who do not know one another. Note that every pair of vertices is connected by either a full or a dashed line. The question is now reformulated as: how many vertices must be there in order that either there is a triangle whose sides are all full or a triangle whose sides are all dashed?

There is no such triangle in the left-hand diagram with four vertices. The example of a regular pentagon, in which all its outside edges are full, while all its diagonals are dashed (draw a picture!), shows that at least six vertices are required.

Such a triangle always exists if the number of vertices is at least six. To show this, consider a set of six vertices, each pair of which is joined by either a dashed line or a full line.

with all degrees and  $V_2 \subset V$ - set of vertices with even degrees. Then,

$$2|E| = \sum_{v \in V} d(v) = \sum_{v \in V_1} d(v) + \sum_{v \in V_2} d(v), \text{ and}$$

$$\sum_{v \in V_1} d(v) = 2|E| - \sum_{v \in V_2} d(v),$$

which is an even number. So,  $|V_1|$  is even. □

**13.A.2.** Does there exist a graph with degree sequence  $(3, 3, 2, 2, 2, 1)$ ?

**Solution.** In this sequence the number of odd-degree vertices equals odd number 3, which is impossible. □

**13.A.3.** Let  $G$  be a graph with minimum degree  $d > 1$ . Prove that  $G$  contains a cycle of length at least  $d + 1$ .

**Solution.** Let  $v_1 \dots v_k$  be a maximal path in  $G$ , i.e., a path that cannot be extended. Then any neighbour of  $v_1$  must be on the path, since otherwise we could extend it. Since  $v_1$  has at least  $d(G)$  neighbors, the set  $\{v_2, \dots, v_k\}$  must contain at least  $d(G)$  elements. Hence  $k \geq d(G) + 1$ , so the path has length at least  $d(G)$ . Now, neighbour of  $v_1$  that is furthest from  $v_1$  along the path must be  $v_i$  with  $i \geq d(G) + 1$ . Then  $v_1 \dots v_i v_1$  form a cycle of length at least  $d(G) + 1$ . □

**13.A.4.** Show that any graph with  $|V| \geq 2$  contains at least 2 vertices with equal degrees

**Solution.** Prove, using pigeon hole principle. Let  $|V| = n$ . Degree  $d(v)$  for any vertex  $v \in V$  can take values from 0 to  $n - 1$ . So, there are  $n$  possible distinct values for  $d(v)$ . However, if one of the degrees  $d(v) = n - 1$ , which means that vertex  $v$  is connected to any other vertex, no other degree can be 0. Thus,  $d(v)$  can take no more than  $n - 1$  distinct values, and, by pigeon hole principle, among  $n$  values of  $d(v)$  at least two coincide. □

**13.A.5.** Show that if  $n$  people attend a party and some shake hands with others, then at the end, there are at least two people who have shaken hands with the same number of people.

**Solution.** Let  $g$  be a graph with the set of vertices  $V$  being the set of people. If two people shake hands, that would represent an edge  $e$  between those two vertices. by previous problem, there will be at least two vertices with equal degrees. □

**13.A.6.** Show that if every connected component of a graph is bipartite, then the graph is bipartite.

**Solution.** Graph is bipartite, if we can divide its vertices into two subsets  $A$  and  $B$  such that every edge in the graph connects a vertex in set  $A$  to a vertex in set  $B$ . If the vertex sets of components are divided into sets  $A_i$  and  $B_i$ , we set  $A = \cup_i A_i$  and  $B = \cup_i B_i$ . Subsets  $A$  and  $B$  impose the graph with bipartite structure. □

If  $v$  is one of the vertices, then it is joined by five outgoing lines.

At least three of these lines are of one type, without loss of generality, full, joining to vertices  $v_A, v_B, v_C$ . Then either the triangle formed by the vertices  $v_A, v_B, v_C$ , contains only dashed lines, which is then the desired triangle, or one of its edges is full in which case there is a full triangle.

As another example, consider a black box which consumes one bit after another and shines in blue or in red according to whether the last bit is zero or one. Imagine this could be a light over the toilet door recognizing whether the last person came out (0) or in (1). Again, this scheme can be illustrated by a diagram:

The third vertex which has only two outgoing arrows represents the beginning of the system (before the first bit is sent).

Both situations share the same scheme: there is a finite set of objects represented by vertices. There is a set of their properties represented by connecting lines between particular vertices. The scheme can be modified by distinguishing the directions of the connecting lines by arrows.

Such a situation can be described in terms of relations; see the text from subsection 1.6.1 on in the sixth part of chapter one. But this is a complicated terminology for describing simple situations: In the first case, there is one set of people with two complementary symmetric and non-reflexive relations. In the second case, there are two antisymmetric relations on three elements.

**13.1.2. Fundamental concepts of graphs.** We use the terminology which corresponds to the latter diagrams.

#### GRAPHS AND DIRECTED GRAPHS

**Definition.** A *graph* (also an *undirected graph*) is a pair  $G = (V, E)$ , where  $V$  is the set of its *vertices* and  $E$  is a subset of the set  $\binom{V}{2}$  of all 2-element subsets of  $V$ .

The elements of  $E$  are called *edges* of the graph. The vertices of an edge  $e = \{v, w\}$ ,  $v \neq w$ , are called the *endpoints* of  $e$ . An endpoint of an edge is said to be *incident* to that edge. Two edges which share a vertex are called *adjacent*. Any two vertices which are the endpoints of an edge are called adjacent.

**13.A.7.** Show that a graph is bipartite if and only if it contains no cycles of odd length.

**Solution.** Suppose there are no cycles of odd length in the graph  $G$ . Choose any vertex from the graph and put it in set  $A$ . Follow every edge from that vertex and put all vertices at the other end in set  $B$ . Erase all the vertices that have been already used. Now for every vertex in  $B$ , follow all edges from each vertex in  $B$  and put the vertices on the other end in  $A$ , erasing all used vertices. Alternate back and forth in this manner until we cannot proceed. This happens when either we exhaust all the vertices or we encounter a vertex that is already in one set and needs to be moved to the other. If the latter occurs, that would represent an odd number of steps from it to itself, so there would be a cycle of odd length. If the graph is not connected, there may still be vertices that have not been assigned. Repeat same process until all vertices are assigned either to set  $A$  or to set  $B$ . Thus, graph  $G$  is bipartite. Suppose now that graph  $G$  is bipartite. Let  $c$  be a cycle  $v_{i_1} \dots v_{i_k}$  of length  $k$ . Vertices along this cycle alternate between subsets  $A$  and  $B$  of  $V$ . Also, the first  $v_{i_1}$  and the last  $v_{i_k}$  vertices on  $c$  should lie in the same set. Therefore, there is the same number of  $A$ -vertices and  $B$ -vertices on  $c$ , and, so,  $k$  is even.  $\square$

**13.A.8.** Show that any tree with at least two vertices is bipartite.

**Solution.** Since a tree does not contain any cycles, it also does not contain odd length cycles, and therefore, it is bipartite.  $\square$

**13.A.9.** Prove that if  $u$  is a vertex of odd degree in a graph, then there exists a path from  $u$  to some other vertex  $v$  of odd degree.

**Solution.** We build a path that does not reuse any edges. As we build the path, we erase edges we used in order not to use them again. Begin at vertex  $u$  and select an arbitrary path emanating from it. If, at any point, the path reaches a vertex of odd degree, we are done, but each time we arrive at a vertex  $t$  of even degree, we are guaranteed that there is another neighbouring vertex where we can move further. By passing through  $t$  we erase two edges from vertex  $t$ . Since the vertex originally was of even degree, coming in and going out reduces its degree by two, so it remains even. In this way, there is always a way to continue when we arrive at a vertex of even degree. Since there are only a finite number of edges, the tour must end eventually, and the only way it can end is if we arrive at a vertex of odd degree.  $\square$

**13.A.10.** If the distance  $d(u, v)$  between two vertices  $u$  and  $v$  that can be connected by a path in a graph is defined to be the length of the shortest path connecting them, then show that the distance function satisfies the triangle inequality:  $d(u, v) + d(v, w) \geq d(u, w)$ .

**Solution.** If one simply connects the paths from  $u$  to  $v$  to the path connecting  $v$  to  $w$  one obtains a path from  $u$  to  $w$  of length  $d(u, v) + d(v, w)$ . Since we are looking for the path

A *directed graph* is a pair  $G = (V, E)$ , where  $V$  is as above, but now,  $E \subseteq V \times V$ . The first of the vertices that define an edge  $e = (v, w)$  is called the *tail of the edge* and the other vertex is called its *head*. From the vertices' point of view,  $e$  is an *outgoing* edge of  $v$  and an *ingoing* edge of  $w$ . The directed edges are also called *arcs* or *arrows*. The head and the tail of a directed edge may be the same vertex; such an edge is called a *loop*.

Two directed edges are called *consecutive* if the tail of one of them is the head of the other one. Similarly, two vertices which are the head and the tail of an edge are called *consecutive*.

To every directed graph  $G = (V, E)$ , its *symmetrization* can be assigned. This is an undirected graph with the same set of vertices as  $G$ . It contains an edge  $e = \{v, w\}$  if and only if at least one of the edges  $e' = (v, w)$  and  $e'' = (w, v)$  belongs to  $E$ .

Graph theory provides an extraordinarily good language for thinking about procedures and deriving properties that concern finite sets of objects. They are a good example of a compromise between the tendency to "think in diagrams" and precise mathematical formulations.

The language of graph theory allows the adding of information about the vertices or edges in particular problems. For instance, the vertices of a graph can be "coloured" according to membership of the corresponding objects to several (pairwise disjoint) classes. Or the edges with several values can be labeled, and so on. The existence of an edge between differently coloured vertices can indicate a "conflict". For example, if the vertices are coloured red and blue according to membership to two groups of people with different interests and the edges represent adjacency at a dining table, then an edge connecting two differently coloured vertices can mean a potential conflict. Our first example from the previous subsection can thus be perceived as a graph with coloured edges. The statement we have checked there reads thus in the language of graph theory:

A graph  $K_n = (V, \binom{V}{2})$  with  $n \geq 6$  vertices and all possible edges which are labeled with two colours always contains a triangle whose sides are of the same colour.

The directed graph in the second example above, whose edges are labeled with zero or one, represents a simple *finite automaton*. This name reflects the idea that the graph describes a process which is, at any moment, in a state represented by the corresponding vertex. It changes to another state, in a step represented by one of the outgoing edges of that vertex. The theory of finite automata is not considered here.

**13.1.3. Examples of useful graphs.** The simplest case of graphs are those which contain no edges. There is no special notation for them. At the other extreme is a graph which contains all possible edges. This is called a *complete graph*, denoted by  $K_n$ , where  $n$  is the number of vertices of the graph. The graphs  $K_4$  and

of minimal length, if there is a shorter path it will be shorter than this one, so the triangle inequality will be satisfied.  $\square$

**13.A.11.** Show that in a directed graph where every vertex has the same number of incoming as outgoing edges there exists an Eulerian path for the graph.

**Solution.** Suppose a path starts at some vertex  $v$ . First edge on the path can be any edge emanating from  $v$ , that we delete from the set of possible further edges on a path. As following the path we arrive at any other vertex  $u$  we choose an edge that is still in the set of possible outgoing from  $u$  edges. We stop as we can no longer choose such an edge. This can happen only if we arrive again at  $v$  and all outgoing edges from  $v$  have been previously engaged in the path. Indeed, if this is any other vertex  $w$  then every arrival at  $w$  engages one incoming edge that can be followed by an outgoing edge as their number is the same. Hence, our path starts and ends at  $v$  and contains all edges of the graph.  $\square$

**13.A.12.** An  $n$ -cube  $Q_n$  is a cube in  $n$  dimensions that consists of vertices with coordinates 0 and 1 and edges, connecting neighbouring vertices, that may differ from each other in just one coordinate. Show that  $Q_n$  possesses a Hamiltonian circuit.

**Solution.** We prove by induction. The  $k + 1$ -dimensional cube  $Q_{k+1}$  can be considered as two copies of  $Q_k$  with every vertex of the first  $Q_k$  having first coordinate 0 and 1 for the second copy of  $Q_k$ . Consider some Hamiltonian cycle  $v_{i_1} \dots v_{i_k} v_{i_1}$  in  $Q_k$ . In the first copy of  $Q_k$  that we take a cycle  $0v_{i_1} \dots 0v_{i_k} 0v_{i_1}$ , and in the second copy  $1v_{i_1} \dots 1v_{i_k} 1v_{i_1}$ . Consider path  $0v_{i_1} \dots 0v_{i_k}, 1v_{i_k} 1v_{i_{k-1}} 1v_{i_1} 0v_{i_1}$  which forms a Hamiltonian cycle on  $Q_{k+1}$ .  $\square$

**13.A.13.** Show that a tree with  $n$  vertices has exactly  $n-1$  edges.

**Solution.** We proceed by induction. Suppose that every tree with  $k$  vertices has precisely  $k - 1$  edges. If the tree  $T$  contains  $k + 1$  vertices, we will show that it contains a vertex with a single edge connected to it. If not, start at any vertex, and start following edges marking each vertex as we pass it. If we ever come to a marked vertex, there is a loop in the edges which is impossible. But since each vertex is assumed to have more than one vertex coming out, there is never a reason that we have to stop at one, so we eventually encounter a marked vertex, which is a contradiction. Take the vertex with a single edge connecting to it, and delete it and its edge from the tree  $T$ . The new graph  $T_0$  will have  $k$  vertices. It must be connected, since the only thing we removed was a vertex that was not connected to anything else, and all other vertices must be connected. If there were no loops before, removing an edge certainly cannot produce a loop, so  $T_0$  is a tree. By the induction hypothesis,  $T_0$  has  $k-1$  edges. But to convert  $T_0$  to  $T$  we need to add one edge and one vertex, so  $T$  also satisfies the formula for the number of edges.  $\square$

$K_6$  are presented in the introductory subsection. The graph  $K_3$  is called a *triangle*.

An important type of graph, is a *path*. This is a graph whose vertices are ordered as  $(v_0, \dots, v_n)$  so that  $E = \{e_1, \dots, e_n\}$ , where  $e_i = \{v_{i-1}, v_i\}$  for all  $i = 1, \dots, n$ . A *path graph of length  $n$*  is denoted by  $P_n$ . If the first and last vertices coincide for the path graph ( $n \geq 3$ ), it is called a *cycle graph of length  $n$* , denoted by  $C_n$ . The graphs  $K_3 = C_3$ ,  $C_5$ , and  $P_5$  are shown in the following diagram.

Another type of graph is the *complete bipartite graph*. Its vertices can be coloured with two (distinct) colours. All possible edges between vertices of different colours are present, but no other edges. Such a graph is denoted by  $K_{m,n}$ , where  $m$  and  $n$  are the numbers of vertices of particular colours. The diagram below illustrates the graphs  $K_{1,3}$ ,  $K_{2,3}$ , and  $K_{3,3}$ .

Another interesting example of a graph is the *hypercube  $H_n$*  in dimension  $n$ , whose vertices are the integers  $0, \dots, 2^n - 1$  and whose edges join those pairs of vertices whose binary expansions differ by exactly one bit. The following diagram depicts the hypercube  $H_4$ , with labels of the vertices indicated.

From the definition it follows that a hypercube of given dimension can always be composed from two hypercubes of dimension one lower, connecting them with edges in an appropriate way. These new edges between the two disjoint copies of  $H_3$  are the dashed ones in the diagram. Obviously, the hypercube  $H_4$  can be similarly decomposed in several ways (just looking at one fixed bit position, as is done with the very first position in the diagram).

Here are two more examples. The first is the *cycle ladder graph  $CL_n$*  with  $2n$  vertices. This consists of two cycle graphs  $C_n$  whose vertices are connected by edges according to their order in the cycles. The second is the *Petersen graph*.

**13.A.14.** If  $u$  and  $v$  are two vertices of a tree  $T$ , show that there is a unique path connecting them.

**Solution.** Since  $T$  is a tree, it is connected, and therefore there has to be at least one path connecting  $u$  and  $v$ . Suppose there are two different paths  $P$  and  $Q$  connecting  $u$  to  $v$ . Reverse  $Q$  to make a path  $Q'$  leading from  $v$  to  $u$ , and the path made by concatenating  $P$  and  $Q'$  leads from  $u$  back to itself. Now this path  $PQ'$  may not necessarily be a loop, since it may use some of the same edges in both directions, but we assumed that there are some differences between  $P$  and  $Q$ .

We can, from  $PQ'$ , generate a simple loop. Begin at  $u$  and continue back one node at a time until the paths  $P$  and  $Q'$  differ. At this point, the paths split. Continue along both paths of the beyond the bifurcation point until they join again for the first time, and this must occur eventually, since we know they are joined at the end. The two fragments of  $P$  and  $Q'$  form a smaller circuit in the tree, which is impossible, since  $T$  is a tree.  $\square$

**13.A.15.** If  $G$  is a connected graph and  $k \geq 2$  is the maximum path length, then any two paths in  $G$  with length  $k$  share at least one common vertex.

**Solution.** Suppose, not. Let  $P = v_{i_1} \dots v_{i_k}$  and  $Q = v_{j_1} \dots v_{j_k}$  be two paths of maximal length  $k$  that do not share any vertex. Vertices  $v_{i_1}$  and  $v_{j_1}$  are connected by a path  $R = u_{i_1} \dots u_{i_s}$ , where  $u_{i_1} = v_{i_1}$  and  $u_{i_s} = v_{j_1}$ . Path  $R$  coincides with  $P$  on some vertices, then it deviates from  $P$ . Maybe, returns to  $P$  again, then deviates from  $P$  for the last time and connects to  $Q$ . Denote this fragment of  $R$  by  $v_{i_r} = u_{i_m} u_{i_{m+1}} \dots u_{i_{m+t}} = v_{j_\ell}$ , where  $t \geq 1$ . Let  $P'$  be path  $v_{i_1} \dots v_{i_r}$ ,  $T' = u_{i_m} \dots u_{i_{m+t}}$  and  $Q'$  be the longest part of  $Q$  going forward or backwards from  $v_{j_\ell}$ , which length is obviously, at least,  $k + 1$ .  $\square$

**13.A.16. Solution.**

$\square$

**13.A.17.** In a dormitory, there is a party held every night. Every time, the organizer of the party invites all of his/her acquaintances so that at the end of the party, all of the guests know each other. Suppose that each member of the dormitory has organized a party at least once, yet there are still two students who do not know each other. Show that they will not meet at the next party.

**Solution.** Consider the acquaintance graph of the students at the beginning (the vertices correspond to the students, and the edges to the acquaintances). We are going to show that if two students lie in the same connected component of this graph (i. e., there exists a chain of acquaintances beginning with one of the considered students and ending with the other one), see 13.1.10, then they will know each other as soon as each member of the dormitory has held a party. Indeed, consider the shortest path (acquaintance chain) between two students that lie in the same connected component. Every time someone from this path organizes a party, this path is made one shorter

This is somewhat similar to  $CL_5$ , yet it is actually the simplest counterexample for many propositions about graphs.

**13.1.4. Morphisms of graphs.** Mappings between the sets of vertices or edges which respect the considered structure are of great importance in graph theory. It is enough to consider mappings between the vertices only.

MORPHISMS OF GRAPHS

**Definition.** Let  $G = (V, E)$  and  $G' = (V', E')$  be two given graphs. A *morphism* (or *homomorphism*)  $f : G \rightarrow G'$  is a mapping  $f_V : V \rightarrow V'$  between the sets of vertices such that if  $e = \{v, w\}$  is an edge in  $E$ , then  $e' = \{f_V(v), f_V(w)\}$  is an edge in  $E'$ .

In practice, there is no need to distinguish between the morphism  $f$  and the mapping  $f_V$ .

The definition is the same for directed graphs, using ordered pairs  $e = (v, w)$  as edges.

In the case of undirected graphs, the definition implies that if  $f(v) = f(w)$  for distinct  $v, w \in V$ , then they are not connected by an edge. On the other hand, such an edge is admissible for directed graphs provided the common image of the vertices has a loop.

An important special case of a morphism of a graph  $G$  is one whose codomain is  $K_m$ . Such a morphism is equivalent to a labeling of the vertices of  $G$  with  $m$  colours (or any other names) of the vertices of  $K_m$  so that vertices of one colour are not adjacent. In this case, it is a (vertex) *colouring of the graph  $G$  with  $m$  colours*.

If a morphism  $f : G \rightarrow G'$  is a bijection between the sets of vertices such that the inverse mapping  $f^{-1}$  is also a morphism, then  $f$  is called an *isomorphism* of graphs. Two graphs are isomorphic if they differ only in the labeling of the vertices.

Every morphism of directed graphs is also a morphism of their symmetrizations. The converse is not true in general.

There are simple and extraordinarily useful examples of graph morphisms: namely a *path*, a *walk*, and a *cycle* in a graph:

(the organizer falls out). Since we assume that each of the students on the path has organized a party, the marginal students must know each other as well. Therefore, if there are two students who do not know each other even after everyone has held a party, then they lie in different connected components of the graph, so they will never meet at a party (in particular, not at the upcoming one).  $\square$

Now, we are going to practice the fundamental concepts of graph theory on simple combinatorial problems.

**13.A.18.** Determine the number of edges of each of the graphs  $K_6$ ,  $K_{5,6}$ ,  $C_8$ .

**Solution.** The complete graph  $K_6$  on 6 vertices has  $\binom{6}{2} = 15$  edges. The complete bipartite graph  $K_{5,6}$  (see 13.1.3) has  $5 \cdot 6 = 30$  edges. Finally, the cycle graph  $C_8$  has 8 edges.  $\square$

**13.A.19. Degree sequence.** Verify whether each of the following sequences is the degree sequence (see 13.1.7) of some graph. If so, draw one of the corresponding graphs.

- i) (1, 2, 3, 4, 5, 6, 7, 8, 9),
- ii) (1, 1, 1, 2, 2, 3, 4, 5, 5).

**Solution.** First of all, we should check the necessary condition from (1). In the former case, we have  $1 + \dots + 9 = \frac{1}{2} \cdot 9 \cdot 10 = 45$ , so the condition is not satisfied. Therefore, the first sequence does not correspond to any graph.

As for the latter sequence, the sum of the wanted degrees equals 24, so the necessary condition is satisfied. Now, we proceed by the Havel–Hakimi theorem from subsection 13.1.7.

$$\begin{aligned} (1, 1, 1, \underline{2}, \underline{2}, \underline{3}, \underline{4}, \underline{5}, \underline{5}) &\longleftrightarrow (1, 1, 1, \underline{1}, \underline{1}, \underline{2}, \underline{3}, \underline{4}) \longleftrightarrow \\ &\longleftrightarrow (1, 1, 1, 0, 0, 1, 2) \longleftrightarrow (0, 0, 1, 1, \underline{1}, \underline{1}, \underline{2}) \longleftrightarrow \\ &\longleftrightarrow (0, 0, 1, 1, 0, 0) \longleftrightarrow (0, 0, 0, 0, \underline{1}, \underline{1}) \longleftrightarrow \\ &\longleftrightarrow (0, 0, 0, 0, 0). \end{aligned}$$

Of course, it was not necessary to execute the procedure to the very end. We could have finished as soon as we saw that the obtained sequence indeed is the degree sequence of some graph. Now, we construct the corresponding graph “backwards” (however, we must take care to always add edges to vertices of appropriate degrees—it is this place where we have the option and can obtain non-isomorphic graphs with the same degree sequence). One of the possible outcomes is the following graph (the order in which each vertex was selected is written inside it):

WALKS, PATHS, TRAILS, AND CYCLES

A *walk of length  $n$*  in a graph  $G$  is a morphism  $s : P_n \rightarrow G$ . Both vertices and edges may repeat in the image.

A *trail* is a walk, where vertices are allowed to repeat, but edges are not allowed to repeat.

A *path of length  $n$*  in a graph  $G$  is any morphism  $p : P_n \rightarrow G$  such that  $p$  is an injective mapping. The images of the vertices  $v_0, \dots, v_n$  from  $P_n$  are pairwise distinct.

A *cycle of length  $n$*  in a graph  $G$  is any morphism  $c : C_n \rightarrow G$  such that  $c$  is an injective mapping of the vertices.

For simplicity, the morphism is often identified with its image. Walks are often written explicitly in the form  $(v_0, e_1, v_1, \dots, e_n, v_n)$ , where  $e_i = \{v_{i-1}, v_i\}$  for  $i = 1, \dots, n$ .

A walk can be thought of as the trajectory of a “pilgrim” moving from the vertex  $f(v_0)$  to the vertex  $f(v_n)$ , not stopping at any vertex of an (undirected) graph.  $P_n$  always contains an edge connecting the adjacent vertices  $v_{i-1}$  and  $v_i$ , while loops are not admitted in undirected graphs. The pilgrim can enter a vertex more than once or even go along an edge already visited. The pilgrim making a “trail” is a little wiser – he does not go along an edge already visited for the second time on his walk from the initial vertex  $f(v_0)$  to the terminal vertex  $f(v_n)$ .

**13.1.5. Subgraphs.** The images of paths, walks, and cycles are examples of *subgraphs*, but not in the same way.

SUBGRAPHS

**Definition.** A graph  $G' = (V', E')$  is a subgraph of a graph  $G = (V, E)$  if and only if and only if  $V' \subseteq V$ , and  $E' \subseteq E$ .

Consider a graph  $G = (V, E)$ . Choose a subset  $V' \subseteq V$ . The largest subgraph (with respect to the number of edges) with  $V'$  as its set of vertices is called an *induced subgraph*. It is the graph  $G' = (V', E')$ , where an edge  $e \in E$  belongs to  $E'$  if and only if both of its endpoints lie in  $V'$ . Therefore, the set  $E'$  of  $G'$ 's edges is given as the intersection  $E \cap \binom{V'}{2}$ .

A *spanning subgraph* (also *factor*) of a graph  $G = (V, E)$  is any graph  $G' = (V, E')$  with  $V = V'$ . Hence  $G'$  has the same vertex set as  $G$ , but the set of edges  $E' \subset E$  may be arbitrary. A *clique* is a subgraph of the graph  $G$  which is isomorphic to a complete graph.

Every subgraph can be constructed by a step-by-step application of these two cases – first, select  $V' \subseteq V$ , then choose the target edge set  $E'$  in the subgraph induced on  $V'$ .

Every image of a homomorphism (vertices as well as edges) forms a subgraph.

□

**13.A.20.** Find the number of pairwise non-isomorphic complete bipartite graphs with 1001 edges.

**Solution.** A complete bipartite graph  $K_{m,n}$  has  $m \cdot n$  edges. Therefore, the problem can be stated as follows: In how many ways can we write the integer 1001 as the product of two integers? Since  $1001 = 7 \cdot 11 \cdot 13$ , we get  $1001 = 1 \cdot 1001 = 7 \cdot (11 \cdot 13) = 11 \cdot (7 \cdot 13) = 13 \cdot (7 \cdot 11)$ .

Thus, there are four non-isomorphic complete bipartite graphs having 1001 edges:

$$K_{1,1001}, K_{7,143}, K_{11,91} \text{ and } K_{13,77}. \quad \square$$

**13.A.21.** Find the number of graph homomorphisms (see 13.1.4)

- a) from  $P_2$  to  $K_5$ ,
- b) from  $K_3$  to  $K_5$ .

**Solution.** We can see from the definition of the graph homomorphism that the only condition which must be satisfied is that adjacent vertices must not be mapped to the same vertex.

- a)  $5 \cdot 4 \cdot 4 = 80$ . □
- b)  $5 \cdot 4 \cdot 3 = 60$ .

**13.A.22. Number of walks.** Using the adjacency matrix (see 13.1.8), find the number of trails of length 4 from vertex 1 to vertex 2 in the following graph:

**Solution.** The adjacency matrix of the given graph is

$$A_G = \begin{pmatrix} 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 \end{pmatrix}.$$

**13.1.6. How many non-isomorphic graphs are there?** It

is easy to draw all graphs (up to isomorphism) with a predetermined small number of vertices (three or four for instance). Generally this is a complicated combinatorial problem. It is often difficult to decide whether or not two given graphs are isomorphic.

**Remark.** This problem, known as the *Graph isomorphism problem*, is a somewhat peculiar member of the class  $\mathbf{NP}^1$  – it is known neither whether it is  $\mathbf{NP}$ -complete nor whether it can be solved in polynomial time. This is a special case of the problem of deciding whether or not a given graph is isomorphic to a subgraph of another graph. This *Subgraph isomorphism problem* is known to be  $\mathbf{NP}$ -complete.

Just to get some feeling, let us find a rough lower estimate of the total number of non-isomorphic graphs. There are the same number of graphs on a given set of  $n$  vertices as the number of subsets of the edge set. A  $k$ -element set has  $2^k$  subsets. There are at most  $n!$  graphs isomorphic to a given one, since this is the number of bijections between  $n$ -element sets. It follows that there are at least

$$k(n) = \frac{2^{\binom{n}{2}}}{n!}$$

pairwise non-isomorphic graphs. From this,

$$\log_2 k(n) = \binom{n}{2} - \log_2 n! \geq \frac{n^2}{2} \left( 1 - \frac{1}{n} - \frac{2 \log_2 n}{n} \right),$$

since  $n! \leq n^n$ . The asymptotic estimate for large  $n$ :

$$\log_2 k(n) \geq \frac{1}{2}n^2 - O(n \log_2 n),$$

follows. (See the notation for asymptotic bounds from subsection 6.1.12 on page 520). Thus the logarithm of the number of non-isomorphic graphs grows at least as fast as  $n^2$ .

**13.1.7. Vertex degree and degree sequence.** It is relatively

easy to verify that two given graphs are *not* isomorphic. Since isomorphic graphs differ in the relabeling of the vertices only, they share all numerical and other characteristics which are not changed by the relabeling. Simple data of this type includes, for instance, the number of edges incident to particular vertices.

<sup>1</sup>Wikipedia, *NP (complexity)*, [http://en.wikipedia.org/wiki/NP\\_\(complexity\)](http://en.wikipedia.org/wiki/NP_(complexity)) (as of Aug. 7, 2013, 13:44 GMT).

The number of walks of length 4 from vertex 1 to vertex 2 is the element at  $[1, 2]$  in the matrix  $A_G^4$ . Since

$$A_G^2 = \begin{pmatrix} 2 & 1 & 1 & 2 & 2 \\ 1 & 4 & 3 & 2 & 2 \\ 1 & 3 & 4 & 2 & 2 \\ 2 & 2 & 2 & 3 & 2 \\ 2 & 2 & 2 & 2 & 3 \end{pmatrix},$$

we have  $(A_G^4)_{1,2} = (2, 1, 1, 2, 2) \cdot (1, 4, 3, 2, 2)^T = 17$ . Therefore, there are 17 walks of length 4 between the vertices 1 and 2.  $\square$

**13.A.23.** A *cut edge* (also called bridge) in a graph is such an edge that its removal increases the number of connected components of the graph. Similarly, a *cut vertex* (also called articulation point) is a vertex with this property, i. e., when removed (with the edges incident to it, of course), the graph splits up into more connected components.

Find all cut edges and vertices of the following graph:

**13.A.24.** Prove that a Hamiltonian graph (see 13.1.13) must be 2-vertex-connected. Give an example of a graph which is 2-vertex-connected yet does not contain a Hamiltonian cycle.

**Solution.** Considering any pair of vertices in a Hamiltonian graph, there are two disjoint (except for the two vertices) paths between them (the “arcs” of the Hamiltonian cycle). Therefore, if we remove one of the vertices, the graph clearly remains connected (the vertex to be removed lies on one of the two paths only). As for the example of a non-Hamiltonian graph which is 2-vertex-connected, we can recall the Petersen graph (see the picture at the beginning of this chapter).  $\square$

**13.A.25.** Determine the number of cycles (see 13.1.3) in the graph  $K_5$ .

**Solution.** We sort the cycles by their lengths, i. e., we count separately the numbers of cycles upon three, four, and five vertices. A cycle of length three is determined uniquely by its three vertices, and there are  $\binom{5}{3}$  ways how to choose them. A cycle of length four is determined by its vertices (which can be chosen in  $\binom{5}{4}$  ways) and the pair of neighbors of a fixed vertex (the pair can be selected from the remaining three vertices in  $\binom{3}{2}$  ways). Finally, a cycle of length five is given by the pair of neighbors of a fixed vertex as well as the other neighbor (from the two remaining) of a fixed vertex of this

VERTEX DEGREE AND DEGREE SEQUENCE

The *degree* of a vertex  $v \in V$  in a graph  $G = (V, E)$  is the number of edges from  $E$  incident to  $v$ . It is denoted by  $\deg v$ .

The *degree sequence* of a graph  $G$  with vertices  $V = (v_1, \dots, v_n)$  is the sequence

$$(\deg v_1, \deg v_2, \dots, \deg v_n).$$

Sometimes, it is required that the sequence be sorted in ascending or descending order rather than correspond to the selected order of vertices.

In the case of directed graphs, distinguish between the *indegree*  $\deg_+ v$  of a vertex  $v$  and its *outdegree*  $\deg_- v$ . A directed graph is said to be *balanced* if and only if for all vertices  $v$   $\deg_- v = \deg_+ v$ .

The degree sequence of a graph (and its isomorphic copies) is unique up to permutation. Therefore, if the degree sequences of two graphs differ not merely by permutation, then the graphs are not isomorphic. The converse statement is not true in general. Two non-isomorphic graphs with the same degree sequence are the graph  $G = C_3 \cup C_3$  which has degree sequence  $(2, 2, 2, 2, 2, 2)$ , and  $C_6$ . However,  $C_6$  contains a path of length 5, but  $C_3 \cup C_3$  does not contain a path of length 5. Therefore, these two graphs cannot be isomorphic.

Since every edge has two endpoints, it is counted twice in the sum of the degree sequence (this condition is sometimes known as *handshaking lemma*). It follows that

$$(1) \quad \sum_{v \in V} \deg v = 2|E|.$$

In particular, the sum of the degree sequence must be even.

The following theorem<sup>2</sup> illustrates how useful invariants like the degree sequences can be. The proof is constructive. It describes an algorithm for constructing a graph with a given degree sequence if there is one, or shows that there is no such graph.

DECIDING ABOUT A GIVEN DEGREE SEQUENCE

**Theorem.** For any natural numbers  $0 \leq d_1 \leq \dots \leq d_n$ , there exists a graph  $G$  on  $n$  vertices with the above values as its degree sequence if and only if there exists a graph on  $n - 1$  vertices with degree sequence

$$(d_1, d_2, \dots, d_{n-d_n} - 1, d_{n-d_n+1} - 1, \dots, d_{n-1} - 1).$$

**PROOF.** If there exists a graph  $G'$  on  $n - 1$  vertices with degree sequence as stated in the theorem, then a new vertex  $v_n$  can be added to  $G'$ . Connect  $v_n$  with edges to the last  $d_n$  vertices of  $G'$ , thereby obtaining a graph  $G$  with the desired degree sequence.

<sup>2</sup>Proved independently by Václav J. Havel in 1955 in the Časopis pro pěstování matematiky (in Czech) and S. L. Hakimi in 1962 in the Journal of the Society for Industrial and Applied Mathematics.

pair. Altogether, there are

$$\binom{5}{3} + \binom{5}{4} \cdot \binom{3}{2} + \binom{5}{5} \cdot \binom{4}{2} \cdot \binom{2}{1} = 37$$

cycles. □

**13.A.26.** Determine the number of subgraphs (see 13.1.4) of the graph  $K_5$ .

**Solution.** Again, we count the number of subgraphs separately by the number  $v$  of their vertices:

- $v = 0$ . There is a unique graph on 0 vertices, the empty graph.
- $v = 1$ . There are 5 ways of selecting 1 vertex, resulting in 5 subgraphs.
- $v = 2$ . Two vertices can be chosen in  $\binom{5}{2}$  ways. Further, there may or may not be an edge between them. Altogether, we get  $\binom{5}{2} \cdot 2$  such subgraphs.
- $v = 3$ . Three vertices can be selected in  $\binom{5}{3}$  ways. For each pair of them, there may or may not be an edge. This results in  $\binom{5}{3} \cdot 2^{\binom{3}{2}}$  subgraphs.
- $v = 4$ . Here, we calculate  $\binom{5}{4} \cdot 2^{\binom{4}{2}}$  subgraphs.
- $v = 5$ . Finally, in this case, there are  $\binom{5}{5} \cdot 2^{\binom{5}{2}}$  subgraphs.

Altogether, we have found 1550 subgraphs of the graph  $K_5$ . □

**13.A.27.** Determine the number of paths between a fixed pair of different vertices in the graph  $K_7$ .

**Solution.** We sort the paths by their lengths. There is a unique path of length one (it consists of the edge that connects the selected vertices). There are five paths of length two (it may lead through any of the remaining vertices). There are  $5 \cdot 4$  paths of length three (we select the two vertices through which it leads, and their order matters). Similarly, there are  $5 \cdot 4 \cdot 3$  paths of length four,  $5 \cdot 4 \cdot 3 \cdot 2$  paths of length five, and also  $5!$  paths of length six. Clearly, there are no longer paths in  $K_7$ . Altogether, we have  $1 + 5 + 5 \cdot 4 + 5 \cdot 4 \cdot 3 + 5! + 5! = 326$  paths. □

At the end of this subsection, we present one more amusing problem.

**13.A.28.** The towns of a certain country are connected with roads. Each town is directly connected to exactly three other towns. Prove that there exists a town from which we can make a sightseeing tour such that the number of roads we use is not divisible by three.

**Solution.** First of all, we reformulate this problem in the language of graph theory. Our task is to prove that every 3-regular graph (i. e., such that the degree of every vertex equals three) contains a cycle whose length is not divisible by three. We will proceed by induction, and actually, we will prove a stronger proposition: every graph each of whose vertices has degree at least three contains a cycle whose length is not divisible by three. In fact, the original proposition could not be proved by induction since the induction hypothesis

The reverse implication is more difficult. The following needs to be proved. Suppose a fixed degree sequence  $(d_1, \dots, d_n)$  with  $0 \leq d_1 \leq \dots \leq d_n$  is given. Then there exists a graph whose vertex  $v_n$  is adjacent to exactly the last  $d_n$  vertices  $v_{n-d_n}, \dots, v_{n-1}$ .

The idea is simple – if any of the last  $d_n$  vertices  $v_k$  is not adjacent to  $v_n$ , then  $v_n$  must be adjacent to one of the prior vertices. We want to interchange the endpoints of two edges so that the vertices  $v_n$  and  $v_k$  become adjacent and the degree sequence remains unchanged.

Technically, this can be done as follows: Consider all graphs  $G$  with a given degree sequence and let, for each  $G$ ,  $\nu(G)$  denote the greatest index of a vertex which is not adjacent to the vertex  $v_n$ . Fix  $G$  to be such that  $\nu(G)$  is as small as possible. Then, either  $\nu(G) = n - d_n - 1$  (and the graph is obtained) or  $\nu(G) \geq n - d_n$ .

If the latter is true, then  $v_n$  is adjacent to one of the vertices  $v_i$ ,  $i < \nu(G)$ . Since,  $\deg v_{\nu(G)} \geq \deg v_i$ , there exists a vertex  $v_\ell$  which is adjacent to  $v_{\nu(G)}$ , but not to  $v_i$ . Replace the edge  $\{v_\ell, v_{\nu(G)}\}$  for  $\{v_\ell, v_i\}$  as well as  $\{v_i, v_n\}$  for  $\{v_{\nu(G)}, v_n\}$ , to get a graph  $G'$  with the same degree sequence, but with  $\nu(G') < \nu(G)$ , which contradicts the choice of  $G$ . (Draw a diagram!)

Therefore, the former possibility is true. So the graph is created by adding the last vertex and connecting it to the last  $d_n$  vertices with edges. □

The theorem describes an exact procedure for constructing a graph with a given degree sequence. If there is no such graph, the algorithm so indicates during the computation. Begin with the degree sequence in (say) ascending order. Then delete the largest value  $d$  and subtract one from  $d$  remaining values on the very right. Then sort the obtained degree sequence and continue with the above step until either there is an example of a graph with the current degree sequence or the degree sequence does not correspond to any graph. If, eventually, a graph is constructed after a number of steps, then one can reverse the procedure, adding one vertex in each step, connected to those vertices where ones were subtracted during the procedure. (Try examples by yourself!) The algorithm constructs only one of the many graphs which share the same degree sequence.

**13.1.8. Matrix representation.** The efficiency of graph representations is of importance for running algorithms. One of them is useful in theoretical considerations:

would be too weak. The induction will be carried on the number  $k$  of vertices of the graph. Clearly, the statement holds for  $k = 4$ . Now, consider a graph where the degree of each vertex is at least three and suppose that the statement is true for any such graph on fewer vertices. The reader should be able to prove that there exists a cycle in the graph. If its length is not divisible by three, we are done. Thus, suppose from now on that  $C = v_1v_2 \dots v_{3n}$ . Each vertex of this cycle is connected to at least one more (different from the neighbors on the cycle) in the graph. If there is a vertex  $v_i$  on the cycle that is connected to a vertex  $v_j$  on the cycle ( $j > i + 1$ ), then the lengths of the cycles  $v_1v_2 \dots v_iv_jv_{j+1} \dots v_{3n}$  and  $v_iv_{i+1} \dots v_j$  total up to  $3n + 2$ , so the length of at least one of them is not divisible by three, as wanted. The situation is similar if there are two vertices  $v_i$  and  $v_j$ ,  $1 \leq i < j \leq 3n$ , which are connected to the same vertex outside the cycle.

Therefore, suppose that each vertex of the cycle is connected to some vertices outside  $C$  and no two vertices of the cycle are adjacent to the same vertex outside. Then, we

can consider the graph which is obtained from the original one by replacing the vertices  $v_1, v_2, \dots, v_{3n}$  with a single vertex  $V$ .

In this new graph, there are also at least three edges leading from each vertex (including  $V$ ), so we can apply the induction hypothesis to it. Therefore, there is a cycle  $w_1w_2 \dots w_k$  where  $3 \nmid k$ . If it does not contain the vertex  $V$ , then it is a cycle in the original graph as well. If it does, then we proceed analogously as above: we consider two cycles whose lengths sum up to  $3n + 2k$ , so the length of at least one of them is not divisible by three. We have found the wanted cycle in every case, which finishes the proof.  $\square$

## B. Fundamental algorithms

Let us begin with breadth-first search and depth-first search, which serve as a basis for more sophisticated algorithms. Their actual implementations may differ; therefore, the answers to the following problems may be ambiguous.

**13.B.1.** Consider a graph on six vertices which are labeled  $1, 2, \dots, 6$ . A pair of vertices is connected with an edge if

## ADJACENCY MATRIX

The *adjacency matrix* of the (undirected) graph  $G = (V, E)$  is defined as follows. Fix a (total) ordering of its vertices  $V = (v_1, \dots, v_n)$ . Define the matrix  $A_G = (a_{ij})$  over  $\mathbb{Z}_2$  (entries are zero and ones)

$$a_{ij} = \begin{cases} 1 & \text{if the edge } e_{ij} = \{v_i, v_j\} \in E, \\ 0 & \text{if the edge } e_{ij} = \{v_i, v_j\} \notin E. \end{cases}$$

It is recommended to write explicitly the adjacency matrices of the graphs mentioned at the beginning of this chapter! By definition, adjacency matrices are symmetric.

There are straightforward generalizations of this concept for more general graphs. For oriented edges their directions may be indicated by the sign, multiple edges might be encoded by appropriate integers, etc.

If the matrix is stored in a two-dimensional array, then this method of graph representation is very inefficient. It consumes  $O(n^2)$  memory. However, if the graph is rather sparse, i.e. there are only a few edges, then almost all of the entries of the matrix are zeros. There are many methods of storing such matrices more efficiently.

The matrix representation of graphs is suggestive of linear algebra considerations. For example, there is the following beautiful theorem:

**Theorem.** Let  $G = (V, E)$  be a graph with vertices ordered as  $V = (v_1, \dots, v_n)$ , and let  $A_G$  be its adjacency matrix. Further, let  $A_G^k = (a_{ij}^{(k)})$  denote the entries of the  $k$ -th power of the matrix  $A_G = (a_{ij})$ .

Then,  $a_{ij}^{(k)}$  is the number of walks of length  $k$  between the vertices  $v_i$  and  $v_j$ .

**PROOF.** The proof is by induction on the length of the walks. For  $k = 1$ , the statement is simply a reformulation of the definition of the adjacency matrix. Suppose the proposition holds for a fixed positive integer  $k$ . Examine the number of walks of length  $k + 1$  between the vertices  $v_i$  and  $v_j$  for some fixed indices  $i$  and  $j$ . Each walk can be obtained by attaching an edge from  $v_i$  to a vertex  $v_\ell$  to a walk of length  $k$  between  $v_\ell$  and  $v_j$ . Further, each walk of length  $k + 1$  can be obtained uniquely in this way. Therefore, if  $a_{\ell j}^{(k)}$  denotes the number of walks of length  $k$  from  $v_\ell$  to  $v_j$ , then the number of walks of length  $k + 1$  is

$$a_{ij}^{(k+1)} = \sum_{\ell=1}^n a_{i\ell} \cdot a_{\ell j}^{(k)}.$$

This is exactly the formula for the product of the matrix  $A_G$  and the power  $A_G^k$ . It follows that the entries of the matrix  $A_G^{k+1}$  are the integers  $a_{ij}^{(k+1)}$ .  $\square$

**Corollary.** If  $G = (V, E)$  and  $A_G$  are as above, then each pair of vertices in  $G$  is connected by a path if and only if the matrix  $(A + \mathbb{E}_n)^{n-1}$  has only positive entries ( $\mathbb{E}_n$  is the  $n$ -by- $n$  identity matrix).

and only if the sum of their labels is odd. Describe the run of the breadth-first search algorithm on this graph. Which of the edges is visited at the end provided the search is initiated at vertex 5 and the neighbors of a given vertex are visited in ascending order?

**Solution.** The algorithm starts at vertex 5 and goes along the edges (5, 2), (5, 4), (5, 6), thereby visiting the vertices 2, 4, 6 (the queue of vertices to be processed is 2, 4, 6). The first vertex to have been visited is 2, so the algorithm continues the search from there, i. e., vertex 5 is processed and vertex 2 becomes active. The algorithm goes along the edges (2, 1), (2, 3), (2, 5) (the last one has already been used), thereby visiting the vertices 1 and 3 (the queue of vertices to be processed is 4, 6, 1, 3). Now, vertex 2 becomes processed and the first unprocessed vertex to have been visited becomes active. That is vertex 4. The algorithm discovers the edges (4, 1) and (4, 3), yet no new vertices. Vertex 4 becomes processed and vertex 6 becomes active. This leads to discovery of the edges (6, 1) and (6, 3). If the algorithm know the number of edges in the graph, it terminates at this moment. Otherwise, it goes through the vertices 1 and 3, finding out that there are no new edges or vertices, and then it terminates. In either case, the last edge to have been discovered is (3, 6).  $\square$

**13.B.2.** Consider a graph on six vertices which are labeled 1, 2, ..., 6. A pair of vertices is connected with an edge if and only if the sum of their labels is odd. Describe the run of the depth-first search algorithm on this graph. Which of the edges is visited at the end provided the search is initiated at vertex 5 and the neighbors of a given vertex are visited in ascending order?

**Solution.** The algorithm starts at vertex 5 and goes along the edges (5, 2), (5, 4), (5, 6), thereby visiting the vertices 2, 4, 6 in this order (the stack of vertices to be processed is 6, 4, 2). Vertex 5 becomes processed and the last vertex to have been visited (i. e., vertex 6) becomes active. The algorithm goes along the edges (6, 1) and (6, 3) (the edge (6, 5) has already been used), thereby visiting the vertices 1 and 3 (the stack of vertices to be processed is 3, 1, 4, 2). Now, vertex 2 becomes processed and the last unprocessed vertex to have been visited becomes active. This is vertex 3. The algorithm discovers the edges (3, 2) and (3, 4), so the stack becomes 4, 2, 1, 4, 2. Vertex 3 becomes processed and vertex 4 becomes active. This leads to discovery of the edge (4, 1), leaving the stack at 1, 2, 1, 2. The algorithm continues the search from vertex 1, visiting the last edge (1, 2). (Note: only unprocessed vertices are pushed into the stack.)  $\square$

**Remark.** If we had chosen the opposite edge priority, the edges would have been visited in the following order: (5, 2), (2, 1), (1, 4), (4, 3), (3, 2), (3, 6), (6, 1), (6, 5), (4, 5). Intuitively, the depth-first search can be perceived so that the algorithm examines the first undiscovered edge in each step.

**13.B.3.** Let the vertices of the graph  $K_6$  be labeled 1, 2, ..., 6. Write the order of edges of  $K_6$  in which they are visited by the depth-first search algorithm, supposing the search is initiated

**PROOF.**

$$(A + \mathbb{E}_n)^{n-1} = A^{n-1} + \binom{n-1}{1}A^{n-2} + \dots + \binom{n-1}{n-2}A + \mathbb{E}_n.$$

The entries of the resulting matrix are (using the notation as above)

$$a_{ij}^{(n-1)} + \dots + \binom{n-1}{\ell}a_{ij}^{(n-1-\ell)} + \dots + (n-1)a_{ij} + \delta_{ij},$$

where  $\delta_{ii} = 1$  for all  $i$ , and  $\delta_{ij} = 0$  for  $i \neq j$ .

This gives the sum of numbers of walks of length  $0, \dots, n-1$  between the vertices  $v_i$  and  $v_j$ , multiplied by positive constants. Therefore, it is non-zero if and only if there is a path between these vertices.  $\square$

**13.1.9. Remark.** Observe how permuting the vertices of  $V$  affects the adjacency matrix of the corresponding graph. It is not hard to see that each such permutation permutes both the rows and columns of the matrix  $A_G$  in the same way. Such a permutation can be given uniquely by the permutation matrix, each of whose rows and columns contain zeros only except for one entry, which is 1. If  $P$  is a permutation matrix, then the new adjacency matrix of the isomorphic graph  $G'$  is

$$A_{G'} = P \cdot A_G \cdot P^T,$$

where (the dots stand for matrix multiplication). The transposed matrix  $P^T$  is also the inverse matrix to  $P$ , since permutation matrices are orthogonal. Every permutation can be written as a composition of transpositions; hence every permutation matrix can be obtained as the product of the matrices corresponding to the transpositions.

Of course, this is exactly how the matrices of linear mappings change under the change of basis. Understanding the adjacency matrix as a linear mapping is often useful. For example, the adjacency matrix may be thought of as hitting vectors of zeros and ones (imagine the ones indicating active vertices of interest) and yielding vectors of integers (showing how many times the given vertices are arrived at from all active vectors along the edges in one step).

This observation also shows that the question whether two adjacency matrices describe isomorphic graphs is equivalent to asking for the equivalence of the matrices via a permutation matrix  $P$ .

**13.1.10. Connected components of a graph.** Every graph  $G = (V, E)$  naturally partitions into disjoint subgraphs  $G_i$  such that two vertices  $v \in G_i$  and  $w \in G_j$  are connected by a path if and only if  $i = j$ .

This procedure can be formalized as follows: Let  $G = (V, E)$  be an undirected graph. Define a relation  $\sim$  on the set  $V$ . Set  $v \sim w$  for vertices  $v, w \in V$  if and only if there exists a path from  $v$  to  $w$  in  $G$ . This relation is clearly a well-defined equivalence relation. Every class  $[v]$  of this equivalence determines the induced subgraph  $G_{[v]} \subseteq G$ , and the (disjoint) union of these subgraphs actually gives the original graph  $G$ . According to the definition of an equivalence

from vertex 3 and the neighbors of a given vertex are visited in ascending order. ○

**13.B.4.** Let the vertices of the graph  $K_6$  be labeled 1, 2, ..., 6. Write the order of edges of  $K_6$  in which they are visited by the breadth-first search algorithm, supposing the search is initiated from vertex 3 and the neighbors of a given vertex are visited in ascending order. ○

**13.B.5.** Apply Dijkstra's algorithm to find the shortest path from vertex number 9 to each of the other vertices.

**13.B.6.** Give an example of

- i) a graph on at least 4 vertices which does not contain a negative cycle, yet Dijkstra's algorithm fails on it;
- ii) a graph on at least 4 vertices which contains a negative edge, yet Dijkstra's algorithm succeeds on it.

**Solution.** In both cases, we must be well aware how Dijkstra's algorithm works. Then, it is easy to find the wanted examples (apparently, there are many more possibilities). As for the first problem, we can consider the following graph (where  $S$  is the initial vertex):

If Dijkstra's algorithm is run from  $S$ , then it visits the vertex  $A$  and fixes its distance from  $S$  to 1. However, there is a shorter path, namely the path  $(S, B, C, A)$  of length 0. As for the second problem, consider the following:

**Bellman-Ford algorithm.** This algorithm is based on the same principle as Dijkstra's. However, instead of going through particular vertices, it processes them "simultaneously"—the *relaxation* loop (i. e., finding out whether the temporary distances of the vertices can be improved using a given edge) is iterated  $(|V|-1)$ -times over all edges. The advantage is that this approach works even with negative edges, and it

relation, no edge of the original graph can connect vertices that belong to different components. The subgraphs  $G_{[v]}$  are called *connected components* of the graph  $G$ .

A graph  $G = (V, E)$  is said to be *connected* if and only if it has exactly one connected component.

If the graph  $G$  is directed, then the definition is analogous to the case of undirected graphs – it is only required that there exist both paths from  $v$  to  $w$  and from  $w$  to  $v$  in order for the pair  $(v, w)$  to be related. Using this definition, strongly connected components can be discussed. On the other hand, it may only be required that the symmetrization of the graph be connected (in the undirected sense); then *weak connectedness* can be discussed.

**13.1.11. Multiply connected graphs.** It is useful to consider the concept of connectedness in a much stronger sense, i.e. to enforce a certain redundancy in the number of paths between vertices.

**Definition.** A graph  $G = (V, E)$  is said to be

- *k-vertex-connected* if and only if it has at least  $k + 1$  vertices, and remains connected whenever any  $k-1$  vertices are removed;
- *k-edge-connected* if and only if it has at least  $k$  edges, and remains connected whenever any  $k - 1$  edges are removed.

In the case  $k = 1$ , the definition simply says that the graph is connected (in both cases) since the condition is vacuously true. Stronger graph connectedness is desirable with any networks supporting some surfaces (roads, pipelines, internet connection, etc.) where the clients prefer considerable redundancy of the provided service for the case if several connections in the network (i.e. edges in a graph) or nodes in the network (vertices in a graph) break down.

In general, *Menger's theorem*<sup>3</sup> holds. It says that for every pair of vertices  $v$  and  $w$ , the number of pairwise edge-disjoint paths from  $v$  to  $w$  equals the minimum number of edges that must be removed so as to leave  $v$  and  $w$  in different components of the new graph. Similarly, the number of pairwise vertex-disjoint paths from  $v$  to  $w$  equals the number of vertices that must be removed in order to disconnect  $v$  from  $w$ .

We return to this topic in subsection 13.2.13. Right now, we consider the simplest interesting case in detail. These are graphs (on at least three vertices) such that deleting any one vertex does not destroy the connectedness.

**Theorem.** If  $G = (V, E)$  has at least three vertices, then the following conditions are equivalent:

- $G$  is 2-vertex-connected;
- every pair of vertices  $v$  and  $w$  in  $G$  lie on a common cycle;
- the graph  $G$  can be constructed from the triangle  $K_3$  by repeatedly adding and splitting edges.

<sup>3</sup>Karl Menger proved this as early as in 1927; that is, before graph theory came into being.

is able to detect negative cycles (if another iteration of the relaxation loop leads to a change, then there must be a negative cycle in the graph). However, we pay for that with increased time complexity.

**13.B.7.** Use the Bellman-Ford algorithm to find the shortest paths from the vertex  $S$  to all other vertices. Assume that the edges are ordered by the number of the tail (or head) and the initial vertex is the least one. Then, change the value of the edge  $(8, 6)$  from 18 to  $-18$ , execute the algorithm on this new graph, and show the detection of negative cycles.

picture skipped

**Solution.** According to the conditions, the edges are visited in the following order:  $(S,4)$ ,  $(S,7)$ ,  $(1,2)$ ,  $(1,5)$ ,  $(2,1)$ ,  $(2,3)$ ,  $(2,6)$ ,  $(3,7)$ ,  $(4,7)$ ,  $(4,8)$ ,  $(5,1)$ ,  $(5,6)$ ,  $(6,2)$ ,  $(6,5)$ ,  $(7,8)$ ,  $(8,6)$ . The vertex distances (potential higher values computed earlier during the same iteration are written in parentheses):

	$S$	1	2	3	4	5	6	7	8
1	0	$\infty$	$\infty$	$\infty$	1	$\infty$	22	3(6)	4
2	0	$\infty$	23	$\infty$	1	24	22	3	4
3	0	25(30)	23	26	1	24	22	3	3
4	0	25	23	26	1	24	22	3	3

Since the fourth iteration does not lead to any change, we can terminate the algorithm at this moment.

In the changed graph, the execution is as follows (for the sake of clarity, we do not write the values of vertices that are untouched by the change):

	$S$	1	2	3	4	5	6	7	8
1	0	$\infty$	$\infty$	$\infty$	1	$\infty$	-14	3(6)	4
2			-13			-12			
3		-11(-6)		-10			-19	-2	-1
4			-18			-17			
5		-16		-15			-24	-7	-6
6			-23			-22			
7		-21		-20			-29	-12	-11
8			-28			-27			
9		-26		-25			-34	-17	-16

The graph has 9 vertices, and since the ninth iteration changed the distance of one of the vertices, there is a negative cycle. Of course, we could have terminated the algorithm much earlier if we had noticed exactly what changes took place between the particular steps. Clearly, the values of the vertices 1, 2, 3, 5, 6, 7, 8 keep decreasing below all bounds. The algorithm can also be implemented so that it produces the tree of shortest paths and also finds the vertices lying on a negative cycle if there is one.  $\square$

**Paths between all pairs of vertices.** We often need to know the shortest paths between all pairs of vertices. Of course, we could apply the above algorithms to all initial vertices. However, there is a more effective method to do this. One of the possibilities is to use the similarity with matrix multiplication, which is the basis of the *Floyd-Warshall algorithm* (the best-known among algorithms of the *all pairs shortest paths* type), which:

- computes the distances between all pairs of vertices in time  $O(n^3)$ ;

**PROOF.** If the second proposition is true, there are at least two different paths between any two vertices. So deleting a vertex cannot destroy the connectedness and the first proposition follows.

Conversely, suppose the first proposition is true. Proceed by induction on the minimal length of a path between  $v$  and  $w$ . Suppose first that the vertices are the endpoints of an edge  $e$ , and that the shortest path is of length 1. If removing the edge  $e$  splits the graph into two components, then this would also occur if the vertex  $v$  is removed or if the vertex  $w$  is removed. Therefore, the graph is connected even without the edge  $e$ , so there is a path between  $v$  and  $w$ . This path, together with the edge  $e$ , forms a cycle.

For the induction hypothesis, assume that such a shared cycle is constructed for all pairs of vertices connected by a path whose length does not exceed  $k$ . Consider vertices  $v, w$  and one of the shortest paths between them:

$$(v = v_0, e_1, v_1, e_2, \dots, v_{k+1} = w)$$

of length  $k + 1$ . Then,  $v_1$  and  $w$  can be connected by a path of length at most  $k$ , hence they lie on a common cycle. Denote by  $P_1$  and  $P_2$  the corresponding two disjoint paths between  $v_1$  and  $w$ . Now, the graph  $G \setminus \{v_1\}$  is also connected, so there exists a path  $P$  from  $v$  to  $w$  which does not go through the vertex  $v_1$ , and this path must once meet either of the paths  $P_1, P_2$ . Without loss of generality, suppose that this occurs on the path  $P_1$ , at vertex  $z$ . Now, the cycle can be built: it consists of the part of  $P$  from  $v$  to  $z$ , the part of  $P_1$  from  $z$  to  $w$ , and  $P_2$  (directed the other way) from  $w$  to  $v$  (draw a diagram!). It follows that the second proposition is a consequence of the first proposition, and hence first condition is equivalent to the second one.

Suppose the third proposition is true. Neither splitting an edge nor adding a new one in a 2-vertex-connected graph destroys the 2-connectedness. So the first proposition follows from the third proposition.

It remains to prove that third proposition follows from the first proposition. From the first proposition,  $G$  is 2-connected, so there exists a cycle, which can be obtained from  $K_3$  by splitting edges. Consider the subgraph  $G' = (V', E')$  determined by this cycle, and consider an edge  $e = \{v, w\} \notin E'$  such that one of its endpoints lies in  $V'$ . If both of its endpoints lie there, a new edge can simply be added to the graph  $G'$ , which leads to the subgraph  $(V', E' \cup \{e\})$  in  $G$ , which contains more vertices and edges than the graph  $G'$ . Consider the remaining possibility, i.e.  $v \in V'$  while  $w \notin V'$ . Since  $G$  is 2-connected, it remains connected even if the vertex  $v$  is removed, and it contains a shortest path  $P$  between the vertex  $w$  and some vertex (denote it as  $v'$ ) in  $G'$  (apart from the removed vertex  $v$ ) and containing no other vertex from  $V'$ . Adding this path to the graph  $G'$ , together with the edge  $e$  (which can be done by adding the edge  $\{v, v'\}$  splitting it to the desired number of “new” vertices and edges), A new subgraph is obtained which satisfies the requirements

- starts with the matrix  $U_0 = A = (a_{ij})$  of edge lengths (setting  $u_{ii} = 0$  for each vertex  $i$ ) and then iteratively computes the matrices  $U_0, U_1, \dots, U_{|V|}$ , where  $u_k(i, j)$  is the length of the shortest path from  $i$  to  $j$  such that all of its inner vertices are among  $\{1, 2, \dots, k\}$ ;
- the matrices are computed using the formula

$$u_k(i, j) = \min\{u_{k-1}(i, j), u_{k-1}(i, k) + u_{k-1}(k, j)\}.$$

In other words, considering the shortest path from  $i$  to  $j$  which can go only through the vertices  $1, \dots, k$ , we can ask whether it uses the vertex  $k$ . If so, then this path consists of the shortest path from  $i$  to  $k$  and the shortest path from  $k$  to  $j$  (and these two paths use only the vertices  $1, \dots, k - 1$ ). Otherwise, the wanted path is also the shortest path from  $i$  to  $j$  which can go only through the vertices  $1, \dots, k - 1$ . Clearly, for  $k = |V|$ , we get the shortest paths between all pairs of vertices without any restrictions. Moreover, we can maintain the so-called predecessor matrix (i. e., the predecessor of each vertex on the shortest path from each vertex and update it as follows:

- Initialization:

$$(P_0)_{ij} = i \text{ for } i \neq j \text{ and } a_{ij} < \infty,$$

- In the  $k$ -th step, we update

$$(P_k)_{ij} = \begin{cases} (P_{k-1})_{kj}, & \text{if the path through } k \text{ is better,} \\ (P_{k-1})_{ij}, & \text{otherwise.} \end{cases}$$

As soon as the algorithm terminates, we can easily construct the shortest path between any pair of vertices  $u, v$ : we derive it from the matrix  $P = P_n = (p_{ij})$  (in the reverse order) as  $v, w = p_{uv}, p_{uw}, \dots$

**13.B.8.** Apply the Floyd–Warshall algorithm to the graph in the picture. Write the intermediate results into matrices. Show the detection of negative cycles. Maintain all information necessary for the construction of the shortest paths.

picture skipped

**Solution.** We proceed according to the algorithm, obtaining the following shortest-length matrices and predecessor matrices:

$$U_0 = \begin{pmatrix} 0 & 4 & -3 & \infty \\ -3 & 0 & -7 & \infty \\ \infty & 10 & 0 & 3 \\ 5 & 6 & 6 & 0 \end{pmatrix}, \quad P_0 = \begin{pmatrix} - & 1 & 1 & - \\ 2 & - & 2 & - \\ - & 3 & - & 3 \\ 4 & 4 & 4 & - \end{pmatrix};$$

$$U_1 = \begin{pmatrix} 0 & 4 & -3 & \infty \\ -3 & 0 & -7 & \infty \\ \infty & 10 & 0 & 3 \\ 5 & 6 & \mathbf{2} & 0 \end{pmatrix}, \quad P_1 = \begin{pmatrix} - & 1 & 1 & - \\ 2 & - & 2 & - \\ - & 3 & - & 3 \\ 4 & 4 & 1 & - \end{pmatrix};$$

$$U_2 = \begin{pmatrix} 0 & 4 & -3 & \infty \\ -3 & 0 & -7 & \infty \\ \mathbf{7} & 10 & 0 & 3 \\ \mathbf{3} & 6 & -1 & 0 \end{pmatrix}, \quad P_2 = \begin{pmatrix} - & 1 & 1 & - \\ 2 & - & 2 & - \\ 2 & 3 & - & 3 \\ 2 & 4 & 2 & - \end{pmatrix};$$

and contains more vertices than the considered graph  $G'$ . After a finite number of these steps, the entire graph  $G$  is built from the triangle  $K_3$ , as desired. The proof is complete.  $\square$

**13.1.12. Eulerian graphs.** There are problems of the type “draw a graph without removing the pencil from the paper”. In the language of graph theory, this can be stated as follows:

EULERIAN TRAILS

**Definition.** A trail which visits every edge exactly once and whose initial and terminal vertices are the same is called a *Eulerian trail*. Connected graphs that admit such a trail are called *Eulerian graphs*.

Of course, an Eulerian trail goes through every vertex at least once, but it can visit a vertex more than once. To draw a graph without removing the pencil from the paper while ending at the same point where one started means to find an Eulerian trail. The terminology refers to the classical story about the seven bridges in Königsberg. There, the task was to go for a walk and visit each of the bridges exactly once. The first proof that this is impossible is by Leonhard Euler, in 1736.

The situation is depicted in the diagram. On the left, there is a sketch of the river with the islands and bridges. The corresponding multigraph is caught in the right-hand diagram. The vertices of this graph correspond to the “connected land”, while the edges correspond to the bridges. If it is desired to do without the multiple edges (which have not been admitted so far), it would suffice to place another vertex inside each bridge (i.e. to split the edges with new vertices). Surprisingly, the general solution of this problem is quite simple, as shown by the following theorem. Of course, this also shows that Euler could not design the desired walk.

EULERIAN GRAPHS

**Theorem.** A graph  $G$  is Eulerian if and only if it is connected and all vertices of  $G$  have even degree.

**PROOF.** If a graph is Eulerian, for every vertex entered there is an exit. Therefore, the degree of every vertex is even. More formally: consider a trail that begins and ends at a vertex  $v_0$  and passes through all edges. Every vertex occurs once or more on this trail and its degree equals twice the number of its occurrences.

Now suppose that all vertices of a graph  $G$  have even degree. Consider the longest possible trail  $(v_0, e_1, \dots, v_k)$  in  $G$

$$U_3 = \begin{pmatrix} 0 & 4 & -3 & \mathbf{0} \\ -3 & 0 & -7 & -4 \\ 7 & 10 & 0 & 3 \\ 3 & 6 & -1 & 0 \end{pmatrix}, \quad P_3 = \begin{pmatrix} - & 1 & 1 & 3 \\ 2 & - & 2 & 3 \\ 2 & 3 & - & 3 \\ 2 & 4 & 2 & - \end{pmatrix};$$

$$U_4 = \begin{pmatrix} 0 & 4 & -3 & 0 \\ -3 & 0 & -7 & -4 \\ \mathbf{6} & \mathbf{9} & 0 & 3 \\ 3 & 6 & -1 & 0 \end{pmatrix}, \quad P_4 = \begin{pmatrix} - & 1 & 1 & 3 \\ 2 & - & 2 & 3 \\ 2 & 4 & - & 3 \\ 2 & 4 & 2 & - \end{pmatrix}.$$

Since there is no negative number on the diagonal of  $U_4$ , there is no negative cycle in the graph. Suppose we would like to find the shortest path from vertex 3 to vertex 1, for instance: The predecessor of 1 is  $P_4[3, 1] = 2$  and the predecessor of 2 is  $P_4[3, 2] = 4$ . Therefore, the wanted path is 3, 4, 2, 1 and its length is  $U_4[3, 1] = 6$ . □

**Hamiltonian graphs.** To decide whether a given graph is Hamiltonian is an NP-complete problem. Therefore, it might be useful to have some simpler necessary or sufficient conditions for this property at our disposal.

We mention three sufficient conditions: Dirac’s, Ore’s, and the Bondy–Chvátal theorem.

**Dirac:** Let a graph  $G$  with  $n \geq 3$  vertices be given. If each vertex of  $G$  has degree at least  $n/2$ , then  $G$  is Hamiltonian.

**Ore:** Let a graph  $G$  with  $n \geq 3$  vertices be given. If the sum of the degrees of each pair of non-adjacent vertices is at least  $n$ , then  $G$  is Hamiltonian.

The *closure* of a graph  $G$  is the graph  $cl(G)$  obtained from  $G$  by repeatedly adding an edge  $u, v$  such that  $u, v$  have not been adjacent and  $\deg(u) + \deg(v) \geq n$  until no such pair of vertices  $u, v$  exists.

**Bondy, Chvátal:** A graph  $G$  is Hamiltonian if and only if  $cl(G)$  is.

**13.B.9.** Prove the Bondy–Chvátal theorem.

**Solution.** Clearly, it suffices to prove that if  $G$  is Hamiltonian after addition of an edge  $\{u, v\}$  such that  $u, v$  have not been adjacent and  $\deg(u) + \deg(v) \geq n$ , then it is already Hamiltonian without this edge. Suppose that  $G + \{u, v\}$  is Hamiltonian, but  $G$  is not. Then, there exists a Hamiltonian path from  $u$  to  $v$  in  $G$ . It must hold for each vertex adjacent to  $u$  that its predecessor on this path is not adjacent to  $v$  (otherwise, there would be a Hamiltonian cycle in  $G$ ). Therefore,  $\deg(u) + \deg(v) \leq n - 1$ . □

**13.B.10.**

- i) Prove that the Bondy–Chvátal theorem implies Ore’s and Ore’s implies Dirac’s.
- ii) Give an example of a Hamiltonian graph which satisfies Ore’s condition but not Dirac’s.
- iii) Give an example of a Hamiltonian graph whose closure is not a complete graph.

**Solution.**

where no edge occurs twice or more. First, suppose for a moment that  $v_k \neq v_0$ . This would mean that the number of edges of the trail that enter or leave the vertex  $v_0$  is odd, so there must be an edge which is incident to  $v_0$  and not contained in the trail. However, then the trail can be prolonged while still using every edge of the graph at most once, which is a contradiction. Therefore,  $v_0 = v_k$ .

Define a subgraph  $G' = (V', E')$  of  $G$  as follows: It contains the vertices and edges of our fixed trail and nothing else. If  $V' \neq V$ , then (since the graph  $G$  is connected) there exists an edge  $e = \{v, w\}$  such that  $v \in V'$  and  $w \notin V'$ . However, then the trail can be “rotated” so that it begins and ends at the vertex  $v$ . It can be prolonged with the edge  $e$ , which contradicts the assumption of the greatest possible length. Therefore,  $V' = V$ .

It remains to show that  $E' = E$ . So suppose there is an edge  $e = \{v, w\} \notin E'$ . As above, the trail can be rotated so that it begins and ends at the vertex  $v$  and then it can continue the edge  $e$  – a contradiction. □

**Corollary.** A connected graph can be drawn without removing the pencil from the paper if and only if there are either no vertices of odd degree or exactly two of them.

**PROOF.** Let  $G$  be a connected graph with exactly two odd-degree vertices. Construct a new graph  $G'$  by attaching a new vertex  $w$  to the original graph  $G$  and connecting it to both the odd-degree vertices. This graph is Eulerian, and the Eulerian trail in it leads to the desired result.

On the other hand, if a graph  $G$  can be drawn in the desired way, then the graph  $G'$  is necessarily Eulerian, so the degrees of the vertices in  $G$  are as stated. □

The situation for directed graphs is similar. A directed graph is called *balanced* if and only if the outcoming and incoming degrees coincide, i.e.  $\deg_+(v) = \deg_-(v)$ , for all vertices  $v$ .

**Proposition.** A directed graph  $G$  is Eulerian if and only if it is balanced and its symmetrization is connected (i.e. the graph  $G$  is weakly connected).

**PROOF.** The proof is analogous to the undirected case. (Work out the details yourself!) □

**13.1.13. Hamiltonian cycles.** Find a walk or cycle that visits every vertex of a graph  $G$  exactly once. Of necessity, such a walk can visit every edge at most once. Such a cycle is called a *Hamiltonian cycle* in the graph  $G$ . A graph is called *Hamiltonian* if and only if it contains a Hamiltonian cycle. This problem seems to be very similar to the above one of visiting every edge exactly once. But while the problem of deciding about the existence of a Eulerian trail is trivial, the problem of deciding whether a graph is Hamiltonian is **NP**-complete.

Of course, this problem can be solved by “brute force”. Given a graph on  $n$  vertices, generate all  $n!$  possible orders of the  $n$  vertices, and for each of them, verify whether it is a cycle in  $G$ .

- i) If a graph  $G$  satisfies Ore's condition, then its closure is a complete graph, which is Hamiltonian, of course. By the Bondy–Chvátal theorem, the original graph is Hamiltonian as well. Further if  $G$  satisfies Dirac's condition, then it clearly satisfies Ore's as well and thus is Hamiltonian.
- ii) Consider the following example:

The degree of vertex 5 is 2, which is less than  $\frac{5}{2}$ . The sum of the degrees of any pair of (not only non-adjacent) vertices is at least 5.

- iii) The wanted conditions are satisfied by the cycle graphs  $C_n, n > 4$ , for which  $cl(C_n) = C_n$ .  $\square$

**Planar graphs.**

- 13.B.11.** Decide whether the graph in the picture is planar.

**Solution.** By the Kuratowski theorem (see page 1162), this graph is not planar since one of its subgraphs is a subdivision of  $K_{3,3}$ .  $\square$

- 13.B.12.** Decide whether there is a graph with degree sequence

$$(6, 6, 6, 7, 7, 7, 7, 8, 8, 8).$$

If so, is there a planar graph with this degree sequence?  $\bigcirc$

- 13.B.13.** What is the minimum number of edges of a hexahedron?

**Solution.** In any polyhedron, every face is bounded by at least three edges. At the same time, every edge belongs to two faces. If  $f$  is the number of faces and  $e$  the number of edges of the polyhedron, then we have  $3f \leq 2e$  (see also 13.1.20). For a hexahedron, this bound yields  $18 \leq 2e$ , i. e.,  $e \geq 9$ . Indeed, there exists a hexahedron with nine edges. It can be obtained by “gluing” two identical regular tetrahedra together along one face. Therefore, the minimum number of edges of a hexahedron is nine.  $\square$

This problem forms a vital field of research. For instance, in 2010, A. Björklund published a randomized algorithm based on the Monte Carlo method, which counts the number of Hamiltonian cycles in a graph on  $n$  vertices in time  $O(1,567^n)$ .<sup>4</sup>

Finding Hamiltonian cycles is desired in many problems related to logistics. For example, finding optimal paths for goods delivery.

**13.1.14. Trees.** Sometimes it is desired to minimize the number of edges in the graph while keeping it connected. Of course, this is possible if and only if there is at least one cycle in the graph. The graphs without cycles are extremely important as we shall see below.

FORESTS, TREES, LEAVES

A connected graph which does not contain a cycle is called a *tree*. A graph which does not contain a cycle is called a *forest* (a forest is not required to be connected). Every vertex of degree one in any graph is called a *leaf*.

The definition suggests an easily memorable “theorem”: *A tree is a connected forest.*

**Lemma.** Every tree with at least two vertices contains at least two leaves.

For any graph  $G$  with a leaf  $v$ , the following propositions are equivalent:

- $G$  is a tree;
- $G \setminus v$  is a tree.

**PROOF.** Let  $P = (v_0, \dots, v_k)$  be (any) longest possible path in a tree  $G$ . If the vertex  $v_0$  is not a leaf, then there is an edge  $e$  incident to it whose other endpoint  $v$  is not in  $P$  since this would form a cycle in the tree. Then the path  $P$  with this edge could be prolonged, which contradicts “longest”. So the vertex  $v_0$  is a leaf. The proof for the vertex  $v_k$  is similar. Thus, if the longest path is not trivial, then it must contain two leaves  $v_0$  and  $v_k$ .

Next, consider any leaf  $v$  of a tree  $G$ . Consider any two other vertices  $w, z$  in  $G$ . There exists a path between them, and no vertex on this path has degree one. Therefore, this path remains the same in  $G \setminus v$ . Hence the graph remains connected even after removing the vertex  $v$ . There is no cycle, since it is constructed by removing a vertex from a tree.

Conversely, if  $G \setminus v$  is a tree, then adding a vertex with degree 1 cannot create a cycle. The resulting graph is evidently connected.  $\square$

Trees can be characterized by many equivalent and useful properties. Some of them appear in the following theorem which is more difficult to formulate than to prove.

<sup>4</sup>Björklund, Andreas (2010), "Determinant sums for undirected Hamiltonicity", Proc. 51st Annual Symposium on Foundations of Computer Science (FOCS '10), pp. 173-182, arXiv:1008.0541, doi:10.1109/FOCS.2010.24.

**13.B.14.** Decide whether the given planar graph is maximal. Add as many edges as possible while keeping the graph planar.

**Solution.** The graph has 14 vertices and 20 edges, hence  $3|V| - 6 - |E| = 16$ . Therefore, it is not maximal, and 16 edges can be added so that it is still planar.

Ten (dashed) have been added. For the sake of clarity, the other 6 edges that connect the vertices of the “outer” 9-gon are not drawn.

□

**13.B.15.** Prove or disprove each of the following propositions.

- i) Every graph with fewer than 9 edges is planar.
- ii) Every graph which is not planar is not Hamiltonian.
- iii) Every graph which is not planar is Hamiltonian.
- iv) Every graph which is not planar is not Eulerian (see 13.1.12).
- v) Every graph which is not planar is Eulerian.
- vi) Every Hamiltonian graph is planar.
- vii) No Hamiltonian graph is planar.
- viii) Every Eulerian graph is planar.
- ix) No Eulerian graph is planar.

**Trees.**

**13.B.16.** Determine the code of the following graph as a

- i) plane tree,
- ii) tree.

**13.1.15. Theorem.** Let  $G = (V, E)$  be a graph. The following conditions are equivalent:

- (1)  $G$  is a tree.
- (2) For every pair of vertices  $v, w$ , there is exactly one path from  $v$  to  $w$ .
- (3)  $G$  is connected but ceases to be such if any edge is removed.
- (4)  $G$  does not contain a cycle, but the addition of any edge creates one.
- (5)  $G$  is a connected graph, and the number of its vertices and edges satisfies

$$|V| = |E| + 1.$$

**PROOF.** The properties 2–5 are satisfied in every tree. Indeed, by the previous lemma, every tree which has at least two vertices has a leaf  $v$ . It continues to be a tree when this leaf  $v$  is removed. Therefore, it suffices to show that if any of the statements 2–5 is true for a given tree, then it holds when a leaf is added to the tree as well. This is clear.

In the case of properties 2 and 3, the graph is connected, and their formulation directly excludes the existence of cycles. As for the fourth property, it suffices to verify that  $G$  is connected. However, any two of vertices  $v, w$  in  $G$  are either connected with an edge, or adding this edge to the graph creates a cycle. So there exists a path between them even without this edge.

The last implication can be proved by induction on the number of vertices. Suppose that all connected graphs on  $n$  vertices and  $n - 1$  edges are trees. The sum of vertex degrees of any graph on  $n + 1$  vertices and  $n$  edges is  $2n$ , so the graph must contain a leaf. It follows from the induction hypothesis that this graph can be constructed by attaching a leaf to a tree; hence it is also a tree. □

**13.1.16. Rooted trees, binary trees, and heaps.** Trees are often suitable structures for data storage. They permit basic database operations (e.g. finding a particular piece of information) efficiently.

Since there is no cycle in a tree, fixing one vertex  $v_r$  defines the orientation of all edges. For every vertex  $v$ , there is exactly one path from  $v_r$  to  $v$ , so the orientation can be defined accordingly. Since there are no cycles, it is impossible for two such paths to force both orientations of a particular edge.

If one of the vertices of a tree is fixed, the situation is similar to a real tree in nature – there is a distinctive vertex which “grows from the ground”. Trees with a fixed distinguished vertex  $v_r$  are called *rooted trees*, and  $v_r$  is said to be the *root of the tree*.

In a rooted tree, the terms *successor* and *predecessor* of a vertex are defined as follows: a vertex  $w$  is a successor of  $v$  (or  $v$  is a predecessor of  $w$ ) if and only if the path from the root of the tree to the vertex  $w$  goes through  $v$  and  $v \neq w$ . If the vertices are directly connected with an edge, we can talk about a *direct successor* and a *direct predecessor*. More

○

**Solution.**

- i) Using the procedure from 13.1.18, we get the following code of the plane tree:

0 0 0001100100101111 1 0 0101000010101111 1 1

The highlighted vertex in the graph is indeed the appropriate candidate to be the root since it is the only element of the center of the tree.

- ii) As for the unique construction of a plane tree, we sort the descendants lexicographically in ascending order. Thus, the wanted code is

0000001010111101011 0000010110110011111. □

**13.B.17.** For each of the following codes, decide whether there exists a tree with this code. If so, draw the corresponding tree.

- 00011001111001,
- 0000011001001011111001010000101011111.

**Huffman coding.** We are working with plane binary trees where every edge is *colored* with a symbol of an output alphabet  $A$  (we often have  $A = \{0, 1\}$ ). The codewords  $C$  are those words over the alphabet  $A$  to which we translate the symbols of the input alphabet. Our task is to represent a given text using suitable codewords over the output alphabet.

We can easily see that it makes sense to require that the set of codewords be *prefix*, (i. e., no codeword can be a prefix of another one); otherwise, we could get into trouble when decoding.

We will use binary trees for the construction of binary prefix codes (i. e. over the alphabet  $A = \{0, 1\}$ ). We label the edges going from each vertex by 0 and 1. Further, we label the leaves of our tree with symbols of the input alphabet. This results in a prefix code over  $A$  for these symbols by concatenating the edge labels along the path from the root to the corresponding leaf.

Clearly, this code is *prefix*. Moreover, if we take into account the frequencies of particular symbols of the input alphabet in the input text, we obtain a *lossless data compression*.

often, they are called a *child* and a *parent* (motivated by the genealogical trees).

The most common data structures are the *binary trees*, which are special cases of a rooted trees: there, every vertex has at most two children (sometimes, the term *binary tree* implies that every vertex is either a leaf, or has *exactly* two children; to avoid ambiguity, such trees are often called full binary trees). Such trees are very useful in search procedures. If the vertices are associated to keys from a totally ordered set (eg. the integers), the search for the vertex with a given key is performed by searching the path from the root of the tree to that vertex. At every vertex, compare its key to the desired one. This decides whether one continues to the left or to the right, or stop the search if it is found. If this algorithm is to be correct, one of the children with all its successors must have lower keys than the keys of the other child and all its successors.

In order for the search to be efficient, some effort must be made to keep the binary trees *balanced*, with the lengths of the paths from the root to the leaves differing by at most one. The most unfortunate example of a binary tree on  $n$  vertices is the path graph  $P_n$  (which may be formally considered a binary tree), while the most desired case is the perfect complete binary tree, where every vertex that is not a leaf has exactly two children, and all leaves are at the same level. Such a tree can be constructed only when the number of vertices is of the form  $n = 2^k - 1$ ,  $k = 1, 2, \dots$ . Therefore, in a balanced tree, finding the vertex with a given key value can be done in  $O(\log_2 n)$  steps. Such trees are often called *binary search trees*. Think out as an exercise how to efficiently perform basic graph operations over binary search trees (additions and removals of the vertex with a given key as well as how to keep the tree balanced).

An extraordinarily useful example of binary trees is the structure of a *heap*. It is a full balanced binary tree, where the keys are either strictly decreasing along each path from the root (the so called *max heap*), or they are increasing (the *min heap*). Because of this ordering along the paths in a max heap, the maximum key value of the heap can be found in constant time and removed in logarithmic time (similarly with minimum in the min heap). The desired maximum is just at the root and after removing it we need to balance the shape of the heap. Prove this is possible in logarithmic time yourself!

The left-hand diagram shows a binary search tree. In the right-hand diagram, there is a max heap.

Much literature is devoted to trees, their applications and miscellaneous variations.

Let  $M$  be the list of frequencies of the symbols of the input alphabet in the input text. The algorithm constructs the optimal binary tree (the so-called *minimum-weight binary tree*) and the assignment of the symbols to the leaves.

- Select the two least frequencies  $w_1, w_2$  from  $M$ . Create a tree with two leaves labeled by the corresponding symbols and root labeled by  $w_1 + w_2$ , then replace the values  $w_1, w_2$  with the new value  $w_1 + w_2$  in  $M$ .
- Repeat the above step; if the selected value from  $M$  is a sum, then simply “connect” the existing subtree.
- The code of each symbol is determined by the path from the root to the corresponding leaf (left edge = “0”, right edge = “1”, for instance).

**13.B.18.** Find the Huffman code for the input alphabet with the frequencies [‘A’:16, ‘B’:13, ‘C’:9, ‘D’:12, ‘E’:45, ‘F’:5].

**Solution.** If we naively assign a 3-bit code to each letter of the alphabet, then this message of length 100 consumes 300 bits.

We show that Huffman code is more succinct. We build the tree according to the algorithm.

We have thus obtained the codes  $A : 111, B : 100, C : 1101, D : 101, E : 0, F : 1100$ . Multiplying the code lengths by the frequencies, we can see that a 100-letter message with the given distribution of letters is encoded into only

$$3 \cdot 16 + 3 \cdot 13 + 4 \cdot 9 + 3 \cdot 12 + 1 \cdot 45 + 4 \cdot 5 = 224 \text{ bits.} \quad \square$$

**C. Minimum spanning tree**

**13.C.1.** How many spanning trees (see 13.2.6) of the graph  $K_5$  are there? And how many are there if we do not distinguish isomorphic ones?

**Solution.** There are three pairwise non-isomorphic spanning trees (with degree sequences  $(1, 2, 2, 2, 1), (1, 2, 3, 1, 1), (4, 1, 1, 1, 1)$ ). The corresponding classes of isomorphic spanning trees have  $5 \cdot \binom{4}{2} \cdot 2, 5 \cdot 4 \cdot 3,$  and  $5$  elements, respectively. Altogether, there are  $125 = 5^3$  spanning trees, which is in accordance with Cayley’s formula for the number of spanning trees of a complete graph (see 13.4.11).  $\square$

**13.1.17. Remarks on sorting.** Suppose it is required to distinguish all different sortings of  $n$  elements, thus distinguishing among  $n!$  different objects. If there is no information other than comparing the order of two single elements, then the tree of all possible decision paths can be written down. The sorting provides a path through this binary tree. As seen, any binary tree of depth  $h$  (i.e.  $h - 1$  is the length of the longest path from the root to a leaf) has at most  $2^{h-1}$  leaves. It follows that a tree of depth  $h$  satisfying  $2^{h-1} \geq n!$  is needed.

Consequently the depth  $h$  satisfies  $h \log 2 > \log n!$ .

$$\begin{aligned} \log n! &= \log 1 + \log 2 + \dots + \log n \\ &> \int_1^n \log x \, dx = n \log n - (n - 1) \\ h &> \frac{n \log n - n}{\log 2} > n \log n - n \end{aligned}$$

It is proved that the depth of the necessary binary tree is bounded from below by an expression of size  $n \log n$ . Hence no algorithm based only on the comparison of two elements of the ordered set can have a better worst case run than  $O(n \log n)$ .

The latter claim is not true if there is further relevant information. For example, if it is known that only a finite number of  $k$  values may appear among our  $n$  elements, then one may simply run through the list counting how many occurrences of the individual values are there, and hence write the right ordered list from scratch. This all happens in linear time!

**13.1.18. Tree isomorphisms.** Simple features of trees are exploited in order to illustrate the (generally difficult) problem of graph isomorphisms on this special class of graphs.

First, strengthen the structure to be preserved by the isomorphisms. Then show that the obtained procedure is also applicable to the most general trees.

In order to keep more information about the structure of rooted trees, remember the relations parent–child. Also have the children of every node sorted in a specific order (for instance, from left to right if drawn on a diagram). Such trees are called *ordered trees* or *plane trees*. They are formally defined as a tuple  $T = (V, E, v_r, \nu)$ , where  $\nu$  is a partial order on the edges such that a pair of edges is comparable if and only if they have the same tail (i.e. they all go from one parent vertex to all its children).

A homomorphism of rooted trees  $T = (V, E, v_r)$  and  $T' = (V', E', v'_r)$  is a graph morphism  $\varphi : T \rightarrow T'$  such that  $v_r$  is mapped to  $v'_r$ ; similarly for isomorphisms. For plane trees, it is further required that the morphism preserves the partial orders  $\nu$  and  $\nu'$ .

**13.C.2.** Let the vertices of  $K_6$  be labeled  $1, 2, \dots, 6$  and let every edge  $\{i, j\}$  be assigned the integer  $[(i + j) \bmod 3] + 1$ . How many minimum spanning trees are there in this graph?

**Solution.** There are five edges whose value is 1: four of them lie on the cycle 12451 and the remaining one is the edge 36. Therefore, they form a disconnected subgraph of the complete graph, so the spanning tree must contain at least one edge of value 2. Thus, the total weight of a minimum spanning tree is at least  $4 \cdot 1 + 2 = 6$ . And indeed, there exist spanning trees with this weight. We select all the edges of value 1 except for one that lies on the mentioned cycle and connect the resulting components 1245 and 36 with any edge of value 2. There are four such edges. Altogether, there are  $4 \cdot 4 = 16$  minimum spanning trees.  $\square$

**13.C.3.** Find a minimum spanning tree of the following graph using

- i) Kruskal's algorithm,
- ii) Jarník's (Prim's) algorithm.

Explain why we cannot apply Borůvka's algorithm directly.

**Solution.** The spanning tree is

Borůvka's algorithm cannot be applied directly since the mapping of the weights to the edges is not injective. However, this can be fixed easily by slight modifications of the weights.  $\square$

**13.C.4.** Consider the following procedure for finding the shortest path between a given pair of vertices in an undirected weighted graph: First, we find a minimum spanning tree. Then, we proclaim that the only path between the pair of vertices in the obtained spanning tree is the shortest one. Prove the correctness of this method, or disprove it by providing a counterexample.  $\circ$

**13.C.5.** We are given the following table of distances of world metropolises: London, Mexico City, New York, Paris,  $\square$

CODING THE PLANE TREES

Given the plane tree  $T = (V, E, v_r, \nu)$ . It has a code  $W$  by strings of ones and zeros, defined recursively as follows:

Start with the word 01 for the root  $v_0$  and write  $W = 0W_1 \dots W_\ell 1$ , where  $W_i$  are the  $\ell$  still unknown words for the subtrees rooted by the children of  $v_0$ . In particular the code of the tree with just one vertex is  $W = 01$ .

Applying the same procedure recursively over the children and concatenating the results defines the code.

The tree in the left-hand diagram above (in the end of 13.1.16) is encoded as follows (the children of a vertex are ordered from left to right,  $W_r$  is for the code of the child with key  $r$ ):

$$\begin{aligned} 0W_3W_81 &\mapsto 00W_1W_510W_911 \\ &\mapsto 00010W_4W_61100W_{11}111 \\ &\mapsto 000100101110001111. \end{aligned}$$

Imagine drawing the entire plane tree with one move of the pencil, starting with an arrow ending in the root and going downwards with arrows towards the leaves and then upwards to the predecessors, reaching consecutively all the leafs from the left to the right and writing 0 when going down and 1 when going up. The very last arrow is then leaving the root upwards.

**Theorem.** Two plane trees are isomorphic if and only if their codes are the same.

**PROOF.** By construction, two isomorphic trees are assigned the same code. It remains to show that different codes lead to non-isomorphic plane trees.

This is proved by induction on the length of the code (i.e. the number of zeros and ones). This length is  $2(|E| + 1)$ , (twice the number of vertices; therefore, the proof can be viewed as an induction on the number of vertices of the tree  $T$ ). The shortest code corresponds to the smallest tree on one vertex. Assume that the proposition holds for all trees up to  $n$  vertices, i.e. for codes of length up to  $k = 2n$ , and consider a code of the form  $0W1$ , where  $W$  is a code of length  $2n$ . Find the shortest prefix of  $W_1$  which contains the same number of zeros and ones (when drawing a diagram of the tree, this is the first moment when we return to the root of the tree that corresponds to the code  $0W1$ ). Similarly, find the next part of the code  $W$  that contains the same number of zeros and ones, etc. Hence the code  $W$  can be written as  $W = W_1W_2 \dots W_\ell$ . By the induction hypothesis, the codes  $W_i$  correspond uniquely (up to isomorphism) to plane trees, and the order of their roots, being the children of our tree  $T$ , is given uniquely by the order in the code. Therefore, the tree  $T$  is determined uniquely by the code  $0W1$  up to isomorphism.  $\square$

Peking, and Tokyo:

$$\begin{pmatrix} & L & MC & NY & P & Pe & T \\ L & & 5558 & 3469 & 214 & 5074 & 5959 \\ MC & & & 2090 & 5725 & 7753 & 7035 \\ NY & & & & 3636 & 6844 & 6757 \\ P & & & & & 5120 & 6053 \\ Pe & & & & & & 1307 \end{pmatrix}$$

What is the least total length of wire used for interconnecting these cities (assuming the length necessary to connect a given pair of cities is equal to the distance in the table). ○

13.C.6. Using the matrix variation of the JarnÅk-Prim algorithm, find a minimum spanning tree of the graph given by the following matrix:

$$\begin{pmatrix} - & 12 & - & 16 & - & - & - & 13 \\ 12 & - & 16 & - & - & - & 14 & - \\ - & 16 & - & 12 & - & 14 & - & - \\ 16 & - & 12 & - & 13 & - & - & - \\ - & - & - & 13 & - & 14 & - & 15 \\ - & - & 14 & - & 14 & - & 15 & - \\ - & 14 & - & - & - & 15 & - & 14 \\ 13 & - & - & - & 15 & - & 14 & - \end{pmatrix}$$

D. Flow networks

13.D.1. An example of bad behavior of the Ford-Fulkerson algorithm. The worst-case time complexity of the Ford-Fulkerson algorithm is  $O(E \cdot |f|)$ , where  $|f|$  is the size of a maximum flow. Consider the following network:

The bad behavior of the algorithm is due to the fact that it uses depth-first search to find unsaturated paths.

Solution. We proceed strictly by depth-first search (examining the vertices from left to right and then top down):

Use the encoding of plane trees to encode any tree. Deal first with the case of rooted trees. Determine the order of the children of every vertex uniquely up to isomorphism. The order is unimportant if and only if the subgraphs determined by the respective children are isomorphic.

The same construction can be used as for the plane trees, ordering the vertices lexicographically with respect to their codes (see 12.6.5 for the related concepts). This means that codes  $W_1, W_2$  satisfy  $W_1 > W_2$  if and only if  $W_1$  contains a one at an earlier position than  $W_2$  or  $W_2$  is a prefix of  $W_1$ . The rooted tree as a whole is described by the same recursive procedure: if the children of a vertex  $v$  are coded by  $W_1, \dots, W_\ell$ , then the code of the vertex  $v$  is

$$0W_1 \dots W_\ell 1,$$

where the order is selected so that  $W_1 \leq W_2 \leq \dots \leq W_\ell$ .

If no vertex is designated to be the root of a tree, the root can be designed so that it would be almost “in the middle” of the tree. This can be realized by assigning an integer to every vertex of the tree which describes its *eccentricity*. That eccentricity  $ex_T(v)$  of a vertex  $v$  in a graph  $T$  is defined to be the greatest possible distance between  $v$  and some vertex  $w$  in  $T$ . This concept is meaningful for all graphs; however, by the absence of cycles in trees, it is guaranteed that there are at most two vertices with the minimal eccentricity. ○

Lemma. Let  $C(T)$  be the set of those vertices of a tree  $T$  whose eccentricity is minimal. Then,  $C(T)$  contains either a single vertex, or exactly two vertices, which are connected with an edge in  $T$ .

PROOF. The claim is proved by induction, using the trivial fact that the most distant vertex from any vertex  $v$  must be a leaf. Therefore, the center of  $T$  coincides with the center of the tree  $T'$  which is created from the tree  $T$  by removing all its leaves and the corresponding edges. After a finite number of such steps, there remains either just one vertex, or a subtree with two vertices. □

$C(T)$  determined by the latter lemma is called the *center of the graph*, and the minimal eccentricity is called the *radius of the graph*.

A unique (up to isomorphism) code can now be assigned to every tree. If the center of  $T$  contains only one vertex, use it as the root. Otherwise, create the codes for the two rooted subtrees of the original tree without the edge that connects the vertices of the center, and the code of  $T$  is the code of the rooted tree  $(T, x)$ , where  $x$  is the vertex of the center whose subtree has lexicographically smaller code.

Corollary. Trees  $T$  and  $T'$  are isomorphic if and only if they are assigned the same code.

The above ideas imply that the algorithm for verifying planar tree isomorphism can be implemented in linear time with respect to the number of vertices of the trees.

We can see that 200 iterations were needed in order to find the maximum flow.  $\square$

**13.D.2.** Find the size of a maximum flow in the network given by the following matrix  $A$ , where vertex 1 is the source and vertex 8 is the sink. Further, find the corresponding minimum cut.

$$A = \begin{pmatrix} - & 16 & 24 & 12 & - & - & - & - \\ - & - & - & - & 30 & - & - & - \\ - & - & - & - & 9 & 6 & 12 & - \\ - & - & - & - & - & - & 21 & - \\ - & - & - & - & - & 9 & - & 15 \\ - & - & - & - & - & - & - & 9 \\ - & - & - & - & - & - & - & 18 \\ - & - & - & - & - & - & - & - \end{pmatrix}$$

**Solution.** The following augmenting semipaths are found:

- 1–2–5–8 with residual capacity 15.
- 1–2–5–6–8 with residual capacity 1.
- 1–3–5–6–8 with residual capacity 8.
- 1–4–7–8 with residual capacity 12.
- 1–3–7–8 with residual capacity 6.

The total size of the found flow is 42. We can see that it is indeed of maximum size from the fact the cut consisting of edges  $(5, 8)$ ,  $(6, 8)$ , and  $(7, 8)$  has also size 42 (and it is thus a minimum cut).  $\square$

**13.D.3.** The following picture depicts a flow network (the numbers  $f/c$  define the actual flow and the capacity of a given edge, respectively). Decide whether the given flow is maximum. If so, justify your answer. If not, find a maximum flow and describe the used procedure in detail. Find a minimum cut in the network.

picture skipped

**Solution.** In the given network, There exists an augmenting (semi)path 1–2–3–4–8 with residual capacity 4. Its saturation results in a flow of size 32. Since the cut  $(3, 8)$ ,  $(5, 8)$ ,  $(2, 4)$ ,  $(6, 4)$  is of the same size, we have found a maximum flow.  $\square$

**13.D.4.** Find a maximum flow and a minimum cut in the following flow network (source=1,sink=14).

The trees form a special class of graphs. They are often used in miscellaneous variations and with additional requirements. We return to them later, in connection with practical applications.

Now follows another extraordinarily important class of graphs.

**13.1.19. Planar graphs.** Some graphs are drawn in the

plane in such a way that their edges do not “cross” one another. This means that every vertex of the graph is identified with a point of the plane, and an edge between vertices  $v$ ,  $w$  corresponds to a continuous curve  $c : [0, 1] \rightarrow \mathbb{R}^2$  that connects the vertices  $c(0) = v$  and  $c(1) = w$ . Furthermore, suppose that edges may intersect only at their endpoints. This describes a *planar graph*  $G$ .

The question whether a given graph admits a realization as a planar graph often emerges in practical problems. Here is an example:

Providers of water, electricity, and gas have their connection spots near three houses (each provider has one spot). Each house wants to be connected to each resource so that the connections would not cross (they might want not to dig too deep, for instance). Is it possible to do this? The answer is: “no”.

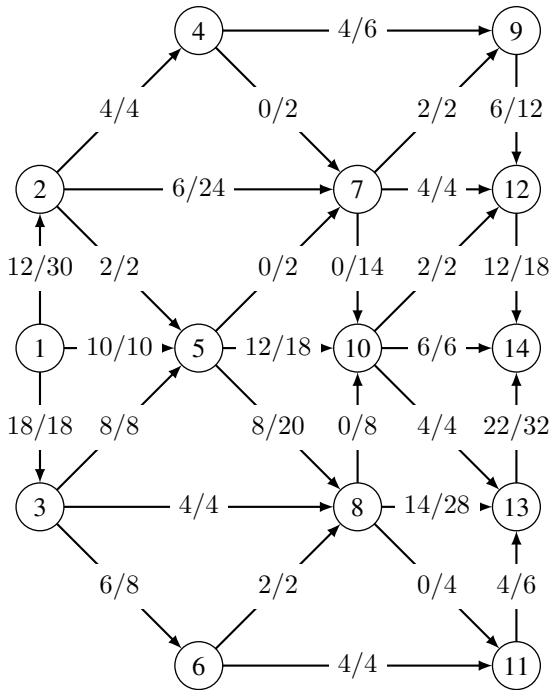

In this particular case, it is clear from the diagram. There is a complete bipartite graph  $K_{3,3}$ , where three of the vertices correspond to the connection spots, while the other three represent the houses. The edges are the connections between the spots and the houses. All edges can be placed except the last one – see the diagram, where the dashed edge cannot be drawn without crossing any more:

For a complete proof, more mathematical tools are needed. A complete explanation is not provided here, but an indication of the reasoning follows.

One of the basic results from the topology of the plane (the *Jordan curve theorem*) states that every closed continuous curve  $c$  in the plane that is not self-intersecting (i.e. it is a “crooked circle”) divides the plane into two distinct parts. In other words, every other continuous curve which connects a point inside a curve  $c$  and a point outside  $c$  must intersect  $c$ . If the edges are realized as piecewise linear curves (every edge composed of finitely many adjacent line segments), then it is quite easy to prove the Jordan curve theorem (you might do it yourself!). The general theorem can be proved by approximating the continuous curves by piecewise linear ones (quite difficult to do, but it is much easier if the curve is assumed to be piecewise differentiable).

**Solution.** The paths are saturated in the following order:

$$\begin{aligned}
 &1 \xrightarrow{18} 2 \xrightarrow{18} 7 \xrightarrow{14} 10 \xleftarrow{12} 5 \xrightarrow{12} 8 \xrightarrow{4} 11 \xrightarrow{2} 13 \xrightarrow{10} 14 \\
 &1 \xrightarrow{16} 2 \xrightarrow{16} 7 \xrightarrow{12} 10 \xleftarrow{10} 5 \xrightarrow{10} 8 \xrightarrow{14} 13 \xrightarrow{8} 14
 \end{aligned}$$

We have found a flow of size 50. And indeed, it is a maximum flow since there is no further unsaturated path. If we look for the reachable vertices, we can also find a cut with capacity 50, consisting of edges

$$[2, 4] : 4, [7, 9] : 2, [7, 12] : 4, [10, 12] : 2, [10, 14] : 6, [13, 14] : 32. \quad \square$$

**13.D.5.** Find a maximum flow in the following network on the vertex set  $\{1, 2, \dots, 9\}$  with source 1 and sink 9 using the Ford-Fulkerson algorithm (during the depth-first search, choose the vertices in ascending order). Find a minimum cut in this network. Describe the steps of the procedure in detail. The edges  $e \in E$  as well as the lower and upper bounds on the flow ( $l(e)$  and  $u(e)$ ) and the current flow  $f(e)$  are given in the table:

Consider the graph  $K_{3,3}$ . The triples of vertices that are not connected with edges are indistinguishable up to order. Therefore the thick cycle can be considered the general case of a cycle with four points in the graph. The position of the remaining two vertices can then be discussed. In order for the graph to be planar, either both of the vertices must lie inside the cycle, or both outside. Again, these possibilities are equivalent, so it can be assumed without loss of generality that they are in opposite sides, as are the black vertices on the diagram. Now, their position with respect to a suitable cycle with two thick edges and two thin black edges can be discussed (i.e. through three gray vertices and one black one). Then, we can discuss the position of the remaining black vertex with respect to this cycle. This leads to the impossibility of drawing the last (dashed) edge without crossing the thick cycle.

It can be shown similarly that the complete graph  $K_5$  is not planar either. We provide a pure combinatorial argument why  $K_5$  and  $K_{3,3}$  cannot be planar graphs below, see the Corollary in the end of the next subsection.

Notice that if a graph  $G$  is “expanded” by dividing some of its edges (i.e. adding new vertices in the edges), then the new graph is planar if and only if  $G$  is planar. The new graph is a *subdivision* of  $G$ . Planar graphs must not contain any subdivision of  $K_{3,3}$  or  $K_5$ . The reverse implication is also true:

KURATOWSKI THEOREM

**Theorem.** A graph  $G$  is planar if and only if none of its subgraphs is isomorphic to a subdivision of  $K_{3,3}$  or  $K_5$ .

The proof is complicated, so it is not discussed here. Much attention is devoted to planar graphs both in research and practical applications.

There are algorithms which are capable of deciding whether or not a given graph is planar in linear time. Direct application of the Kuratowski theorem would lead to a worse time complexity.

**13.1.20. Faces of planar graphs.** Consider a planar graph  $G$  embedded in the plane  $\mathbb{R}^2$ . Let  $S$  be the set of those points  $x \in \mathbb{R}^2$  which do not belong to any edge of the graph (nor are vertices). In this way, the set  $\mathbb{R}^2 \setminus G$  is partitioned into connected subsets  $S_i$ , called the *faces of the planar graph*  $G$ . Since the graphs are finite, there is exactly one unbounded face  $S_0$ . The set of all faces are denoted by  $S = \{S_0, S_1, \dots, S_k\}$ , and the planar graph by  $G = (V, E, S)$ .

The simplest case of a planar graph is a tree. Every tree is a planar graph since it can be constructed by step-by-step addition of leaves, starting with single vertex. Of course, the Kuratowski theorem can also be applied—when there is no cycle in a graph  $G$ , then there cannot be a subdivision of  $K_{3,3}$  or  $K_5$ , either. Since a tree  $G$  cannot contain a cycle, there is

$e$	$l(e)$	$u(e)$	$f(e)$
(1,2)	0	6	0
(1,3)	0	6	0
(1,6)	0	4	0
(2,3)	0	2	0
(2,4)	0	3	0
(3,4)	0	4	0
(3,5)	0	4	0
(4,5)	3	5	4
(4,8)	0	3	0
$e$	$l(e)$	$u(e)$	$f(e)$
(5,1)	0	3	0
(5,6)	0	6	0
(5,7)	0	5	4
(5,8)	0	5	0
(6,9)	0	5	0
(7,4)	1	6	4
(7,9)	0	3	0
(8,9)	0	9	0

**13.D.6.** A cut in a network  $(V, E, s, t, w)$  can also be viewed as a set  $C \subset E$  of edges such that in the network  $(V, E \setminus C, s, t, w)$ , there is no path from the source  $s$  to the sink  $t$ , but if any edge  $e$  is removed from  $C$ , then the resulting set does not satisfy this property, i. e., there is a path from  $s$  to  $t$  in  $(V, E \setminus C \cup e, s, t, w)$ . Find all cuts (and their sizes) in the following network:

**Solution.** Let us fix the following edge labeling:

Then, there are cuts:  $\{f,i\}, \{f,h,j,a\}, \{f,j,c,a,d,e\}, \{f,j,c,a,d,g\}, \{b,j,c\}, \{b,j,h\}, \{b,i\}$ . Their capacities are 12, 9, 20, 18, 15, 10, and 15, respectively.  $\square$

**13.D.7.** Find a maximum flow in the network given in the above exercise.  $\circ$

only one face  $S_0$  there (the unbounded face). Since the number of edges of a tree is related to the number of its vertices, cf. the formula 13.1.15(5), it follows that

$$|V| - |E| + |S| = 2$$

for all trees.

Surprisingly, the latter formula linking the number of edges, faces, and vertices can be derived for all planar graphs. The formula is named after Leonhard Euler. Especially, the number of faces is independent of the particular embedding of the graph in the plane:

EULER'S FORMULA

**Theorem.** Let  $G = (V, E, S)$  be a connected planar graph. Then,

$$|V| - |E| + |S| = 2.$$

**PROOF.** The proof is by induction on the number of edges. The graph with zero or one edge satisfies the formula. Consider a graph  $G$  with  $|E| > 1$ . If  $G$  does not contain a cycle, then it is a tree, and the formula is already proved for this case.

Suppose that there is an edge  $e$  of  $G$  that is contained in a cycle. Then, the graph  $G' = G \setminus e$  is connected, and it follows from the induction hypothesis that  $G'$  satisfies Euler's formula:

$$|V| - (|E| - 1) + (|S| - 1) = 2,$$

since removing an edge necessarily leads to merging two faces of  $G$  into one face in  $G'$ . Hence Euler's formula is valid for the graph  $G$ .  $\square$

**Corollary.** Let  $G = (V, E, S)$ , be a planar graph with  $|V| = n \geq 3$ , and  $|E| = e$ . Then

- There is the inequality  $e \leq 3n - 6$  which becomes equality if and only if  $G$  is a maximal planar graph (adding any edge to  $G$ , would violate planarity).
- If  $G$  does not contain a triangle (i.e. the graph  $K_3$  is not a subgraph), then  $e \leq 2n - 4$ .

**PROOF.** Continue adding edges to a given graph until it is maximal. If the obtained maximal graph  $G$  satisfies the inequality with equality, then the inequality holds for the original graph as well.

Similarly, if the graph  $G$  is not connected, two of its components can be connected with a new edge, so such a graph cannot be maximal. Even if it were connected but not 2-connected, there would exist a vertex  $v \in V$  such that when it is removed, the graph  $G$  collapses into several components  $G_1, \dots, G_k, k \geq 2$ . However, then an edge can be added between these components without destroying the planarity of the original graph  $G$  (draw a diagram!). Therefore, it can be assumed from the beginning that the original graph  $G$  is a maximal planar 2-connected graph.

As shown in theorem 13.1.11, every 2-connected graph can be constructed from the triangle  $K_3$  by splitting edges and attaching new ones. It is easily proved by induction that every

Further exercises on maximum flows and minimum cuts can be found on page 1220.

**E. Classical probability and combinatorics**

In this section, we recall the methods we learned as early as in the first chapter.

**13.E.1.** We throw  $n$  dice. What is the probability that none of the values 1, 3, 6 is cast?

**Solution.** We can also see the problem as throwing one dice  $n$  times. The probability that none of the values 1, 3, 6 is cast in the first throw is  $1/2$ . The probability that they are cast neither in the first throw nor in the second one is clearly  $1/4$  (the result of the first throw has no impact on the result of the second one). Since this holds generally, i. e., the results of different throws are (stochastically) independent, the wanted probability is  $1/2^n$ .  $\square$

**13.E.2.** We have a pack of ten playing cards, exactly one of which is an Ace. Each time, we randomly draw one of the ten cards and then put it back. How many times do we have to repeat this experiment if we require the probability of getting the Ace at least once to be at least 0.9?

**Solution.** Let  $A_i$  be the event “the Ace is picked in the  $i$ -th draw”. The events  $A_i$  are (stochastically) independent. Hence, we know that

$$P\left(\bigcup_{i=1}^n A_i\right) = 1 - (1 - P(A_1)) \cdot (1 - P(A_2)) \cdot \dots \cdot (1 - P(A_n))$$
 for every  $n \in \mathbb{N}$ . We are looking for an  $n \in \mathbb{N}$  such that

$$P\left(\bigcup_{i=1}^n A_i\right) = 1 - (1 - P(A_1)) \cdot (1 - P(A_2)) \cdot \dots \cdot (1 - P(A_n)) > 0.9.$$

Apparently, we have  $P(A_i) = 1/10$  for any  $i \in \mathbb{N}$ . Therefore, it suffices to solve the inequality

$$1 - \left(\frac{9}{10}\right)^n > 0.9,$$

whence

$$n > \frac{\log_a 0.1}{\log_a 0.9}, \quad \text{where } a > 1.$$

Evaluating this, we find out that we have to repeat the experiment at least 22 times.  $\square$

**13.E.3.** We randomly draw six cards from a pack of 32 cards (containing four Kings). Calculate the probability that the sixth card is a King and, at the same time, it is the only King drawn.

**Solution.** By the theorem on product of probabilities, the result is

$$\frac{28}{32} \cdot \frac{27}{31} \cdot \frac{26}{30} \cdot \frac{25}{29} \cdot \frac{24}{28} \cdot \frac{4}{27} \doteq 0.0723. \quad \square$$

**13.E.4.** We randomly draw two cards from a pack of 32 cards (containing four Aces). Calculate the probability that the second card drawn is an Ace if:

- a) the first card is put back; b) the first card is not put back.

**Solution.** If the first card is put back in the pack, then we clearly repeat an experiment with 32 possible outcomes (with the same probability), 4 of which are favorable. Therefore,

face of a planar graph must be bounded by a cycle (which seems intuitively apparent).

However, if there is a face of our maximal planar graph  $G$  that is not bounded by a triangle, then this face can be split with another edge (a “diagonal” in geometrical terminology), so  $G$  would not be maximal. It follows that all faces of  $G$  are bounded by triangles  $K_3$ . Hence  $3|S| = 2|E|$ .

It suffices to substitute  $|S| = \frac{2}{3}|E|$  for the number of faces in Euler’s formula.

The second proposition is analogous; now, the faces of the maximal planar graph without triangles are bounded by either four or five edges, whence it follows that  $4|S| \leq 2|E|$  with the equality if and only if there are just quadrangles there.  $\square$

The corollary implies (even without the Kuratowski theorem) that neither  $K_5$  nor  $K_{3,3}$  is planar: in the former case,  $|V| = 5$  and  $|E| = 10 > 3|V| - 6$ , while in the latter,  $|V| = 6, |E| = 9 > 2|V| - 4$ , which is again a contradiction since  $K_{3,3}$  does not contain a triangle.

**13.1.21. Convex polyhedra in the space.** Planar graphs can

be imagined as drawn on the sphere instead in the plane. The sphere can be constructed from the plane by attaching one point “at infinity”. Again, faces of such graphs can be discussed, and the faces are now equivalent to one another (even the face  $S_0$  is bounded).

On the contrary, every convex polyhedron  $P \subseteq \mathbb{R}^3$  can be imagined as a graph drawn on the sphere (project the vertices and edges of the polyhedron onto a sufficiently large sphere from any point inside  $P$ ). Dropping a point inside one of the faces (that face becomes the unbounded face  $S_0$ ) then leads to the planar graph as above – the sphere with the hole is spread in the plane.

The planar graphs that are formed of convex polyhedra are clearly 2-connected since every pair of vertices of a convex polyhedron lies on a common cycle. Moreover, every face is interior to its boundary cycle and the graphs of convex polyhedra are always 3-connected.

In fact, they are just such graphs as the following Steinitz’s theorem says (we omit the proof):

STEINITZ’S POLYHEDRA THEOREM

**Theorem.** A graph  $G$  is the graph of a convex polyhedron if and only if it is planar and 3-vertex-connected.

**13.1.22. Platonic solids.** As an illustration of the combinatorial approach to polyhedral graphs, we classify all the regular polyhedra. These are those built up from one type of regular polygons so that the same number of them touch at every vertex. It was known as early as in the epoch of the ancient philosopher Plato that there are only five of them:

the wanted probability is  $1/8$ . However, even if we do not put the first card back, the probability is the same. Clearly, the probability of a given card being drawn the first time is the same as for the second time. Of course, we can also apply the conditional probability. This leads to

$$\frac{4}{32} \cdot \frac{3}{31} + \frac{28}{32} \cdot \frac{4}{31} = \frac{1}{8}. \quad \square$$

**13.E.5. Combinatorial identities.** Use combinatorial means to derive the following important identities (in particular, do not use induction):

Arithmetic series  $\sum_{k=0}^n k = \frac{n(n+1)}{2} = \binom{n+1}{2}$

Geometric series  $\sum_{k=0}^n x^k = \frac{x^{n+1}-1}{x-1}$

Binomial theorem  $(x+y)^n = \sum_{k=0}^n \binom{n}{k} x^k y^{n-k}$

Upper binomial theorem  $\sum_{k=0}^n \binom{k}{m} = \binom{n+1}{m+1}$

Vandermonde's convolution<sup>1</sup>  $\binom{m+n}{r} = \sum_{k=0}^r \binom{m}{k} \binom{n}{r-k}$ .

○

**13.E.6.** An urn consists of 30 red balls and 70 green balls. What is the probability of getting exactly  $k$  red balls in a sample of size 20,  $0 \leq k \leq 20$  if the sampling is done with replacement (repetition allowed)?

**Solution.** Any time we take a sample from the urn we put it back before the next sample (sampling with replacement). Thus in this experiment each time we sample, the probability of choosing a red ball is  $\frac{30}{100}$  and we repeat this in 20 independent trials. Thus, using the binomial formula, we obtain

$$P(k \text{ red balls}) = \binom{20}{k} (0.3)^k (0.7)^{20-k}$$

□

**13.E.7.** An urn consists of 30 red balls and 70 green balls. What is the probability of getting exactly  $k$  red balls in a sample of size 20,  $0 \leq k \leq 20$  if the sampling is done without replacement (repetition not allowed)?

**Solution.** Let  $A$  be the event of getting exactly  $k$  red balls. To find  $P(A)$  we need to find  $|A|$  and the total number of possibilities  $|S|$ . Here  $|S| = \binom{100}{20}$ . Next, to find  $|A|$ , we need to find out in how many ways one can choose  $k$  red balls and  $20 - k$  green balls. Thus,

$$|A| = \binom{30}{k} \binom{70}{20-k}.$$

Thus,

$$P(A) = \frac{|A|}{|S|} = \frac{\binom{30}{k} \binom{70}{20-k}}{\binom{100}{20}}.$$

□

**13.E.8.** Assume that there are  $k$  people in a room and we know that

- $k = 5$  with probability  $\frac{1}{4}$ ;
- $k = 10$  with probability  $\frac{1}{4}$ ;
- $k = 15$  with probability  $\frac{1}{2}$ .

<sup>1</sup>Also called hockey identity.

Translate the condition of regularity to the properties of the corresponding graphs: Every vertex needs the same degree  $d \geq 3$ , and the boundary of every face must contain the same number  $k \geq 3$  of vertices. Let  $n, e, s$  denote the total number of vertices, edges, and faces, respectively.

Firstly, the relation of the vertex degrees and the number of edges requires

$$dn = 2e.$$

Secondly, every edge lies in the boundary of exactly two faces, so

$$2e = ks.$$

Thirdly, Euler's formula states that

$$2 = n - e + s = \frac{2e}{d} - e + \frac{2e}{k}.$$

Put this together. The constants  $d$  and  $k$  must satisfy

$$\frac{1}{d} - \frac{1}{2} + \frac{1}{k} = \frac{1}{e}.$$

Since  $d, k, e, n$  are positive integers (in particular,  $\frac{1}{e} > 0$ ), this equality restricts the possibilities. Especially, the left-hand side is maximal for  $d = 3$ . Substitute this value, to obtain the inequality

$$-\frac{1}{6} + \frac{1}{k} = \frac{1}{e} > 0.$$

It follows that  $k \in \{3, 4, 5\}$  for a general  $d$ . The roles of  $k$  and  $d$  are symmetric in the original equality, so also  $d \in \{3, 4, 5\}$ . Checking each of the remaining possibilities, yields all the solutions:

$d$	$k$	$n$	$e$	$s$
3	3	4	6	4
3	4	8	12	6
4	3	6	12	8
3	5	20	30	12
5	3	12	30	20

It remains to show that the corresponding regular polyhedra exist. This is already seen in the above diagrams, but that is not a mathematical proof. The existence of the first three is apparent. Concentrate on the geometrical construction of the regular dodecahedron (draw a diagram!).

Begin with a cube, building "A-tents" on all its sides simultaneously. The upper horizontal poles are set on the level of the cube's sides so that those of adjacent sides are perpendicular to each other. Its length is chosen so that the trapezoids of the lateral sides would have three sides of the same length. Now, simultaneously

- i) What is the probability that at least two of them have been born in the same month? Assume that all months are equally likely.
- ii) Given that we already know there are at least two people that celebrate their birthday in the same month, what is the probability that  $k = 10$ ?

**Solution.** Let  $A_k$  be the event that at least 2 people out of  $k$  people have birthdays on the same month. We have The complimentary event  $B_k$  is that none out of  $k$  people have birthday on the same month, i.e. there are exactly  $k$  distinct months when these people were born. Thus

$$P(A_k) = 1 - \frac{P_1^k 2}{7} 12^k, \text{ for } 2 \leq k \leq 12.$$

For  $k > 12$ , obviously,  $P(A_k) = 1$ . Therefore the required

$$\begin{aligned} P &= \frac{1}{4}P(A_5) + \frac{1}{4}P(A_{10}) + \frac{1}{2}P(A_{15}) \\ &= \frac{1}{4}\left(1 - \frac{P_1^5 2}{7} 12^5\right) + \frac{1}{4}\left(1 - \frac{P_1^{10} 2}{7} 12^{10}\right) + \frac{1}{2}. \end{aligned}$$

The second part of the question asks for conditional probability  $P(k = 10|A)$ . According to Bayes' rule:

$$\begin{aligned} P(k = 10|A) &= \frac{P(A|k = 10)P(k = 10)}{P(A)} = \frac{P(A_{10})}{4P(A)} \\ &= \frac{1 - \frac{P_1^{10} 2}{7} 12^{10}}{\left(1 - \frac{P_1^5 2}{7} 12^5\right) + \left(1 - \frac{P_1^{10} 2}{7} 12^{10}\right) + 2} \end{aligned}$$

□

**13.E.9. Hat matching problem**  $N$  guests arrive at a party. Each person is wearing a hat. All hats are collected and then randomly redistributed at the departure. What is the probability that at least one person receives his/her own hat?

**Solution.** Let  $A_i$  be the the event that person  $i$  receives own hat. Then the task is to find  $P(E)$ , where  $E = \cup_{i=1}^N A_i$ . To find  $P(E)$  we use inclusion-exclusion principle:

$$\begin{aligned} P(E) &= P(\cup_{i=1}^N A_i) = \sum_{i=1}^N P(A_i) - \sum_{i < j} P(A_i \cap A_j) + \\ &\sum_{i < j < k} P(A_i \cap A_j \cap A_k) - \dots + (-1)^{N-1} P(\cap_{i=1}^N A_i) \end{aligned}$$

Note, that due to symmetry, the probability of any such intersection depends only on the number of sets  $A_i$  in the intersection, so

$$\begin{aligned} \sum_{i=1}^N P(A_i) &= NP(A_1); \\ \sum_{i < j} P(A_i \cap A_j) &= \binom{N}{2} P(A_1 \cap A_2); \\ \sum_{i < j < k} P(A_i \cap A_j \cap A_k) &= \binom{N}{3} P(A_1 \cap A_2 \cap A_3); \\ &\dots \end{aligned}$$

raise all tents while keeping the ratio of the three sides of the trapezoids. There is a position at which the adjacent trapezoid and triangle sides are coplanar. At that position, the regular dodecahedron is created.

Now, the regular icosahedron can be constructed via the so called *dual graph* construction. The dual graph  $G'$  to a planar graph  $G = (V, E, S)$  has vertices defined as the faces in  $S$  and there is an edge between faces  $S_1$  and  $S_2$  if and only if they share an edge (i.e. were neighbours) in  $G$ . Clearly the dual graph to the dodecahedron is the isosahedron. Exactly as the cube and the octohedron are dual, while tetrahedron is dual to itself.

## 2. A few graph algorithms

In this part, we consider several applications of graph concepts and the algorithms built upon them.

**13.2.1. Graph representations.** As already indicated, algorithms are often formulated with the help of the language of graphs.

The concept of an algorithm can be formalized as a procedure dealing with a (directed) graph whose vertices and/or edges are equipped with further information. The procedure consists in walking through the graph along its edges, while processing the information associated to the visited vertices and edges. Of course, processing the information includes also the decision which outgoing edges must be investigated in a further walk, and in which order.

In the case of an undirected graphs, each (undirected) edge can be replaced with a pair of directed edges.

The graph may also be changed during the run of the algorithm, i.e. vertices and/or edges may be added or removed.

In order to execute such algorithms efficiently (usually on a computer), it is necessary to represent the graph in a suitable way. The adjacency matrix representation is one possibility, cf. 13.1.8. There are many other options based on various lists with suitable pointers.

The *edge list* (also the *adjacency list*) of the graph  $G = (V, E)$  consists of two lists  $V$  and  $E$  that are interconnected by pointers so that every vertex points to the edges it is incident to. and every edge points to its endpoints.

The necessary memory to represent the graph as an edge list is  $O(|V| + |E|)$  since every edge is pointed at twice and every vertex is pointed at  $d$  times, where  $d$  is its degree, and the sum of the degrees of all vertices equals twice the number of edges. Therefore, up to a constant multiple, this is an optimal way of graph representation in memory. It is of interest in how the basic graph operations are processed in both representations. By the basic operations, is meant:

- *removal of an edge,*
- *addition of an edge,*
- *removal of a vertex,*
- *addition of a vertex,*
- *splitting an edge with a new vertex.*

Therefore,

$$P(E) = NP(A_1) - \binom{N}{2} P(A_1 \cap A_2) + \binom{N}{3} P(A_1 \cap A_2 \cap A_3) - \dots$$

We need to find  $P(A_1)$ ,  $P(A_1 \cap A_2)$ ,  $P(A_1 \cap A_2 \cap A_3)$ , ... and so on for all numbers of intersecting sets. Obviously,

$$P(A_1) = \frac{|A_1|}{|S|} = \frac{(N-1)!}{N!} = \frac{1}{N},$$

since  $|S| = N!$  and  $|A_1| = (N-1)!$ . Similarly

$$P(A_1 \cap A_2) = \frac{|A_1 \cap A_2|}{N!} = \frac{(N-2)!}{N!} = \frac{1}{N(N-1)};$$

$$P(A_1 \cap A_2 \cap A_3) = \frac{(N-3)!}{N!} = \frac{1}{N(N-1)(N-2)};$$

Thus,

$$P(E) = N \frac{1}{N} - \binom{N}{2} \frac{1}{N(N-1)} + \binom{N}{3} \frac{1}{N(N-1)(N-2)} - \dots + (-1)^{N-1} \frac{1}{N!},$$

$$= 1 - \frac{1}{2!} + \frac{1}{3!} - \dots + (-1)^{N-1} \frac{1}{N!},$$

which approaches  $1 - \frac{1}{e}$  as  $N \rightarrow \infty$ . □

**13.E.10. Texas Hold 'em Poker.** Now, we solve several simple problems about one of the most popular card games—Texas Hold'em Poker. We do not present its rules; they can be easily found on the Internet. What is the probability that:

- i) we are dealt a pair?
- ii) we are dealt an Ace?
- iii) we have one of the six best poker combinations at the end?
- iv) we win if we are holding an Ace and a Three and there are three Twos and the differently-suited Ace on the table (the river has not been dealt yet)?

**Solution.**

- i) There are 4 cards of each of 13 ranks. Therefore, there are  $13 \binom{4}{2} = 78$  pairs. The total number of pairs is  $\binom{13 \cdot 4}{2} = 1326$ . Thus, the wanted probability is  $\frac{1}{17} \doteq 0.06$ .
- ii) One of the cards is an Ace (there are four possibilities) and the other one is arbitrary (51 possibilities). However, this includes the  $\binom{4}{2} = 6$  pairs of Aces twice. Therefore, the number of favorable cases is only  $4 \cdot 51 - 6 = 198$  and the wanted probability is  $\frac{198}{1326} \doteq 0.15$ .
- iii) We compute the probabilities of the particular combinations when dealt five cards at random:  
**ROYAL FLUSH:** There is exactly one such combination for each suit—four in total. Further, there are  $\binom{52}{5} = 2598960$  possibilities for a hand of five cards. Thus, the probability is approximately  $1.5 \cdot 10^{-6}$ , very low indeed.  
**STRAIGHT FLUSH:** The highest card of the straight must be between 5 and K, i. e., there are 9 possibilities for each suit. Altogether, the probability is  $\frac{36}{2598960} \doteq 1.4 \cdot 10^{-5}$ .  
**POKER (FOUR OF A KIND):** There are 13 possibilities

It is apparent that if the matrix is represented by an array of zeros and ones, then the first and second operations can be executed in  $O(1)$  (constant time), while the others are in  $O(n)$  (linear time).

In the case of the adjacency list, implementation of the data structures is crucial for the time complexity. However, all of the operations should be proportional to the number of edited data units provided the corresponding item(s) are already found. For instance, if a vertex is removed, then all of the edges that are incident to it must also be removed.

The matrix representation is also useful in theoretical discussions about graphs, using matrix calculus.

**13.2.2. Searching in graphs.** Many useful algorithms are based on going through all vertices of a given graph step by step. Usually, the vertex is given to start with or it is selected at the beginning of the procedure.

At every stage of the search, each vertex has (exactly) one of the following statuses:

- *processed* – it has been visited and completely processed;
- *active* – it has been visited and is prepared to be processed;
- *sleeping* – it has not been visited yet.

At the same time, information about processed edges is retained. At every stage, the sets of vertices and/or edges in these groups must form a partition of the sets  $V$  and  $E$  while one of the active vertices is being processed.

The general principle on searching through the vertices is illustrated first. In the subsequent subsections, such procedures are used to build algorithms solving particular problems.

At the beginning of the algorithm, there is just one active vertex and all the others are sleeping. At the first step, traverse all edges incident to the active vertex and change the status of their other endpoints from sleeping to active. Then, the active vertex started may be marked as processed, and another active vertex may be chosen. In the following steps, always go through those adjacent edges not yet met, marking their other endpoints as active. This algorithm can be applied to both directed and undirected graphs.

In practical problems, the search is often restricted to only some edges going from the current vertex. This is an insignificant change to the algorithm.

To specify the algorithm completely, a decision must be made in which order to process the active vertices and in which order to process the edges going from the current vertex. In general, the two simplest possibilities of processing the vertices are:

- (1) they are processed in the same order as they were visited (queue),
- (2) they are processed in the reversed order than they were visited (stack).

The former case, is called a *breadth-first search*. The latter case is called a *depth-first search*.

for the quad and the fifth card can be arbitrary (48 possibilities). Hence:  $\frac{624}{2598960} \doteq 2.4 \cdot 10^{-4}$ .

FULL HOUSE: There are  $13 \binom{4}{3} = 52$  possibilities for the triple and  $12 \binom{4}{2} = 72$  possibilities for the remaining pair. Altogether,  $\frac{3744}{2598960} \doteq 1.4 \cdot 10^{-3}$ .

FLUSH: There are 4 suits and  $\binom{13}{5}$  hands for each suit, i. e.,  $4 \cdot \binom{13}{5} = 5148$  possibilities in total. However, we must not count the straights again. There are 40 of them, so the resulting probability is  $\frac{5108}{2598960} \doteq 2 \cdot 10^{-3}$ .

STRAIGHT: The highest card of the straight is between 5 and A, so there are 10 possibilities. Selecting the suit of each card arbitrarily, this gives  $10 \cdot 4^5 = 10240$  possibilities. However, we must exclude flushes, so the total probability is  $\frac{10200}{2598960} \doteq 3.9 \cdot 10^{-3}$ .

Altogether, the probability of one of the best six combinations is approximately  $3.9 \cdot 10^{-3} + 2 \cdot 10^{-3} + 1.4 \cdot 10^{-3} + 0.24 \cdot 10^{-3} = 7.54 \cdot 10^{-3}$ , i. e., about 0.75%.

In the Texas Hold 'em variation, the best 5-card hand of the seven cards is always considered. We have computed the number of favorable 5-card hands and there are  $\binom{52-5}{2}$  possibilities for the remaining two cards. The total number of 7-card hands is  $\binom{52}{7}$ . We can thus approximate the probability for Texas Hold 'em for the classic Poker by multiplying by the coefficient  $\frac{\binom{52}{5} \binom{47}{2}}{\binom{52}{7}} = 21$ .

However, note that this is indeed only an approximation of the actual probability since some favorable combinations are counted more than once this way. For instance, we have a full house in the considered 5-card hand and if the arbitrary pair contains the fourth card of the triple, then we actually have a poker (four of a kind), so this combination has been counted more times. On the other hand, the true result only merely differs from the computed approximation, so the probability of one of the best six poker combinations is about twenty times higher than in classic Poker. This may be the reason why this variation is so popular.

- iv) Clearly, our situation is very good. Hence, it will be easier to count the unfavorable cases when the other player has a better combination. We have Twos full of Aces, so we lose only if the opponent has Aces full of Twos or a poker of Twos, i. e., he must hold the remaining Two or an Ace. In the former case, he surely wins, and this happens in  $0 + 3 + 4 + \dots + 4 + 2 = 45$  cases (we can see the remaining Twos, a Three, and two Aces) out of all  $\binom{46}{2} = 1035$ , so the probability of this loss is about 0.043. In the latter case, there are more possibilities. If he holds a pair of Aces and the river card is not the remaining Two, then we lose; otherwise (i. e., if he has only one Ace or the Two appears on the river), it is a tie. Thus, we lose in this case by  $\frac{1}{1035} \cdot \frac{43}{44} \doteq 10^{-3}$ . Altogether, the probability that we win or draw is almost 96 %.

The role of the data structures used for representing the graph is immediately apparent: The adjacency list allows passage through all edges going from a given vertex in a time proportional to the number of them. Each edge is visited at most twice since it has only two endpoints. Hence the following result:

**Theorem.** Both the breadth-first and depth-first searches run in  $O((n + m)K)$  time, where  $n$  and  $m$  are the number of vertices and edges of the graph, respectively.  $K$  is the time needed for processing an edge or a vertex.

The following diagram illustrates the breadth-first search through the Petersen graph:

The first 8 steps are shown here. The circled vertex is the one to be processed, the bold vertices are the already processed one, while the dashed edges are those that have been processed, and the small vertices adjacent to some dashed edges are the active ones. At the given vertex, the edges are processed counterclockwise, beginning with the direction “straight down”.

The diagram below illustrates the depth-first search applied to the same graph. Note that the first step is the same as above.

As a simple example of graph searching, consider an algorithm for finding all connected components of a given graph. The only information that must be processed during the search (no matter whether breadth-first or depth-first) is which component is being examined.

The search, as here presented, passes exactly the vertices of a single component. Hence, one can start with all vertices in the sleeping state and choose any one of them. During the search, whenever there are no more active vertices to be processed, the search of one component is finished. One can then choose an arbitrary sleeping vertex and continue likewise. The algorithm terminates as soon as there are no more sleeping vertices remaining.

**13.E.11.** Four players are given two cards each from a pack consisting of four Aces and four Kings. What is the probability that at least one of the players is given a pair of Aces? Express the result as a ratio of two-digit integers. ◻

**13.E.12.** Alex owns two special dice: one of them has only 6's on its sides. The other one has two 4's, two 5's, and two 6's. Martin has two ordinary dice. Each of the players throws his dice and the one whose sum is higher wins. What is the probability that Alex wins? Express the result as a ratio of two-digit integers. ◻

**13.E.13.** In how many ways can we place  $n$  rooks on an  $n \times n$  chessboard so that every unoccupied square is guarded by at least one of the rooks?

**Solution.** Clearly, the condition is satisfied if and only if at least one of the following holds: There is at least one rook in each rank (which implies that there must be exactly one rook in each rank—there are  $n^n$  such placements since the particular squares can be selected independently for each rank); or there is at least one rook in each file (again resulting in  $n^n$  placements). However, there are  $n!$  placements which satisfy both (we have  $n$  squares where to put a rook in the first rank,  $n - 1$  squares for the second rank since one of the files is already occupied, etc.). By the inclusion-exclusion principle, the wanted number of placements is:

$$2n^n - n!. \quad \square$$

**13.E.14.** We flip a coin five times. Every time it comes up heads, we put a white ball into a hat. Every time it comes up tails, we put a black ball into the hat. Express the probability that there are more black balls than white ones provided there is at least one black ball.

**Solution.** Let us define the events

- $A$  – there are more black balls than white ones,
- $H$  – there is at least one black ball.

We want to compute  $P(A|H)$ . Clearly, the probability  $P(H^C)$  of the complementary event to  $H$  is  $2^{-5}$ . Further, the probability of  $A$  is the same as the probability  $P(A^C)$ . Therefore,  $P(H) = 1 - 2^{-5}$  and  $P(A) = 1/2$ . Further,  $P(A \cap H) = P(A)$  since the event  $H$  contains the event  $A$  (the event  $A$  implies the event  $H$ ). Altogether, we have obtained

$$P(A|H) = \frac{P(A \cap H)}{P(H)} = \frac{\frac{1}{2}}{1 - (\frac{1}{2})^5} = \frac{16}{31}. \quad \square$$

**F. More advanced problems from combinatorics**

In the first chapter, we met the fundamental methods used in combinatorics. Even using merely these ideas, we are able to solve relatively complicated problems.

◻ **13.2.3. Natural metrics on graphs.** The concept of “path length” is used earlier. This recalls the general idea of distance. The concept of distance in graphs can be built mathematically in this manner.

For an (undirected) graph, define the *distance between vertices*  $v$  and  $w$  to be the number  $d_G(v, w)$ . This is the number of edges on the shortest path from  $v$  to  $w$ . If there is no such path, write  $d_G(v, w) = \infty$ .

For the sake of simplicity, consider only connected graphs  $G$ . The function  $d_G : V \times V \rightarrow \mathbb{N}$  defined as above satisfies the usual three properties of a distance (it is recommended to compare this to the issues from the relevant part of chapter seven, see 7.3.1 (the page 666):

- $d_G(v, w) \geq 0$ , and  $d_G(v, w) = 0$  if and only if  $v = w$ ;
- the distance is symmetric, i.e.  $d_G(v, w) = d_G(w, v)$ ;
- the triangle inequality holds; i.e. for every triple of vertices  $v, w, z$ ,

$$d_G(v, z) \leq d_G(v, w) + d_G(w, z).$$

$d_G$  is a *metric on the graph*  $G$ .

Besides these three properties, every such metric on a graph apparently satisfies the following:

- $d_G(v, w)$  is always a non-negative integer;
- if  $d_G(v, w) > 1$ , then there exists a vertex  $z$  distinct from  $v$  and  $w$  such that  $d_G(v, w) = d_G(v, z) + d_G(z, w)$ .

The following is true:

Every function  $d_G$  on  $V \times V$  (for a finite set  $V$ ), satisfying the five properties listed above, allows to define the edges  $E$  so that  $G = (V, E)$  is a graph with metric  $d_G$ .

Prove this yourself as an exercise! (It is quite clear how to construct the corresponding graph. It remains “merely” to show that the given function  $d_G$  could be achieved as the metric on the constructed graph.)

**13.2.4. Dijkstra’s shortest-path algorithm.** One may suspect that the shortest path between a given vertex  $v$  and another given vertex  $w$  can be found by breadth-first searching the graph. With this approach, discuss first the vertices which are reachable with one edge from the initial vertex  $v$ , then those which are two edges distant, and so on. This is the fundamental idea of one of the most often used graph algorithms – the *Dijkstra’s algorithm*<sup>5</sup>.

This algorithm is able to find the shortest paths even in problems from practice, where each edge  $e$  is assigned a *weight*  $w(e)$ , which is a positive real number. When looking for shortest paths, the weights are to represent lengths of the

<sup>5</sup>Edsger Wybe Dijkstra (1930 - 2002) was a famous Dutch computer scientist, being one of the fathers of this discipline. Among others, he is credited as one of founders of concurrent computing. He published the above algorithm in 1959

**13.F.1.** There are  $n$  ( $n \geq 3$ ) fortresses positioned on a circle, numbered 1 through  $n$ . At a given moment, every fortress shoots at one of its neighbors (i. e., fortress 1 shoots at  $n$  or 2, fortress 2 shoots at 1 or 3, etc.). We will refer to the set of hit fortresses as a *result* (i. e., we are only interested in whether each fortress was hit or not; it does not matter whether it was hit once or twice). Let  $P(n)$  denote the number of possible results. Prove that the integers  $P(n)$  and  $P(n + 1)$  are coprime.

**Solution.** First of all, note that a set of hit fortresses is a possible result if and only if no pair of adjacent-but-one fortresses (i. e., whose numbers differ by 2 modulo  $n$ ) is unhit. Therefore, if  $n$  is odd, then  $P(n)$  is equal to the number  $K(n)$  of results where no pair of *adjacent* fortresses is unhit (consider the order  $1, 3, 5, \dots, n, 2, 4, \dots, n - 1$ ). If  $n$  is even, then  $P(n)$  equals  $K(n/2)^2$  since fortresses at even positions and those at odd positions can be considered independently.

We can easily derive the following recurrent formula for  $K(n)$ :  $K(n) = K(n - 1) + K(n - 2)$ . (Well, on the other hand, it is not so trivial... It is left as an exercise for the reader.) Further, we can easily calculate that  $K(2) = 3$ ,  $K(3) = 4$ ,  $K(4) = 7$ , so  $K(2) = F(4) - F(0)$ ,  $K(3) = F(5) - F(1)$ ,  $K(4) = F(6) - F(2)$ , and simple induction argument shows that  $K(n) = F(n + 2) - F(n - 2)$ , where  $F(n)$  denotes the  $n$ -th term of the Fibonacci sequence ( $F(0) = 0$ ,  $F(1) = F(2) = 1$ ). Moreover, since  $(K(2), K(3)) = 1$ , we have for  $n \geq 3$  that (similarly as with the Fibonacci sequence)

$$\begin{aligned} (K(n), K(n - 1)) &= (K(n) - K(n - 1), K(n - 1)) = \\ &= (K(n - 2), K(n - 1)) = \dots = 1. \end{aligned}$$

Now, we are going to show that, for every  $n = 2a$ ,  $P(n) = K(a)^2$  is coprime to both  $P(n + 1) = K(2a + 1)$  and  $P(n - 1) = K(2a - 1)$ . It suffices to realize that for  $a \geq 2$ , we have

$$\begin{aligned} (K(a), K(2a + 1)) &= (K(a), F(2)K(2a) + F(1)K(2a - 1)) \\ &= (K(a), F(3)K(2a - 1) + F(2)K(2a - 2)) = \dots \\ &= (K(a), F(a + 1)K(a + 1) + F(a)K(a)) \\ &= (K(a), F(a + 1)) = (F(a + 2) - F(a - 2), F(a + 1)) \\ &= (F(a + 2) - F(a + 1) - F(a - 2), F(a + 1)) \\ &= (F(a) - F(a - 2), F(a + 1)) \end{aligned}$$

edges. However, in general, the weights may have other meanings: they may stand for profits or costs, network flows, and so on.

The input of the algorithm consists of an edge-weighted graph  $G = (V, E)$  and an initial vertex  $v_0$ . The output consists of the numbers  $d_w(v)$ , which give the least possible sum of the weights of edges along a path from the vertex  $v_0$  to the vertex  $v$ . This procedure works in undirected graphs as well as in directed ones.

In order to ensure the termination and the correctness of the algorithm, it is important that all of the weights are positive – see example 13.B.6. Dijkstra's algorithm needs only a little modification of the general breadth-first search:

- For every vertex  $v$ , keep the information  $d(v)$ , which is an upper bound for the actual distance of  $v$  from the initial vertex  $v_0$ .
- At every stage, the already processed vertices are those for which the shortest path is already known. Then,  $d(v) = d_w(v)$ .
- When some sleeping vertices are to be made active, choose exactly those vertices  $y$  from the set  $Z$  of sleeping vertices for which  $d(y) = \min\{d(z); z \in Z\}$ .

Suppose that the graph  $G$  has at least two vertices. More formally, Dijkstra's algorithm can be described as follows:

#### DIJKSTRA'S ALGORITHM

*Input:* vertex  $v_0$  in the graph  $G = (V, E)$  with weights on all edges.

*Output:* the distances from  $v_0$  within  $G$  associated to all vertices.

- (1) *Initialization step:* Set the values for all  $v \in V$ :

$$d(v) = \begin{cases} 0 & \text{for } v = v_0, \\ \infty & \text{for } v \neq v_0. \end{cases}$$

Set  $Z = V$ ,  $W = \emptyset$ .

- (2) *Cycle condition:* If every vertex  $y \in Z$  is assigned  $\infty$ , the algorithm terminates; otherwise the algorithm continues with another iteration. (In particular, the algorithm terminates if  $Z = \emptyset$ .)

- (3) *Update of the vertex statuses:*

- Find the set  $N$  of those vertices  $v \in Z$  for which  $d(v) = \delta$  is as small as possible:

$$\delta = \min\{d(y); y \in Z\}.$$

- All vertices which have been in  $W$  are removed and marked as processed; the new set of active vertices is  $W = N$ , while all these vertices are removed from  $Z$ , i.e. they are no more sleeping.

- (4) *Cycle body:* For each edge  $e \in E_{WZ}$  (i.e. whose tail is an active vertex  $v$  and head is a sleeping vertex  $y$ :

- if  $d(v) + w(e) < d(y)$ , then update  $d(y)$  to  $d(v) + w(e)$ .

Move back to check the cycle condition (step 2).

$$\begin{aligned}
 &= (F(a-1), F(a+1)) = (F(a-1), F(a)) = 1. \\
 &(K(a), K(2a-1)) \\
 &= (K(a), F(2)K(2a-2) + F(1)K(2a-3)) \\
 &= (K(a), F(3)K(2a-3) + F(2)K(2a-4)) \\
 &= \dots = (K(a), F(a)K(a) + F(a-1)K(a-1)) \\
 &= (K(a), F(a-1)) = (F(a+2) - F(a-2), F(a-1)) \\
 &= (F(a+2) - F(a), F(a-1)) \\
 &= (F(a+2) - F(a+1), F(a-1)) = (F(a), F(a-1))
 \end{aligned}$$

This proves the proposition.  $\square$

### G. Probability in combinatorics

Classical probability is tightly connected to combinatorics, as we have already seen in the first chapter. Now, we present another example, which is a bit more complicated.

Combinatorics is hidden even in the following “probabilistic” problem.

**13.G.1.** There are 100 prisoners in a prison, numbered 1 through 100. The chief guard has placed 100 chests (also numbered 1 through 100) into a closed room and randomly put balls with numbers 1 through 100 on them into the chests so that each chest contains exactly one ball. He has decided to play the following game with the prisoners: He calls them one by one into the room and the invited prisoner is allowed to gradually open 50 chests. Then, he leaves without any possibility to talk to the other prisoners, the guard closes all the chests, and another prisoner is let in. The guard has promised to free all the prisoners provided each of them finds the ball with his number in one of the 50 opened chests. However, if any of the prisoners fails to find his ball, all will be executed. Before the game begins, the prisoners are allowed to agree on a strategy. Does there exist a strategy that gives the prisoners a “reasonable” chance of winning?

**Solution.** Clearly, if the prisoners choose to open the chests randomly (where the choices of the particular prisoners are independent), the chance for one prisoner to find his ball is  $1/2$ , so the total probability of success is merely  $1/2^{100}$ . Therefore, it is necessary to look for a strategy where the successes of the prisoners are as dependent as possible. First of all, we should realize that the invited prisoner has no information from other prisoners and does not know the positions of particular balls in the chests. However, once he opens a chest, he knows the ball number it contains and may choose the next chest accordingly. This suggests the following simple strategy: Every prisoner starts with the chest that bears his number. If it contains the corresponding ball, the prisoner succeeds and can open the remaining chests at random. If not, he opens the chest with the number of the found ball. He continues this way until he eventually finds his ball or opens the fiftieth chest. Since every chest “points” at another chest according to the described procedure, let us call this strategy the *pointer strategy*.

**13.2.5. Theorem.** For a given vertex  $v_0$ , the Dijkstra’s algorithm finds the distance  $d_w(v)$  of each vertex  $v$  in  $G$  that lies in the connected component of the vertex  $v_0$ . For the vertices  $v$  of other connected components,  $d(v) = \infty$  remains.

The algorithm can be implemented in such a way that it terminates in time  $O(n \log n + m)$ , where  $n$  is the number of vertices and  $m$  is the number of edges in  $G$ .

**PROOF.** The algorithm is correct, since

- it terminates after a finite number of steps;
- when it does, its output has the desired properties.

The cycle condition guarantees that in each iteration, the number of sleeping vertices decreases by one at least since  $N$  is always non-empty. Therefore, the algorithm necessarily terminates after a finite number of steps.

After going through the initialization cycle,

$$(1) \quad d_w(v) \leq d(v)$$

for all vertices  $v$  of the graph. Now assume that this property holds when the algorithm enters the main cycle and show that it holds when it leaves the cycle as well. Indeed, if  $d(y)$  is changed during step 4, then it is caused by finding a vertex  $v$  such that

$$d_w(y) \leq d_w(v) + w(\{v, y\}) \leq d(v) + w(\{v, y\}) = d(y),$$

where the new value is on the right-hand side.

The inequality (1) is satisfied when the algorithm terminates. It remains to verify that the other inequality holds as well. For this purpose, consider what is actually done in steps 3 and 4 of the algorithm.

Let  $0 = d_0 < \dots < d_k$  denote all (distinct) finite distances  $d_w(v)$  of the vertices in  $G$  from the initial vertex  $v_0$ . At the same time, this partitions the vertex set of the graph  $G$  into clusters  $V_i$  of vertices whose distance from  $v_0$  is exactly  $d_i$ . During the first iteration of the main cycle,  $N = V_0 = \{v_0\}$ , the number  $\delta$  is just  $d_1$ , and the set of sleeping vertices is changed to  $V \setminus V_0$ .

Suppose this holds up to  $j$ -th iteration (inclusive), i.e. the algorithm enters the cycle with  $N = V_j$ ,  $\delta = d_j$ , and  $\bigcup_{i=0}^j V_i = V \setminus N$ . Consider a vertex  $y \in V_{j+1}$ , i.e.  $d_w(y) = d_{j+1} < \infty$ , and there exists a path  $(v_0, e_1, v_1, \dots, v_\ell, e_{\ell+1}, y)$  with total length  $d_{j+1}$ . However, then

$$(2) \quad d_w(v_\ell) \leq d_{j+1} - w(\{v_\ell, y\}) < d_{j+1}.$$

It follows from the assumption that the vertex  $v_\ell$  was active during an earlier iteration of the main cycle, and  $d_w(v_\ell) = d(v_\ell) = d_i$  for some  $i \leq j$  then. Therefore, after the current iteration of the main cycle has been finished,

$$d(y) = d_w(v_\ell) + w(\{v_\ell, y\}) = d_{j+1}$$

and this does not change any more. It follows that the inequality (1) holds with equality when the algorithm terminates.

**Probability of success.** The guard's possible placements of the balls bijectively correspond to permutations of the numbers 1 through 100. In order to find the probability of success, we must realize for which permutations the pointer strategy works. Recall that every permutation can be expressed as the composition of pairwise disjoint cycles. If each prisoner were allowed to open an arbitrary number of chests, he would find his ball as the last one of the corresponding cycle since he begins with the chest with his number, which is pointed at just by the chest with his ball. It follows that the strategy fails if and only if there is a cycle of length greater than 50 because then no prisoner of this cycle finds his ball in time. Thus, we must count the number of such permutations. In general, the probability that a random permutation of length  $n$  contains a cycle of length  $r > n/2$  (there could be more occurrences of shorter cycles; however, there can be at most one cycle of length greater than  $n/2$ , which simplifies the calculation) is as follows: We must choose the  $r$  elements of the cycle, order them, and then choose an arbitrary permutation of the remaining  $n - r$  numbers. This leads to

$$\binom{n}{r} (r - 1)! (n - r)! = \frac{n!}{r}$$

Therefore, the probability that such permutation is selected (among all the  $n!$  permutations) is  $1/r$ . Thus, the probability that our 100 prisoners succeed is

$$1 - \sum_{k=51}^{100} \frac{1}{k} \approx 0.311828$$

As we can see, this is much higher than the original  $1/2^{100}$ . Now, let us look at the behavior of this probability for a general number  $n$  of the prisoners (then, each prisoner is allowed to open at most  $n/2$  chests). In general, the probability that a random permutation of length  $n$  contains a cycle of length greater than  $n/2$  is equal to

$$p = \sum_{k=1+\frac{n}{2}}^n \frac{1}{k}$$

Recall that  $\sum_{k=1}^n \frac{1}{k} \rightarrow \ln(n) + \gamma$  for  $n \rightarrow \infty$ , where  $\gamma$  is Euler's constant. Thus, we have:

The analysis of the main cycle just made also determines a bound for the running time of the algorithm (i.e. the number of elementary operations with the graph and other corresponding objects). The main cycle is iterated as many times as there are (distinct) distances  $d_i$  in the graph. Every vertex, when processed during step 3, is considered exactly once. The vertices that are still sleeping must be sorted. This gives the bound  $O(n \log n)$  for this part of the algorithm provided the graph is stored as a list of vertices and weighted edges, such that the sleeping vertices are kept in a suitable data structure that allows the finding of the set of  $N$  active vertices in time  $O(\log n + |N|)$ . This can be achieved if a heap is used. Every edge is processed exactly once in step 4 since the vertices are active only during one iteration of the cycle.  $\square$

Note that the inequality (2), essential for the analysis of the algorithm, need not hold if the weights of the edges are allowed to be negative.

In practice, many heuristic improvements of the algorithm are applied. For instance, it is not necessary to compute the distance between all vertices if only the distance between a given pair of vertices is of interest. When the vertex is excluded from the active ones, its distance is final.

Further, it is not necessary to initialize the distances with the value of infinity. Of course, this is technically impossible, and a sufficiently large constant would be needed in the implementation.

**13.2.6. Spanning trees.** In practical applications, graphs often encode all possibilities of connections between particular objects, as in road or electrical networks. If it is only required that each pair of vertices is connected by a path, using as few edges as possible, then what is needed is a subgraph  $T$  which is a tree. This corresponds to the problem of finding a type of minimal network.

#### SPANNING TREE OF A GRAPH

**Definition.** Any tree  $T = (V, E')$  in a graph  $G = (V, E)$ ,  $E' \subseteq E$  is called a *spanning tree* of the graph  $G$ .

A graph can have a spanning tree if and only if it is connected.

A spanning tree is connected since all trees are. Conversely, the following algorithm finds a spanning tree for any given connected graph.

$$p = \sum_{k=1}^n \frac{1}{k} - \sum_{k=1}^{\frac{n}{2}} \frac{1}{k} \rightarrow \ln(n) + \gamma - \ln\left(\frac{n}{2}\right) - \gamma = \ln 2, \text{ pro } n \rightarrow \infty$$

Hence it follows that, for large values of  $n$ , the probability of success approaches  $1 - p \simeq 1 - \ln 2 = 0.30685 \dots$ . Now, we are going to show that the pointer strategy is optimal. **Optimality of the pointer strategy.** In order to prove the optimality of the pointer strategy, we merely modify the rules of the game and further define another game.

Consider the following rules: Every prisoner keeps opening the chests until he finds his ball. The prisoners win iff each opens at most 50 chests. Clearly, this modification does not change the probability of success, but it will help us prove the optimality. We will refer to this game as game A.

Now, consider another game (game B) with the following rules: First, prisoner number 1 enters the chest room and keeps opening the chests until he finds his ball. Then, the guard leaves the opened chests as they are and immediately invites the prisoner with the least undiscovered number. The game proceeds this way until all chests are opened. The prisoners win iff none of them opened more than 50 ( $n/2$  in the general case) chests.

Suppose that the guard notes the ball numbers in the order they were discovered by the prisoners. This results in a permutation of the numbers 1 through 100, from which he can see whether the prisoners won or not. The probability of discovering a particular ball is at every moment independent of the selected strategy. There are 100! permutations which correspond to some strategies (no matter whether they are random or sophisticated) since they are merely the orders in which the ball numbers are discovered. In order to compute the probability of success in game B, we should note that any order can be written as the composition of cycles where each cycle contains the ball numbers discovered by a given prisoner. For the sake of clarity, consider a game with 8 prisoners. If the guard has noted the permutation (2, 5, 7, 1, 6, 8, 3, 4), then we can see that the prisoners win since prisoner 1 discovered numbers (2, 5, 7, 1), then prisoner 3 discovered (6, 8, 3), and finally prisoner 4 discovered only his number (4). In this case, we can write: (2, 5, 7, 1, 6, 8, 3, 4)  $\rightarrow$  (2, 5, 7, 1)(6, 8, 3)(4). Further, any such permutation corresponds to a unique order of the numbers 1 through 8. Having any permutation in the cyclic notation, we first rearrange each cycle so that its least number is the last one and then sort the cycles by their last numbers in ascending order. For instance, we have:

$$(7, 5, 8)(2, 4)(1, 6, 3) \rightarrow (6, 3, 1)(4, 2)(8, 7, 5) \rightarrow (6, 3, 1, 4, 2, 8, 7, 5).$$

We have thus constructed a bijection between the winning orders of discovered numbers and the permutations of the numbers 1 through 8 that do not contain a cycle of length greater than 4. It follows that the probability of success in game B is the same as the probability that a random permutation does

SPANNING FOREST ALGORITHM

**Input:** Graph  $G = (V, E)$   
**Output:** A forest  $T = (V, E')$  consisting of spanning trees of the components of  $G$ .

- (1) Sort all edges  $e_0, \dots, e_m \in E$  in any order.
- (2) Start with  $E_0 = \{e_0\}$  and gradually build the sets of edges  $E_i$  so that in the  $i$ -th step add the edge  $e_i$  to  $E_{i-1}$  unless this creates a cycle in the graph  $G_i = (V, E_{i-1} \cup \{e_i\})$ . If this edge creates a cycle, leave  $E_i = E_{i-1}$  unchanged.
- (3) The algorithm terminates if the graph  $G_i = (V, E_i)$  has exactly  $n - 1$  edges at some step  $i$  or if  $i = m$ , and produces the graph  $T = (V, E_i)$ .

If the algorithm terminates for the latter reason, then the graph is not connected and no spanning tree exists (but there are still the spanning trees of all individual components).

**PROOF.** It follows from the rules of the algorithm that the resulting subgraph  $T$  of  $G$  never contains a cycle. Therefore, it is a forest. If the resulting number of edges is  $n - 1$ , then it must be a tree; see theorem 13.1.15.

It remains to show that the connected components of the graph  $T$  have the same sets of vertices as the connected components of the original graph  $G$ : Every path in  $T$  is also a path in  $G$ ; therefore, all vertices that lie in one tree of  $T$  must lie in the same component of  $G$ . If there is a path in  $G$  from  $v$  to  $w$  such that its endpoints lie in different trees of  $T$ , then one of its vertices  $v_i$  is the last one that is in the component determined by  $v$  (in particular,  $v_{i+1}$  does not lie in this component). The corresponding edge  $\{v_i, v_{i+1}\}$  creates a cycle when examined by the algorithm since otherwise, it would be in  $T$ . Since the edges are never removed from  $T$ , there is a path between  $v_i$  and  $v_{i+1}$  in  $T$ , which contradicts the assumptions. Therefore,  $v$  and  $w$  cannot lie in different trees of  $T$ . The number of components of  $T$  is given by the fact that the number of vertices and edges differs by one in every tree. The difference increases by one with every component so if there are  $n$  vertices and  $k$  edges in the forest, then there are  $n - k$  components.  $\square$

**Remark.** As always, the time complexity of the algorithm is of interest. The addition of an edge creates a cycle if and only if its endpoints lie in the same connected component of the forest  $T$  under construction.

Knowledge of the connected components of the current forest  $T$  is helpful. To implement the algorithm, it is needed to unite two equivalence classes of a given equivalence relation on a given set (the vertex set) and to find out whether two vertices are in the same class or not. The union requires time  $O(k)$ , where  $k$  is the number of elements to be united.  $k$  can be bounded from above by  $n$ , the total number of vertices.

However, for each equivalence class it can be noted how many vertices it contains. If, for each vertex, the information to which class it belongs is kept, then the union operation

not contain a cycle of length greater than 4 ( $n/2$  in the general case). This corresponds to the probability of success in the original game using the pointer strategy. Now, this implies an important conclusion for game A. Indeed, the prisoners may apply any strategy from game A to game B as follows: each prisoner behaves like in game A, but he considers open chests to be closed, i. e., if he wants to open a chest which has already been opened, he just “p”asses this move and further behaves as if he had just discovered the ball number in the considered chest. Therefore, any strategy that succeeds for a given placement of the balls in game A must succeed for the same placement in game B as well. Therefore, if there existed a better strategy for game A, we could apply it to game B and obtain a higher chance of winning there. However, this is impossible since all strategies in game B lead to the same probability of success. Therefore, the pointer strategy is better than or equally good as any other strategy.  $\square$

**13.G.2.** In a competition, there are  $m$  contestants and  $n$  officials, where  $n$  is an odd integer greater than two. Each official judges each contestant as either good or bad. Suppose that any pair of officials agree on at most  $k$  contestants. Prove that

$$\frac{k}{m} \geq \frac{n-1}{2n}.$$

Let us look at two possible approaches to this problem.

**Solution.** Let us count the number  $N$  of pairs ( $\{\text{official, official}\}$ , contestant) where the officials are distinct and agree on the contestant. Altogether, there are  $\binom{n}{2}$  pairs of officials, and each pair can agree on at most  $k$  contestants. Therefore,  $N \leq k\binom{n}{2}$ .

Now, let us fix a contestant  $X$  and count the number of pairs of officials who agree on  $X$ . Say that  $x$  officials said  $X$  was good. Then, there are  $\binom{x}{2}$  pairs who agree that  $X$  is good and  $\binom{n-x}{2}$  pairs who agree that  $X$  is bad. Altogether, there are

$$\binom{x}{2} + \binom{n-x}{2} = \frac{x(x-1)}{2} + \frac{(n-x)(n-x-1)}{2}$$

pairs that agree on  $X$ . We have:

$$\begin{aligned} \frac{x(x-1)}{2} + \frac{(n-x)(n-x-1)}{2} &= \frac{2x^2 - 2nx + n^2 - n}{2} = \\ &= \left(x - \frac{n}{2}\right)^2 + \frac{n^2}{4} - \frac{n}{2} \geq \frac{n^2}{4} - \frac{n}{2} = \frac{(n-1)^2}{4} - \frac{1}{4}. \end{aligned}$$

Since  $n$  is odd, the expression  $(n-1)^2/4$  is an integer. Thus, the number of pairs that agree on  $X$  is at least  $(n-1)^2/4$ . Hence  $N \geq m(n-1)^2/4$ . Combining these two inequalities together, we get

$$\frac{k}{m} \geq \frac{n-1}{2n}.$$

**An alternative solution - using probabilities.** Let choose a pair of officials at random. Let  $X$  be the random variable which tells the number of cases when this pair agrees. We are going to prove the contrapositive implication, i. e., if  $\frac{k}{m} < \frac{n-1}{2n}$ , then  $X$  is greater than  $k$  with probability greater than zero, which will be denoted  $P(X > k) > 0$ .

means to relabel the vertices of one of the united classes. If the smaller class is always selected to be relabeled, then the total number of operations of the algorithm is  $O(n \log n+m)$ . (As an exercise, complete the details of these considerations yourself!)

The above reasoning shows that slightly better in time might be achieved, if only the spanning tree of the connected component of a given starting vertex is of interest:

ANOTHER SPANNING TREE ALGORITHM

**Input:**  $G = (V, E)$  with  $n$  vertices and  $m$  edges, vertex  $v \in V$ .

**Output:** The tree  $T$  spanning the connected component of  $v$ .

- (1) Initialize  $T_0 = (\{v\}, \emptyset)$ .
- (2) In the  $i$ -th step, we build the tree  $T_i$  as follows. Look for edges  $e$  which are not in  $T_{i-1}$ , but their tail vertex  $v_e$  is. Take one of them and add it to  $T_{i-1}$ , i.e. add the head vertex to  $V_{i-1}$  and  $e$  to  $E_{i-1}$ .
- (3) The algorithm terminates as soon as no such edge exists. Apparently, the resulting graph  $T$  is connected. The count of its vertices and edges shows that it is a tree.

**PROOF.** The vertices of  $T$  coincide with the vertices of the connected component of the graph  $G$  containing the starting vertex  $v$ .

Suppose there is a path from  $v$  to a given vertex  $w$ . If  $w$  does not lie in  $T$ , then label by  $v_i$  the last of its vertices that lie in  $T$  (just like in the proof of the previous lemma). However, the subsequent edge of the path would have to be added to  $T$  by the algorithm when it terminated, which is a contradiction.

Consequently, this algorithm finds a spanning tree of the connected component that contains a given initial vertex  $v$  in time  $O(n+m)$ .  $\square$

**13.2.7. Minimum spanning tree.** All spanning trees of a given graph  $G$  have the same number of edges since this is a general property of trees. Just as

the shortest path in graphs with weighted edges was found, now spanning trees with the minimum sum of their edges' weights is desired.

**Definition.** Let  $G = (V, E, w)$  be a connected graph whose edges  $e$  are labeled by non-negative weights  $w(e)$ . A *minimum spanning tree* of  $G$  is such that its total weight does not exceed that of any other spanning tree.

This problem has many applications in practice. For instance, networks of electricity, gas, water, etc.

Surprisingly, it is quite simple to find a minimum spanning tree (supposing all edge weights  $w(e)$  of  $G$  are non-negative) by the following procedure<sup>6</sup>:

<sup>6</sup>Joseph Bernard Kruskal (1928 - 2010) was a famous American mathematician, statistician, computer scientist, and psychometrician. There are other famous mathematicians of the same surname - his two brothers and one nephew. Martin David co-invented solitons and surreal numbers, William

Consider the random variables  $X_i$  for  $i = 1, 2, \dots, m$  with codomain  $0, 1$ , denoting whether the pair agrees on the  $i$ -th contestant. Let  $X_i = 1$  when they agree, and let  $X_i = 0$  otherwise. Hence we have:

$$X = X_1 + X_2 + \dots + X_m$$

Using the linearity of expectation, we obtain:

$$E[X] = E[X_1] + E[X_2] + \dots + E[X_m].$$

Now, let us calculate  $E[X_i] = \sum_{x_i \in \{0,1\}} x_i \cdot P(X_i = x_i)$ . Since  $X_i$  can be only 0 or 1, we have directly  $E[X_i] = P(X_i = 1)$ . Let us examine the probability  $P(X_i = 1)$ , i. e., that the officials agree on the  $i$ -th contestant. There are  $\binom{n}{2}$  pairs of officials. Let  $t_i$  denote the number of officials who say the  $i$ -th contestant is good and  $n - t_i$  be the number of those who do not. Then, there are  $\binom{t_i}{2}$  pairs who agree that the  $i$ -th contestant is good and  $\binom{n-t_i}{2}$  pairs who agree on the contrary. Altogether, there are  $\binom{t_i}{2} + \binom{n-t_i}{2}$  pairs that agree on the  $i$ -th contestant. Therefore,

$$E[X_i] = P(X_i = 1) = \frac{\binom{t_i}{2} + \binom{n-t_i}{2}}{\binom{n}{2}}.$$

Hence,

$$E[X] = \sum_{i=1}^m \frac{\binom{t_i}{2} + \binom{n-t_i}{2}}{\binom{n}{2}}.$$

We are going to show that for odd values of  $n$ , we have  $\binom{t_i}{2} + \binom{n-t_i}{2} \geq \frac{(n-1)^2}{4}$ . Rearranging this leads to

$$(n - 2t_i)^2 \geq 1 \Leftrightarrow t_i \leq \frac{n-1}{2} \text{ or } t_i \geq \frac{n+1}{2},$$

which is clearly true since  $\frac{n-1}{2}$  and  $\frac{n+1}{2}$  are adjacent integers.

Using the inequality  $\binom{t_i}{2} + \binom{n-t_i}{2} \geq \frac{(n-1)^2}{4}$ , we obtain:

$$E[X] \geq m \frac{\frac{(n-1)^2}{4}}{\frac{n(n-1)}{2}} = \frac{m(n-1)}{2n}.$$

Thanks to the assumption  $\frac{m(n-1)}{2n} > k$ , we have  $E[X] > k$ , and thus  $P(X > k) > 0$ , which finishes the proof.  $\square$

Further, we demonstrate application of probabilities to an interesting problem.

**13.G.3.** Let  $S$  be a finite set of points in the plane which are in general position (i. e., no three of them lie on a straight line). For any convex polygon  $P$  all of whose vertices lie in  $S$ , let  $a(P)$  denote the number of its vertices and  $b(P)$  the number of points from  $S$  which are outside  $P$ . Prove that for any real number  $x$ , we have

$$\sum_P x^{a(P)} (1-x)^{b(P)} = 1$$

where the sum runs over all convex polygons  $P$  with vertices in  $S$ . (A line segment, a singleton, and the empty set are considered to be a convex 2-gon, 1-gon, and 0-gon, respectively.)

KRUSKAL'S ALGORITHM

*Input:* A graph  $G = (V, E, w)$  with non-negative weights over edges.

*Output:* The minimal spanning trees for all components of  $G$ .

- (1) Sort the  $m$  edges in  $E$  so that  $w(e_1) \leq w(e_2) \leq \dots \leq w(e_m)$ .
- (2) For this order of the edges, call the "Spanning forest algorithm" from the previous subsection.

This is a typical example of the "greedy approach", when maximizing profits (or minimizing expenses) is achieved by choosing always the option which is the most advantageous at each stage.

In many problems, this approach fails since low expenses at the beginning may be the cause of much higher ones at the end. Therefore, greedy algorithms are often a base for very useful heuristic algorithms but seldom yield optimal solutions. However, in the case of minimum spanning tree, this approach works:

**Theorem.** *Kruskal's algorithm finds a minimum spanning tree for every connected graph  $G$  with non-negative edge weights. The algorithm runs in  $O(m \log m)$  time where  $m$  is the number of edges of  $G$ .*

**PROOF.** Let  $T = (V, E(T))$  denote the spanning tree generated by Kruskal's algorithm and, further, let  $\tilde{T} = (V, E(\tilde{T}))$  be an arbitrary minimum spanning tree. The minimality implies that  $\sum_{e \in E(\tilde{T})} w(e) \leq \sum_{e \in E(T)} w(e)$ , so the goal is to show that also  $\sum_{e \in E(T)} w(e) \leq \sum_{e \in E(\tilde{T})} w(e)$ .

If  $E(T) = E(\tilde{T})$ , then nothing further is needed. So assume there exists an edge  $e \in E(T)$  such that  $e \notin E(\tilde{T})$ . From all such edges, choose one, call it  $e$  with weight  $w(e)$  as small as possible.

The addition of  $e$  into  $\tilde{T}$  creates a cycle  $ee_1e_2 \dots e_k$  in  $\tilde{T}$ , and at least one of its edges  $e_i$  is not in  $E(T)$ . The choice of the edge  $e$  implies that if  $w(e_i) < w(e)$ , then the edge  $e_i$  would be among the candidate edges in Kruskal's algorithm after a certain subtree  $T' \subseteq T \cap \tilde{T}$  had been created, so its addition to the gradually constructed tree  $T$  would not create a cycle. Therefore, if  $w(e_i) < w(e)$ , the edge  $e_i$  would be chosen in the algorithm. It follows that  $w(e_i) \geq w(e)$ .

However, now the edge  $e_i$  can be replaced with  $e$  in  $\tilde{T}$  (by the choice of  $e_i$ , this results in a spanning tree again) without increasing the total weight. So the resulting  $\tilde{T}$  is a minimum spanning tree. It differs from  $T$  in fewer edges than before. Therefore, in a finite number of steps,  $\tilde{T}$  is changed to  $T$  without increasing the total weight.  $\square$

**13.2.8. Two more algorithms.** The second algorithm for finding a spanning tree, presented in 13.2.6 also leads to a minimum spanning tree:

was active in statistics, Clyde was a computer scientist too. The above algorithm dates from 1956.

**Solution.** First of all, we prove the wanted equality for  $x \in [0, 1]$ . Let us color a point from  $S$  so that it is white with probability  $x$  and black with probability  $1 - x$  (in other words, we consider a random choice of the size  $|S|$  with the binomial probability distribution  $\text{Bi}(n, x)$  and let us say that success corresponds to white and failure corresponds to black). We can note that for any such coloring, there must exist a polygon such that all of its vertices are white and all points outside are black (this polygon is the convex hull of the white points). The above suggests that the probability that the random choice realizes a polygon with all vertices white and all exterior points black is equal to one. However, we can compute this probability in a different way. The event of a polygon having this property is the union of  $k$  disjoint events, where  $k$  is the number of convex polygons, namely that a given polygon has the desired property (note that the property cannot be shared by different convex polygons). For every given convex polygon  $P$ , the probability that its vertices are white and the points outside it are black is equal to  $x^{a(P)}(1 - x)^{b(P)}$ , where  $a(P)$  is the number of vertices of  $P$  and  $b(P)$  is the number of points from  $S$  outside  $P$ . Since the probability of a union of disjoint events is equal to the sum of the particular events' probabilities, we get

$$\sum_P x^{a(P)}(1 - x)^{b(P)} = 1.$$

This proves the equality for all numbers in the interval  $[0, 1]$ . However, we can also perceive this fact as follows: any real number from the interval  $[0, 1]$  is a root of the polynomial  $\sum_P x^{a(P)}(1 - x)^{b(P)} - 1$ . As we know, a non-zero polynomial over the (infinite) field of real numbers can have only finitely many roots (see 12.3.6). Therefore,  $\sum_P x^{a(P)}(1 - x)^{b(P)} - 1$  is the zero polynomial and the equality  $\sum_P x^{a(P)}(1 - x)^{b(P)} = 1$  thus holds for all real numbers  $x$ .  $\square$

**Remark.** This equality holds even if we define the numbers  $a(P)$  and  $b(P)$  in another way: The definition of  $a(P)$  is the same, but now let  $b(P)$  denote the number of points from  $S$  which are not the vertices of  $P$ . (Thus, we always have  $a(P) + b(P) = |S|$ ). Then, the given equality is a corollary of the binomial theorem for  $(x + (1 - x))^{|S|}$ .

**13.G.4.** A competition with  $n$  players is called an  $(n, k)$ -tournament iff it has  $k$  rounds and satisfies the following:

- i) every player competes in every round and any pair of players competes at most once,
- ii) if  $A$  plays with  $B$  in the  $i$ -th round,  $C$  plays with  $D$  in the  $i$ -th round, and  $A$  plays with  $C$  in the  $j$ -th round, then  $B$  plays with  $D$  in the  $j$ -th round

Find all pairs  $(n, k)$  for which there exists an  $(n, k)$ -tournament.

**Solution.** There exists an  $(n, k)$ -tournament if and only if  $2^{\lceil \log_2(k+1) \rceil}$  divides the integer  $n$ . First of all, we are going to show the if-part. We construct a  $(2^t, k)$ -tournament

JARNÍK-PRIM'S ALGORITHM<sup>7</sup>

*Input:* A connected graph  $G = (V, E, w)$  with  $n$  vertices and  $m$  edges, with non-negative weights over the edges.

*Output:* The minimum spanning tree  $T$  of  $G$ .

- (1) Initialize  $T_0 = (\{v\}, \emptyset)$  with some vertex  $v \in V$ .
- (2) In the  $i$ -th step, look for all edges  $e$  which are not in  $T_{i-1}$ , but their tail vertex  $v_e$  is. Take the one of them with minimal weight and add it to  $T_{i-1}$ , i.e. add the head vertex to  $V_{i-1}$  and  $e$  to  $E_{i-1}$ .
- (3) The algorithm terminates when the number of added edges totals at  $n - 1$ .

The *Borůvka's algorithm* is similar. It constructs as many as possible connected components simultaneously: It begins with the singleton components in the graph  $T_0 = (V, \emptyset)$ . In each step, it connects every component to another component with the shortest edge possible. It is easy to prove that (provided the edge weights are pairwise distinct) this results in a minimum spanning tree.

BORŮVKA'S ALGORITHM

*Input:* A connected graph  $G = (V, E, w)$  with non-negative weights on the edges.

*Output:* The minimum spanning tree for  $G$ .

- (1) *Initialization.* Create the graph  $S$  with the same vertex set as  $G$  and no edges;
- (2) *The main loop.* While  $S$  contains more than one component, do:
  - for every tree  $T$  in  $S$ , find the shortest edge that connects  $T$  to  $G \setminus T$ , and add this edge into  $E$ ,
  - add all edges of  $E$  into the graph  $S$  and clear  $E$ .

Note that Borůvka's algorithm can be executed using parallel computation, which is why it is used in many practical modifications.

The proofs that both of these algorithms are correct, are similar to that of Kruskal's. The details are omitted.

13.2.9. Traveling salesman problem.

So far, our short excursion through graph based algorithms could give the feeling that simple and straightforward algorithms for the considered problems can always be found. So far however, only the easy problems have been considered. In all but very few cases, the contrary is true — mostly there are no algorithms running in polynomial time, so one needs to use algorithms which do not always find the optimal solution but give

<sup>7</sup>Robert Clay Prim (born 1921) is an American mathematician and computer scientist. While he published his work already in the realm of computer science and hence the most common name of the algorithm is "Prim's", earlier works by Otakar Borůvka (1899 - 1995) and Vojtěch Jarník (1897–1970) appeared before those by Prim. The Borůvka's algorithm was designed when consulting the construction of new electricity network in Moravia, a region in central Europe, in 1926, and Jarník published the algorithm (recovered much later by Prim) in 1930, motivated by Brůvka.

where  $k \leq 2^t - 1$  (then, the general case  $2^t \mid n$  can be easily derived from that). There are thus  $2^t$  players in the tournament, so we assign to each player a (unique) number from the set  $\{0, 1, \dots, 2^t - 1\}$ . In the  $i$ -th round, player  $\alpha$  competes with player  $\alpha \oplus i$  (where  $\oplus$  is the binary XOR operation, i. e., the  $j$ -th bit of  $a \oplus b$  is one if and only if the  $j$ -th bit of  $a$  is different from the  $j$ -th bit of  $b$ ). This schedule is correct since every player is engaged in every round and different players have different opponents (for  $\alpha \neq \beta$ , we have  $\alpha \oplus i \neq \beta \oplus i$ ). Further, the opponent of the opponent of  $\alpha$  is indeed  $\alpha$  (since  $(\alpha \oplus i) \oplus i = \alpha$ ). Moreover, the second tournament rule is also satisfied: if  $\alpha$  plays with  $\beta$  and  $\gamma$  plays with  $\delta$  in the  $i$ -th round (i. e.,  $\beta = \alpha \oplus i$  and  $\delta = \gamma \oplus i$ ) and if  $j$  is such that  $\alpha$  plays with  $\gamma$  in the  $j$ -th round, then we have  $\beta \oplus j = (\alpha \oplus i) \oplus j = (\alpha \oplus j) \oplus i = \gamma \oplus i = \delta$ , so  $\beta$  indeed plays with  $\delta$  in the  $j$ -th round. Any  $(2^t \cdot s, k)$ -tournament where  $s$  is odd can be obtained as  $s$  parallelized  $(2^t, k)$ -tournaments.

Now, we are going to show that the condition  $2^{\lceil \log_2(k+1) \rceil} \mid n$  is necessary as well. Consider the graph  $G_i$  whose vertices correspond to the players and edges are between the pairs who have played in or before the  $i$ -th round. Consider players  $A$  and  $B$  who play together in round  $i + 1$ . We want to show that we must have  $|T| = |\Delta|$  where  $T$  is the component of  $A$  and  $\Delta$  is the component of  $B$ . Actually, we show that any player of  $T$  competes with a player of  $\Delta$  in round  $i + 1$ . Thus, let  $C \in T$ , i. e., in  $G_i$ , there exists a path  $A = X_1, X_2, \dots, X_m = C$  such that  $X_j$  has played with  $X_{j+1}$ ,  $j = 1, \dots, m - 1$ , in or before the  $i$ -th round. Consider the sequence  $Y_1, Y_2, \dots, Y_m$ , where  $Y_k$  is the opponent of  $X_k$  in round  $i + 1$ ,  $k = 1, \dots, m$  (thus  $Y_1 = B$ ). Then, for any  $1 \leq j \leq m - 1$ , we have that  $X_j$  competes with  $Y_j$  and  $X_{j+1}$  competes with  $Y_{j+1}$  in round  $i + 1$  (by the definition of the sequence  $Y_1, \dots, Y_m$ ) and in a certain  $r$ -th round ( $1 \leq r \leq i$ ),  $X_j$  played with  $X_{j+1}$  (by the definition of the sequence  $X_1, \dots, X_m$ ). However, by the second tournament rule, this means that  $Y_j$  also played with  $Y_{j+1}$  in the  $r$ -th round, so the edge  $Y_j Y_{j+1}$  is contained in  $G_i$  for any  $1 \leq j \leq m - 1$ . Thus,  $Y_1, Y_2, \dots, Y_m$  is a path in  $G_i$ , so  $B = Y_1$  and  $Y_m$  lie in the same component ( $\Delta$ ). It can be deduced analogously that any player from  $\Delta$  competes with a player of  $T$  in round  $i + 1$ , and since every player plays exactly once in a given round, we must have  $|T| = |\Delta|$ . By the definition of a component, the component of  $A$  in  $G_{i+1}$  is equal to  $T \cup \Delta$ . Then, we have either  $T = \Delta$  (then, the component of  $A$  in  $G_{i+1}$  is  $T$ ), or  $T \cap \Delta = \emptyset$  (in this case, the component of  $A$  in  $G_{i+1}$  is the disjoint union  $T \cup \Delta$ ). Altogether, the component of  $A$  in  $G_{i+1}$  is either the same or twice as great as in  $G_i$ . Now, consider the components  $T_1, T_2, \dots, T_k$  of  $A$  in the respective graphs  $G_1, G_2, \dots, G_k$ . We have  $|T_1| = 2$  (since  $A$  had exactly one opponent in the first round) and for  $1 \leq i \leq k - 1$ , we have either  $|T_i| = |T_{i+1}|$ , or  $2|T_i| = |T_{i+1}|$ . Therefore, the number of vertices (players) of every component is a power of two, i. e.,  $|T_k| = 2^l$  for some  $l$ , and  $T_k \geq k + 1$  ( $A$  had different opponents in the  $k$  rounds). Hence,  $2^l \geq k + 1$ , i.

one which is as good as possible. This is called a heuristic approach.

One of the most important combinatorial problems of this class is the problem of finding a minimum Hamiltonian cycle. This is a Hamiltonian cycle with the minimum sum of the weights of its edges among all Hamiltonian cycles.

This problem arises in many practical applications. For instance:

- goods or post delivery (via a given network)
- network maintenance (electricity, water pipelines, IT, etc.)
- request processing (parallel requests for reading from a hard disk, for instance),
- measuring several parts of a system (for example, when studying the structure of a protein crystal using X-rays, the main expenses are due to the movements and focusing for particular measurements),
- material division (for instance, when covering a wall with wallpaper, one tries to keep the pattern continuous while minimizing the amount of unused material)).

The greedy approach can be applied in case of looking for a minimum Hamiltonian cycle as well. The algorithm begins in an arbitrary vertex  $v_1$ , which is set active, and the other vertices are labeled as sleeping. For each step, it examines the sleeping vertices adjacent to the active one and selects the one which is connected by the shortest edge. The active vertex is labeled as processed, and the selected vertex becomes active. The algorithm terminates either with a failure, when there is no edge going from the active vertex to a sleeping one, or it successfully finds a Hamiltonian path. In the latter case, if there exists an edge from the last vertex  $v_n$  to  $v_1$ , a Hamiltonian cycle is obtained.

This algorithm seldom produces a minimal Hamiltonian cycle. At least, it always finds some (and relatively small) Hamiltonian cycle in a complete graph.

**13.2.10. Flow networks.** Another group of applications of the language of graph theory concerns moving some amount of a measurable material in a fixed network. The vertices of a directed graph represent places between which one transports material up to predetermined limits which are given as assessments of the edges (called capacities). There are two important types of vertices: *the sources and sinks of the network*. A network is a directed graph with valued edges, where some of the vertices are labeled as sources or sinks.

Without loss of generality, assume that the graph is directed and has only one source and one sink: In the general case, an artificial source and a sink can always be added, connected with directed edges to the original sources and sinks. Then the capacities of the added edges would cover all maximum capacities of the particular sources and sinks. The situation is depicted in the diagram. There, the black vertices on the left correspond to the given sources, while the black vertices on the right stand for the given sinks. On the left,

e.,  $2^l$  is at least  $2^{\lceil \log_2(k+1) \rceil}$ , so the number of players in each component is divisible by  $2^{\lceil \log_2(k+1) \rceil}$ . Thus, so must be the total number  $n$ .  $\square$

**H. Combinatorial games**

**13.H.1.** Consider the following game for two players: On the table, there are four piles of 9, 10, 11, and 14 tokens, respectively. Players alternate moves where the move consists of selecting one of the piles and removing an arbitrary (positive) number of tokens from that pile. The player who takes the last token wins. Is there a winning strategy for one of the players?

**Solution.** Note that this game is the sum of four games which correspond to one-pile games where an arbitrary (positive) number of tokens can be removed (the sum of combinatorial games is both commutative and associative, so we can talk just about the sum of those games without having to specify the order). A simple induction argument shows that the value of the Sprague-Grundy function (the *SG-value*) of such one-pile game is equal to the number of tokens: Suppose that a natural number  $n$  is such that for all  $k < n$ , the *SG-value* of the game with  $k$  tokens is  $k$ . According to the rules of the game, we can remove an arbitrary (positive) number of tokens, i. e., we can leave there an arbitrary number from 0 to  $n - 1$ . By the induction hypothesis, this means that for any number  $k < n$ , we can reach a position whose *SG-value* is  $k$ , and we cannot reach a position whose *SG-value* would be  $n$ . By the definition of the *SG-function*, the value of the game with  $n$  tokens is  $n$ . It follows from the theorem of subsection 13.2.16 that the *SG-value* of the initial position of our game is equal to the xor of the initial positions of the particular games, namely

$$9 \oplus 10 \oplus 11 \oplus 14 = 6.$$

Since this value is non-zero, there exists a winning strategy for the first player: he always moves to a position whose *SG-value* is zero—such a position must exist by the definition of the *SG-function*. For instance, the first move would be to remove 6 tokens from the pile containing 14. (We look at the highest one in the binary expansion of the *SG-value* and find a pile where the corresponding bit is also one. Then, we set this bit to zero—thereby surely decreasing the number of tokens—and adjust the lower bits so that there would be an even number of ones in each position, resulting in zero *SG-value*.)  $\square$

**13.H.2.** Consider the following game for two players: On the table, there is a pile of tokens. Players alternate moves where the move consists of either splitting one pile into two (non-empty) piles or removing an arbitrary (positive) number of tokens from a pile. The player who takes the last token wins. Find the *SG-value* of the initial position of this game if the pile contains  $n$  tokens.

there is an artificial source (a white vertex), and there is an artificial sink on the right. The edge values are not shown in the diagram.

FLOW NETWORKS

A network is a directed graph  $G = (V, E)$  with a distinctive vertex  $z$ , called the *source*, and another distinctive vertex  $s$ , called the *sink*, together with a non-negative assessment of the edges  $w : E \rightarrow \mathbb{R}$ , which represents their *capacities*. A *flow* in a network  $S = (V, E, z, s, w)$  is an assessment of the edges  $f : E \rightarrow \mathbb{R}$  such that, for each vertex  $v$  except for the source and the sink, the total input is equal to the total output, i.e.

$$\sum_{e \in IN(v)} f(e) = \sum_{e \in OUT(v)} f(e).$$

This rule is often called the Kirchhoff's law (referring to the terminology used in physics).

The *size of a flow*  $f$  is given by the total balance of the source values

$$|f| = \sum_{e \in OUT(z)} f(e) - \sum_{e \in IN(z)} f(e).$$

It follows directly from the definition that the size of a flow  $f$  can also be computed as

$$|f| = \sum_{e \in IN(s)} f(e) - \sum_{e \in OUT(s)} f(e).$$

The left hand part of the following diagram shows a simple network with the source in the white circled vertex and the sink in the black bold vertex. The labels over the edges determine the maximal capacities. Looking at the sum of the capacities that enter the sink, the maximum flow in this network is 5 (the sum of the capacities leaving the source is larger).

**13.2.11. Maximum flow problem.** The next task is to find the maximum possible flow for a given network on a graph  $G$ . The right hand side of the above diagram shows a flow of size five, and the size of any flow cannot exceed this. The fundamental principle is that the capacities of a set of edges

**Solution.** We are going to prove by induction that any positive integer  $k$  satisfies:

$$g(4k + 1) = 4k + 1$$

$$g(4k + 2) = 4k + 2$$

$$g(4k + 3) = 4k + 4$$

$$g(4k + 4) = 4k + 3$$

Clearly, we have  $g(0) = 0$ . The following picture shows how we can deduce the value of the  $SG$ -function for one-, two-, and three-token piles. However, it is apparent that this would be much harder for a general number of tokens.

Now, assume that the above is satisfied for all positive integers below  $4k + 1$  and let us prove that we indeed have  $g(4k + 1) = 4k + 1$ . By the definition, the  $SG$ -value is the least non-negative integer  $l$  such that there is no move to a position with  $SG$ -value  $l$ . Moreover, this property (including that the terminal positions have zero value) determine the Sprague-Grundy function uniquely. Therefore, it suffices to prove that, for each  $l < 4k + 1$ , we can move to a position with  $SG$ -value  $l$ , and that we cannot get into a position with  $SG$ -value  $4k + 1$ . The former is clear since by the induction hypothesis, the  $SG$ -values of one-pile games of  $0, 1, \dots, 4k$  tokens take all the integers  $0, 1, \dots, 4k$  (although not in this order), so we can just remove the corresponding number of tokens from the pile. Now, we are going to show that we cannot reach a position with  $SG$ -value  $4k + 1$ : We already know that the only moves that could possibly lead to this  $SG$ -value are to split the pile into two. If we examine the resulting amounts modulo 4, there are two possibilities: either the number of tokens in one of the resulting piles is divisible by 4 ( $4a$ ) and the other one leaves remainder 1 ( $4b+1$ ), or the numbers leave remainders 2 and 3, respectively. As for the former case, the  $SG$ -values of the resulting piles are, by the induction hypothesis,  $4a - 1$  and  $4b + 1$  (the numbers of tokens in the particular piles are non-zero and less than  $4k+1$ , so we may use the induction hypothesis. In the latter case, i.

through which each path from  $z$  to  $s$  must go have to be added up. In the diagram, there are three such choices providing the limits 12, 8, 5 (from left to right). At the same time, in such a simple case the flow that realizes the maximal possible value is easily found. This idea can be formalized as follows:

CUT IN A NETWORK

A *cut in a network*  $S = (V, E, z, s, w)$  is a minimal set of edges  $C \subseteq E$  such that when these edges are removed, there remains no path from the source  $z$  to the sink  $s$  in the graph  $G = (V, E \setminus C)$ . The number

$$|C| = \sum_{e \in C} w(e)$$

is called the *capacity of the cut*  $C$ .

Clearly, there is no flow whose size is greater than the capacity of a cut. We present the *Ford-Fulkerson algorithm*<sup>8</sup>, which finds a cut with the minimum possible capacity as well as a flow which realizes this value. This proves the following theorem:

**Theorem.** In any network  $S = (V, E, z, s, w)$ , the maximum size of a flow equals the minimum capacity of a cut in  $S$ .

The idea of the algorithm is quite simple. It looks for paths between the vertices of the graph, trying to “saturate” them with the flow. For this purpose, define the following terminology:

An undirected path from the vertex  $v$  to the vertex  $v'$  in a network  $S = (V, E, z, s, w)$  is called *unsaturated* if and only if all edges  $e$  directed along the path from  $v$  to  $v'$  satisfy  $f(e) < w(e)$  and the edges  $e$  in the other direction satisfy  $f(e) > 0$  (sometimes, one tries to saturate the flow in the other direction; yielding a *semipath*, or the *augmenting semipath*). The *residual capacity* of an edge  $e$  is the number  $w(e) - f(e)$  if the edge is directed from  $v$  to  $w$ , and it is the number  $f(e)$  otherwise. The residual capacity of a path is defined to be the minimum residual capacity of its edges. For the sake of simplicity, assume that all the edge capacities are rational numbers.

<sup>8</sup>Ford, L. R.; Fulkerson, D. R. (1956). "Maximal flow through a network". Canadian Journal of Mathematics 8: 399–404.

e., if we split the pile into  $4a+2$  and  $4b+3$  tokens, we get that their  $SG$ -values are  $4a + 2$  and  $4b + 4$ . Furthermore, a two-pile game is the sum of the two corresponding one pile-games, so the  $SG$ -value of the two-pile game is the xor (nim-sum) of the amounts. In both cases, the  $SG$ -value leaves remainder 2 upon division by 4 (consider the last two bits). In particular, it is surely not equal to  $4k + 1$ . This proves the induction step for positive integers of the form  $4k + 1$ .

The proof for integers of the form  $4k + 2$  is analogous. The situation is more amazing in the  $4k + 3$  case: Similarly as above, it follows from the induction hypothesis that the  $SG$ -values of the one-pile positions we can move to exhaust all the non-negative integers up to  $4k + 2$ . However, note that if we split the pile into two containing 1 and  $4k + 2$  tokens, respectively, then their  $SG$ -values are also 1 and  $4k+2$  by the induction hypothesis, and the xor of these integers is  $4k + 3$ . It remains to prove that there is no move into a position with  $SG$ -value  $4k + 4$ : Again, the only remaining possibility is to split the existing pile. Then, the resulting remainders modulo 4 are either 0 and 3, or 1 and 2. By the induction hypothesis the remainders of the corresponding  $SG$ -values are respectively 3 and 0 in the former case, and 1 and 2 in the latter. In either case, the xor of these integers (and thus the  $SG$ -value of the resulting position) leaves remainder 3, so it is not equal to  $4k + 4$ . This proves the induction step for positive integers of the form  $4k + 3$ . The proof for integers of the form  $4k + 4$  is analogous.  $\square$

**I. Generating functions**

**13.I.1.** In how many ways can we buy 12 packs of coffee if we can choose from 5 kinds?

Further, solve this problem with the following modifications:

- i) we want to buy at least 2 packs of each kind;
- ii) we want to buy an even number of packs of each kind;
- iii) there are only 3 packs of one of the kinds.

**Solution.** The basic problem is a classical example of a combinatorial problem on the number of 5-combinations with repetition—the answer is  $\binom{12+5-1}{5-1} = \binom{16}{4}$ . The modifications can also be solved by combinatorial reasonings with a bit of invention. However, we want to demonstrate how these problems can be solved (almost without no need to think) using generating functions.

The wanted number corresponds to the coefficient at  $x^{12}$  in the expansion of the function

$$(1 + x + x^2 + \dots)^5 = (1 + x + \dots)(1 + x + \dots) \dots (1 + x + \dots)$$

into a power series. The number of packs of the first kind determines which term is selected from the first parenthesis, and similarly for the other kinds. (Note that we need not pay special attention to that fact that there cannot be more than 12 packs of a given kind – it turns out that infinite series are usually simpler to work with than finite polynomials.)

**FORD-FULKERSON ALGORITHM**

*Input:* A network  $S = (V, E, z, s, w)$ .

*Output:* A maximal possible flow  $f : E \rightarrow \mathbb{R}$  and a minimal cut  $C$ , which is given by those edges which lead from the set  $U \subseteq V$  of those vertices to which there exists an unsaturated path, to  $V \setminus U$ .

- (1) *Initialization:* Set  $f(e) = 0$  for each edge  $e \in E$ , and using depth-first search from  $z$ , find the set  $U \subseteq V$  of those vertices to which there exists an unsaturated path.
- (2) *The main loop:* While  $s \in U$ , do
  - select an unsaturated path  $P$  from the source  $z$  to the sink  $s$ ; then increase the flow  $f$  along all edges of the path  $P$  by the value of the residual capacity of  $P$ .
  - update  $U$ .

**PROOF.** As seen, the size of any flow cannot exceed the capacity of any cut. Therefore, it suffices to show that when the algorithm terminates, the capacity of the generated cut equals the size of the constructed flow.

The algorithm terminates in the first moment when there is no unsaturated path from the source  $z$  to the sink  $s$ . This means that  $U$  does not contain  $s$  and for all edges  $e$  from  $U$  and ending outside of  $U$ ,  $f(e) = w(e)$  (otherwise, the other endpoint of  $e$  would be added to  $U$  when updating  $U$ ).

For the same reason, all edges  $e$  leading from  $V \setminus U$  to  $U$  must have  $f(e) = 0$ .

Clearly, at each beginning of the main loop the total size of the flow satisfies

$$|f| = \sum_{\text{edges from } U \text{ to } V \setminus U} f(e) - \sum_{\text{edges from } V \setminus U \text{ to } U} f(e)$$

However, when the algorithm terminates, this expression equals to the capacity of the final cut  $C$  which is the desired result.

It remains to show that the algorithm always terminates. Since the edges are assumed assessed with rational numbers, it can be assumed by rescaling that the capacities are integers. Then every flow constructed during the run of the algorithm has integer size. In addition, every iteration of the main loop increases the size of the flow. However, since any cut bounds the maximum size of any flow from above, the algorithm must terminate after a finite number of steps.  $\square$

Since

$$\frac{1}{1-x} = 1 + x + x^2 + \dots$$

(see 13.4.3), the function we are considering is  $(1-x)^{-5}$ . Our task is thus to expand  $(1-x)^{-5}$  into a power series. By the generalized binomial theorem, from 13.4.3, the coefficient at  $x^k$  is the number  $\binom{k+5-1}{5-1}$ , which is  $\binom{16}{4}$  in our case. Note that using generating functions, we have answered the question not only for 12, but rather for an arbitrary number of packs of coffee.

The modifications can be solved analogously:

- i) The generating function is

$$(x^2 + x^3 + \dots)^5 = \left(\frac{x^2}{1-x}\right)^5 = \frac{x^{10}}{(1-x)^5},$$

hence the coefficient at  $x^{12}$  is equal to  $\binom{2+5-1}{5-1}$ .

- ii) An even number of each kind corresponds to the generating function

$$(1 + x^2 + x^4 + \dots)^5 = \frac{1}{(1-x^2)^5}.$$

The coefficient at  $x^{12}$  can be found by many means; the easiest one seems to be the substitution  $y = x^2$  and looking for the coefficient at  $y^6$  (which can be perceived as joining the packs into pairs in the shop). This leads to the answer  $\binom{6+5-1}{5-1}$ .

- iii) In this case, the generating function equals

$$(1 + x + x^2 + x^3)(1 + x + x^2 + \dots)^4,$$

and the wanted result is thus

$$\binom{12+4-1}{4-1} + \binom{11+4-1}{4-1} + \binom{10+4-1}{4-1} + \binom{9+4-1}{4-1}.$$

**13.I.2.** In how many ways can we use the coins of values 1, 2, 5, 10, 20, and 50 crowns to pay exactly 100 crowns?

**Solution.** We are looking for non-negative integers  $a_1, a_2, a_5, a_{10}, a_{20}$ , and  $a_{50}$  such that  $a_i$  is a multiple of  $i$  for all  $i \in \{1, 2, 5, 10, 20, 50\}$  and, at the same time,  $a_1 + a_2 + a_5 + a_{10} + a_{20} + a_{50} = 100$ . We can see that the wanted number of ways can be obtained as the coefficient at  $x^{100}$  in the product

$$\begin{aligned} &(1 + x + x^2 + \dots)(1 + x^2 + x^4 + \dots)(1 + x^5 + x^{10} + \dots) \\ &\cdot (1 + x^{10} + x^{20} + \dots)(1 + x^{20} + x^{40} + \dots) \\ &\cdot (1 + x^{50} + x^{100} + \dots) = \\ &= \frac{1}{1-x} \cdot \frac{1}{1-x^2} \cdot \frac{1}{1-x^5} \cdot \frac{1}{1-x^{10}} \cdot \frac{1}{1-x^{20}} \cdot \frac{1}{1-x^{50}}. \end{aligned}$$

The result can be obtained using the software of SAGE, for instance (the names of the used commands are pretty self-descriptive, aren't they?):

```
sage : f=1/(1-x)*1/(1-x^2)*1/(1-x^5)\
      *1/(1-x^10)*1/(1-x^20)*1/(1-x^50)
sage : r=taylor(f,x,0,100)
sage : r.coeff(x,100)

4562
```

The run of the algorithm is illustrated in two diagrams. On the left, there are two shortest unsaturated paths from the source to the sink in gray (the upper one has two edges, while the lower one has three). On the right, another path is saturated (taking the first turn in the upper path), also drawn in gray. Now, it is apparent that there can be no other unsaturated path from the source to the sink. Therefore, the algorithm terminates at this moment.

**13.2.12. Further remarks.** The algorithm allows for further conditions incorporated in the problem. For instance, capacity limits can be set for the vertices of the network as well. There are not only upper limits for the flows along particular edges or through vertices, but also lower ones.

It is easy to add vertex capacities – just double every vertex (one for the incoming edges, the other for the outgoing edges), connecting each pair with an edge of the corresponding capacity.

The lower limits for the flow can be included in the initialization part of our algorithm. However, one needs to check whether such a flow exists at all. Many other variations can be found in literature.

On the other hand, the algorithm does not necessarily terminate if the edge capacities are irrational. Moreover, the flows that are constructed during the run may not even converge to the optimal solution in such a case. However, it still holds that if the algorithm terminates, then a maximum flow is found.

If the capacities are integers (equivalently rational numbers), the running time of the algorithm can be bounded by  $O(f|E|)$ , where  $f$  is the size of a maximum flow in the network and  $|E|$  is the number of edges. The worst case occurs if every iteration increases the size of the flow by one.

In the proof of correctness, no explicit way of searching the graph when looking for an unsaturated path is used. Another variation of the Ford–Fulkerson algorithm is to use breadth-first search. The resulting algorithm is called Edmonds–Karp, and its running time is  $O(|V|^2|E|)$ .<sup>9</sup> We mention Dinic's algorithm, which simplifies the search for an unsaturated path by constructing the *level graph*, where *augmenting edges* are considered only if they lead between vertices whose distances from the source differ. The time complexity of this algorithm is  $O(|V|^2|E|)$ , which is much better for dense graphs than the Edmonds–Karp algorithm.

**13.2.13. Problems related to flow networks.** A good application of flow networks is the problem of *bipartite matching*. The task is to find a maximum matching in a bipartite graph, i.e. a set of as many edges as possible so that each vertex of the graph is the endpoint of at most one of the selected edges.

<sup>9</sup>Edmonds, Jack; Karp, Richard M. (1972). "Theoretical improvements in algorithmic efficiency for network flow problems". *Journal of the ACM (Association for Computing Machinery)* 19 (2): 248–264. doi:10.1145/321694.321699.

Put some nice example in the other column, e.g. the <https://www.cs.princeton.edu/courses/archive/spring13/cos423/lectures/07DemoFordFulkersonPathological.pdf>

**13.I.3.** Expand the following functions into power series:

- i)  $\frac{x}{x+2}$ ,
- ii)  $\frac{x^2+x+1}{2x^3+3x^2+1}$ .

**Solution.**

i)

$$\begin{aligned} \frac{x}{x+2} &= \frac{x}{2 - (-x)} = \frac{x/2}{1 - (-x/2)} = \\ &= \frac{x}{2} - \frac{x^2}{4} + \frac{x^3}{8} - \dots + \sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{2^n}. \end{aligned}$$

ii) We perform partial fraction decomposition:

$$\begin{aligned} \frac{x^2+x+1}{2x^3+3x^2+1} &= \frac{x^2+x+1}{(x-1)^2(2x+1)} = \\ &= \frac{A}{2x+1} + \frac{B}{x-1} + \frac{C}{(x-1)^2}, \end{aligned}$$

finding out that  $A = B = \frac{1}{3}$  and  $C = 1$ ; hence

$$\begin{aligned} \frac{x^2+x+1}{2x^3+3x^2+1} &= \frac{1/3}{1+2x} - \frac{1/3}{1-x} + \frac{1}{(1-x)^2} = \\ &= \sum_{n=0}^{\infty} \left[ \frac{1}{3} ((-2)^n - 1) + (n+1) \right] x^n \end{aligned}$$

**13.I.4.** Find the generating functions of the following sequences:

- i)  $(1, 2, 3, 4, 5, \dots)$ ,
- ii)  $(1, 4, 9, 16, \dots)$ ,
- iii)  $(1, 1, 2, 2, 4, 4, 8, 8, \dots)$ ,
- iv)  $(9, 0, 0, 2 \cdot 16, 0, 0, 4 \cdot 25, 0, 0, 8 \cdot 36, \dots)$ ,
- v)  $(9, 1, -9, 32, 1, -32, 100, 1, -100, \dots)$ .

**13.I.5.** In how many ways can we buy  $n$  pieces of the following five kinds of fruit if we do not distinguish between particular pieces of a given kind, we need not buy all kinds, and:

- there is no restriction on the number of apples we buy,
- we want to buy an even number of bananas,
- the number of pears we buy must be a multiple of 4,
- we can buy at most 3 oranges, and
- we can buy at most 1 pomelo.

- This is an abstract variation of a quite common problem. For instance, it may be needed to match boys and girls in dancing lessons, provided information about which pairs would be willing to dance together is given.

This problem is easily reduced to the problem of maximum flow. Add an artificial source to the graph and connect it with edges to all vertices of one part of the bipartite graph, while the vertices of the other part are connected to an artificial sink. The capacity of each edge is set to one, and the resulting graph is searched for the maximum flow. Then, the edges that are used in the flow correspond to the selected pairs. Of course, information on which pairs to put together by leaving some of them out, may be included.

Another important application of flow networks is the proof of Menger's theorem (mentioned as a theorem in 13.1.10). It can be understood as follows: Given a directed graph, set the capacity of each edge as well as edge vertex to one. Further, select an arbitrary pair of vertices  $v$  and  $w$ , which are considered to be the source and the sink, respectively. Then, the size of a maximum flow in this graph equals the maximum number of disjoint paths from  $v$  to  $w$  (the paths may share only the source and the sink). Every cut divides  $v$  and  $w$  into different connected components of the remaining graph (since they are chosen to be the source and sink). The desired statements then follow from the fact that the size of a maximum flow equals the capacity of a minimum cut.

**13.2.14. Game trees.** We turn our attention to a very broadly used application of tree structures when analyzing possible strategies or procedures. They can be encountered in the theory of artificial intelligence as well as in the game theory. They play an important role in economics and many other social fields.

This is about *games*. In the mathematical sense, game theory examines models in which one or more players take turns in playing moves according to predetermined and generally known rules. Usually, the moves are assessed with profits or losses for the given player. Then, the task is to find a *strategy* for each player, i.e. an algorithmic procedure which maximizes the profits or minimizes the losses.

We use an extensive description of the games. This means that a complete and finite analysis of all possible states of the game is given, and the resulting analysis gives an exact account about the profits and losses. This is supposing that the other players also play the best moves for them.

A *game tree* is a rooted tree whose vertices are the possible states of the game and they are labeled according to whose turn it is. The outgoing edges of a vertex correspond to the possible moves of the player from that state. This complete description of a game using the game tree may be used for common games like chess, naughts and crosses (known also as tic-tac-toe), etc.

**Solution.** The generating function for the sequence  $(a_n)$  where  $a_n$  is the wanted number of ways to buy  $n$  pieces of fruit is

$$\begin{aligned} & (1 + x + x^2 + \dots)(1 + x^2 + x^4 \dots)(1 + x^4 + x^8 + \dots) \cdot \\ & \cdot (1 + x + x^2 + x^3)(1 + x) = \\ & = \frac{1}{1-x} \cdot \frac{1}{1-x^2} \cdot \frac{1}{1-x^4} \cdot \frac{1-x^4}{1-x} \cdot (1+x) = \\ & = \frac{1}{(1-x)^3}. \end{aligned}$$

By the generalized binomial theorem, we have  $(1-x)^{-3} = \sum_{n=0}^{\infty} \binom{n+2}{2} x^n$ . Therefore, the wanted number of ways satisfies  $a_n = \binom{n+2}{2}$ .  $\square$

**13.I.6.** Using the generalized binomial theorem, prove again the following combinatorial identities:

- $\sum_{k=0}^n \binom{n}{k} = 2^n$ ,
- $\sum_{k=0}^n (-1)^k \binom{n}{k} = 0$ ,
- $\sum_{k=0}^n k \binom{n}{k} = n2^{n-1}$ .

**Solution.** Substituting into the binomial theorem

$$(1+x)^n = \binom{n}{0} + \binom{n}{1}x + \binom{n}{2}x^2 + \dots + \binom{n}{n}x^n$$

the numbers  $x = 1$  and  $x = -1$ , we obtain the first and second identities, respectively. Then, the third one can be obtained by viewing both sides of the binomial theorem “continuously” and using the properties of derivatives.  $\square$

**13.I.7.** In a box, there are 30 red, 40 blue, and 50 white balls. Balls of one color are indistinguishable. In how many ways can we select 70 balls?

**Solution.** The wanted number is equal to the coefficient at  $x^{70}$  in the product

$$(1 + x + \dots + x^{30})(1 + x + \dots + x^{40})(1 + x + \dots + x^{50}).$$

This product can be rearranged to

$$(1-x)^{-3}(1-x^{31})(1-x^{41})(1-x^{51}),$$

whence, using the generalized binomial theorem, we obtain

$$\left( \binom{2}{2} + \binom{3}{2}x + \binom{4}{2}x^2 + \dots \right) (1-x^{31}-x^{41}-x^{51}+x^{72}+\dots).$$

As a simple example, consider a simple variation of the game known as *Nim*.<sup>10</sup>

There are  $k$  tokens on the table (the tokens may be sticks or matches), where  $k > 1$  is an integer, and players take turns at removing one or two tokens. The player who manages to take the last token(s) wins. There is a variation of the game in which the player who is forced to take the last token loses. The tree of this game, including all necessary information about the game, can be constructed as follows:

- The state with  $\ell$  tokens on the table and the first player to move corresponds to the subtree rooted at  $F_\ell$ . The state with the same number of tokens but the second player to move is represented by the subtree rooted at  $S_\ell$ .
- The vertex  $F_\ell$  has  $S_{\ell-1}$  as its left-hand son and  $S_{\ell-2}$  as its right-hand son. Similarly, the sons of the vertex  $S_\ell$  are  $F_{\ell-1}$  and  $F_{\ell-2}$ .
- The leaves are always  $F_0$  or  $S_0$ . (In the variation when the player to take the last token loses, these would be the states  $F_1$  and  $S_1$ .)

Every run of the game starting at root  $F_k$  corresponds to exactly one leaf of the resulting tree. Therefore, the total number  $p(k)$  of possible runs for  $F_k$  is equal to

$$p(k) = p(k-1) + p(k-2)$$

for  $k \geq 3$ , and clearly  $p(1) = 1$  and  $p(2) = 2$ . This difference equation is already considered. It is satisfied by the Fibonacci numbers, which can be computed by an explicit formula (see the subsection on generating functions in the end of this chapter, or the corresponding part about difference equations in chapter three, cf. 3.B.1). A formula is known for the number of possible runs of the game. The number of possible states equals the number of all vertices of the tree. The game always ends in a win of one of the players. We can also consider games where a tie is possible.

**13.2.15. Game analysis.** The tree structure allows an analysis of the game so that an algorithmic strategy for each player can be built. This is done with a simple recursive procedure for assessing the root of a subtree. Each vertex is given a label:  $W$  for vertices where the first player can force a win,  $L$  for those where the first player loses if the other one plays optimally, and, optionally,  $T$  for vertices where optimal play of both players results in a tie. The procedure is as follows:

- (1) The leaves are labeled directly according to the rules of the game (in the case of our Nim, the leaves  $S_0$  are labeled by  $W$ , and the leaves  $F_0$  by  $L$ ).
- (2) Considering the vertex  $F_\ell$ . Label it  $W$  if it has a son who is labeled by  $W$ . If there is no such son, but there is a son labeled by  $T$ , then  $F_\ell$  is given the label  $T$ . Otherwise, i.e. if all sons are labeled by  $L$ , then  $F_\ell$  also gets  $L$ .

<sup>10</sup>The game was given this name by Charles Bouton in his analysis of this type of games from 1901. It refers to the German word “Nimm!”, meaning “Take!”.

Hence, the coefficient at  $x^{70}$  is clearly  $\binom{70+2}{2} - \binom{70+2-31}{2} - \binom{70+2-41}{2} - \binom{70+2-51}{2} = 1061$ .  $\square$

**13.I.8.** Prove that

$$\sum_{k=1}^n H_k = (n+1)(H_{n+1} - 1).$$

**Solution.** The necessary convolution can be obtained as the product of the series  $\frac{1}{1-x}$  and  $\frac{1}{1-x} \ln \frac{1}{1-x}$ . Hence:

$$[x^n] \frac{1}{(1-x)^2} \ln \frac{1}{1-x} = \sum_{k=1}^n \frac{1}{k} (n+1-k),$$

whence the wanted identity follows easily.  $\square$

**13.I.9.** Solve the recurrence

$$\begin{aligned} a_0 &= a_1 = 1, \\ a_n &= a_{n-1} + 2a_{n-2} + (-1)^n. \end{aligned}$$

**Solution.** As always, it may be a good idea to write out a few terms of the sequence (however, this will not help us much in this case; still, it can serve as verification of the result).<sup>2</sup>

Step 1:  $a_n = a_{n-1} + 2a_{n-2} + (-1)^n [n \geq 0] + [n = 1]$ .

Step 2:  $A(x) = xA(x) + 2x^2A(x) + \frac{1}{1+x} + x$ .

Step 3:

$$A(x) = \frac{1+x+x^2}{(1-2x)(1+x)^2}.$$

Step 4:  $a_n = \frac{7}{9}2^n + (\frac{1}{3}n + \frac{2}{9})(-1)^n$ .  $\square$

**13.I.10. Quicksort – analysis of the average case.** Our task is to determine the expected number of comparisons made by Quicksort, a well-known algorithm for sorting a (finite) sequence of elements.

An example of a simple *divide-and-conquer* implementation:

```

if L == []: return []
return qsort ([ x for x in L[1:] if x < L
[0]])
+ L[0:1]
+ qsort ([ x for x in L[1:] if x >= L
[0]])
    
```

It is not too difficult to construct a formula for the number of comparisons (we assume that the particular orders of the sequence to be sorted are distributed uniformly). The following parameters are important for the analysis of the algorithm:

- i) The number of comparisons in the *divide* phase:  $n - 1$ .
- ii) The uniformness assumption: the probability that  $L[0]$  is the  $k$ -th greatest element of the sequence is  $\frac{1}{n}$ .
- iii) The sizes of the sorted subsequences in the *conquer* phase:  $k - 1$  and  $n - k$ .

<sup>2</sup>Despite the statement in *Concrete mathematics*, this sequence can already be found in *The On-Line Encyclopedia of Integer Sequences*.

(3) Similarly, a vertex  $S_\ell$  is labeled  $L$  if it has a son labeled by  $L$ . Otherwise if it has a son labeled by  $T$ , it receives  $T$ . Otherwise (i.e. if it has only  $W$ -sons), it is labeled by  $W$ .

Calling this procedure on the root of the tree gives the labeling of each vertex as well as an optimal strategy for each player:

- The first player tries to move to a vertex labeled by  $W$ ; if this cannot be achieved, he moves to a  $T$ -vertex at least.
- Similarly, the second player tries to move to a vertex labeled by  $L$ ; if this cannot be achieved, he moves to a  $T$ -vertex at least.

The depth of the recursion is given by the depth of the tree. For instance, having a Nim game with  $k$  tokens, the depth is  $k$ .

This analysis is not very useful yet. In order to use it in the mentioned form, the entire game tree is needed for disposal. This can be a great amount of data (for instance, in the case of naughts and crosses on  $3 \times 3$  playground, the corresponding tree has tens of thousands of vertices). Usually, the analysis with game tree is used when only a small part of the whole tree is examined, applying appropriate heuristic methods, and the corresponding part is being created dynamically during the game. This is a fascinating field of the modern theory of artificial intelligence. The details are omitted.

There is a more compact representation of the tree structure for our purposes of complete formal analysis. If the game tree for Nim is drawn, then one state of the game is represented by many vertices which correspond to different histories of the game. However, the strategies depend only on the actual state (i.e. the number of tokens and the player to move) rather than on the history of the game. Therefore, the same game can be described by a graph where for each number of tokens, there is only one vertex, and the whole strategy is determined by identifying who is winning (whether this is the player on move or the other one) Directed edges are used for the description of possible moves and there is then always an acyclic graph.

The example of the game Nim is displayed on the diagram. On the left, there is a complete game tree corresponding to three tokens. The directed graph on the right represents the game with seven tokens. A complete tree for this game would already have 21 leaves, and the number of leaves grows exponentially with the number of tokens.

We thus get the following recurrent formula for the expected number of comparisons:

$$C_n = n - 1 + \sum_{k=1}^n \frac{1}{n} (C_{k-1} + C_{n-k}).$$

It is possible to solve this recurrence (using certain tricks which can be learned to some extent) even without using generating functions.

$$C_n = n - 1 + \frac{2}{n} \sum_{k=1}^n C_{k-1}$$

symmetry of both

$$nC_n = n(n - 1) + 2 \sum_{k=1}^n C_{k-1}$$

multiply by  $n$

$$(n - 1)C_{n-1} = (n - 1)(n - 2) + 2 \sum_{k=1}^{n-1} C_{k-1}$$

the same expression

$$nC_n = (n + 1)C_{n-1} + 2(n - 1)$$

subtracted and rearranged

We have thus obtained a much simpler recurrence:

$$nC_n = (n + 1)C_{n-1} + 2(n - 1).$$

On the other hand, this equation contains non-constant coefficients as well.

We can also note that the recurrence has been simplified to the extent that the values  $C_n$  can be computed iteratively. Nevertheless, it is advantageous to express these values explicitly as a function of  $n$  (or at least to approximate them).

First, we use a slight trick: dividing both sides by  $n(n + 1)$ :

$$\frac{C_n}{n + 1} = \frac{C_{n-1}}{n} + \frac{2(n - 1)}{n(n + 1)}$$

Now, we “expand” this expression (*telescope*, we can also use the substitution  $B_n = C_n/n + 1$ ):

$$\frac{C_n}{n + 1} = \frac{2(n - 1)}{n(n + 1)} + \frac{2(n - 2)}{(n - 1)n} + \dots + \frac{2 \cdot 1}{2 \cdot 3} + \frac{C_1}{2}.$$

Hence

$$\frac{C_n}{n + 1} = 2 \sum_{k=1}^{n-1} \frac{k}{(k + 1)(k + 2)}.$$

This can be summed up using partial fraction decomposition, for instance:  $\frac{k}{(k+1)(k+2)} = \frac{2}{k+2} - \frac{1}{k+1}$ . This leads to

$$\frac{C_n}{n + 1} = 2 \left( H_{n+1} - 2 + \frac{1}{n + 1} \right),$$

whence

$$C_n = 2(n + 1)H_{n+1} - 4(n + 1) + 2$$

( $H_n = \sum_{k=1}^n \frac{1}{k}$  is the sum of the first  $n$  terms of the harmonic progression). At the same time, we can give the bound  $H_n \sim \int_1^n \frac{dx}{x} + \gamma$ , whence

$$C_n \sim 2(n + 1)(\ln(n + 1) + \gamma - 2) + 2.$$

**13.1.11.** Using the generating function  $F(x) = x/(1 - x - x^2)$  for the Fibonacci sequence, find the generating function for the “semi-Fibonacci” sequence  $(F_0, F_2, F_4, \dots)$ .  $\circ$

The individual vertices in the directed acyclic graph on the right-hand side of the diagram indicate the number of tokens left and the information whether the game at that state is won by the player who is to move (letter  $N$  as “next”) or the other one (letter  $P$  as “previous”). Altogether, considering a game with  $k$  tokens, this graph always has only  $k + 1$  vertices. At the same time, there is the complete strategy encoded in the graph: The players always try to move from the current state into a vertex labeled by  $P$  if such one exists.

In fact, every directed acyclic graph can be seen as a description of a game. The initial situations are represented by those vertices which have no incoming edges (there can be none or more of them), and the game ends in leaves, i.e. vertices with no outgoing edges (again, there can be one or more of them).

The strategy for each player can be obtained by a simple recursive procedure as above (for the sake of simplicity, it is assumed that there is no tie):

- The leaves are labeled by  $P$  ( the player who is to move from a leaf loses).
- A non-leaf vertex of the graph is labeled by  $N$  if there is an edge leading to a  $P$ -vertex. Otherwise, it is labeled  $P$ .

In the case of our variation of Nim, the situation is very simple. It follows from the strategy described that the player who is to move loses if and only if the number of tokens is divisible by three.

The games that can be represented by a directed acyclic graph are called *impartial*. These are exactly those games which satisfy:

- in every state, both players choose from the same set of moves;
- the number of possible states is finite;
- the game has “zero sum”, i.e. the better the outcome for one of the players, the worse for the other one.

An example of an impartial game is tic-tac-toe. Although the players use different symbols in this game, they can place them in any of the unoccupied squares. On the other hand, chess is not an impartial game in this sense, since the set of possible moves in every situation depends on the number of pieces the players have at their disposal.

**13.2.16. Sum of combinatorial games.**

The rules of the real classical game Nim are somewhat more complicated: There are three piles of tokens. The move consists of selecting one of the piles and removing an arbitrary (positive) number of tokens from that pile. The player who manages to take the last token wins. There is a variation of the game in which the player who is forced to take the last token loses. If this game is considered with one pile, the situation is easy: The first player takes all the tokens and wins immediately. However, it is not that easy with three piles. Whether the analysis of the one-pile game is of any use for this more complicated game is a good question.

**13.I.12.** The fan of order  $n$  is a graph on  $n + 1$  vertices, which are labeled  $0, 1, \dots, n$ , with the following edges: vertex  $0$  is connected to all other vertices, and for each  $k$  satisfying  $1 \leq k < n$ , vertex  $k$  is connected to vertex  $k + 1$ . How many spanning trees does this graph have?

**Solution.** Denoting by  $v_n$  the wanted number of spanning trees, we clearly have  $v_1 = 1$ , and since the fan of order 2 is the triangle graph  $K_3$ , we have  $v_2 = 3$ . Further, we are going to show that for  $n > 1$ , the following recurrence<sup>3</sup> holds:

$$v_n = v_{n-1} + \sum_{k=0}^{n-1} v_k + 1, \quad v_0 = 0.$$

For a fixed spanning tree of the fan of order  $n$ , let  $k$  be the greatest integer of the set  $\{1, \dots, n - 1\}$  such that the spanning tree contains all edges of the path  $(0, 1, 2, 3, \dots, k)$ . This spanning tree cannot contain the edges  $\{0, 2\}, \dots, \{0, k\}, \{k, k + 1\}$ ; therefore, there are the same number of spanning trees for a fixed  $k$  as in the fan of order  $n - k$  with vertices  $0, k + 1, k + 2, \dots, n$ , i. e.  $v_{n-k}$ . Further, we must count one spanning tree for  $k = n$  and those spanning trees which do not contain the edge  $\{0, 1\}$  (thus they must contain the edge  $\{1, 2\}$ ) – they are obtained from fans of order  $n - 1$  on vertices  $0, 2, \dots, n$ . We have thus obtained the wanted recurrence  $v_n = v_{n-1} + v_{n-1} + v_{n-2} + \dots + v_0 + 1$ .

Now, we have the general formula

$$v_n = v_{n-1} + \sum_{k=0}^{n-1} v_k + 1 - [n = 0],$$

whence the usual procedure for finding the generating function  $V(x)$  of this sequence yields

$$\begin{aligned} V(x) &= x \cdot V(x) + \sum_{n=0}^{\infty} \sum_{k < n} v_k x^n + \frac{1}{1-x} - 1 = \\ &= x \cdot V(x) + \sum_{k=0}^{\infty} \sum_{n > k} v_k x^n + \frac{x}{1-x} = \\ &= \left( \sum_{k=0}^{\infty} v_k x^k \right) \cdot \sum_{n > k} x^{n-k} + \frac{x}{1-x} = \\ &= \left( \sum_{k=0}^{\infty} v_k x^k \right) \cdot \frac{x}{1-x} + \frac{x}{1-x} = V(x) \cdot \frac{x}{1-x} + \frac{x}{1-x} \end{aligned}$$

The solution of the equation  $V(x) = xV(x) + \frac{x}{1-x}V(x) + \frac{x}{1-x}$  is

$$V(x) = \frac{x}{1 - 3x + x^2},$$

whence using the standard method (partial fraction decomposition) or the previous problem leads to the result  $v_n = F_{2n}$ .  $\square$

<sup>3</sup> Using this recurrent formula to calculate more values  $v_n$ , we find out that  $v_3 = 8, v_4 = 21$ , which suggests a hypothesis about connection with the Fibonacci sequence in the form  $v_n = F_{2n}$ . This can be proved easily by induction.

For this purpose, introduce a new concept, the *sum of impartial games*: A situation in the game composed of two simpler games is a pair of possible situations in the particular games. Then, a move consists of selecting one of the two games and performing a move in that game (the other game is left unchanged). Therefore, the sum of impartial games is an operation which assigns to a pair of directed acyclic graphs a new one.

Considering graphs  $G_1 = (V_1, E_1)$  and  $G_2 = (V_2, E_2)$ , its sum  $G_1 + G_2$  is the graph  $G = (V, E)$ , where  $V = V_1 \times V_2$  and

$$E = \{(v_1 v_2, w_1 v_2); (v_1, w_1) \in E_1\} \cup \{(v_1 v_2, v_1 w_2); (v_2, w_2) \in E_2\}.$$

In the case of one game, the vertices can be labeled step-by-step by the letters  $N$  and  $P$  in an upwards manner, according to whether one can get to a  $P$ -vertex along some of the edges. However, in the sum of games, movement along the edges is needed in a much more complicated way. Therefore, finer tools are needed for expressing the reachability of vertices labeled by  $P$  from other vertices.

This needs some preparation which might seem like a strange magic (but the proof of the theorem below shows that all this is quite natural). Define the *Sprague–Grundy function* recursively.  $g : V \rightarrow \mathbb{N}$  on a directed acyclic graph  $G = (V, E)$  as follows:<sup>11</sup>

- (1) for a leaf  $v$ , set  $g(v) = 0$ ;
- (2) for a non-leaf vertex  $v \in V$ , define

$$g(v) = \text{mex}\{g(w); (v, w) \text{ is an edge}\},$$

where the *minimum excluded value* function  $\text{mex}$  is defined on subsets  $S$  of the natural numbers  $\mathbb{N} = \{0, 1, \dots\}$  by

$$\text{mex } S = \min \mathbb{N} \setminus S.$$

The function  $g(v)$  is just the  $\text{mex } S$  operation for the set  $S$  of the values  $g(w)$  over those vertices  $w$  where one can get along an edge from  $v$ .

Note that this definition is correct since, clearly, the formula uniquely defines a function that assigns a natural number to any vertex in the acyclic graph in question.

Yet another operation on the natural numbers is needed. It is the binary XOR operation

$$(a, b) \mapsto a \oplus b,$$

performing the exclusive-or operation bit-wise on the binary expansions of  $a$  and  $b$ . This operation can be considered from the following point of view: Consider the binary expansions of  $a$  and  $b$  to be vectors in the vector space  $(\mathbb{Z}_2)^k$  over  $\mathbb{Z}_2$  (for a sufficiently large  $k$ ), and add them there. The resulting vector is the binary expansion of  $a \oplus b$ .

Now the main result can be formulated:

<sup>11</sup>We are presenting the theory which was developed in combinatorial game theory independently by R. P. Sprague in 1935 and P. M. Grundy in 1939.

**Recursively connected sequences.** Sometimes, we are able to express the wanted number of ways or events only in terms of more mutually connected sequences.

**13.I.13.** In how many ways can we cover a  $3 \times n$  rectangle with  $1 \times 2$  domino pieces? Evaluate this value for  $n = 20$ .

**Solution.** We can easily find out that  $c_1 = 0, c_2 = 3, c_3 = 0$ , and it is reasonable to set  $c_0 = 1$  (this is not merely convention; there is indeed a unique empty covering).

We are looking for a recursive formula—discussing the behavior “on the edge”, we find out that  $c_n = 2r_{n-1} + c_{n-2}$ ,  $r_n = c_{n-1} + r_{n-2}$ ,  $r_0 = 0, r_1 = 1$ , where  $r_n$  is the number of coverings of the rectangle  $3 \times n$  without one of the corner tiles.

The values of  $c_n$  and  $r_n$  for the first few non-negative integers  $n$  are:

$n$	0	1	2	3	4	5	6	7
$c_n$	1	0	3	0	11	0	41	0
$r_n$	0	1	0	4	0	15	0	56

- Step 1:  $c_n = 2r_{n-1} + c_{n-2} + [n = 0]$ ,  $r_n = c_{n-1} + r_{n-2}$ .
- Step 2:

$$C(x) = 2xR(x) + x^2C(x) + 1, \quad R(x) = xC(x) + x^2R(x).$$

- Step 3:

$$C(x) = \frac{1 - x^2}{1 - 4x^2 + x^4}, \quad R(x) = \frac{x}{1 - 4x^2 + x^4}.$$

- Step 4: We can see that both are functions of  $x^2$ . We can thus save much work if we consider the function  $D(z) = 1/(1 - 4z + z^2)$ . Then, we have  $C(x) = (1 - x^2)D(x^2)$ , i. e.,  $[x^{2n}]C(x) = [x^{2n}](1 - x^2)D(x^2) = [x^n](1 - x)D(x)$ , so  $c_{2n} = d_n - d_{n-1}$ .

The roots of  $1 - 4x + x^2$  are  $2 + \sqrt{3}$  and  $2 - \sqrt{3}$ , whence the standard procedure yields

$$c_{2n} = \frac{(2 + \sqrt{3})^n}{3 - \sqrt{3}} + \frac{(2 - \sqrt{3})^n}{3 + \sqrt{3}}.$$

Just like with the Fibonacci sequence, the second term is negligible for large values of  $n$  and is always between 0 and 1. Therefore,

$$c_{2n} = \left\lceil \frac{(2 + \sqrt{3})^n}{3 - \sqrt{3}} \right\rceil.$$

For instance,  $c_{20} = 413403$ . □

**13.I.14.** Using generating functions, find the number of ones in a random bit string.

**Solution.** Let  $B$  the set of bit strings, and for  $b \in B$ , let  $|b|$  denote the length of  $b$  and  $j(b)$  the number of ones in it. The generating function is of the form

$$B(x) = \sum_{b \in B} x^{|b|} = \sum_{n \geq 0} 2^n x^n = \frac{1}{1 - 2x}.$$

SPRAGUE–GRUNDY THEOREM

**13.2.17. Theorem.** Consider a directed acyclic graph  $G = (V, E)$ . Its vertices  $v$  are labeled by  $P$  if and only if  $g(v) = 0$ , where  $g$  is the Sprague–Grundy function.

For any two directed acyclic graphs  $G_1 = (V_1, E_1)$ ,  $G_2 = (V_2, E_2)$  and their Sprague–Grundy functions  $g_1, g_2$ , the Sprague–Grundy function  $g$  of their sum is given by

$$g(v_1 v_2) = g_1(v_1) \oplus g_2(v_2).$$

**PROOF.** The first proposition of the theorem follows directly by induction from the definition of the Sprague–Grundy function  $g$ .

The proof of the other part is more complicated. Let  $(v_1 v_2)$  be a position of the game  $G_1 + G_2 = (V, E)$ , and consider any  $a \in \mathbb{N}_0$  such that  $a < g_1(v_1) \oplus g_2(v_2)$ . There exists a state  $x_1 x_2$  of the game  $G_1 + G_2$  such that  $g(x_1) \oplus g(x_2) = a$  and  $(v_1 v_2, x_1 x_2) \in E$ , and, at the same time, there is no edge  $(v_1 v_2, y_1 y_2) \in E$  such that

$$g_1(y_1) \oplus g_2(y_2) = g_1(v_1) \oplus g_2(v_2).$$

This justifies the recursive definition of the Sprague–Grundy function and proves the rest of the theorem.

To show why, find a vertex  $x_1 x_2$  with a given value  $a < g_1(v_1) \oplus g_2(v_2)$  of the Sprague–Grundy function.

Consider the integer  $b := a \oplus g_1(v_1) \oplus g_2(v_2)$ . Refer to the bit of value  $2^i$  as the  $i$ -th bit of an integer. Clearly,  $b \neq 0$ . Let  $k$  be the position of the highest one in the binary expansion of  $b$ , i.e.  $2^k \leq b < 2^{k+1}$ . This means that the  $k$ -th bit of exactly one of the integers  $a, g_1(v_1) \oplus g_2(v_2)$  is one and that these integers do not differ in higher bits. It follows from the assumption  $a < g_1(v_1) \oplus g_2(v_2)$  that it is the integer  $g_1(v_1) \oplus g_2(v_2)$  whose  $k$ -th bit is one.

Therefore, the  $k$ -th bit of exactly one of the integers  $g_1(v_1), g_2(v_2)$  is one. Assume without loss of generality that it is the integer  $g_1(v_1)$ . Further, consider the integer  $c := g_1(v_1) \oplus b$ . Recall that the highest one of  $b$  is at position  $k$ , so the integers  $c, g_1(v_1)$  do not differ in higher bits and the  $k$ -th bit of  $c$  is zero. Therefore,  $c < g_1(v_1)$ . Then, by the definition of the function value  $g_1(v_1)$ , there must exist a state  $w_1$  of the game  $G_1$  such that  $(v_1, w_1) \in E_1$  and  $g_1(w_1) = c$ . Now,  $(v_1 v_2, w_1 v_2) \in E$  and

$$\begin{aligned} g_1(w_1) \oplus g_2(v_2) &= c \oplus g_2(v_2) = g_1(v_1) \oplus b \oplus g_2(v_2) \\ &= g_1(v_1) \oplus a \oplus g_1(v_1) \oplus g_2(v_2) \oplus g_2(v_2) = a. \end{aligned}$$

This fulfills the first part of our plan.

Further, consider any edge  $(v_1 v_2, y_1 y_2) \in E$  in  $G$ , where  $(v_1, y_1) \in E_1$ , and hence  $v_2 = y_2$ . Suppose that  $g_1(y_1) \oplus g_2(y_2) = g_1(v_1) \oplus g_2(v_2)$ . Then,  $g_1(y_1) \oplus g_2(y_2) = g_1(v_1) \oplus g_2(v_2)$ . Clearly, the terms  $g_2(v_2)$  can be canceled (it is an operation in a vector space), leading to  $g_1(y_1) = g_1(v_1)$ . This contradicts the properties of the Sprague–Grundy function  $g_1$  of the game  $G_1$ . This proves the second part of the theorem. □

The generating function for the number of ones is

$$C(x) = \sum_{b \in B} j(b)x^{|b|}.$$

A string  $b$  can be obtained from the one bit shorter string  $b'$  by adding either a zero or a one, i. e.,  $j(b)$  is the sum of  $j(b')$  ones and  $j(b') + 1$  ones. Therefore,

$$\begin{aligned} C(x) &= \sum_{b' \in B} (1 + 2j(b'))x^{|b'|+1} = \sum_{b' \in B} x^{|b'|+1} + 2 \sum_{b' \in B} j(b')x^{|b'|+1} \\ &= xB(x) + 2xC(x). \end{aligned}$$

Hence

$$C(x) = \frac{x}{(1-2x)^2} = x(1-2x)^{-2}$$

and the  $n$ -th coefficient is  $c_n = 2^{n-1} \binom{-2}{n-1} = n2^{n-1}$ . This number gives the number of ones in strings of length  $n$ , and there are  $b_n = 2^n$  such strings. Therefore, the expected number of ones in such string is  $\frac{c_n}{b_n} = \frac{n}{2}$ , which is, of course, what we have anticipated.  $\square$

**13.I.15.** Find the generating function and an explicit formula for the  $n$ -th term of the sequence  $\{a_n\}$  defined by the recurrent formula

$$\begin{aligned} a_0 &= 1, a_1 = 2 \\ a_n &= 4a_{n-1} - 3a_{n-2} + 1 \text{ for } n \geq 2. \end{aligned}$$

**Solution.** The universal formula which holds for all  $n \in \mathbb{Z}$  is

$$a_n = 4a_{n-1} - 3a_{n-2} + 1 - 3[n = 1].$$

Multiplying by  $x^n$  and summing over all  $n$ , we get the following equation for the generating function:  $A(x) = \sum_{n=0}^{\infty} a_n x^n$ .

Hence, we can express

$$A(x) = \frac{3x^2 - 3x + 1}{(1-x)^2(1-3x)} = \frac{3}{4} \cdot \frac{1}{1-x} - \frac{1}{2} \cdot \frac{1}{(1-x)^2} + \frac{3}{4} \cdot \frac{1}{1-3x}$$

Therefore, the coefficient at  $x^n$  is

$$\begin{aligned} a_n &= \frac{3}{4}(-1)^k \binom{-1}{n} - \frac{1}{2}(-1)^n \binom{-2}{n} + \frac{3}{4}(-3)^n \binom{-1}{n} \\ &= \frac{3}{4} - \frac{1}{2}(n+1) + \frac{3}{4}3^n = d \frac{1-2n+3^{n+1}}{4}. \quad \square \end{aligned}$$

**13.I.16.** Solve the following recurrence using generating functions:

$$\begin{aligned} a_0 &= 1, a_1 = 2 \\ a_n &= 5a_{n-1} - 4a_{n-2} \quad n \geq 2 \end{aligned}$$

**Solution.** The universal formula is of the form

$$a_n = 5a_{n-1} - 4a_{n-2} - 3[n = 1] + [n = 0]$$

Multiplying both sides by  $x^n$  and summing over all  $n$ , we obtain

$$A(x) = 5xA(x) - 4x^2A(x) - 3x + 1.$$

Hence

$$A(x) = \frac{1-3x}{(1-4x)(1-x)} = \frac{2}{3} \cdot \frac{1}{1-x} + \frac{1}{3} \cdot \frac{1}{1-4x}$$

The following useful result is a direct corollary of this theorem:

**Corollary.** A vertex  $v_1v_2$  in the sum of games is labeled by  $P$  if and only if  $g_1(v_1) = g_2(v_2)$ .

For example, if three piles of tokens are combined in the simplified Nim game (it is always allowed to take only one or two tokens), the first player always wins, if all three piles have the same number of tokens, not divisible by three. The individual functions  $g_i(k)$  for the individual piles equal the remainder after dividing  $k$  by 3. It follows that, when summing the first two Nim pile games, the value  $g(v) = 0$  is obtained for the initial position. Summing again with another pile game gives  $g(v) \neq 0$ .

In the original game, the individual piles are described by  $g(k) = k$  (any number of tokens can be chosen, hence the function  $g$  grows in this way). The losing positions are those, where the binary sum of the numbers of tokens is zero. For example, if the two of the initial piles are of equal size, then a simple winning strategy is to remove the third one completely and always make the remaining two equal after the opponent's move.

**Remark.** Further details are omitted in this text. It can be proved that every finite directed acyclic graph is isomorphic to a finite sum of suitably generalized games of Nim.

In particular, the analysis of the simple game and construction of the function  $g$  basically (at least implicitly) gives a complete analysis of all impartial games.

### 3. Remarks on Computational Geometry

A large amount of practical problems consist in constructing or analyzing some finite geometrical objects in Euclidean spaces, mainly in 2D or 3D. This is a very busy area of both applications and research. At the same time, most of the algorithms and their complexity analysis are based on graph theoretical and further combinatorial concepts. We provide several glimpses into this beautiful topic.<sup>12</sup> We discuss convex hulls, triangulations, and Voronoi diagrams and focus on a few basic approaches only.

**13.3.1. Convex hulls.** We start with a simple and practical problem. In the plane  $\mathbb{R}^2$ , suppose  $n$  points  $X = \{v_1, \dots, v_n\}$  are given and the task is to find their convex hull  $CH(X)$ . As learned in the Chapter 4,  $CH(X)$  is given by a convex polygon and it is desired to find it effectively.

First we have to decide how  $CH(X)$  should be encoded as a data structure. Choose the connected list of edges. There is the cyclic list of the vertices  $v_i$  in the polygon, sorted in the counter clock-wise order, together with pointers towards the oriented segments between the consecutive vertices (the

<sup>12</sup>The beautiful book *Computational Geometry, Algorithms and Applications* by de Berg, M., Cheong, O., van Kreveld, M., Overmars, M., published by Springer (1997) can be warmly recommended, <http://www.springer.com/us/book/9783540779735>

and

$$a_n = \frac{2}{3} \binom{-1}{n} + \frac{2}{3} \binom{-1}{n} (-4)^n = \frac{4^n + 2}{3}. \quad \square$$

**13.I.17.** A cash dispenser can provide us with banknotes of values 200, 500, and 1,000 crowns. In how many ways can we pick 7,000 crowns? Use generating functions to find the solution.

**Solution.** The problem can be reformulated as looking for the number of integer solutions of the equation

$$2a + 5b + 10c = 70; \quad a, b, c \geq 0.$$

This number is equal to the coefficient at  $x^{70}$  in the function

$$G(x) = (1+x^2+x^4+\dots)(1+x^5+x^{10}+\dots)(1+x^{10}+x^{20}+\dots)$$

This function is equal to

$$G(x) = \frac{1}{1-x^2} \frac{1}{1-x^5} \frac{1}{1-x^{10}}$$

and since

$$\frac{1-x^{10}}{1-x^5} = 1+x^5 \text{ and } \frac{1-x^{10}}{1-x^2} = 1+x^2+x^4+x^6+x^8,$$

we can transform it into the form

$$G(x) = \frac{(1+x^2+x^4+x^6+x^8)(1+x^5)}{(1-x^{10})^3}.$$

By the binomial theorem, we have

$$(1-x^{10})^3 = \sum_{k=0}^{\infty} (-1)^k \binom{-3}{k} x^{10k}.$$

Therefore,  $G(x)$  equals

$$(1+x^2+x^4+x^5+x^6+x^7+x^8+x^9+x^{11}+x^{13}) \sum_{k=0}^{\infty} (-1)^k \binom{-3}{k} x^{10k}$$

The term  $x^{70}$  can be obtained only as  $7 \cdot 10 + 0$ , i. e., the coefficient at  $x^{70}$  is equal to

$$[x^{70}]G(x) = -\binom{-3}{7} = \binom{3+7-1}{7} = \frac{9 \cdot 8}{2} = 36. \quad \square$$

**13.I.18.** Find the probability of getting exactly  $k$  heads after  $n$  times tossing the coin.

**Solution.** Represent  $H$  outcome as  $x$  and  $T$  as  $y$ . We see that all possible outcomes of  $n$  tosses are represented by expansion of  $f(x) = (x+y)^n$ . The coefficient at  $x^k y^{n-k}$  is the number of outcomes with exactly  $k$  heads. The required probability is, therefore,  $\frac{\binom{n}{k}}{2^n}$ .  $\square$

**13.I.19.** Find the probability of getting exactly  $k$  heads after  $n$  times tossing the coin if the probabilities of a head and a tail equal  $p$  and  $q$ , respectively,  $P + q = 1$ .

**Solution.** Represent  $H$  outcome as  $px$  and  $T$  as  $q$ . We see that all possible outcomes of  $n$  tosses are represented by expansion of  $f(x) = (px + q)^n$ . The coefficient at  $x^k$  is the number of outcomes with exactly  $k$  heads. The required probability is, therefore,  $\frac{p^k q^{n-k} \binom{n}{k}}{2^n}$ .  $\square$

edges). Moreover, there is the list of edges pointing to their tail and head vertices.

There is a simple way, to get  $CH(X)$ . Namely, create the oriented edges  $e_{ij}$  for all pairs  $(v_i, v_j)$  of the points in  $X$ , and decide whether  $e_{ij}$  belongs to  $CH(X)$  by testing whether all the other points of  $X$  are on the left of  $e_{ij}$  (in the obvious sense). It is known already from chapter one, that this is tested in constant time by means of the determinant. Clearly  $e_{ij}$  belongs to  $CH(X)$  if and only if all the latter tests are positive. In the end, the order in which to sort the edges and vertices in the output is found.

This does not look like a good algorithm, since  $O(n^2)$  edges need to be tested against  $O(n)$  points. Hence, cubic time complexity is expected. But there is a strong simple improvement available. Consider the lexicographic order on the points  $v_i$  with respect to their coordinates. Then build the convex hull consecutively and run through the tests only for the edges having the last added vertex as their tail.

GIFT WRAPPING CONVEX HULL ALGORITHM

*Input:* A set of points  $X = \{v_1, \dots, v_n\}$  in the plane.

*Output:* The requested edge list for  $CH(X)$ .

- (1) *Initialization.* Take the smallest vertex  $v_0$  in the lexicographic order with respect to the coordinates, and set  $v_{\text{active}} = v_0$ .
- (2) *Main cycle.*
  - Test edges with tail  $v_{\text{active}}$ , until  $e$  belonging to  $CH(X)$  is found.
  - add  $e$  to  $CH(X)$  and set its head to be the  $v_{\text{active}}$
  - if  $v_{\text{active}} \neq v_0$ , then repeat the cycle.

Obviously, the most left and lowest vertex  $v_0$  in  $X$  is in  $CH(X)$ . Since  $CH(X)$  is a cycle (as a directed graph), the algorithm works correctly. It is necessary to be careful about possible collinear edges in  $CH(X)$  and the lack of robustness of the test for those nearly collinear.

This simple improvement reduces the worst running time of the algorithm to  $O(n^2)$ . The worst case can be obtained if all the points  $v_i$  appear on one circle, and unluckily the right next point is always found as the very last one in partial tests. But the actual running time is much better, at most  $O(ns)$ , where  $s$  is the size of the  $CH(X)$ .

For example, in situations where the distribution of the points in the plane is random with normal distribution (see

**13.I.20.** There are coins  $C_1, \dots, C_n$ . For each  $k$  coin  $C_k$  is biased so that when tossed the probability that it falls heads is  $\frac{1}{2k+1}$ . If  $n$  coins are tossed, what is the probability of an odd number of heads?

**Solution.** Let  $p_k = \frac{1}{2k+1}$  and  $q_k = 1 - p_k$ . The generating function can be written as

$$f(x) = \prod_{i=1}^n (q_i + p_i x) = \sum_{m=0}^n a_m x^m,$$

with  $a_m$  the probability of getting exactly  $m$  heads. Observe that

$$f(1) = \sum a_m = \sum a_{2k} + \sum a_{2k+1}.$$

and

$$f(-1) = \sum a_m (-1)^m = \sum a_{2k} - \sum a_{2k+1}$$

. Hence,

$$\begin{aligned} \sum a_{2k+1} &= \frac{1}{2}(f(1) - f(-1)) = \frac{1}{2}\left(1 - \frac{1}{2n+1}\right) = \frac{n}{n+1}, \\ \text{as } f(1) &= 1 \text{ and } f(-1) = \frac{1}{3} \frac{3}{5} \frac{5}{7} \dots \frac{2n-1}{2n+1} = \frac{1}{2n+1}. \quad \square \end{aligned}$$

**13.I.21.** Let  $n$  be a positive integer. Find the number of polynomials  $P(x)$  with coefficients from the set  $\{0, 1, 2, 3\}$  such that  $P(2) = n$ .

**Solution.** Let  $P(x) = a_0 + a_1x + a_2x^2 + \dots + a_kx^k + \dots$  is such polynomial. Then its coefficients should satisfy the equation

$$a_0 + 2a_1 + 4a_2 + \dots + 2^k a_k + \dots = n$$

with integer coefficients  $0 \leq a_k \leq 3$ . The number of such solutions is given by the coefficient at  $x^n$  in

$$\begin{aligned} f(x) &= (1+x+x^2+x^3)(1+x^2+x^4+x^6)(1+x^4+x^8+x^{12}) \dots \\ &= \prod_{k=0}^{\infty} (1+x^{2^k} + x^{2(2^k)} + x^{3(2^k)}) \\ &= \prod_{k=0}^{\infty} \frac{1-x^{2^{k+2}}}{1-x^{2^k}} = \frac{1}{(1-x)(1-x^2)} \\ &= \frac{1}{4(1-x)} + \frac{1}{2(1-x)^2} + \frac{1}{4(1+x)} = \sum_{n=0}^{\infty} \left(\frac{1}{4} + (-1)^n \frac{1}{4} + \frac{1}{2(n+1)}\right) x^n \end{aligned}$$

Hence, the required coefficient is  $\lfloor \frac{n}{2} \rfloor + 1$ .  $\square$

**13.I.22.** Find the number of subsets of  $\{1, \dots, 2017\}$ , such that the sum of its elements is divisible by 5.

**Solution.** For subset  $S = \{s_1, s_2, \dots, s_k\}$  define  $\sigma(S) = x^{s_1} x^{s_2} \dots x^{s_k}$ . Then

$$\sum_{S \subset \{1, \dots, 2017\}} \sigma(S) = (1+x)(1+x^2) \dots (1+x^{2017}).$$

The coefficient at  $x^n$  in  $f(x)$  is the number of subsets in  $\{1, \dots, 2017\}$  with the sum of its elements being exactly  $n$ . Let  $f(x) = \sum a_n x^n$ . We are looking for the sum  $A_5 = a_0 + a_5 + a_{10} + \dots$ . Let  $\omega_j = \exp(\frac{2j\pi}{5}), j = 0, \dots, 4$  be the 5-th roots of unity with  $\omega_0 = 1$ . Then

$$A_5 = \frac{1}{5}(f(\omega_0) + f(\omega_1) + f(\omega_2) + f(\omega_3) + f(\omega_4)).$$

the chapter 10 for what this means), then it is known that the expected size would be logarithmic.

At the same time, finding  $CH(X)$  for  $X$  distributed on a circle is equivalent to sorting the points along the circle. So the worst time run cannot be better than  $O(n \log n)$  for all algorithms (cf. 13.1.17).

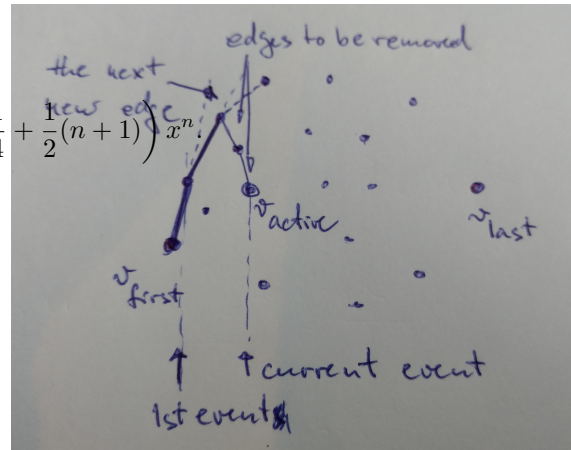

**13.3.2. The sweep line paradigm.** We illustrate several main approaches to computational geometry algorithms for the same convex hull problem.

The latter algorithm is close to the idea of having a special object  $L$  running through all the objects in the input  $X$  consecutively, taking care of constructing the relevant partial output of the algorithm on the run. This is the *event structure* describing all the events needing consideration, and the *sweep line structure* carrying all the information to deal with the individual events. The procedure is similar to the search over a graph discussed earlier. For a shortcut, this may reduce the dimension of the problem (e.g. from 2D to 1D) on the cost of implementing dynamical structures.

To start, initialize the queue of the events and begin dealing with them. At each step, there are the still sleeping events (those further in the queue not yet treated), the current active events (those under consideration) and the already processed ones.

With the  $CH(X)$ , this idea can be implemented as follows. Initialize the lexicographically ordered points  $v_i$  in  $X$ . Notice that the first and last ones necessarily appear in the  $CH(X)$ . This way,  $CH(X)$  splits into the two disjoint chains of edges between them. We call them the upper and the lower convex hulls. Hence the entire construction can be split into the upper convex hull and lower convex hull.

As in the diagram, moving through the events one by one, it is only needed to check, whether the edge joining the last but one active vertex with the current one makes a left or right turn (as usual, right means the clockwise orientation). If right, then add the edge to list, if left, omit the recent edges one by one, until the right turn is obtained.

Obviously  $f(\omega_0) = f(1) = 2^{2017}$ . For  $1 \leq j \leq 4$

$$f(\omega_j) = ((1+\omega_j^0)(1+\omega_j)(1+\omega_j^2)(1+\omega_j^3)(1+\omega_j^4))^{403}(1+\omega_j)(1+\omega_j^2)(1+\omega_j^3)(1+\omega_j^4)$$

Therefore,

$$\sum_{j=1}^4 F(\omega_j) = 2^{403}(4 - 1 - 1 - 1) = 2^{403}.$$

Therefore, the answer is  $\frac{1}{5}(2^{2017} + 2^{403})$ , which is an integer as 2 is the last digit in  $2^{2017}$  and 8 is the last digit in  $2^{403}$ .  $\square$

**13.I.23.** Using generating functions, solve recursive equation

$$a_{k+1} = 2a_k + 4^k, \quad a_1 = 3.$$

**Solution.** From  $a_1 = 2a_0 + 4^0$  follows  $a_0 = 1$ . Multiplying both sides of the recursion by  $x^k$  by summation on  $k$  we obtain

$$\sum_{k=0}^{\infty} a_{k+1}x^k = 2 \sum_{k=0}^{\infty} a_kx^k + \sum_{k=0}^{\infty} 4^kx^k.$$

Therefore, for generating function  $f(x) = \sum_{k=0}^{\infty} a_kx^k$  we have

$$\frac{1}{x} \sum_{k=0}^{\infty} a_{k+1}x^{k+1} = 2f(x) + \sum_{k=0}^{\infty} (4x)^k,$$

that is

$$\frac{1}{x}(f(x) - 1) = 2f(x) + \frac{1}{1 - 4x}.$$

Therefore,

$$f(x) = \frac{1}{1 - 2x} + \frac{x}{(1 - 2x)(1 - 4x)} = \frac{\frac{1}{2}}{1 - 2x} + \frac{\frac{1}{2}}{1 - 4x}.$$

Expanding  $f(x)$ , we obtain:

$$f(x) = \frac{1}{2} \sum_{k=0}^{\infty} (2x)^k + \frac{1}{2} \sum_{k=0}^{\infty} (4x)^k,$$

and so,  $a_k = \frac{1}{2}2^k + \frac{1}{2}4^k$ .  $\square$

**13.I.24.** In how many ways can  $n$  balls be distributed in 4 boxes if the first box has at least two balls.

**Solution.** The generating function for the first box is  $b_1(x) = x^2 + x^3 + x^4 + \dots = \frac{x^2}{1-x}$ . The generating function for each other box is  $b(x) = 1 + x + x^2 + x^3 + \dots = \frac{1}{1-x}$ . For all 4 boxes it has to be  $f(x) = b_1(x)(b(x))^3 = \frac{x^2}{(1-x)^4}$ . The coefficient at  $x^n$  in  $f(x)$  that indicates the number of options to distribute  $n$  balls, equals

$$\binom{n}{n} - 2 + 4 - 1, 4 - 1 = \binom{n}{n} + 1, 3).$$

SWEEP LINE UPPER CONVEX HULL

**Input:** A set of points  $X = \{p_1, \dots, p_n\}$  in the plane.  
**Output:** The directed path  $UCH(X)$ .

(1) *Initialization.*

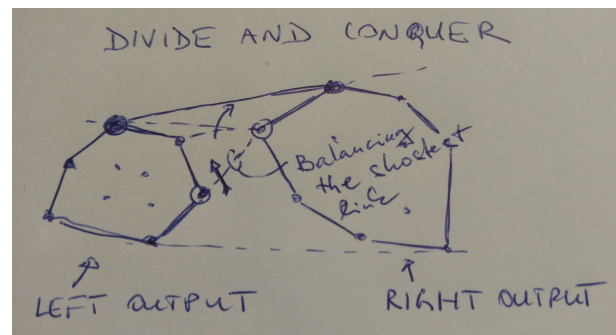

- Set the event structure to be the lexicographically ordered list of points  $v_{\text{first}}, \dots, v_{\text{last}}$ . There is no special sweep line structure but the indicator distinguishing the stage of the event.
- Set the active event to be  $v_{\text{active}} = v_{\text{first}}$  and initiate the  $UCH(X)$  as the trivial path with one vertex  $v_{\text{first}}$  (this is the current last vertex of the path in construction).

(2) *Main cycle.*

- Set the active event to the next point  $v$  in the queue, and consider the potential edge  $e$  having  $v_{\text{active}}$  as the tail and the last vertex in  $UCH(X)$  as head.
- Check whether the  $UCH(X)$  is to the left of  $e$  (check it only against the last edge in the current  $UCH(X)$ ). If so, add  $e$  and the  $v_{\text{active}}$  to the  $UCH(X)$ . If not, remove edges in  $UCH(X)$  one by one, until the test turns positive.
- Repeat the cycle until the next event is the  $v_{\text{last}}$ .

It is easy to check that the algorithm is correct. Exactly  $n$  events need to be considered, and at each of it up to  $O(n)$  vertices can be removed in the current  $UCH(X)$ . This occurs in  $O(n^2)$  time, but in fact none of the vertices is added again to the  $UCH(X)$  after removal. It follows that the asymptotic estimate for the main cycle run is  $O(n)$  in total and it is the ordering in the initialization dominating with its  $O(n \log n)$  time. Clearly the linear  $O(n)$  memory is sufficient and so the optimal solution is achieved again for the convex hull problem.

**13.3.3. The divide and conquer paradigm.** Another very standard idea is to divide the entire problem into pieces, apply recursively the same procedure on them, and merge the partial results together. These are the two phases of the *divide and conquer* approach. This paradigm is common in many areas, cf. 13.I.10.

With convex hulls, adopt the gift wrapping approach for the conquer phase. The idea is to split recursively the task producing disjoint “left  $CH(X)$ ” and “right  $CH(X)$ ” and to

**13.I.25.** How many sequences of  $\{0, 1, 2, 3\}$  of length  $n$  have at least 2 zeroes?

**Solution.** Exponential generating function for 0- entry is

$$b_0(x) = \frac{x^2}{2!} + \frac{x^3}{3!} + \dots = e^x - 1 - x$$

. Exponential generating function for other entries is  $e^x$  as there are no restrictions. Hence, the exponential generating function in question is  $f(x) = e^{4x} - e^{3x} - x e^{3x}$ . The answer to the question is  $n!$  times the coefficient at  $x^n$  in  $f(x)$ , which is

$$n! \left( \frac{4^n}{n!} - \frac{3^n}{n!} - n \frac{3^{n-1}}{n!} \right) = 4^n - 3^n - n3^{n-1}.$$

□

merge them by finding the upper and lower “tangent edge” of those two parts.

DIVIDE AND CONQUER CONVEX HULL

*Input:* Set of points  $X = \{v_1, \dots, v_n\}$  in the plane, ordered lexicographically.

*Output:* The directed path  $CH(X)$ .

(1) *Divide.* If  $n \leq 3$ , return the  $CH(X)$ . Otherwise, split  $X = X_1 \cup X_2$  into two subsets of (roughly) same sizes, respecting the order (i.e. all vertices in  $X_1$  smaller than those in  $X_2$ ).

(2) *Merge.*

- Start with the edge joining the largest point in  $CH(X_1)$  and the smallest in  $CH(X_2)$ , and iteratively balance it to the lower tangent segment  $e_l$  to  $CH(X_1)$  and  $CH(X_2)$ .
- Proceed similarly to get the upper tangent  $e_u$ .
- Merge the relevant parts of the  $CH(X_1)$  and  $CH(X_2)$  with the help of  $e_l$  and  $e_u$ .

Perhaps the merge step requires some more explanation. The situation is illustrated in the diagram. For the upper tangent, first fix the right-hand vertex of the initial edge joining the two convex polygons. Then find the tangent to the left polygon from this vertex. Then fix the head of the moving edge and find the right hand touch point of the potential tangent. After a finite number of exchanges like this, the edge stabilizes. This is the upper tangent edge  $e_u$ . Observe that during the balancing, we move only clockwise on the right-hand polygon and counter-clockwise on the other one. Notice also that it is the smart divide strategy which prevents any of the points of the input  $X_1$  to appear inside of the  $CH(X_2)$  and vice versa.

Again the analysis of the algorithm is easy. The typical merge time is asymptotically linear and then the recursive call yields  $O(\log n)$  runs of the procedures. The total estimated time is again  $O(n \log n)$ . Notice, there is no initialization in the procedure itself. Just assume that the points in  $X$  are already ordered. Hence another  $O(n \log n)$  time must be added to prepare for the very first call. The memory necessary for running the algorithm is estimated by  $O(n)$  if the recursions are implemented properly.

**13.3.4. The incremental paradigm.** This approach consists in taking the input objects one by one and consecutively build the required resulting structure. This is particularly useful if the application does not allow to have all the points available in the beginning. Imagine *incrementally* building the convex hull of shots into the target, as they occur.

Another good use is in the *randomized algorithms*, where all the data is known in the beginning, but treated in a random order. Typically the expected time for running is then very good, while there might be much less effective, but improbable, worst time runs.

The former case is easy to illustrate on the convex hull problem. In each step employ the merge step of the very degenerate version of the divide and conquer algorithm, merging  $CH(X_1)$  of the previously known points  $X_1$ , while  $X_2 = CH(X_2) = \{v_k\}$  is just the new point. But an extra step is needed to check whether  $v_k$  is inside of  $CH(X_1)$  or not. If it is, then skip the new point and wait for the next one. If not, then merge. The worst time of this algorithm is  $O(n^2)$ , but as with the gift wrapping method, it depends on the actual size of the output as well as on the quality of the algorithm checking whether  $v_k$  is inside of the  $CH(X_1)$ .

We illustrate the second case with a more elaborate convex hull algorithm. The main idea is to keep track of the position of all points in  $X$  with respect to the convex hull  $CH(X_k)$  of the first  $k$  of them (in the fixed order chosen at the beginning).

With this goal in mind, keep the dynamical structure of a bipartite graph  $G$  whose first group of vertices consists of those points which have not been processed yet, while the other group contains all the faces of the current convex polygon  $S = CH(X_k)$  (call them faces, not to be confused with the edges in the graph in  $G$ ). Remember the faces in  $S$  are oriented. Such a face  $e$  is in conflict with the point  $v$  if the face is “visible” from  $v$ , i.e.  $v$  is in the right-hand halfplane determined by  $e$ . Keep all points joined to each of their faces in conflict in the bipartite graph. Call  $G$  the *graph of conflicts*. The algorithm can now be formulated:

#### RANDOMIZED INCREMENTAL CONVEX HULL ALGORITHM

*Input:* A set  $X = \{v_1, \dots, v_n\}$ ,  $n > 3$ , of at least four points in the plane.

*Output:* The edge list  $R$  of the convex hull  $CH(X)$ .

- (1) *Initialization.* Fix a random order on  $X$ . Choose the first three points as  $X_0$ , create the list of conflicts for the edge list  $R = CH(X_0)$  (i.e. state which of the three faces are seen from which points) and remove the three points from  $X$ .
- (2) *Main cycle.* Repeat until the list  $X$  is empty:
  - choose the first point  $v \in X$ ;
  - if there are some conflicts of  $v$  in  $G$ , then
    - remove all the faces in conflict with  $v$  from both  $R$  and  $G$ ,
    - find the two new faces (the upper and lower tangents from the new point  $v$  to the existing  $CH(X)$  – they are easily found by taking care of the “vertices without missing edges”),
    - add the two new faces to both  $R$  and  $G$  and find all their conflicts;
  - remove the point  $v$  from the list  $X$ , and from the graph  $G$ .

The complete analysis of this algorithm is omitted. Notice that finding the newly emerging conflicts is easy since it is only necessary to check the potential conflicts of points

which are in conflict with the faces incident to those two vertices in  $G$  before the update, to which the two new faces are attached.

It can be proved that the expected time for this algorithm is  $O(n \log n)$ , while the worst time is  $O(n^2)$ . The complete framework for the analysis of randomized algorithms is nicely explained in the book mentioned in the very beginning of this part, see page 1188.

**13.3.5. Convex hull in 3D.** Many applications need convex hulls of finite sets of points in higher dimensions, in particular in 3D. There are several ways of adjusting 2D algorithms to their 3D versions.

First, it needs to be stated what the right structure is for the  $CH(X)$ . As seen in 13.1.21, the convex polyhedra in  $\mathbb{R}^3$  can be perfectly described by planar graphs. In order to modify the algorithms into 3D, some good encoding for them is needed. We want to find all vertices with edges or faces which are incident or neighbouring in time proportional to the output.

This is nicely achieved by the *double connected edge lists*.

DOUBLE CONNECTED EDGE LIST – DCEL

Let  $G = (V, E, S)$  be a planar graph. The *double connected edge list* is the list  $E$  such that each edge is represented by two oriented twin-edges  $e, \bar{e}$ , equipped with the pointers

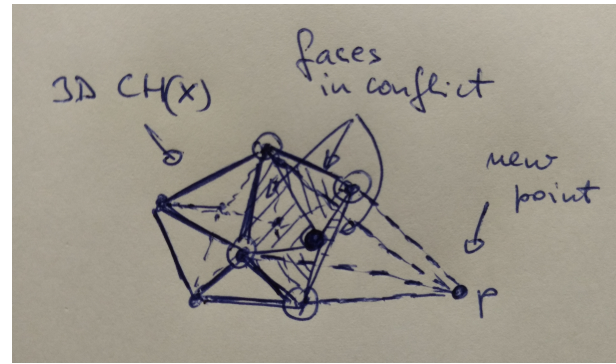

- $V_t, V_h$  to tail and head of  $e$
- $F$  to the incident face (the left one with respect to the directed edge  $e$ ) and the pointer to the twin  $\bar{e}$
- $P$  to the edge following along the face  $F$  (in the counter clockwise direction).

At the same time, keep the list of vertices and the list of faces, always with just one pointer towards some of the incident edges.

Clearly, we can remove or add faces, edges, vertices, or find all kind of neighbors in time proportional to the output (notice the use of the twins and think about the details!).

Next, look at the 2D incremental algorithm above and try to imagine what needs changing there to get it to work in 3D. First, we have to deal with the 2D faces  $S$  of the DCEL of the convex hull and instead of their boundary vertices, deal with boundary edges. Again, all the faces with conflicts with the just processed point have to be removed (see the picture). This leads to a directed cycle of edges the pointers  $F$  missing (call them “unsaturated edges”). Finally, instead of adding

two new faces in 2D, add the tangent cone of faces joining the point  $v$  with the unsaturated edges. Of course the graph of conflicts must also be updated.

#### RANDOMIZED INCREMENTAL 3D CONVEX HULL ALGORITHM

*Input:* A set  $X = \{v_1, \dots, v_n\}$ ,  $n \geq 4$ , of at least five points in the space  $\mathbb{R}^3$ .

*Output:* The DCEL  $R$  for the convex hull  $CH(X)$ .

- (1) *Initialization.* Fix a random order on  $X$ . Choose the first four points as  $X_0$ , create the list of conflicts  $G$  and the DCEL  $R$  for  $CH(X_0)$  (i.e. tell which of the four faces are seen from which points) and remove the four points from  $X$ .
- (2) *Main cycle.* Until the list  $X$  is empty, repeat:
  - take the first point  $v \in X$ ;
  - if there are some conflicts of  $v$  in  $G$ , then
    - remove all the faces of  $R$  in conflict with  $v$  (from both  $R$  and  $G$ ), and take care of the (oriented) edges  $e$  in  $R$  left without their incident faces,
    - build the “tangent cone” from the new point  $v$  to the current  $R$  by connecting  $v$  to the latter “unsaturated” edges,
    - add the new faces to both  $R$  and  $G$  and find all their conflicts (again, note that the check for new conflicts can be restricted to the points which were in conflict with the faces incident to those edges where the cone has been attached to the previous  $R$ ).
  - remove the point  $v$  from the list  $X$  and from the graph  $G$ .

A detailed analysis is omitted. As with the 2D case, the expected running time for this algorithm is  $O(n \log n)$ . By the very well adapted DCEL data structure for the convex hull, it is a very good algorithm.

The divide and conquer algorithm from the 2D case can be easily adapted, too. Skipping details, the initial ordering of the input points lexicographically allows to recursively call the same procedure producing two DCELs of disjoint convex polytopes. This allows us to apply a more sophisticated “gift wrapping” approach when merging the results. A sort of “tubular collar” wrapping of the two polytopes to create their

convex hull is desired. Imagine rotating the hyperplanes similarly as with the lines in 2D in order to get the first edge in the tubular set of faces to be added. Then the first plane containing one of the missing new faces is obtained. Continue breaking the plane along the new edges, until both directed cycles along of which the collar is attached to the previous two polytopes are closed. All that is done by bending the planes by the smallest possible angle in each step and checking to arrive at the right position. Of course, the DCEL structure is essential to update all the data properly in time proportional to the size of the changes.

With reasonably smart implementation, this algorithm achieves the optimal  $O(n \log n)$  running time.

Both of the latter algorithms can be generalized to all higher dimensions, too.

**13.3.6. Voronoi diagrams.** The next stop is at one of

the most popular and useful planar divisions (and searching in them). For a finite set of points  $X = \{v_1, \dots, v_n\}$  in the plane  $\mathbb{R}^2$ , write  $VR(v_i)$  for the set of points in  $\mathbb{R}^2$  sharing  $v_i \in X$  as their uniquely given closest point in  $X$ . Define:

VORONOI DIAGRAM

For a given set of points  $X = \{v_1, \dots, v_n\}$  (not all colinear), the *Voronoi regions* are

$$VR(v_i) = \{x \in \mathbb{R}^2; \|x - v_i\| < \|x - v_k\|, \text{ for all } v_k \in X, k \neq i\}.$$

This is an intersection of  $n - 1$  open half-planes bounded by lines, so it is an open convex set. Its boundary is a convex polygon.

The *Voronoi diagram*  $VD(X)$  is the planar graph whose faces are the open regions  $VR(v_i)$ , while the boundaries of  $VR(v_i)$  yield the edges and vertices.

4

Care is needed about collinearity since if all the points  $v_i$  are on same line in  $\mathbb{R}^2$ , then their Voronoi regions are strips in the plane bounded by parallel lines. Under all other circumstances, the planar graph  $VD(X)$  from the latter definition is well defined and connected.

By definition, the vertices  $p$  of  $VD(X)$  are the points in the plane, such that at least three points  $v, w, u \in X$  are the same distance from  $p$  and no more points of  $X$  are inside the circle through  $v, w, u$ . If there are no more points of  $X$  on the latter circle, then the degree of this vertex  $p$  is 3.

The most degenerate situation occurs if all the points of  $X$  are on one circle. Then, obviously, the Voronoi regions are delimited by two half lines, all emanating from the center of the circle and cutting the angles properly. The construction of the  $VD(X)$  is then equivalent to ordering of the points by angles. At least  $O(n \log n)$  time is needed for the worst case estimate in any algorithm building the Voronoi diagrams.

Some of the Voronoi regions are unbounded, others bounded. If just two points  $v$  and  $w$  are considered, then the axis of the segment  $vw$  is the boundary for the regions

$VR(v)$  and  $VR(w)$ . In particular, the region  $VR(v)$  must be bounded for each  $v$  in the interior of the convex hull of  $X$ . On the contrary, consider an edge in the  $CH(X)$  with incident vertices  $v$  and  $w$ , and the “outer” half-axis of the segment  $vw$ . If one considers any interior point  $u$  in the  $CH(X)$ , then it is in the other halfplane with respect to the segment  $vw$ . Sooner or later the points in the latter half-axis are closer to  $v$  and  $w$  than to  $u$ . It follows that both  $VR(v)$  and  $VR(w)$  are unbounded. Summarizing:

**Lemma.** *Each Voronoi region  $VR(v)$  of the Voronoi diagram  $VD(X)$  is an open convex polygon region. It is unbounded if and only if  $v$  belongs to the convex hull of  $X$ .*

**13.3.7. An incremental algorithm.** Each Voronoi diagram represents a planar division and adding a new point  $p$  as a vertex, it is quite obvious how to update the diagram. First assume, we know which  $VR(v)$  the point  $p$  hits. Then choose the center  $v$ , split the region  $VR(v)$  by the relevant part of the axis of the segment  $pv$ . Add this new edge  $e$  into the updated  $VD(X)$ , simultaneously creating the two new faces and removing the  $VR(v)$  one. The new edge  $e$  hits the boundary of the current  $VR(v)$  in either two points or one point (if the new edge is unbounded). These hits show what is the next region of the updated diagram to be split. “Walk” further with the new hit at the boundary revealing the next center of region playing the role of  $v$  above. Ultimately this walk consecutively splits the visited old regions and creates the new directed cycle of edges bounding the new region, or it has an unbounded path of boundary edges, if the new region is unbounded. See the diagram for an illustration.

If the new point  $p$  is on the boundary, i.e. hitting one of the edges or vertices in  $VD(X)$ , then the same algorithm works. Just start with one of the incident regions.

So far this looks easy, but how does one find the relevant region hit by the new point? An efficient structure to search for it on the run of the algorithm is desired. Build an acyclic directed graph  $G$  for that purpose. The vertices in  $G$  are all the temporary Voronoi regions as they were created in the individual incremental steps. Whenever a region is split by the above procedure, new leaves in  $G$  are created. Draw edges towards these leaves from all the earlier regions which have some nontrivial overlap. Of course, care must be taken how

the old regions are overlap with the new ones, but this is not difficult. We illustrate the procedure on the diagram, updating from one point to four points.

INCREMENTAL VORONOI DIAGRAM

*Input:* The set of points  $X = \{v_1, \dots, v_n\}$  in the plane, not all collinear.

*Output:* The DCEL of  $VD(X)$  and the search graph  $G$ .

- (1) *Initialization.* Consider the first two points  $X_0 = \{v_1, v_2\}$  and create the DCEL for  $VD(X_0)$  with two regions. Create the acyclic directed graph  $G$  (just root and two leaves).
- (2) *Main cycle.* Repeat until there are no new points  $z \in X$ :
  - localize the  $VR(v)$  hit by  $z$  (by the search in  $G$ )
  - perform the path walk finding the boundary of the new region  $VR(z)$  in  $VD(X)$
  - update the DCEL for  $VD(X)$  and the acyclic directed search graph  $G$ .

This algorithm is easy to implement. It produces directly a search structure for finding the proper Voronoi regions of given points. Unfortunately, it is very far from optimal in both aspects - the worst running time is  $O(n^2)$ , and the worst depth of the search acyclic graph is  $O(n)$ . If this is treated as a randomized incremental algorithm, the expected values is better, but not optimal either. Below is a useful modification via triangulations.

**13.3.8. Delaunay triangulation.** One remarkable feature

of the Voronoi diagrams should not remain unnoticed. Right after the definition of the Voronoi diagram, an important fact was mentioned. The vertices of the planar graph  $VD(X)$  are centers of circles containing at least three points

of  $X$ , and no other points of  $X$  are inside of the circle. The dual graph to  $VD(X)$  (see 13.1.22 for the definition) can be realized by taking the vertices  $V = X$  and the edges indicate the neighboring faces. Then this is again a tessellation of the plane. Actually, the convex hull of  $X$  is tessellated into convex regions, and one unbounded region remains. It is called the Delaunay tessellation  $DT(X)$ . In the generic case, the degrees of all vertices in  $VD(X)$  are 3 (i.e. no four points of  $X$  lie on one circle). This is the *Delaunay triangulation* of the convex hull of  $X$ .<sup>13</sup> Notice that it is easy to turn any Delaunay tessellation into a triangulation by adding the necessary edges to triangulate the convex regions with more edges. Any of these refined tessellations is called the Delaunay triangulation associated to the  $VD(X)$ .

In general, a planar graph  $T$  is called a *triangulation* of its vertices  $X \subset \mathbb{R}^2$ ,  $|X| = n$ , if all its bounded faces have just 3 vertices. It is easy to see that each triangulation  $T$  has  $\tau = 2n - 2 - k$  triangles and  $\nu = 3n - 3 - k$  edges, where  $k$  is the number of vertices in the boundary of the unbounded face. Indeed, by the Euler formula (13.1.20)  $n - \nu + \tau + 1 = 2$  (there is an unbounded face on top of all the triangles). Now, every triangle has 3 edges, while there are  $k$  edges around the unbounded face. It follows that  $3\tau + k = 2\nu$ . It remains to solve the two linear equations for  $\tau$  and  $\nu$ .

The triangulations are extremely useful in numerical mathematics and in computer graphics as the typical background mesh for processing of approximate values of functions. Of course, there are many triangulations on a given set and one of the qualitative requests is to aim at triangles as close to the equilateral triangles as possible. This could be phrased as the goal to maximize the minimal angles inside the triangles.

A practical way to do this is to write the *angle vector of the triangulation*

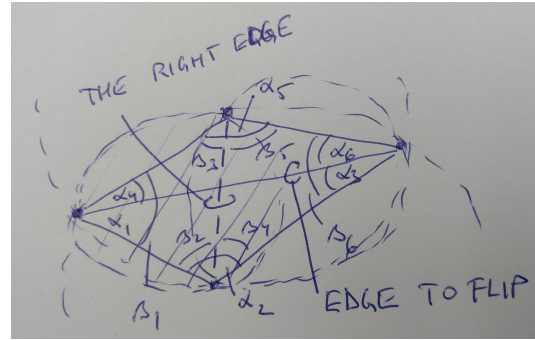

$$\mathcal{A}(T) = (\gamma_1, \gamma_2, \dots, \gamma_{3\tau}),$$

where  $\gamma_j$  are the angles of all the triangles in  $T$  sorted by their value,  $\gamma_j \leq \gamma_k$  for all  $j < k$ .

A triangulation  $T$  on  $X$  is said to be *angle optimal*, if  $\mathcal{A}(T) \geq \mathcal{A}(T')$  for all triangulations  $T'$  on the same set of vertices  $X$ , in the lexicographic ordering. In particular, an angle optimal triangulation achieves the maximum over the minimal angles of the triangles.

Surprisingly, there is a very simple (though not very effective) procedure to produce (one of) the angle optimal triangulations. Consider any two adjacent triangles and check the six angle sequences of their interior angles. If the current position of the diagonal edge provides the worse sequence, flip it. See the diagram.

<sup>13</sup>Although the name sounds French, Boris Nikolaevich Delone (1890 - 1990) was a Russian mathematician using the French transcription of his name in his publications. His name is associated with the triangulation because of his important work on this from 1934.

The flip is necessary if and only if one of the vertices outside the diagonal is inside the circle drawn through the remaining three vertices.

Since each such flipping of an edge inside of a triangulation  $T$  definitively increases the angle vector, the following algorithm must stop and achieve an angle optimal triangulation:

EDGE FLIPPING DELAUNAY

*Input:* Any triangulation  $\tilde{T}$  of points  $X$  in the plane.  
*Output:* An angle minimal triangulation  $T$  of the same set  $X$ .

(1) *Main cycle.* Repeat until there are no edges to flip:

- Find an edge which should be flipped and flip it.

**Theorem.** A triangulation  $T$  on a set of points  $X$  in the plane  $\mathbb{R}^2$  is angle optimal if and only if it is a Delaunay triangulation associated to the Voronoi diagram  $VD(X)$ .

**PROOF.** Consider any Delaunay triangulation  $T$  associated to  $VD(X)$  and one of the vertices  $p$  of  $VD(X)$ . If the four vertices of two neighboring triangles are not all on the same circle, then by the very definition of  $VD(X)$ , the two circles in question do not contain the remaining points and thus there is no need for any flips. Further, let  $v_1, \dots, v_k$  be all the points of  $X$  lying on the circle determining  $p$ . Fix an edge with two neighbouring endpoints on a circle. All triangles with the third vertex on the circle above the edge share the same angle. A simple check now verifies that different ways of triangulating the same region of  $VD(X)$  with more than 3 boundary edges lead always to the same angle vector.

In particular, there are no flips at all necessary in the above algorithm if one starts with the Delaunay triangulation  $T$ . Hence the angle optimal triangulation is arrived at.

In order to prove the other implication, recall the comments on the diagram above. All triangles in the angle optimal triangulations  $T$  have the following two properties: (1) the circle drawn through their three vertices do not include any other point in its interior: (2) the circle having any of their edges as diameter does not have any other point in its interior.

Consider the dual graph  $G$  of  $T$  and consider its realization in the plane by drawing the vertices as the centers of the circles drawn through the vertices of individual triangles,

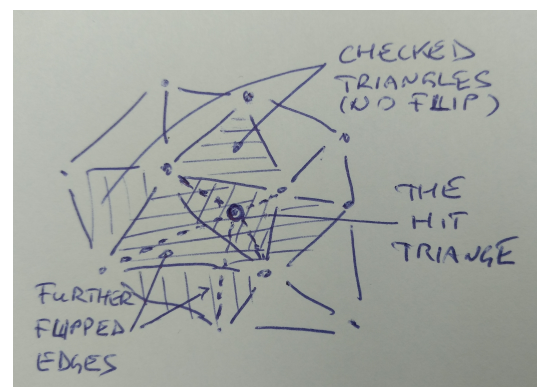

while the edges are the segments joining them. If there are not more than 3 points on any of those circles, then  $G = VD(X)$  is obtained. In the degenerate situations, all the triangles sharing the circle produce the same vertex in the plane and some of the relevant edges degenerate completely. Identify those collapsing elements in  $G$ , to get the right  $VD(X)$ .  $\square$

**13.3.9. Incremental Delaunay.** We return to the general idea for the Voronoi diagram, namely to design an algorithm which constructs both  $VD(X)$  and  $DT(X)$  and which behaves very well in its randomized implementation.

The idea is straightforward. Use the incremental approach as with the Voronoi diagrams for refining the consecutive Delaunay triangulations, employing the flipping of edges method.

By looking at the diagram, the Voronoi algorithm is easily modified. Care must be taken of three different cases for the new points – hitting the unbounded face, hitting one of the internal triangles, hitting one of the edges.

## INCREMENTAL DELAUNAY TRIANGULATION

*Input:* The set of points  $X = \{v_1, \dots, v_n\}$  in the plane, not all collinear.

*Output:* The DCEL of both  $DT(X)$  and the search graph  $G$  for this triangulation.

- (1) *Initialization.* Consider the first three points  $X_0 = \{v_1, v_2, v_3\}$ . Create the DCEL for  $DT(X_0)$  with two regions, and create the  $CH(X_0)$  (the connected edge list). Create the acyclic directed graph  $G$  (just root and two leaves).
- (2) *Main cycle.* Repeat until there are no new points  $z \in X$ :
  - Localize the face  $\Delta$  in  $DT(X_k)$  hit by  $z$  (by the search in  $G$ )
  - if  $z$  is in the unbounded face, then
    - add the new triangles  $\Delta_1, \dots, \Delta_\ell$  to  $DT(X_k)$  by joining  $z$  to visible edges in  $CH(X_k)$
    - update the  $CH(X)$ .
  - if  $z$  hits a (bounded) triangle  $\Delta$ , then split it into the three new triangles  $\Delta_1, \Delta_2, \Delta_3$ .
  - if  $z$  hits an edge  $e$ , then split the adjacent bounded triangles into  $\Delta_1, \dots, \Delta_4$  (only two, if an edge in  $CH(X_k)$  is hit).
  - Create a queue  $Q$  of not yet checked modified triangles and repeat as long  $Q$  is not empty:
    - take the first  $\Delta$  from the queue  $Q$ , look for its neighbour not in  $Q$  and not yet checked, and flip the edge if necessary;
    - if an edge is flipped, put the newly modified triangles into  $Q$

Detailed analysis of the algorithm is omitted. It is almost obvious that the algorithm is correct. It is only necessary to prove that the proposed version of the flip edge algorithm update ensures that after each addition of the new point  $z$  in  $k$ th step, the correct Delaunay triangulation of  $X_k$  arises. Once an edge is flipped, then it is not necessary to consider it any time later.

Finally, if the Voronoi diagram is needed instead, it can be obtained from the  $DT(X)$  in linear time. Obviously the search structures can be used directly.

Surprisingly enough, it turns out that the expected number of total flips necessary over all the run is of size  $O(n \log n)$ . Hence the algorithm achieves the perfect expected time  $O(n \log n)$ . Detailed analysis of this beautiful example of results in computational geometry can be found in the section 9.4. of the book by Berg et al., cf. the link on page 1188.

**13.3.10. The beach line Voronoi.** The Voronoi algorithm provides a perfect example for the sweep line paradigm, where the extra structure to keep track of the events has to be quite smart.<sup>14</sup>

<sup>14</sup>This is mostly called the *Fortune Voronoi algorithm*. Not because this is such a lucky construction, but rather because the algorithm was published by Steven Fortune of the Bell Laboratories in 1986

Imagine the horizontal line  $L$  (parallel to the  $x$  axis) flows in the top-down direction and meets the points in  $X = \{v_1, \dots, v_n\}$ . Of course  $VD(X)$  including all points above the current position of  $L$  cannot be drawn, since it depends also on the points below the line. It is better to look at the part  $R_L$  in the plane,

$$R_L = \{p \in \mathbb{R}^2; \text{dist}(p, L) \geq \text{dist}(p, v_i), v_i \in X \text{ above } L\}.$$

This is exactly the part of  $\mathbb{R}^2$  which can be tessellated into the Voronoi diagram with the information collected at the current position of  $L$ . Obviously,  $R_L$  is bounded by a continuous curve consisting of parts of parabolas, since for one point  $v_i$  this is the case, and the intersection of the conditions is relevant.

Call the boundary of  $R_L$  the *beach line*  $B_L$ . The vertices on  $B_L$  draw the  $VD(X)$  when  $L$  is moving. Since the Voronoi diagram consists of lines, we do not even compute the parabolas and take care of the arrangements of the still active parts of parabolas in the beachline, as determined by the individual points. New parts of the beachline arise when the line  $L$  meets one of the points. Add all the points to an ordered list in the obvious lexicographic order. Call them the *point events*. The active arc in the beachline disappears if the line  $L$  meets the bottom of the circle drawn through three points determining a vertex in the Voronoi diagram. Such an event is called a *circle event*.

Both types of the events are illustrated in the diagram above. There is a striking difference between them.

The point events always initiate a new arc and start “drawing” two edges of the Voronoi diagram. They initiate previously unknown circle events.

The circle events might disappear without creating a genuine vertex in  $VD(X)$ . Look at the diagram at the  $s$  point event. The new  $s, r, q$  circle event is encountered there. But this would not create a vertex in the diagram if there was the next point  $u$  somewhere close enough to the indicated vertex. One could find it out as soon as such a point event  $u$  is met. Such “ineffectively disappearing” circle events are called *false alarms*. On the contrary the  $p, q, r$  circle event shown in the diagram gives rise to the indicated vertex.

Summarizing, the emerged circle events must be inserted properly into the ordered queue of events and handled properly at each of the point events.

Further details are not considered here. When implemented properly, this algorithm runs in the optimal  $O(n \log n)$  time and  $O(n)$  storage. See again the above mentioned book by Berg et al. (section 7) for details.

**13.3.11. Geometric transformations.** Various geometric transformations of the basic ambient space can often help to transform one problem into another one. This is illustrated in a beautiful construction relating the convex hulls and the Voronoi diagrams.

Of course transformations which behave well on lines and planes and preserve incidences should be well thought of. The affine and projective transformations behave well in this respect as in the fourth chapter. Introduce a more interesting one – the *spherical inversion*. In the plane  $\mathbb{R}^2$ , consider the unit circle  $x^2 + y^2 = 1$ . For arbitrary  $v = (x, y) \neq (0, 0)$  define

$$\varphi(v) = \frac{1}{\|v\|^2} v = \frac{1}{x^2 + y^2} (x, y)$$

Clearly  $\varphi$  is a bijection on  $\mathbb{R}^2 \setminus \{(0, 0)\}$ . The geometric meaning of such a transform is clear from the formula, see the diagram. "The general" point  $v$  is sent to a point on the same line through the origin, but with reciprocal size. The unit sphere is the set of all fixed points.

The same principle works for all dimensions, so we may equally well (and more interestingly) consider  $v \in \mathbb{R}^3$  in the sequel.

Next follows the crucial property of  $\varphi$ .

**Lemma.** *The mapping  $\varphi$  maps the spheres and planes in  $\mathbb{R}^3$  onto spheres and planes. The image of a sphere is a plane if and only if the sphere contains the origin.*

**PROOF.** Consider a sphere  $C$  with the center  $c$  and radius  $r$ . The equation for its general points  $p$  reads

$$\|p - c\|^2 = r^2.$$

By drawing a few images as in the diagram above, it is easily guessed that the images will be a circle with the center  $s = \frac{1}{\|c\|^2 - r^2} c$  (i.e. again on the same line through the origin). Now consider  $q = \varphi(p)$  and compute (using just

$2p \cdot c = \|p\|^2 + \|c\|^2 - r^2$  from the latter equation)

$$\begin{aligned} \|q - s\|^2 &= \left\| \frac{p}{\|p\|^2} - \frac{c}{\|c\|^2 - r^2} \right\|^2 \\ &= \frac{1}{\|p\|^2} + \frac{1}{(\|c\|^2 - r^2)^2} \|c\|^2 - 2 \frac{p \cdot c}{(\|c\|^2 - r^2)\|p\|^2} \\ &= \frac{1}{(\|c\|^2 - r^2)^2} \|c\|^2 - \frac{1}{\|c\|^2 - r^2} \\ &= \left( \frac{r}{\|c\|^2 - r^2} \right)^2. \end{aligned}$$

The latter computation assumes  $\|c\| \neq r$ . Fix the center  $c \neq 0$  and consider diameters  $r$  approaching  $\|c\|$  from below or above. Then the images are circles with the centers  $s$  approaching one or the other infinite points of the line  $\text{span}\{c\}$  and fast growing radii. In the limit position, the plane is obtained as requested. (Check this asymptotic computation directly yourself, if any doubts.)  $\square$

The continuity of  $\varphi$  has got important consequences. Consider a general plane  $\mu$  (not containing the origin). The inversion  $\varphi$  maps one of the half-spaces determined by  $\mu$  to the interior of the image sphere. The other half-space maps to the unbounded complement of the sphere. The latter is of course the half-space containing the origin.

The efficient link between the Voronoi diagrams and convex hulls can now be explained. Assume a set of points  $X = \{v_1, \dots, v_n\}$  in the plane is given. View them as the points in the plane  $z = 1$  in  $\mathbb{R}^3$ , i.e. add the same coordinates  $z = 1$  to all the points  $(x, y)$  in  $X$ . For simplicity, assume that no three of them are collinear and no four of them lie on the same circle.

The spherical inversion  $\varphi$  maps the entire plane  $z = 1$  to the sphere  $S$  with center  $c = (0, 0, 1/2)$  and radius  $1/2$ . Write  $w_1, \dots, w_n$  for the images  $w_i = \varphi(v_i)$ .

Now, consider  $CH(Y)$  for the set of the images  $Y = \{w_1, \dots, w_n\}$ . This is a convex polytope with all vertices on the sphere  $S$ . All its faces represent planes not containing the origin (this is due to the assumption that no three points of  $X$  are collinear).

Split the faces of  $CH(Y)$  into those “visible” from the origin and the “invisible” ones. In the latter case, all points of  $Y$  are on the same side of plane  $\mu$  generated by the face as the origin. This implies that all the other points are outside of the image sphere  $S_\mu = \varphi(\mu)$ . In particular, there are no points of  $X$  inside of the intersection of  $S_\mu$  with the plane  $z = 1$ . This is the defining condition for obtaining one of the vertices of the Voronoi diagram. Since the map  $\varphi$  preserves incidences, the entire DCEL for  $VD(X)$  is easily reconstructed from the DCEL of  $CH(Y)$  and vice versa.

This resembles the construction of the dual graph, i.e. the Delaunay triangulation  $DT(X)$  from the Voronoi diagram, with further geometric transformation in the back.

Last, but not least, the faces of  $CH(Y)$  visible from the origin are worth mentioning too. For the same reason as above, all the points of  $Y$  appear on the other side from

the origin and so, all the points in  $X$  are inside the image sphere. This means the diagram of furthest points instead of the Voronoi diagram of the closest ones is obtained.

This is a very useful tool in several areas of mathematics, see some of the exercises (??) for further illustration.

**4. Remarks on more advanced combinatorial calculations**

**13.4.1. Generating functions.** The worlds of discrete and continuous mathematics meet all the time.

There are already many instances of useful interactions. With some slight exaggeration, we can claim that all results in

analysis were achieved by an appropriate reduction of the continuous tasks to some combinatorial problem (for instance, integration of rational functions is reduced to partial fraction decomposition, solution of analytic differential equations possibly boils down to some recurrences, etc.). In the opposite direction, we demonstrate how handy continuous methods can be in purely combinatorial problems.

We begin with a simple combinatorial question: *There are four 1-crown coins, five 2-crown coins, and three 5-crown coins at our disposal. Suppose we want to buy a bottle of coke which costs 22 crowns. In how many ways can we pay the exact amount of money with the given coins?*

We are looking for integers  $i, j, k$  such that  $i+j+k = 22$  and

$$i \in \{0, 1, 2, 3, 4\}, j \in \{0, 2, 4, 6, 8, 10\}, k \in \{0, 5, 10, 15\}.$$

Consider the product of polynomials (over the real numbers, for instance)

$$(x^0 + x^1 + x^2 + x^3 + x^4)(x^0 + x^2 + x^4 + x^6 + x^8 + x^{10})(x^0 + x^5 + x^{10} + x^{15}).$$

It should be clear that the number of solutions equals the coefficient at  $x^{22}$  in the resulting polynomial. This corresponds to the four possibilities of choosing the values  $i, j, k$ :  $3 \cdot 5 + 3 \cdot 2 + 1 \cdot 1$ ,  $3 \cdot 5 + 2 \cdot 2 + 3 \cdot 1$ ,  $2 \cdot 5 + 5 \cdot 2 + 2 \cdot 1$ , and  $2 \cdot 5 + 4 \cdot 2 + 4 \cdot 1$ .

This simple example deserves more attention.

The coefficients of the particular polynomials represent sequences of numbers, referring to how many times we can achieve the given value with one type of coins only. Work with an infinite sequence to avoid a prior bound on how many available values there can be. Encode the possibilities in infinite sequences

$$(1, 1, 1, 1, 1, 0, 0, \dots) \quad \text{1-crowns}$$

$$(1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0, \dots) \quad \text{2-crowns}$$

$$(1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, \dots) \quad \text{5-crowns.}$$

Each such sequence with only finitely many non-zero terms can be assigned a polynomial. The solution of the problem is given by the product of these polynomials, as noted before.

This is an instance of a general procedure for handling sequences effectively.

## GENERATING FUNCTION OF A SEQUENCE

**Definition.** An (ordinary) *generating function* for an infinite sequence  $a = (a_0, a_1, a_2, \dots)$  is a (formal) power series

$$a(x) = a_0 + a_1x + a_2x^2 + \dots = \sum_{i=0}^{\infty} a_i x^i.$$

The values  $a_i$  are considered in some fixed field  $\mathbb{K}$ , normally the rational numbers, real numbers, or complex numbers.

In practice, there are several standard ways for defining and using generating functions:

- to find an *explicit formula* for the  $n$ -th term of a sequence;
- to derive *new recurrent relations* between values (although generating functions are often based on recurrent formulae themselves);
- for *calculation of means* or other statistical dependencies (for instance, the average time complexity of an algorithm);
- to prove *miscellaneous combinatorial identities*;
- to find an *approximate formula* or the *asymptotic behaviour* when the exact formula is too hard to get.

We shall see examples of some of these.

### 13.4.2. Operations with generating functions.

Several basic operations with sequences correspond to simple operations over power series (which can be easily proved by performing the relevant operation with the power series):

- Component wise, the sum  $(a_i + b_i)$  of the sequences corresponds to the sum  $a(x) + b(x)$  of the generating functions.
- Multiplication  $(\alpha \cdot a_i)$  of all terms by a given scalar  $\alpha$  corresponds to the same multiplication  $\alpha \cdot a(x)$  of the generating function.
- Multiplication of the generating function  $a(x)$  by a monomial  $x^k$  corresponds to shifting the sequence  $k$  places to the right and filling the first  $k$  places with zeros.
- In order to shift the sequence  $k$  places to the left (i.e. omit the first  $k$  terms), subtract the polynomial  $b_k(x)$  corresponding to the sequence  $(a_0, \dots, a_{k-1}, 0, \dots)$  from  $a(x)$ , and then divide the generating function by the expression  $x^k$ .
- Substitution of a polynomial  $f(x)$  for  $x$  leads to a specific combination of the terms of the original sequence. They can be expressed easily for  $f(x) = \alpha x$ , which corresponds to multiplication of the  $k$ -th term of the sequence by the scalar value  $\alpha^k$ . The substitution  $f(x) = x^n$  inserts  $n - 1$  zeros between each pair of adjacent terms.

The first and second rules express the fact that the assignment of the generating function to a sequence is an isomorphism of the two vector spaces (over the field in question).

There are other important operations which often appear when working with generating functions:

- *Differentiation* with respect to  $x$ : the function  $a'(x)$  generates the sequence  $(a_1, 2a_2, 3a_3, \dots)$ ; the term at index  $k$  is  $(k+1)a_{k+1}$  (i.e. the power series is differentiated term by term).
- *Integration*: the function  $\int_0^x a(t) dt$  generates the sequence  $(0, a_0, \frac{1}{2}a_1, \frac{1}{3}a_2, \frac{1}{4}a_3, \dots)$ ; for  $k \geq 1$ , the term at index  $k$  is equal to  $\frac{1}{k}a_{k-1}$  (clearly, differentiation of the corresponding power series term by term leads to the original function  $a(x)$ ).
- *Product of power series*: the product  $a(x)b(x)$  is the generating function for the sequence  $(c_0, c_1, c_2, \dots)$ , where

$$c_k = \sum_{i+j=k} a_i b_j,$$

i.e. the terms of the product are up to  $c_k$  the same as in the product  $(a_0 + a_1x + a_2x^2 + \dots + a_kx^k)(b_0 + b_1x + b_2x^2 + \dots + b_kx^k)$ . The sequence  $(c_n)$  is also called the *convolution of the sequences*  $(a_n), (b_n)$ .

**13.4.3. More links to continuous analysis.** There are useful examples of generating functions. Most of them are seen when working with power series in chapters five and six.

Perhaps the reader recognizes the generating function given by the geometric series:

$$a(x) = \frac{1}{1-x} = 1 + x + x^2 + \dots,$$

which corresponds to the constant sequence  $(1, 1, 1, \dots)$ . As we know, this power series converges for  $x \in (-1, 1)$  and equals  $1/(1-x)$ .

It works the other way round as well: Expand this function into its Taylor series at the point 0. The original series is obtained. This “encoding” of a sequence into a function and then decoding it back is the key idea in both the theory and practice of generating function.

Generally, consider any sequence  $a_i$  with  $\sqrt[n]{a_n}$  bounded. Then there is a neighbourhood on which its generating function converges (see 5.4.10 on page 428). For example, an easy check shows that this happens whenever  $|a_n| = O(n^k)$  with a constant exponent  $k \geq 0$ . On this neighbourhood, the generating functions can be worked with as with ordinary functions. In particular, one can add, multiply, compose, differentiate, and integrate them. All the equalities obtained carry over to the relevant sequences.

Recall several very useful basic power series and their sums:

$$\begin{aligned} \frac{1}{1-x} &= \sum_{n \geq 0} x^n, \\ \ln(1+x) &= \sum_{n \geq 1} (-1)^{n+1} \frac{x^n}{n}, \\ \ln \frac{1}{1-x} &= \sum_{n \geq 1} \frac{x^n}{n}, \\ e^x &= \sum_{n \geq 0} \frac{x^n}{n!}, \end{aligned}$$

$$\sin x = \sum_{n \geq 0} (-1)^n \frac{x^{2n+1}}{(2n+1)!},$$

$$\cos x = \sum_{n \geq 0} (-1)^n \frac{x^{2n}}{(2n)!}.$$

**13.4.4. Binomial theorem.** Recall the standard finite binomial formula  $(a+b)^r = a^r(1+c)^r = a^r \sum_{n=0}^r \binom{r}{n} c^n$ , where  $r \in \mathbb{N}$ ,  $0 \neq a, b \in \mathbb{C}$ ,  $c = b/a$ . Even if the power  $r$  is not a natural number, the Taylor series of  $(1+x)^r$  can still be computed. This yields the following generalization:

GENERALIZED BINOMIAL THEOREM

**Theorem.** For any  $r \in \mathbb{R}$ ,  $k \in \mathbb{N}$ , write

$$\binom{r}{k} = \frac{r(r-1)(r-2)\cdots(r-k+1)}{k!}$$

(in particular  $\binom{r}{0} = 1$ , having empty product divided by 1 in the latter formula). The power series expansion

$$(1+x)^r = \sum_{k \geq 0} \binom{r}{k} x^k$$

converges on a neighbourhood of zero, for each  $r \in \mathbb{R}$ . The latter formula is called the generalized binomial theorem.

In particular, the function  $\frac{1}{(1-x)^n}$ ,  $n \in \mathbb{N}$  can be expanded into the series

$$1 + \binom{1+n-1}{n-1} x + \cdots + \binom{k+n-1}{n-1} x^k + \cdots.$$

**PROOF.** The theorem is obvious if  $r \in \mathbb{N}$  since it is then the finite binomial formula. So assume  $r$  is not a natural number and thus zero is never obtained when evaluating  $\binom{r}{k}$ .

First, differentiate the function  $a(x) = (1+x)^r$  and evaluate all the derivatives in  $x = 0$ . Obviously

$$\begin{aligned} a^{(k)}(0) &= r(r-1)\cdots(r-k+1)(1+x)^{r-k} \Big|_{x=0} \\ &= r(r-1)\cdots(r-k+1) \end{aligned}$$

which provides the coefficients  $a_k = \binom{r}{k}$  of the series. In 5.4.5, there are several simple tests to decide about convergence of a number series. The ratio test helps here:

$$\frac{a_{k+1} x^{k+1}}{a_k x^k} = \frac{\frac{r(r-1)\cdots(r-k)}{(k+1)!}}{\frac{r(r-1)\cdots(r-k+1)}{k!}} x = \frac{r-k}{k+1} x.$$

By the ratio test, the radius of convergence is 1 for all  $r \notin \mathbb{N}$ .

The generalized binomial formula for negative integers is a straightforward consequence. If  $r = -n$ , we may write  $\binom{-n}{k} = (-1)^k \frac{1}{k!} (n+k-1)(n+k-2)\cdots n = \binom{n+k-1}{n-1}$  and substituting  $-x$  for the argument just kills the signs as requested.  $\square$

**13.4.5. Examples.** The formulae with  $r$  as a negative integer are very useful in practice. The simplest one is the geometric series with  $r = -1$ . Write down two more of them.

$$\frac{1}{(1-x)^2} = \sum_{n \geq 0} (n+1)x^n$$

$$\frac{1}{(1-x)^3} = \sum_{n \geq 0} \binom{n+2}{2} x^n.$$

The same results can be obtained by consecutive convolutions. Indeed, for the generating function  $a(x)$  of a sequence  $(a_0, a_1, a_2, \dots)$ ,  $\frac{1}{1-x}a(x)$  is the generating function for the sequence of all the partial sums  $(a_0, a_0+a_1, a_0+a_1+a_2, \dots)$ . For instance,

$$\frac{1}{1-x} \ln \frac{1}{1-x}$$

is the generating function of the *harmonic numbers*

$$H_n = 1 + \frac{1}{2} + \dots + \frac{1}{n}.$$

**13.4.6. Difference equations.** Typically, the generating functions can be very useful, if the sequences are defined by relations between their terms.

An instructive example of such an application is the complete discussion of the solutions of linear difference equations with constant coefficients. This is examined in the second part of chapter one, see 1.2.4. Back there, a formula is derived for first-order equations, the uniqueness and existence of the solution is justified, after only “guessing” the solution. Now, it can be truly derived in another straight forward way, working also in more complex and non-linear problems.

First, sort out the well-known example of the Fibonacci sequence, given by the recurrence

$$F_{n+2} = F_n + F_{n+1}, \quad F_0 = 0, \quad F_1 = 1,$$

and write  $F(x)$  for the (yet unknown) generating function of this sequence. We want to compute  $F(x)$  and so obtain an explicit expression for the  $n$ th Fibonacci number.

The defining equality can be expressed in terms of  $F(x)$  if we use our operations for shifting the terms of the sequence. Indeed,  $xF(x)$  corresponds to the sequence  $(0, F_0, F_1, F_2, \dots)$ , and  $x^2F(x)$  does to  $(0, 0, F_0, F_1, \dots)$ . Therefore, the generating function

$$G(x) = F(x) - xF(x) - x^2F(x)$$

represents the sequence

$$(F_0, F_1 - F_0, 0, 0, \dots, 0, \dots).$$

Substitute in the values  $F_0 = 0, F_1 = 1$  (the initial condition). Obviously  $G(x) = x$  and hence

$$(1 - x - x^2)F(x) = x.$$

$F(x)$  is a rational function. It can be rewritten as a linear combination of simple rational functions. This is helpful, since a

linear combination of generating functions corresponds to the same combination of the sequences.

Rational functions can be decomposed into partial fractions, see 6.2.7. Using this procedure, we find a generating function for  $1/(1 - x - x^2)$ . Namely, write  $r \in \mathbb{N}$

$$\begin{aligned} F(x) &= \frac{1}{1 - x - x^2} = \frac{A}{x - x_1} + \frac{B}{x - x_2} \\ &= \frac{a}{1 - \lambda_1 x} + \frac{b}{1 - \lambda_2 x}, \end{aligned}$$

where  $A, B$  are suitable (generally) complex constants, and  $x_1, x_2$  are the roots of the polynomial in the denominator. The ultimate constants  $a, b, \lambda_1$ , and  $\lambda_2$  can be obtained by a simple rearrangement of the particular fractions. This leads to the general solution for the generating function

$$F(x) = \sum_{n=0}^{\infty} (a\lambda_1^n + b\lambda_2^n)x^n,$$

and so the general solution of the recurrence is known as well.

In the present case, the roots of the quadratic polynomial are  $\frac{1 \pm \sqrt{5}}{2}$ . Hence the reciprocal values of the roots are  $\lambda_{1,2} = \frac{2}{1 \pm \sqrt{5}}$ . The partial fraction decomposition equality gives

$$x = a \left(1 - \frac{2}{1 - \sqrt{5}}x\right) + b \left(1 - \frac{2}{1 + \sqrt{5}}x\right)$$

and so  $a = -b = \frac{1}{\sqrt{5}}$ . Finally the requested solution

$$F_n = \frac{1}{\sqrt{5}} \left( \left(\frac{1 + \sqrt{5}}{2}\right)^n - \left(\frac{1 - \sqrt{5}}{2}\right)^n \right)$$

is obtained. Compare this procedure to the approach in 3.2.2 and 3.B.1. This expression, full of irrational numbers, is an integer. The second summand is approximately  $(1 - \sqrt{5})/2 \simeq -0.618$ . Its value is negligible for large  $n$ . Hence  $F_n$  can be computed by evaluating just the first summand and approximating to the nearest integer.

Of course, the same procedure can be applied for general  $k$ -th order homogeneous linear difference equations. Consider the recurrence

$$F_{n+k} = \alpha_0 F_n + \cdots + \alpha_{k-1} F_{n+k-1}.$$

The generating function for the resulting sequence is

$$F(x) = \frac{g(x)}{1 - \alpha_0 x^k - \cdots - \alpha_{k-1} x},$$

where the polynomial  $g(x)$  of order at most  $k - 1$  is determined by the chosen initial conditions.

Using partial fraction decomposition, the general result follows as in subsection 3.2.4.

**13.4.7. The general method.** Power series are a much stronger tool for solving recurrences. The point is that one is not restricted to linearity and homogeneity. Using the following general approach, recurrences that seem intractable at first sight can quite often be managed. The first steps are just algorithmic, while the final solution of the equation on the generating function may need very diverse approaches.

In order to be able to write down the necessary equations efficiently, adopt the convention of the *logical predicate*  $[\delta(n)]$  which is attached before the expression it should govern. Simply multiply by the coefficient 1 if  $\delta(n)$  is true, and by zero otherwise. For instance, the equation

$$F_n = F_{n-2} + F_{n-1} + [n = 1]1 + [n = 0]1$$

defines the above Fibonacci recurrence with initial conditions  $F_0 = 1$  and  $F_1 = 2$ .

METHOD TO RESOLVE RECURRENCES

Recurrent definitions of sequences  $(a_0, a_1, \dots)$  may be solved in the following 4 steps:

- (1) Write the complete dependence between the terms in the sequence as a single equation expressing  $a_n$  in terms of terms with smaller indices. This *universal formula* must hold for all  $n \in \mathbb{N}$  (supposing  $a_{-1} = a_{-2} = \dots = 0$ ).
- (2) Both sides of the equation are multiplied by  $x^n$ . Then sum the resulting expressions over all  $n \in \mathbb{N}$ . One of the summands is  $\sum_{n \geq 0} a_n x^n$ , which is the generating function  $A(x)$  for the sequence. Rearrange other summands so that they contain only the terms  $A(x)$  and some other polynomial expressions.
- (3) Solve the resulting equation with respect to  $A(x)$  explicitly.
- (4) The function  $A(x)$  is expanded into the power series. Its coefficients at  $x^n$  are the requested values of  $a_n$ .

As an example, consider a second order linear difference equation with constant coefficients, but a non-linear right hand side.

The recurrence is  $a_n = 5a_{n-1} - 6a_{n-2} - n$  with initial conditions  $a_0 = 0, a_1 = 1$ . The individual steps in the latter procedure are as follows:

*Step 1.* The universal equation is clear, up to the initial conditions. First check  $n = 0$ , which yields no extra term, but then  $n = 1$  enforces the extra value 2 to be added. Hence,

$$a_n = 5a_{n-1} - 6a_{n-2} - n + [n = 1]2.$$

*Step 2.*

$$\begin{aligned} \sum_{n \geq 0} a_n x^n &= 5x \sum_{n \geq 0} a_{n-1} x^{n-1} - 6x^2 \sum_{n \geq 0} a_{n-2} x^{n-2} \\ &\quad - \sum_{n \geq 0} n x^n + 2x \end{aligned}$$

Next, one of the terms is nearly the power series for  $(1-x)^{-2}$ . Thus remove one  $x$  there in order to get the equality on  $A(x)$  in the form as required (ignore the negative values of indices since all  $a_{-1}, a_{-2}, \dots$  vanish by assumption).

$$A(x) = 5xA(x) - 6x^2A(x) - x \frac{1}{(1-x)^2} + 2x.$$

*Step 3.* Find the reciprocal values to the roots, 2 and 3, of the polynomial  $1-5x+6x^2 = (1-2x)(1-3x)$ . An elementary

calculation yields

$$A(x) = \frac{2x^3 - 4x^2 + x}{(1-2x)(1-3x)(1-x)^2}.$$

*Step 4.* Partial fraction decomposition directly leads to the result

$$A(x) = -\frac{1}{4} \frac{1}{1-3x} + 2 \frac{1}{1-2x} - \frac{1}{2} \frac{1}{(1-x)^2} - \frac{5}{4} \frac{1}{1-x}.$$

This corresponds to the solution (notice the last but one term yields  $\sum_n (n+1)x^n$  and thus the constant term in our formula is the sum  $-1/2 - 5/4$ )

$$a_n = -\frac{1}{4} 3^n + 2^{n+1} - \frac{1}{2} n - \frac{7}{4}.$$

The first eight terms in the sequence are 0, 1, 3, 6, 8, -1, -59, -296, all integers of course.

### 13.4.8. Plane binary trees and Catalan numbers.

The next application of the generating functions answers the question about the number  $b_n$  of non-isomorphic plane binary trees on  $n$  vertices (cf. 13.1.18 for plane trees). Treat these trees in the form of the root (of a subtree) with a pair [*the left binary subtree, the right binary subtree*].

Examine the initial values of  $n$ , namely

$$b_0 = 1, b_1 = 1, b_2 = 2, b_3 = 5.$$

It is more or less obvious that for  $n \geq 1$ , the sequence  $b_n$  satisfies the recurrent formula

$$b_n = b_0 b_{n-1} + b_1 b_{n-2} + \cdots + b_{n-1} b_0,$$

and this is actually close to a convolution of two equal sequences. Rearrange the expression so that it holds for all  $n \in N_0$ :

$$b_n = \sum_{0 \leq k < n} b_k b_{n-k-1} + [n=0]1.$$

This finishes step 1 of the procedure.

In step 2, multiply both sides by  $x^n$  and add it all together. Write  $B(x)$  for the generating function of the sequence  $b_n$ .

$$\begin{aligned} B(x) &= \sum_{n,k} b_k b_{n-k-1} x^n + \sum_{n,k} [n=0] x^n \\ &= \sum_k b_k x^k \left( \sum_n b_{n-k-1} x^{n-k} \right) + 1 \\ &= \sum_k b_k x^k (xB(x)) + 1 = B(x) \cdot xB(x) + 1. \end{aligned}$$

Notice that the convolution  $b_n = b_0 b_{n-1} + b_1 b_{n-2} + \cdots + b_{n-1} b_0$  is replaced by

$$b_n = b_0 b_{n-1} + \cdots + b_{n-1} b_0 + b_n b_{-1} + b_{n+1} b_{-2} + \cdots.$$

This is no problem by the convention. It helps with processing the sums (it is much easier to work with infinite sums here than to keep an eye on the bounds all the time).

In step 3, the quadratic equation  $B(x) = xB(x)^2 + 1$  must be solved for  $B(x)$ . So

$$B(x) = \frac{1 \pm \sqrt{1 - 4x}}{2x}.$$

Although there are two solutions, not necessarily both must produce a valid solution to our problem. The sign  $+$  in the formula is impossible since then, the limit of  $B(x)$  for  $x \rightarrow 0_+$  is  $\infty$ , but the generating function for our sequence must have the value  $b_0 = 1$  at 0.

In the last step, expand  $B(x)$  into a power series. The expansion can be obtained using the generalized binomial theorem

$$\begin{aligned} (1 - 4x)^{1/2} &= \sum_{k \geq 0} \binom{1/2}{k} (-4x)^k \\ &= 1 + \sum_{k \geq 1} \frac{1}{2k} \binom{-1/2}{k-1} (-4x)^k. \end{aligned}$$

Dividing  $1 - \sqrt{1 - 4x}$  by the expression  $2x$  leads to

$$\begin{aligned} B(x) &= \sum_{k \geq 1} \frac{1}{k} \binom{-1/2}{k-1} (-4x)^{k-1} \\ &= \sum_{n \geq 0} \binom{-1/2}{n} \frac{(-4x)^n}{n+1} \end{aligned}$$

Substitute the  $(-4)^n$  multiple of  $\binom{-1/2}{n}$  into the definition of the generalized binomial numbers. A straightforward check shows  $(-4)^n \binom{-1/2}{n} = \binom{2n}{n}$ , which yields a final, much neater, formula for the coefficients. We conclude that the number of plane binary trees on  $n$  vertices equals

$$b_n = \frac{1}{n+1} \binom{2n}{n}.$$

These are known as the *Catalan numbers*. They occur surprisingly often:

- the number of well-parenthesized words of length  $2n$ , i.e. words consisting of  $n$  opening and  $n$  closing parentheses so that no prefix of the word contains more closing parentheses than closing ones;
- this also corresponds to the number of ways an unsupplied vending machine can accept  $n$  5-crown coins and  $n$  10-crown coins for 5-crown orders so that it can always give the change (hence the probability that a random ordering is satisfactory can also be found)
- the number of *monotonic* paths from  $[0, 0]$  to  $[n, n]$  along the sides of the unit squares of the grid such that the path does not cross the diagonal
- the number of triangulations of a convex  $(n + 2)$ -gon.

The intuitive reasoning for this is that they come from the expansion of the square root within  $B(x)$  and quadratic equalities appear often in real world.

**13.4.9. Quicksort analysis.** The next task is to determine the expected number of comparisons made by the Quicksort, a well-known algorithm for sorting a (finite) sequence of elements. This is the following divide and conquer type of algorithm:

PROCEDURE QSORT

*Input:* A (non-sorted) list of elements  $L = (L[0], \dots, L[n])$

*Output:* The sorted list  $L$  with the same elements.

- (1) if  $L$  is empty, then return the empty list  $()$ .
- (2) *Divide phase.* Create a sublist  $L_1$  by going through  $L$  and leaving only the elements  $x$  with  $L[0] > x$ , while putting the other elements into the list  $L_2$ .

- (3) *Conquer phase.* Combine the lists

$$L = \text{Qsort}(L_1) + (L[0]) + \text{Qsort}(L_2)$$

and return the list  $L$ .

We analyze how many comparisons are needed. Assume that all possible orderings of the list  $L$  to be sorted are distributed uniformly. The following parameters are crucial:

- The number of comparisons in the divide phase is  $n - 1$ .
- The assumption of uniformity ensures that the probability of  $L[0]$  being the  $k$ -th greatest element of the sequence is  $\frac{1}{n}$ .
- The sizes of the sublists to be sorted in the conquer phase are  $k - 1$  and  $n - k$ .

There is the following recurrent formula for the expected number of comparisons  $C_n$ :

$$(1) \quad C_n = n - 1 + \sum_{k=1}^n \frac{1}{n} (C_{k-1} + C_{n-k}).$$

One could work the steps of the general method directly, but the symmetry of the two summands allows a rewrite (1), multiplying by  $n$  at the same time

$$(2) \quad nC_n = n(n - 1) + 2 \sum_{k=1}^n C_{k-1}.$$

In the first step, care is needed concerning about  $n = 0$ . In the defining recurrence (1),  $n = 0$  is not treated at all (since the equation does not make sense). So the convention must be extended to include  $C_0 = 0$  in the computation. Then the equation (2) defines the  $C_1 = 0$  properly. It is not necessary to add any terms in view of the initial conditions.

Next, multiply both sides by  $x^n$  and add

$$\sum_{n \geq 0} nC_n x^n = \sum_{n \geq 0} n(n - 1)x^n + 2 \sum_{n \geq 0} \sum_{k=1}^n C_{k-1} x^n.$$

All the terms look familiar. The left hand side shows the derivative of the generating function  $C(x) = \sum_{n \geq 0} C_n x^n$  if one  $x$  is removed. The first term on the right is the series for  $(1 - x)^3$ , up to a constant and shift of powers by 2. Finally the last term is the convolution with  $(1 - x)^{-1}$ , up to one  $x$

and the coefficient 2. Hence the equation

$$xC'(x) = \frac{2x^2}{(1-x)^3} + 2\frac{x C(x)}{1-x}.$$

The third step is straightforward see 8.3.3. Divide by  $x$  to obtain

$$C'(x) = \frac{2}{1-x}C(x) + \frac{2x}{(1-x)^3}.$$

The corresponding integrating factor is  $e^{-\int \frac{2}{1-x} dx} = (1-x)^2$ . Hence

$$((1-x)^2 C(x))' = \frac{2x}{1-x},$$

and finally

$$C(x) = 2 \left( \frac{1}{(1-x)^2} \ln \frac{1}{1-x} - \frac{x}{(1-x)^2} \right).$$

The first terms in the bracket corresponds to the convolution of two known sequences, so it contributes to  $C_n$  by

$$\begin{aligned} \sum_{k=1}^n \frac{1}{k}(n-k+1) &= (n+1) \sum_{k=1}^n \frac{1}{k} - n \\ &= (n+1)H_n - n = (n+1)(H_{n+1} - 1), \end{aligned}$$

where  $H_n$  are the harmonic numbers. The result is

$$C_n = 2(n+1)(H_{n+1} - 1) - 2n.$$

Notice in 13.I.10, the very same recurrence is solved by different (more direct and simpler) tricks, without any differential equations involved.

Since the harmonic numbers  $H_n$  are easily approximated by  $\ln n = \int_1^n \frac{1}{x} dx$ , the analysis shows that the estimated time cost of quicksort is  $O(n \log n)$ . But it is easy to see that the worst time case is  $O(n^2)$  (in this version it happens if the list was already ordered properly – then  $L_1$  is always empty and the depth of the recursion is linear).

**13.4.10. Exponential generating functions.** Another approach

to generating functions is to take the exponential  $e^x = \sum_{n \geq 0} \frac{1}{n!} x^n$  as the power series corresponding to the constant sequence  $(1, 1, \dots)$ .

In general, this is called the *exponential generating functions*

$$\widehat{A}(x) = \sum_{n \geq 0} a_n \frac{x^n}{n!}.$$

Here are a few elementary examples:

$$\begin{aligned} e^x &\xleftrightarrow{\text{e.g.f.}} (1, 1, 1, \dots), \\ \frac{1}{1-x} &\xleftrightarrow{\text{e.g.f.}} (1, 1, 2, 6, 24, \dots, n!, \dots) \\ \ln \frac{1}{1-x} &\xleftrightarrow{\text{e.g.f.}} (0, 1, 1, 2, 6, 24, \dots) \end{aligned}$$

The slight modification of the definition (just reconsidering the  $\frac{1}{n!}$  coefficient) is responsible for a very different behaviour, compared to the ordinary generating functions. Indeed, now the elementary operations are:

- Multiplication of  $\widehat{A}(x)$  by  $x$  yields the sequence with terms  $\tilde{a}_n = na_{n-1}$ .
- Differentiation of  $\widehat{A}(x)$  shifts the sequence to the left.
- Integration of  $\widehat{A}(x)$  shifts the sequence to the right.
- The product of functions  $\widehat{A}(x)$  and  $\widehat{B}(x)$  corresponds to the sequence with terms  $h_n = \sum_k \binom{n}{k} a_k b_{n-k}$ , the *binomial convolution* of  $a_n$  and  $b_n$ .

As before, the exponential generating functions might become useful when resolving recurrences. Here is a simple example. Define the sequence by the initial conditions  $g_0 = 0$ ,  $g_1 = 1$  and the formula

$$g_n = -2ng_{n-1} + \sum_{k \geq 0} \binom{n}{k} g_k g_{n-k}.$$

At the first glance, seeing the binomial convolution suggests trying the exponential version.

Write  $\widehat{G}(x)$  for the corresponding power series and proceed in the usual four steps again.

*Step 1.* Complete the formula to accommodate the initial conditions:

$$g_n = -2ng_{n-1} + \sum_{k=0}^n \binom{n}{k} g_k g_{n-k} + [n = 1].$$

There seems to be a subtle point about  $g_0$  here, because the equation gives  $g_0 = g_0^2$ , with two solutions 0 and 1. The proper choice of  $g_0$  now yields the correct value for  $g_1$ , but the right solution  $\widehat{G}$  is chosen later.

*Step 2.* Multiply by  $\frac{x^n}{n!}$  and add over all  $n$ , to obtain

$$\widehat{G}(x) = -2x\widehat{G}(x) + \widehat{G}(x)^2 + x.$$

*Step 3.* Now, solve the easy quadratic equation, arriving at

$$\widehat{G}(x) = 1/2(1 + 2x \pm \sqrt{1 + 4x^2}).$$

The evaluation at zero provides  $g_0$ . Hence the right choice for  $g_0 = 0$  is the minus sign. Hence,

$$\widehat{G}(x) = \frac{1 + 2x - \sqrt{1 + 4x^2}}{2}.$$

*Step 4.* Apply the generalized binomial theorem, to expand  $\widehat{G}(x)$  into a power series. See 13.4.8.

$$\sqrt{1 + 4x^2} = 1 + \sum_{k \geq 1} \frac{1}{k} \cdot (-1)^{k-1} \cdot 2 \cdot \binom{2k-2}{k-1} \cdot x^{2k}.$$

Further, since

$$\widehat{G}(x) = \sum_{n \geq 0} g_n \frac{x^n}{n!} = \frac{1 + 2x - \sqrt{1 + 4x^2}}{2},$$

$g_{2k+1} = 0$  and

$$g_{2k} = (-1)^k \cdot \frac{1}{k} \binom{2k-2}{k-1} \cdot (2k)! = (-1)^k \cdot (2k)! \cdot C_{k-1},$$

where  $C_n$  is the  $n$ -th Catalan number.

**13.4.11. Cayley's formula.** We conclude this chapter by a more complicated example.

Cayley's formula computes the number of trees (i.e. graphs with unique paths between all pairs of vertices) on  $n$  given vertices,

$$\kappa(K_n) = n^{n-2}.$$

The notation refers to the equivalent formulation to find all spanning trees in the complete graph  $K_n$ . Equivalently, in how many ways can a tree be realized on  $n$  vertices with the vertices labeled. For example, already the path  $P_n$  can be realized in  $n!$  ways, so there must be very many of them. This result is proved with the help of the exponential generating functions.

Write  $T_n = \kappa(K_n)$  for the unknown values. It is easily shown that  $T_1 = T_2 = 1$ ,  $T_3 = 3$ ,  $T_4 = 16$ . For instance, consider trees on 4 vertices. Out of the  $\binom{6}{3} = 20$  potential graphs with exactly three edges, those where the edges form a triangle must not be counted. There are  $\binom{4}{3} = 4$  of them. In the diagram, there are four different possibilities, and each of them can be rotated into another three, hence the solution is 16.

The recurrent formula can be obtained by fixing one of the vertices and add together the possibilities for all available degrees of this vertex. This suggests looking rather at the number  $R_n$  of the rooted trees. It is clear that  $R_n = nT_n$  because there are  $n$  possibilities to place the root at each of the trees. Also, one can work with one fixed ordering of the vertices in  $K_n$  and multiply the result by  $n!$  in the end. In this way, go through the possible degrees  $m$  of the first vertex and for each  $m$  to find the different possibilities for the sizes  $k_1 \dots, k_m$  of the corresponding subtrees. Obviously  $k_1 + \dots + k_m = n - 1$ , all  $k_i > 0$ , and since the labeling of all vertices is fixed, all the orders of the subtrees must be considered as equivalent. Multiply the contribution by  $\frac{1}{m!}$  and similarly for each of the possibilities of the subtrees. The recurrent formula is

$$R_n = n! \sum_{m>0} \frac{1}{m!} \sum_{k_1+\dots+k_m=n-1} \frac{1}{k_1! \dots k_m!} R_{k_1} \dots R_{k_m}.$$

Of course,  $R_0 = 0$ ,  $R_1 = 1$  and, already using the formula,  $R_2 = 2u_1 = 2$ . Next,  $R_3 = 3u_2 + 3u_1^2 = 9$ ,  $R_4 = 4R_3 + 24R_1R_2 + 4R_1^3 = 64$ , all as expected. The first step of the standard procedure is accomplished.

Next, write  $\widehat{R}(x) = \sum_{n \geq 0} R_n \frac{1}{n!} x^n$ . The inner sum is the coefficient at  $x^{n-1}$  in the  $m$ -th power of the series  $\widehat{R}(x)$ . Therefore,

$$R_n \frac{1}{n!} = [x^{n-1}] \sum_{m \geq 0} \frac{1}{m!} \widehat{R}(x)^m,$$

and hence have the required equation on  $\widehat{R}$ :

$$\widehat{R}(x) = x e^{\widehat{R}(x)}.$$

There are several ways, of solving such functional equations. Here is one such tool without proof.

maybe, get it as application of residue theorem in chapter 9

**Theorem** (Lagrange inverse formula). *Consider an analytic function  $f$ ,  $f(0) = 0$  and  $f'(0) \neq 0$ . Then there (locally) is the analytic inverse of  $f$ , i.e  $w = g(z) = \sum_{n \geq 1} g_n \frac{z^n}{n!}$  and  $z = f(g(z))$ . Moreover, for all  $n > 0$ ,*

$$g_n = \lim_{w \rightarrow 0} \left( \frac{d^{n-1}}{dw^{n-1}} \left( \frac{w}{f(w)} \right)^n \right).$$

In this case, solve the equation  $x = \frac{\widehat{R}(x)}{e^{\widehat{R}(x)}}$ , so that we may apply the latter theorem with  $g = \widehat{R}$  and  $f(w) = \frac{w}{e^w}$ . It follows that

$$\begin{aligned} [x^n] \widehat{R}(x) &= \frac{1}{n} [w^{n-1}] \left( \frac{w}{w/e^w} \right)^n \\ &= \frac{1}{n} [w^{n-1}] e^{wn} = \frac{1}{n} \frac{n^{n-1}}{(n-1)!} = \frac{n^{n-1}}{n!} \end{aligned}$$

In particular,  $R_n = n^{n-1}$  and so,

$$T_n = \frac{R_n}{n} = n^{n-2}.$$

**J. Additional exercises to the whole chapter**

**13.J.1.** Determine the number of edges that must be added into

- i) the cycle graph  $C_n$  on  $n$  vertices,
- ii) the complete bipartite graph  $K_{m,n}$

in order to obtain a complete graph. ○

**13.J.2.** Let the vertices of  $K_6$  be labeled  $1, 2, \dots, 6$  and let every edge  $\{i, j\}$  be assigned the integer  $[(i + j) \bmod 3] + 1$ . How many maximum spanning trees are there in this graph? ○

**13.J.3.** Let the vertices of  $K_7$  be labeled  $1, 2, \dots, 7$  and let every edge  $\{i, j\}$  be assigned the integer  $[(i + j) \bmod 3] + 1$ . How many maximum spanning trees are there in this graph? ○

**13.J.4.** Let the vertices of  $K_5$  be labeled  $1, 2, \dots, 5$  and let every edge  $\{i, j\}$  be assigned the integer: 1 if  $i + j$  is odd; 2 if  $i + j$  is even. How many maximum spanning trees are there in this graph? ○

**13.J.5.** Let the vertices of  $K_5$  be labeled  $1, 2, \dots, 5$  and let every edge  $\{i, j\}$  be assigned the integer: 1 if  $i + j$  is odd; 2 if  $i + j$  is even. How many minimum spanning trees are there in this graph? ○

**13.J.6.** Let the vertices of  $K_6$  be labeled  $1, 2, \dots, 6$  and let every edge  $\{i, j\}$  be assigned the integer: 1 if  $i + j$  leaves remainder 1 upon division by 3; 2 if  $i + j$  leaves remainder 2 upon division by 3; 3 if  $i + j$  is divisible by 3; How many minimum spanning trees are there in this graph? ○

**13.J.7.** Let the vertices of  $K_6$  be labeled  $1, 2, \dots, 6$  and let every edge  $\{i, j\}$  be assigned the integer: 1 if  $i + j$  leaves remainder 1 upon division by 3; 2 if  $i + j$  leaves remainder 2 upon division by 3; 3 if  $i + j$  is divisible by 3; How many maximum spanning trees are there in this graph? ○

**13.J.8. Icosian Game** – find a Hamiltonian cycle in the graph consisting of the vertices and edges of the regular dodecahedron. □

**Solution.** See Wikipedia<sup>4</sup>. □

**13.J.9.** Does there exist a Hamiltonian cycle in the Petersen graph?

**Solution.** No (however, when any one of the vertices is removed, the resulting graph is already Hamiltonian). This can be shown by enumerating all 3-regular Hamiltonian graphs on 10 vertices and finding a cycle of length less than 5 in each of them. □

**13.J.10.** If  $G = (V, E)$  is Hamiltonian and  $\emptyset \neq W \subsetneq V$ , then  $G \setminus W$  has at most  $|W|$  connected components. Give an example of a graph where the converse does not hold.

**Solution.** □

**13.J.11.** Find a maximum flow and the corresponding minimum cut in the following weighted directed graph:

**13.J.12.** Find a maximum flow and the corresponding minimum cut in the following weighted directed graph: ○

<sup>4</sup>Wikipedia, *Icosian game*, [http://en.wikipedia.org/wiki/Icosian\\_game](http://en.wikipedia.org/wiki/Icosian_game) (as of Aug. 8, 2013, 13:24 GMT).

13.J.13. Find a maximum flow and the corresponding minimum cut in the following weighted directed graph:

13.J.14. Find a maximum flow and the corresponding minimum cut in the following weighted directed graph:

13.J.15. Find the generating functions of the following sequences:

- i)  $(1; 2; 1; 4; 1; 8; 1; 16; \dots)$
- ii)  $(1; 1; 0; 1; 1; 0; 1; 1; \dots)$
- iii)  $(1; -1; 2; -2; 3; -3; 4; -4; \dots)$

**Solution.**

i)  $(1; 2; 1; 4; 1; 8; 1; 16; \dots) = (1; 0; 1; 0; \dots) + (0; 2; 0; 4; 0; 16; \dots)$ . Thus, we find the generating functions for each sequence separately. As for the first one, consider the sequence  $(1, 1, 1, 1, \dots)$ . It is generated by the function  $\frac{1}{1-x}$ .

The zeros can be inserted by substituting  $x^2$  for  $x$ . As for the second sequence, we proceed similarly, starting with  $(1; 2; 4; 8; 16; \dots)$ , then multiplying by two, inserting zeros, and finally shifting to the right by multiplying by  $x$ .

ii)  $(1; 1; 0; 1; 1; 0; 1; 1; \dots) = (1; 0; 0; 1; 0; 0; 1; \dots) + (0; 1; 0; 0; 1; 0; 0; 1; \dots)$ .

i)  $\frac{1}{1-x^2} + \frac{2x}{1-2x^2}$

ii)  $\frac{1+x}{1-x^3}$

iii)  $\frac{-1}{(1-x^2)^2} + \frac{x}{(1-x^2)^2}$

□

**13.J.16.** Find the coefficient at  $x^{17}$  in  $(x^3 + x^4 + x^5 + \dots)^3$ .

**Solution.**  $(x^3 + x^4 + x^5 + \dots)^3 = \frac{x^9}{(1-x)^3} = x^9 \cdot \frac{1}{(1-x)^3}$ . We are thus looking for the coefficient at  $x^8$  in  $\frac{1}{(1-x)^3}$ . This is equal to  $\binom{10}{2}$ , i. e. 45.  $\square$

**13.J.17.** There are 30 red, 40 blue, and 50 white balls in a box (balls of the same color are indistinguishable). In how many ways can we pick up 70 balls from the box?  $\circ$

**Solution.** Clearly, the number of possibilities is equal to the coefficient at  $x^{70}$  in the expression

$$(1 + x + \dots + x^{30})(1 + x + \dots + x^{40})(1 + x + \dots + x^{50}).$$

Mere rearrangements lead to

$$(1+x+\dots+x^{30})(1+x+\dots+x^{40})(1+x+\dots+x^{50}) = \frac{1}{(1-x)^3} \dots (1-x^{31})(1-x^{41})(1-x^{51}).$$

Applying the generalized binomial theorem, we obtain the solution  $\binom{72}{2} - \binom{41}{2} - \binom{31}{2} - \binom{21}{2}$ .  $\square$

**13.J.18.** What is the probability that a roll of 12 dice results in the sum of 30?

*Hint: Express the number of possibilities when the sum is 30. Consider  $(x + x^2 + x^3 + x^4 + x^5 + x^6)^{12}$ .*  $\circ$

**13.J.19.** A fruit grower wants to plant 25 new trees, having four species at his disposal. However, his wife insists that there be at most 1 walnut, at most 10 apples, at least 6 cherries, and at least 8 plums. In how many ways can he fulfill his beloved's wishes?

*Hint: We are interested in the coefficient at  $x^{25}$  in the expression*

$$(1+x)(1+x+\dots+x^{10})(x^6+x^7+\dots)(x^8+x^9+\dots).$$

**Solution.**

$$(1+x)(1+x+\dots+x^{10})(x^6+x^7+\dots)(x^8+x^9+\dots) = \frac{x^{14}(1-x^2)(1-x^{11})}{(1-x)^4}.$$

Therefore, we are looking for the coefficient at  $x^{11}$  in  $(1-x^2-x^{11}\dots) \cdot \frac{1}{(1-x)^4}$ , which is equal to  $\binom{14}{3} - \binom{12}{3} - \binom{3}{3}$ .  $\square$

**13.J.20.** Express the general term of the sequences defined by the following recurrences:

i)  $a_1 = 3, a_2 = 5, a_{n+2} = 4a_{n+1} - 3a_n$  for  $n = 1, 2, 3, \dots$

ii)  $a_0 = 0, a_1 = 1, a_{n+2} = 2a_{n+1} - 4a_n$  for  $n = 0, 1, 2, 3, \dots$

**Solution.**

i)  $a_n = 2 + 3^{n-1}$ .

ii)  $a_n = \frac{1}{2}\sqrt{-3} \cdot ((1 + \sqrt{-3})^n - (1 - \sqrt{-3})^n)$ .

$\square$

**13.J.21.** Solve the recurrence where each term of the sequence  $(a_0, a_1, a_2, \dots)$  is equal to the arithmetic mean of the preceding two terms.  $\circ$

**13.J.22.** Solve the recurrence  $a_{n+2} = \sqrt{a_{n+1}a_n}$  with the initial conditions  $a_0 = 2, a_1 = 8$ .

*Hint: Create a new sequence  $b_n = \log_2 a_n$ .*  $\circ$

**13.J.23.** Solve the recurrence given by

$$a_n = \sum_{k \geq 0} \binom{n}{k} \frac{a_k}{2^k}, a_0 = 1.$$

*Hint: Multiply both sides by  $\frac{x^n}{n!}$  and sum it up. Note that  $\widehat{A}(X)$  is the exponential generating function for the sequence  $(a_n)$ .*  $\circ$

**13.J.24.** Find the number of triangulations of a convex  $n$ -gon.

*Hint: Select any diagonal that goes through a fixed vertex, this splits the polygon in two.*

**Solution.**  $t_n = C_{n-2}$ , where  $C_n$  denotes the  $n$ -th Catalan number. □

**13.J.25.** Find the number of walks in a square grid of size  $n \times n$  from the lower left-hand corner  $A$  to the upper right-hand corner  $B$  which go only upwards or rightwards and intersect the diagonal  $AB$  at exactly one point (besides  $A$  and  $B$ ).

*Hint: Catalan numbers.* ○

**13.J.26.** Prove that the Fibonacci number satisfy:

i)  $F_2 + F_4 + \cdots + F_{2n} = F_{2n+1} - 1$

ii)  $F_1 + F_3 + \cdots + F_{2n-1} = F_{2n}$

○

**13.J.27.** Recall the well-known puzzle Tower of Hanoi and let  $H_n$  denote the minimum number of steps necessary to move a tower consisting of  $n$  disks from one rod to another one. Find a recurrent formula for  $H_n$  as well as its general solution.

**Solution.**  $H_{n+1} = 2H_n + 1$ ,  $H_n = 2^n - 1$ . □

At the very end of the book, we present one problem from practice.

- 13.J.28.** A volleyball team (with a libero, i. e. 7 people) are sitting in a pub, drinking their favorite and well-deserved beer. However, there are only 7 beer mugs available. What is the probability that in the next round, i) exactly one volleyball player is not given the same mug as the last time,  
 ii) no one is given the same mug as the last time,  
 iii) exactly three players are given the same mug.

**Solution.**

- i) If six of the seven people are given the same mug, then so must the last one. Therefore, the probability is zero.  
 ii) Let  $M$  be the set of all orders of the 7 players and let  $A_i$  be the event of orders where the  $i$ -th player is given his mug. We want to calculate  $|M - \cup_i A_i|$ . We get  $7! \sum_{k=0}^7 \frac{(-1)^k}{k!} = 1854$ , so the probability is  $\frac{1854}{5040} = \frac{103}{280} \doteq 0,37$ .  
 iii) There are  $\binom{7}{3} = 35$  ways to select the three people who are to get the same mug. The remaining four people must be given different mugs. Again, we can apply the formula from above, i. e., there are  $4! \sum_{k=0}^4 \frac{(-1)^k}{k!} = 9$  possibilities. Altogether, there are  $9 \cdot 35 = 315$  favorable cases, so the probability is  $\frac{315}{5040} = \frac{1}{16}$ .

□

Key to the exercises

**13.A.23.** The cut vertices are 0, 1, 9, 10; the cut edges are (0, 1), (0, 12), (9, 10).

**13.B.3.** (3, 1), (3, 2), (3, 4), (3, 5), (3, 6), (6, 1), (6, 2), (6, 4), (6, 5), (5, 1), (5, 2), (5, 4), (4, 1), (4, 2), (2, 1).

**13.B.4.** (3, 1), (3, 2), (3, 4), (3, 5), (3, 6), (1, 2), (1, 4), (1, 5), (1, 6), (2, 4), (2, 5), ... (5, 6).

**13.B.5.** Solution is missing.

**13.B.12.**

It can be shown using the Havel–Hakimi procedure that such graph indeed exists. However, it cannot be planar:  $|V| = 10$ ,  $|E| = 35$ , but if it were planar, we would have  $3|V| - 6 \geq |E|$ , i. e.,  $24 \geq 35$ .

**13.B.15.**

- i) Yes. This follows immediately from the Kuratowski theorem ( $K_5$  has 10 edges and  $K_{3,3}$  has 9).
- ii) No. Consider  $K_5$  or  $K_{3,3}$ .
- iii) No. There are many counterexamples, for instance  $K_{3,3}$  with another vertex and an edge leading to it.
- iv) No. Consider  $K_5$ .
- v) No. Consider  $K_{3,3}$ .
- vi) The same as (ii).
- vii) No. Consider  $C_n$ .
- viii) No. Consider  $K_5$ .
- ix) No. Consider  $C_n$ .

**13.B.17.** The first code does not represent a tree (it has a proper prefix with the same number of zeros and ones). There is a tree corresponding to the second code.

**13.C.4.** The procedure is incorrect. As a counterexample, consider a cycle graph with one edge of length two and all other edges of length one.

**13.C.5.** Applying any algorithm for finding a minimum spanning tree, we find out that the wanted length is 12154 (the spanning tree consists of edges LPe, LP, LNY, PeT, MCNY).

**13.C.6.** Solution is missing.

**13.D.5.** We find a maximum flow of size 15 and the cut [1, 6], [1, 3], [2, 4], [2, 3] of the same capacity.

**13.D.7.** We know from the theory and the result of the above exercise that the minimum capacity of a cut is 9. There are more maximum flows in the network. For instance, we can set  $f(a) = 2$ ,  $f(b) = 4$ ,  $f(c) = 1$ ,  $f(h) = 1$ ,  $f(j) = 4$ ,  $f(f) = 2$ ,  $f(i) = 7$ , and  $f(v) = 0$  for all other edges  $v$  of the graph.

**13.E.5.** Solution is missing.

**13.E.11.**

$$1 - \frac{4! \cdot 4!}{2^4} = \frac{27}{35}$$

**13.E.12.**  $\frac{49}{54}$ .

**13.I.4.**

- i) We know from the exercise of subsection 13.4.3 that the generating function of the sequence (1, 2, 3, 4, ...) is  $\frac{1}{(1-x)^2}$ .
- ii) Since we have (by the previous exercise as well)

$$\frac{x}{(1-x)^2} \xleftrightarrow{\text{o.g.f.}} (0, 1, 2, 3, \dots),$$

mÄĀme pro derivaci tÄĀsto funkce

$$\left( \frac{x}{(1-x)^2} \right)' = \frac{1+x}{(1-x)^3} \xleftrightarrow{\text{o.g.f.}} (1 \cdot 1, 2 \cdot 2, 3 \cdot 3, \dots).$$

Let us emphasize that this problem could also be solved using the fact that  $\frac{1}{(1-x)^3} \xleftrightarrow{\text{o.g.f.}} \binom{n+2}{n}$ .

iii) We have

$$\begin{aligned} \frac{1}{1-x} &\overset{\text{o.g.f.}}{\longleftrightarrow} (1, 1, 1, 1, \dots), \\ \frac{1}{1-2x} &\overset{\text{o.g.f.}}{\longleftrightarrow} (1, 2, 4, 8, \dots), \\ \frac{1}{1-2x^2} &\overset{\text{o.g.f.}}{\longleftrightarrow} (1, 0, 2, 0, 4, 0, \dots), \\ \frac{x}{1-2x^2} &\overset{\text{o.g.f.}}{\longleftrightarrow} (0, 1, 0, 2, 0, 4, \dots), \end{aligned}$$

whence we get the result

$$\frac{1+x}{1-2x^2} \overset{\text{o.g.f.}}{\longleftrightarrow} (1, 1, 2, 2, 4, 4, 8, 8, \dots).$$

iv) We know from the above that  $f(x) = \frac{1+x}{(1-x)^3} \overset{\text{o.g.f.}}{\longleftrightarrow} (1^2, 2^2, 3^2, \dots)$ , hence

$$\frac{f(x) - (1+4x)}{x^2} \overset{\text{o.g.f.}}{\longleftrightarrow} (3^2, 4^2, 5^2, \dots).$$

Substituting  $2x^3$  for  $x$ , we obtain

$$\frac{f(2x^3) - (1+8x^3)}{4^6} \overset{\text{o.g.f.}}{\longleftrightarrow} (9, 0, 0, 2 \cdot 16, 0, 0, 4 \cdot 25, \dots).$$

v) If we denote the result of the previous problem as  $F(x)$ , then the result of this one is

$$F(x) - x^2 F(x) + \frac{x}{1-x^3}.$$

**13.I.11.**  $x/(1-3x+x^2)$ .

**13.J.1.**

- i) The complete graph on  $n$  vertices has  $\frac{n(n-1)}{2}$  edges, the cycle graph on  $n$  vertices has  $n$  edges. Therefore,  $\frac{n(n-1)}{2} - n$  edges must be added to the cycle graph.
- ii) Similarly as above, we get the result  $\frac{(m+n)(m+n-1)}{2} - m \cdot n$ .

**13.J.2.** There are five edges whose value is 3: four of them lie on the cycle 23562 and the remaining one is the edge 14. Therefore, they form a disconnected subgraph of the complete graph, so the spanning tree must contain at least one edge of value 2. Thus, the total weight of a maximum spanning tree is at most  $4 \cdot 3 + 2 = 14$ . And indeed, there exist spanning trees with this weight. We select all the edges of value 3 except for one that lies on the mentioned cycle and connect the resulting components 2356 and 14 with any edge of value 2. There are four such edges. Altogether, there are  $4 \cdot 4 = 16$  maximum spanning trees.

**13.J.3.** The edges of value 1 form a subgraph with two connected components, namely  $\{1, 2, 4, 5, 7\}$  a  $\{3, 6\}$ . Further, there are six edges of value 2 that lead between these two components. Therefore, the total weight of a minimum spanning tree is  $6 \cdot 1 + 2 = 8$ . Moreover, there are exactly three cycles in the former component, each of length 4, and each of the 6 edges of this component belongs to exactly two of the three cycles. In order to obtain a tree from this component, we must omit two edges, which can be done in  $6 \cdot 4/2$  ways. Altogether, we get  $12 \cdot 6 = 72$  minimum spanning trees.

**13.J.4.** 18.

**13.J.5.** 12.

**13.J.6.** 16.

**13.J.7.** 16.

**13.J.11.** The minimum cut is given by the set  $\{Z, A, E\}$ . Its value is 32.

**13.J.12.** The minimum cut is given by the set  $\{B, D, S\}$ . Its value is 40.

**13.J.13.** The minimum cut is given by the set  $\{F, S, D\}$ . Its value is 29.

**13.J.14.** The minimum cut is given by the set  $\{F, S\}$ . Its value is 39.

**13.J.18.** The resulting probability is the ratio of the number of favorable cases to the number of all cases. Clearly, the latter is  $6^{12}$ . Now, let us compute the number of favorable cases. Consider the expression  $(x + x^2 + x^3 + x^4 + x^5 + x^6)^{12}$ . Then, the number of favorable cases is the coefficient at  $x^{30}$ . We have:

$$(x+x^2+x^3+x^4+x^5+x^6)^{12} = \left(\frac{x(1-x^6)}{1-x}\right)^{12} = x^{12} \cdot \left(\frac{1-x^6}{1-x}\right)^{12}$$

Therefore, we are interested in the coefficient at  $x^{18}$  in

$$\left(\frac{1-x^6}{1-x}\right)^{12} = (1-12x^6+66x^{12}-220x^{18}) \cdot \frac{1}{1-x}^{12}.$$

It follows from the generalized binomial theorem that the number of favorable cases is

$$\binom{29}{11} - 12 \cdot \binom{23}{11} + 66 \cdot \binom{17}{11} - 220 \cdot \binom{11}{11}.$$

**13.J.21.**  $a_n = k \left(-\frac{1}{2}\right)^n + l$ .

**13.J.22.** Solution is missing.

**13.J.23.** Solution is missing.

**13.J.25.** Solution is missing.

**13.J.26.** Solution is missing.

- the lower Riemann integral, 369
- the main normal, 356
- the primitive function, 358
- the second derivative, 342
- the sources and sinks of the network, 653
- the uniform continuity, 369
- the upper Riemann integral, 369
- the Weierstrass test, 382
- topology, 264, 447
- topology of the complex plane, 264
- topology of the metric spaces, 447
- topology of the real line, 264
- torsion of the curve, 356
- totally bounded, 457
- Trace of mapping, 111
- trace of matrix, 111
- trail, 625
- transformation, 489
- transient, 152
- transitive, 39
- translation, 25, 203
- transpose, 86
- transposition, 84
- trapezoidal rule, 385
- tree, 640
- triangle, 208, 623
- triangle inequality, 155
- trigonometric functions, 297
  
- unbounded, 264
- undirected graph, 622
- uniform continuity, 368
- uniformly bounded, 460
- uniformly Cauchy, 380
- unit decomposition subordinate to a locally finite cover, 519
- unit matrix, 32, 75
- unitary group, 157
- Unitary isomorphism, 154
- unitary mapping, 154
- unitary matrices, 157
- Unitary space, 153
- universal formula, 667
- unsaturated, 655
- upper bound, 259
- upper Riemann sum, 366
  
- Vandermonde determinant, 252
- variation, 387
- vector, 72
- vector field, 541
- vector field  $X$ , 513
- vector field  $X$  along the curve  $M$ , 513
- vector functions, 354
- vector functions of one real variable, 354
- vector of restrictions, 134
- Vector space, 92
- vector subspace, 94
  
- vectors, 24
- vertices, 622
  
- walk, 625
- walk of length  $n$ , 625
- wavelet mother function, 427
- weak connectedness, 633
- weakly connected, 639
- weight, 636
  
- zero curvature, 352
- zero matrix, 74
- zero measure, 388
- zero vector, 24

**Based on the earlier textbook:**  
**Matematika drsně a svižně**  
**Jan Slovák, Martin Panák, Michal Bulant**  
**a kolektiv**
