Either the series converges absolutely, or it does not converge if this limit is different from 1. It follows that it converges for  $|x| < \rho$  and diverges for  $|x| > \rho$ . If the limit does not exist, use the upper limit in the same way. The same argument based on the ratio test of convergence leads to the other formula for  $r$ .

The statements about continuity and the derivatives are proved later in a more general context, see 6.3.7–6.3.9, or check the straightforward proof in the complex setting in 9.4.2.  $\square$

**5.4.11. Remarks.** If the coefficients of the series increase rapidly enough, (for example  $a_n = n^n$ ), then  $r = \infty$ . Then the radius of convergence is zero, and the series converges only at  $x = 0$ .

Here are some examples of convergence of power series (including the boundary points of the corresponding interval): Consider

$$S(x) = \sum_{n=0}^{\infty} x^n, \quad T(x) = \sum_{n=1}^{\infty} \frac{1}{n} x^n.$$

The former example is the *geometric series*, which was already discussed. Its sum is, for every  $x$ ,  $|x| < 1$ ,

$$S(x) = \frac{1}{1-x},$$

while  $|x| > 1$  guarantees that the series diverges. For  $x = 1$ , we obtain the series  $1 + 1 + 1 + \dots$ , which is divergent. For  $x = -1$ , the series is  $1 - 1 + 1 - \dots$ , whose partial sums do not have a limit. The series oscillates.

Theorem 5.4.5(2) shows that the radius of convergence of the series  $T(x)$  is again 1 because

$$\lim_{n \rightarrow \infty} \left| \frac{\frac{1}{n+1} x^{n+1}}{\frac{1}{n} x^n} \right| = |x| \lim_{n \rightarrow \infty} \left| \frac{n}{n+1} \right| = |x|.$$

For  $x = 1$ , the series  $1 + \frac{1}{2} + \frac{1}{3} + \dots$ , is divergent: By summing up the  $2^{k-1}$  adjacent terms  $1/2^{k-1}, \dots, 1/(2^k - 1)$  and replacing each of them by  $2^{-k}$  (thus they total up to  $1/2$ ), the partial sums are bounded from below by the sum of these  $1/2$ 's. Since the bound from below diverges to infinity, so does the original series.

On the other hand, the series  $T(-1) = -1 + \frac{1}{2} - \frac{1}{3} + \dots$  converges although of course, it cannot converge absolutely. Of course, this is true since we deal here with an alternating series.

Notice that the convergence of a power series is relatively fast near  $x = 0$ . It is slower near the boundary of the convergence interval.

**5.4.12. Trigonometric functions.** Another important observation is that a power series is a series of numbers for each fixed  $x$  and the individual terms make sense for complex numbers  $x \in \mathbb{C}$ . Thus the domain of convergence of a power series is always a disc in the complex plane  $\mathbb{C}$  centered at the origin.

However, we may rely on the properties of natural logarithm, as follows:

$$\begin{aligned} \sum_{n=1}^{\infty} a_n &= \lim_{n \rightarrow \infty} \left( \ln \frac{2}{1} + \ln \frac{3}{2} + \ln \frac{4}{3} + \dots + \ln \frac{n+1}{n} \right) \\ &= \lim_{n \rightarrow \infty} \ln \frac{2 \cdot 3 \cdot 4 \cdot \dots \cdot (n+1)}{1 \cdot 2 \cdot 3 \cdot \dots \cdot n} \\ &= \lim_{n \rightarrow \infty} \ln(n+1) = +\infty. \end{aligned}$$

Thus the series  $\mathcal{Y}$  also diverges to  $+\infty$ .  $\square$

*The infinite number series*

$$\zeta(p) = \sum_{n=1}^{\infty} \frac{1}{n^p} = 1 + \frac{1}{2^p} + \dots + \frac{1}{n^p} + \dots$$

is called the  $p$ -series, and it is known that converges for all  $p > 1$ . For  $0 < p \leq 1$ , the  $p$ -series diverges (observe that for  $p = 1$  coincides with the harmonic series discussed above). For  $p > 1$  the  $p$ -series  $\zeta(p)$  is a monotone decreasing function of  $p$ , called the “Riemann zeta function”.<sup>9</sup> Euler proved that

$$\sum_{n=1}^{\infty} \frac{1}{n^p} = \prod_s \left( 1 + \frac{1}{s^p} \right),$$

where  $s$  ranges over all prime numbers. This formula, which is now known as the Euler product formula, makes  $\zeta$  a very important tool in number theory. However, for most of the  $p$  with  $p > 1$ , the value  $\zeta(p)$  is still unknown, though there are some accurate approximations (as for  $p = 3$  or  $p = 5$ , etc). Next we will use Sage to evaluate  $\zeta(p)$  for some  $p$ .

**5.D.2.** Evaluate the zeta function  $\zeta(p)$  for  $p = 2, \dots, 9$  with the aid of Sage. Is this feasible for all the given values of  $p$ ?  $\circ$

*Infinite sums naturally appear in many practical problems. Perhaps the best known ancient example is the Achilles paradox noticed by Aristoteles, which we briefly highlight by the next exercise. Later we will discuss more sophisticated problems, starting for example with 5.D.10.*

**5.D.3. Achilles’ paradox.** Although Achilles runs much faster than the turtle on the beach, he needs some time  $t_n$  for shortening their distance to the half. Thus Achilles needs the infinite sum of these time intervals  $t_n$  to catch the turtle. Explain why this sum is still a finite number.

**Solution.** If the current distance was  $d$ , and the velocity of the turtle was 1 while the velocity of Achilles was  $\alpha$ , we could write  $d + t - \alpha t$  for their distance after time  $t$ . Thus, shortening it to the half means  $t = \frac{1}{2} \frac{d}{\alpha - 1}$ . Repeating this  $n$  times, we obtain the time intervals

$$t_n = \frac{d}{\alpha - 1} \cdot \frac{1}{2^n}.$$

<sup>9</sup>Named for F. B. Riemann (1826 - 1866).

More generally, we can write power functions centered at an arbitrary (complex) point  $x_0$ ,

$$S(x) = \sum_{n=0}^{\infty} a_n (x - x_0)^n,$$

which converge absolutely again on the disc of radius  $\rho$ ,  $\rho^{-1} = \limsup_{n \rightarrow \infty} \sqrt[n]{|a_n|}$ , but this time centered at  $x_0$ .

Earlier we proved explicitly (by a simple application of the ratio test) that the exponential function series converges everywhere. Thus this defines a function for all complex numbers  $x$ .

Its values are the limits of values of (complex) polynomials with real coefficients and each polynomial is completely determined by finitely many of its values. In particular, the values of each series are completely determined on the complex domain by their values at the real input values  $x$ . Therefore, the complex exponential must also satisfy the usual formulae which we have already derived for the real values  $x$ . In particular, for all  $x, y \in \mathbb{C}$

$$e^{x+y} = e^x \cdot e^y,$$

which can be also easily checked directly by the formula for the product in theorem 5.4.4(3).

Substitute the values  $x = it$ , where  $i \in \mathbb{C}$  is the imaginary unit,  $t \in \mathbb{R}$  arbitrary. We get the complex valued function on  $\mathbb{R}$

$$e^{it} = 1 + it - \frac{1}{2}t^2 - i\frac{1}{3!}t^3 + \frac{1}{4!}t^4 + i\frac{1}{5!}t^5 - \dots$$

The conjugate number to  $z = e^{it}$  is the number  $\bar{z} = e^{-it}$ . Hence

$$|z|^2 = z \cdot \bar{z} = e^{it} \cdot e^{-it} = e^0 = 1.$$

All the values  $z = e^{it}$  lie on the unit circle centered at the origin, in the complex plane.

The real and imaginary parts of the points lying on the unit circle are named as the trigonometric functions  $\cos \theta$  and  $\sin \theta$ , where  $\theta$  is the corresponding angle.

Differentiating the parametric description of the points of the circle  $t \mapsto e^{it}$ , gives the vectors of “velocities” which are easily computed. Differentiating the real and imaginary parts separately (knowing that the real power series can be differentiated term by term) gives :

$$\begin{aligned} (e^{it})' &= \left( 1 - \frac{1}{2}t^2 + \frac{1}{4!}t^4 \dots \right)' + i \left( t - \frac{1}{3!}t^3 + \frac{1}{5!}t^5 \dots \right)' \\ &= -\left( t - \frac{1}{3!}t^3 + \frac{1}{5!}t^5 \dots \right) + i \left( 1 - \frac{1}{2}t^2 + \frac{1}{4!}t^4 \dots \right) \end{aligned}$$

The procedure of summing all these  $t_n$  follows the rule of geometric series (see 5.B.16). Thus the result is

$$\sum_{n=0}^{\infty} \frac{1}{2^n} = \frac{1}{1 - \frac{1}{2}} = 2$$

and so Achilles needs the time  $\frac{d}{\alpha - 1}$  (here we sum from  $n = 1$ ). This perfectly matches the fact that their relative mutual velocity is  $\alpha - 1$  (explain why this assertion is true).  $\square$

*An infinite series, whether real or complex, that is absolutely convergent is also convergent. This is fundamentally due to the completeness of both the real numbers ( $\mathbb{R}$ ) and the complex numbers ( $\mathbb{C}$ ). Conversely, a series that is convergent but not absolutely convergent is termed “conditionally convergent”, see in the end of Section 5.4.7. In the following sections we will examine a range of examples that encompass all possible cases of convergence and divergence.*

**5.D.4.** Exam which of the following series is convergent or divergent:

$$\begin{aligned} T_1 &= \sum_{n=1}^{\infty} \frac{n^2 + 1}{2n^2 - 1}, & T_2 &= \sum_{n=1}^{\infty} \frac{2^n}{n}, \\ T_3 &= \sum_{n=1}^{\infty} \frac{2^n}{(n+2)!}, & T_4 &= \sum_{n=1}^{\infty} \frac{1}{n \cdot 2^{2025}}, \\ T_5 &= \sum_{n=1}^{\infty} \frac{n^7 + 7^n + 2}{(7^n + 2) \cdot n^7}, & T_6 &= \sum_{n=1}^{\infty} \frac{e^n}{n^2}, \\ T_7 &= \sum_{n=0}^{\infty} \frac{1}{(n+1) \cdot 3^n}, & T_8 &= \sum_{n=1}^{\infty} \frac{n^2 + 1}{n^3}, \\ T_9 &= \sum_{n=0}^{\infty} \frac{2^n + 3^n}{n!}, & T_{10} &= \sum_{n=1}^{\infty} 2^n \cdot \left(\frac{4}{5}\right)^{n^2}, \\ T_{11} &= \sum_{n=0}^{\infty} \frac{2 + \sin^3(n+1)}{4^n + n^2}, & T_{12} &= \sum_{n=1}^{\infty} \frac{n^n}{n^2 \cdot n!}. \end{aligned}$$

**Solution.** 1) We see that  $\lim_{n \rightarrow \infty} \frac{n^2+1}{2n^2-1} = \frac{1}{2} \neq 0$ , so by (1) in Theorem 5.4.5 the series  $T_1$  is divergent.

2) Similarly we see that  $\lim_{n \rightarrow \infty} \frac{2^n}{n} = \infty$ , hence  $T_2$  is divergent. Notice however that when the terms of the series are positive, absolute convergence is the same as convergence. Hence the same result follows by the ratio test, also known as the d’Alembert criterion (see (4) of Theorem 5.4.5). This is because

$$\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n \rightarrow \infty} \left| \frac{\frac{2^{n+1}}{n+1}}{\frac{2^n}{n}} \right| = \lim_{n \rightarrow \infty} \frac{2(n+1)}{n} = 2 > 1.$$

One may like to verify the divergent of  $T_2$  (or  $T_1$ ) also in Sage. This can be done just by typing

```
var("n"); sum(2^n/n, n, 1, oo)
```

and what we should essentially keep from the answer that Sage returns is the very final output: **Sum is divergent.** Thus, the sum method in Sage can be used as a verification

which means  $(e^{it})' = i \cdot e^{it}$ . So the velocity vectors all have unit length. Hence the entire circle is parametrized if  $t$  is moved through the interval  $[0, 2\pi]$ , where  $2\pi$  stands for the length of the circle (a thorough definition of the length of a curve needs integral calculus, which we will develop in the next chapter). In particular, this procedure of parameterizing the circle can be used to define the *number*  $\pi$ , also called Archimedes’ constant or the Ludolphian number,<sup>15</sup> half the length of the unit circle in the Euclidean plane  $\mathbb{R}^2$ . It can be found by computing the first positive zero point of the imaginary part of  $e^{it}$ .

For example, use the 10th order approximation

$$\sin t \simeq t - \frac{1}{6}t^3 + \frac{1}{120}t^5 - \frac{1}{5040}t^7 + \frac{1}{362880}t^9.$$

Ask any computer algebra system to find the first positive root. The result is  $\pi \simeq 3.148690$ , for which only the first 2 decimal points are correct. But with the 20th order approximation this gets 3.141592 with 5 digits correct. The reason for the slow approximation is that  $\pi$  is relatively far from zero.

The explicit representation of trigonometric functions in terms of the power series is now apparent:

$$\begin{aligned} \cos t &= \operatorname{Re} e^{it} = 1 - \frac{1}{2}t^2 + \frac{1}{4!}t^4 - \frac{1}{6!}t^6 + \\ &\quad \dots + (-1)^k \frac{1}{(2k)!}t^{2k} + \dots \\ \sin t &= \operatorname{Im} e^{it} = t - \frac{1}{3!}t^3 + \frac{1}{5!}t^5 - \frac{1}{7!}t^7 + \\ &\quad \dots + (-1)^k \frac{1}{(2k+1)!}t^{2k+1} + \dots \end{aligned}$$

The following diagram illustrates the convergence of the series for the cosine function. It is the graph of the corresponding polynomial of degree 68. Drawing partial sums shows that the approximation near zero is very good. As the order increases, the approximation is better further away from the origin as well.

<sup>15</sup>This number describes the ratio of the circumference to the diameter of an (arbitrary) circle. It was known to the Babylonians and the Greeks in ancient times. The term Ludolphian number is derived from the name of German mathematician Ludolph van Ceulen of the 16th century, who produced 35 digits of the decimal expansion of the number, using the method of inscribed and circumscribed regular polygons, invented by Archimedes.

of divergence, as well.

3) We see that

$$\left| \frac{a_{n+1}}{a_n} \right| = \left| \frac{2^{n+1}(n+2)!}{2^n(n+3)!} \right| = \left| \frac{2}{n+3} \right| = \frac{2}{n+3},$$

which tends to  $0 < 1$  as  $n$  tends to infinity. By the ratio test we deduce that the series  $T_3$  is absolute convergent and hence also convergent.

4) Let  $\sum_{n=1}^{\infty} a_n$  be a non-convergent series. Taking some constant  $c \neq 0$  and considering the new series  $\sum_{n=1}^{\infty} (ca_n)$ , it is easy to see that this is also a non-convergent series. This is because by assumption the sequence of partial sums  $s_n = \sum_{k=1}^n a_k$  cannot converge, and hence also the sequence  $(S_n)$  of partial sums of the new series cannot converge (since  $S_n = \sum_{k=1}^n (ca_k) = c \cdot s_n$ ). We can apply this conclusion for  $T_4$ :

$$T_4 = \sum_{n=1}^{\infty} \frac{1}{n \cdot 2^{2025}} = \frac{1}{2^{2025}} \cdot \sum_{n=1}^{\infty} \frac{1}{n},$$

that is, the series is a multiple of the harmonic series. Thus, in combination with 5.D.1 we see that  $T_4$  is not convergent.

5) Obviously,

$$T_5 = \sum_{n=1}^{\infty} \frac{1}{n^7} + \sum_{n=1}^{\infty} \frac{1}{7^n + 2} = T_5^1 + T_5^2.$$

Hence it is sufficient to deduce about the convergence or divergence of the series  $T_5^1$  and  $T_5^2$ , as defined above. We see that  $T_5^2 = \sum_{n=1}^{\infty} \frac{1}{7^n + 2} < \sum_{n=1}^{\infty} \frac{1}{7^n}$  and the geometric series  $\sum_{n=1}^{\infty} \frac{1}{7^n}$  converges (see 5.B.16). Thus, the series  $T_5^2$  converges as well. The series  $T_5^1 = \sum_{n=1}^{\infty} \frac{1}{n^7}$  is also convergent (is a  $p$ -series with  $p = 7 > 1$ ). As a result, the relation  $T_5 = T_5^1 + T_5^2$  implies that  $T_5$  is a convergent series, (since it is the sum of two convergent series, see Corollary 5.4.3).

6) The series  $T_6$  is not convergent. Let us apply for example the d'Alembert criterion (ratio test):

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| &= \lim_{n \rightarrow \infty} \frac{e^{n+1} \cdot n^2}{e^n \cdot (n+1)^2} \\ &= e \cdot \lim_{n \rightarrow \infty} \left( \frac{n}{n+1} \right)^2 = e \cdot 1 = e > 1. \end{aligned}$$

7) The series  $T_7$  converges, because

$$T_7 = \sum_{n=0}^{\infty} \frac{1}{(n+1) \cdot 3^n} \leq \sum_{n=0}^{\infty} \left( \frac{1}{3} \right)^n = \frac{1}{1 - \frac{1}{3}} = \frac{3}{2} < +\infty.$$

The result now follows by the comparison test (see Theorem 5.4.5).

8) The series  $T_8$  consists only of non-negative terms, as  $T_7$  for example, but it diverges (necessarily to  $+\infty$ ), as a direct computation shows:

$$T_8 = \sum_{n=1}^{\infty} \frac{n^2 + 1}{n^3} \geq \sum_{n=1}^{\infty} \frac{n^2}{n^3} = \sum_{n=1}^{\infty} \frac{1}{n} = +\infty.$$

9) Observe that  $T_9$  is again the sum of two series:

$$T_9 = \sum_{n=0}^{\infty} \frac{2^n}{n!} + \sum_{n=0}^{\infty} \frac{3^n}{n!} = T_9^1 + T_9^2$$

The well-known formula

$$e^{it} e^{-it} = \sin^2 t + \cos^2 t = 1$$

is immediate. From the derivative  $(e^{it})' = i e^{it}$  it follows that

$$(\sin t)' = \cos t, \quad (\cos t)' = -\sin t$$

by considering real and imaginary parts. Let  $t_0$  denote the smallest positive number for which  $e^{-it_0} = -e^{it_0}$ . The value  $t_0$  is the first positive zero point of the function  $\cos t$ . According to the definition of  $\pi$ ,  $t_0 = \frac{1}{2}\pi$ . If approximating the function  $\cos$  by the 10th order approximation, then twice the first positive root yields  $\pi \sim 3.1415917$  with 5 digits correct, while the 20th order approximation provides 10 correct digits after the decimal point.

Squaring yields  $e^{i2t_0} = e^{-i2t_0} = (e^{-it_0})^2$ . So  $\pi$  is a zero point of the function  $\sin t$ . Of course, for any  $t$ ,

$$e^{i(4kt_0+t)} = (e^{it_0})^{4k} \cdot e^{it} = 1 \cdot e^{it}.$$

Therefore, both trigonometric functions  $\sin$  and  $\cos$  are *periodic*, with period  $2\pi$ . This is their prime period.

Now the usual formulae connecting the trigonometric functions are easily derived. For illustration, we introduce some of them. First, the definition says that

$$\begin{aligned} (1) \quad \cos t &= \frac{1}{2}(e^{it} + e^{-it}) \\ (2) \quad \sin t &= \frac{1}{2i}(e^{it} - e^{-it}). \end{aligned}$$

Thus the product of these functions can be expressed as

$$\begin{aligned} \sin t \cos t &= \frac{1}{4i}(e^{it} - e^{-it})(e^{it} + e^{-it}) \\ &= \frac{1}{4i}(e^{i2t} - e^{-i2t}) = \frac{1}{2} \sin 2t. \end{aligned}$$

Further, by utilizing our knowledge of derivatives:

$$\cos 2t = \left( \frac{1}{2} \sin 2t \right)' = (\sin t \cos t)' = \cos^2 t - \sin^2 t.$$

The properties of other trigonometric functions

$$\tan t = \frac{\sin t}{\cos t}, \quad \cot t = (\tan t)^{-1}$$

can easily be derived from their definitions and the formulae for derivatives. The graphs of the functions sine, cosine, tangent, and cotangent are displayed on the diagrams (they are distinguished as the solid and dashed lines, respectively):

and hence it is sufficient to deduce about the convergence of  $T_9^1$  and  $T_9^2$ . By applying the ratio test to  $T_9^1$ , we see that

$$\lim_{n \rightarrow \infty} \left| \frac{2^{n+1}}{(n+1)!} \cdot \frac{n!}{2^n} \right| = \lim_{n \rightarrow \infty} \frac{2}{n+1} = 0 < 1$$

so  $T_9^1$  converges. Similarly for  $T_9^2$ , and hence  $T_9$  converges.

10) We can apply the root test, see (5) in Theorem 5.4.5:

$$\begin{aligned} \lim_{n \rightarrow \infty} \sqrt[n]{\left| 2^n \cdot \left(\frac{4}{5}\right)^{n^2} \right|} &= \lim_{n \rightarrow \infty} \sqrt[n]{2^n \cdot \left(\frac{4}{5}\right)^{n^2}} \\ &= \lim_{n \rightarrow \infty} \left( 2 \cdot \left(\frac{4}{5}\right)^n \right) = 0 < 1. \end{aligned}$$

Thus  $T_{10}$  is a convergent series. In Sage you can compute this limit as usual:

```
var("n"); lim(2*(4/5)**n, n=oo)
```

11) For the series  $T_{11}$  we see that

$$0 \leq \frac{2 + \sin^3(n+1)}{4^n + n^2} < \frac{3}{4^n}.$$

However,  $\sum_{n=1}^{\infty} \frac{3}{4^n} = 3 \sum_{n=1}^{\infty} \frac{1}{4^n}$  and the latter is a convergent geometric series. Thus the series  $T_{11}$  converges as well.

12) For the series  $T_{12}$  an application of the ratio test gives

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n} &= \lim_{n \rightarrow \infty} \left( \frac{(n+1)^{n+1}}{(n+1)^2 \cdot (n+1)!} \cdot \frac{n^2 \cdot n!}{n^n} \right) \\ &= \lim_{n \rightarrow \infty} \frac{n^2}{(n+1)^2} \cdot \lim_{n \rightarrow \infty} \frac{(n+1)^n}{n^n} \\ &= \lim_{n \rightarrow \infty} \frac{n^2}{n^2} \cdot \lim_{n \rightarrow \infty} \left( 1 + \frac{1}{n} \right)^n = 1 \cdot e > 1. \end{aligned}$$

Thus,  $T_{12}$  is not converge and in particular it diverges to  $+\infty$ .  $\square$

Next, we will explore how to program in Sage to utilize it as a tool for analyzing the convergence or divergence of infinite series. We introduce a syntax using the command `def` to construct a routine tailored for this purpose. The essence of this routine revolves around implementing the ratio test. Later on, we will demonstrate how this technique can be adapted to apply the root test (see 5.E.136), as well as other convergence criteria.

**5.D.5.** Let  $S = \sum_{n=0}^{\infty} f_n$  be an infinite series for which the limit  $\lim_{n \rightarrow \infty} |f_{n+1}/f_n|$  exists, and equals to  $q$ . Present in Sage a syntax appropriate to deduce the absolute convergence/divergence of  $S$  based on the ratio test. Then apply your program with aim to:

(a) Prove that the following infinite series converge:

$$S_1 = \sum_{n=1}^{\infty} \frac{2^n \cdot (n+1)^3}{3^n}, \quad S_2 = \sum_{n=1}^{\infty} \frac{6^n}{n!}.$$

Next provide a formal proof.

(b) Deduce, if possible, the convergence/divergence of  $S_3 =$

*Cyclometric functions* are the functions inverse to trigonometric functions. Since the trigonometric functions all have period  $2\pi$ , their inverses can be defined only inside one period, and further, only on the part where the given function is either increasing or decreasing. Two inverse trigonometric functions are

$$\arcsin = \sin^{-1}$$

with domain  $[-1, 1]$  and range  $[-\pi/2, \pi/2]$  and

$$\arccos = \cos^{-1}$$

with domain  $[-1, 1]$  and range  $[0, \pi]$ . See the left-hand illustration..

The remaining functions are (displayed in the diagram on the right)

$$\arctan = \tan^{-1}$$

with domain  $\mathbb{R}$  and range  $(-\pi/2, \pi/2)$ , and finally

$$\operatorname{arccot} = \cot^{-1}$$

with domain  $\mathbb{R}$  and range  $(0, \pi)$ .

The *hyperbolic functions* are also of big importance. Two basic ones are

$$\sinh x = \frac{1}{2}(e^x - e^{-x}), \quad \cosh x = \frac{1}{2}(e^x + e^{-x}).$$

The name indicates that they should have something in common with a hyperbola. From the definition,

$$(\cosh x)^2 - (\sinh x)^2 = 2 \frac{1}{4} (2e^x e^{-x}) = 1.$$

The points  $[\cosh t, \sinh t] \in \mathbb{R}^2$  parametrically describe a hyperbola in the plane. For hyperbolic functions, one can easily derive identities similar to the ones for trigonometric functions. By substituting into (1) and (2), one can obtain for example

$$\cosh x = \cos(ix), \quad i \sinh x = \sin(ix).$$

$\sum_{n=1}^{\infty} \frac{n^n}{n^2 \cdot n!}$  and  $S_4 = \sum_{n=1}^{\infty} \frac{n^2}{n+1}$  (notice  $S_3$  is the last series in 5.D.4).

**Solution.** As we said, we will use the command `def` to define a routine, which we will call `ratiotest`. First it is useful to introduce  $n$  as a symbolic variable. It is also convenient to introduce the subset  $(-1, 1) \subset \mathbb{R}$ . This is because of the ratio test (see Theorem 5.4.5), which states that  $S$  converges absolutely for  $|q| < 1$ , does not converge absolutely for  $|q| > 1$ , while for  $q = 1$  the series may or may not converge.

The aim now is to encode the above criterion in a Sage routine. For this we may type

```
var("n")
s=RealSet(-1, 1)
def ratiotest(f):
    q=lim(abs(f(n+1)/f(n)), n=oo)
    if q in s:
        return "converges absolutely"
    elif q==1:
        return "no conclusion"
    else:
        return "does not converge absolutely"
    return
```

Our routine is now ready to be tested.<sup>10</sup>

(a) First we will prove formally that  $S_1, S_2$  are both convergent series. Notice that for  $S_1, S_2$  the defining terms are positive, and hence

$$q = \lim_{n \rightarrow \infty} \left| \frac{f_{n+1}}{f_n} \right| = \lim_{n \rightarrow \infty} \frac{f_{n+1}}{f_n}.$$

So, for  $S_1$  we compute

$$\begin{aligned} q &= \lim_{n \rightarrow \infty} \frac{2^{n+1} \cdot (n+2)^3 \cdot 3^n}{3^{n+1} \cdot 2^n \cdot (n+1)^3} \\ &= \lim_{n \rightarrow \infty} \frac{2(n+2)^3}{3(n+1)^3} = \lim_{n \rightarrow \infty} \frac{2n^3}{3n^3} = \frac{2}{3} < 1. \end{aligned}$$

Or you can directly use Sage to compute this limit:

```
var("n")
f(n)=(2^(n+1)*(n+2)^3*3^n)/(3^(n+1)*(n+1)^3*2^n)
lim(f(n), n=oo)
```

Similarly, for  $S_2$ :

$$q = \lim_{n \rightarrow \infty} \left( \frac{6^{n+1}}{(n+1)!} \cdot \frac{n!}{6^n} \right) = \lim_{n \rightarrow \infty} \frac{6}{n+1} = 0 < 1,$$

where again one can compute the limit directly in Sage:

```
var("n")
g(n)=(factorial(n)*6^(n+1))/(factorial(n+1)*6^n)
lim(g(n), n=oo)
```

Notice here the command `factorial(n)` corresponds to  $n!$ . Since for both cases we obtained  $q < 1$ , our claim follows by the ratio test.

To check our routine using  $S_1, S_2$ , we type

<sup>10</sup>In general, detailed “return inputs” are more than welcome. However, here we kept them “short” to save some space.

**5.4.13. Notes.** (1) If a power series  $S(x)$  is expressed with the variable  $x$  moved by a constant offset  $x_0$ , we arrive at the function  $T(x) = S(x - x_0)$ . If  $\rho$  is the radius of convergence of  $S$ , then  $T$  will be well-defined on the interval  $(x_0 - \rho, x_0 + \rho)$ . We say that  $T$  is a *power series centered at  $x_0$* .

The power series can be defined in the following way:

$$S(x) = \sum_{n=0}^{\infty} a_n(x - x_0)^n,$$

where  $x_0$  is an arbitrary fixed real number. All of the previous reasonings are still valid. It is only necessary to be aware of the fact that they relate to the point  $x_0$ . Especially, such a power series converges on the interval  $(x_0 - \rho, x_0 + \rho)$ , where  $\rho$  is its radius of convergence.

Further, if a power series  $y = T(x)$  has its values in an interval where a power series  $S(y)$  is well-defined, then the values of the function  $S \circ T$  are also described by a power series which can be obtained by formal substitution of  $y = T(x)$  for  $y$  into  $S(y)$ .

(2) As soon as a power series with a suitable center is available, the coefficients of the power series for inverse functions can be calculated. We do not introduce a list of formulae here. It is easily obtained in Maple, for instance, by the procedure “series”. For illustration, here are two examples:

Begin with

$$e^x = 1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \dots$$

Since  $e^0 = 1$ , we search for a power series centered at  $x = 1$  for the inverse function  $\ln x$ . So assume

$$\ln x = a_0 + a_1(x-1) + a_2(x-1)^2 + a_3(x-1)^3 + a_4(x-1)^4 + \dots$$

Apply the equality  $x = \ln(e^x)$ , regroup the coefficients by the powers of  $x$  and substitute. The result is:

$$\begin{aligned} x &= a_0 + a_1 \left( x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \dots \right) \\ &\quad + a_2 \left( x + \frac{1}{2}x^2 + \dots \right)^2 + a_3 \left( x + \frac{1}{2}x^2 + \dots \right)^3 + \dots \\ &= a_0 + a_1 x + \left( \frac{1}{2}a_1 + a_2 \right) x^2 + \left( \frac{1}{6}a_1 + a_2 + a_3 \right) x^3 \\ &\quad + \left( \frac{1}{24}a_1 + \left( \frac{1}{4} + \frac{2}{6} \right) a_2 + \frac{3}{2}a_3 + a_4 \right) x^4 + \dots \end{aligned}$$

Comparing the coefficients of the corresponding powers on both sides, gives

$$a_0 = 0, \quad a_1 = 1, \quad a_2 = -\frac{1}{2}, \quad a_3 = \frac{1}{3}, \quad a_4 = -\frac{1}{4}, \dots$$

This corresponds to the valid expression (to be verified later):

$$\ln x = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} (x-1)^n.$$

Similarly, we can begin with the series

$$\sin t = t - \frac{1}{3!}t^3 + \frac{1}{5!}t^5 - \frac{1}{7!}t^7 + \dots$$

```
f(n) = ((2^n) * (n+1)^3) / 3^n; ratiotest(f)
```

and

```
f(n) = (6^n / factorial(n)); ratiotest(f)
```

respectively. Our routine verifies our result, by printing out the answer “converges absolutely”.

On the other hand, in 5.D.4 we saw that  $S_3$  satisfies  $q = e > 1$ , in particular,  $S_3$  cannot converge. The same verifies our routine:

```
f(n) = n^n / (n^2 * factorial(n)); ratiotest(f)
```

with answer “does not converge absolutely”. For the final case notice that running the command

```
print(lim((n+1)^3 / (n^2 * (n+2)), n=oo))
```

we obtain 1, that is,  $\lim_{n \rightarrow \infty} \left| \frac{f(n+1)}{f(n)} \right| = 1$ , where  $f(n) = \frac{n^2}{n+1}$ . This means that the ratio test is inconclusive and we cannot determine if the series converges or diverges using this test. Our routine is also able to certify this claim, and we just need to type

```
f(n) = n^2 / (n+1)
ratiotest(f)
```

which prints out “no conclusion”. To answer however this case, one may add the syntax `sum(n^2/(n+1), n, 1, oo)`, which shows to us that  $S_4$  is divergent. Try to describe a formal proof of this conclusion.  $\square$

**5.D.6. Alternating series.** Determine whether or not the following series converge:

$$S_1 = \sum_{n=1}^{\infty} (-1)^n \frac{n^2 + 3n - 1}{(3n - 2)^2},$$

$$S_2 = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{3n^4 - 3n^3 + 9n - 1}{(5n^3 - 2) \cdot 4^n}.$$

**Solution.** We have  $\lim_{n \rightarrow \infty} \frac{n^2 + 3n - 1}{(3n - 2)^2} = \lim_{n \rightarrow \infty} \frac{n^2}{9n^2} = \frac{1}{9} \neq 0$ . Thus the limit

$$\lim_{n \rightarrow \infty} (-1)^n \frac{n^2 + 3n - 1}{(3n - 2)^2}$$

does not exist, and the series  $S_1$  does not converge.

For  $S_2$  an application of the ratio (or root) test shows that the polynomials in the numerator or in the denominator do not affect the value of the considered limit, and we may consider the series

$$\sum_{n=1}^{\infty} (-1)^{n-1} \frac{1}{4^n}$$

For this, we see that  $\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = \frac{1}{4} < 1$ . Thus this series (absolutely) converges and as a conclusion the series  $S_2$  is also (absolutely) convergent.  $\square$

**5.D.7.** Decide whether the series

$$S_1 = \sum_{n=1}^{\infty} \frac{\sin(n)}{n^2}, \quad S_2 = \sum_{n=1}^{\infty} \frac{\cos(\pi n)}{\sqrt[3]{n^2}}$$

and the (unknown so far) power series for its inverse centered at zero (since  $\sin 0 = 0$ )

$$\arcsin t = a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + \dots$$

Substitution gives

$$\begin{aligned} t &= a_0 + a_1 \left( t - \frac{1}{3!} t^3 + \frac{1}{5!} t^5 + \dots \right) + \\ & a_2 \left( t - \frac{1}{3!} t^3 + \frac{1}{5!} t^5 + \dots \right)^2 + \dots \\ &= a_0 + a_1 t + a_2 t^2 + \left( -\frac{1}{6} a_1 + a_3 \right) t^3 + \\ & \left( -\frac{2}{6} a_2 + a_4 \right) t^4 + \left( \frac{1}{120} a_1 - \frac{3}{6} a_3 + a_5 \right) t^5 + \dots, \end{aligned}$$

hence

$$\arcsin t = t + \frac{1}{6} t^3 + \frac{3}{40} t^5 + \dots$$

(3) Notice that if it is assumed that the function  $e^x$  can be expressed as a power series centered at zero, and that power series can be differentiated term by term, then the difference equation for the coefficients  $a_n$  is easily obtained since  $(x^{n+1})' = (n+1)x^n$ . Therefore, from the condition that the exponential function has its derivative equal to its value at every point,

$$a_{n+1} = \frac{1}{n+1} a_n, \quad a_0 = 1$$

and hence it is clear that  $a_n = \frac{1}{n!}$ .

converges absolutely, converges conditionally, or does not converge at all.  $\circ$

*Computing the exact values of infinite series is generally a challenging task. Sometimes, we can compare these values with known results. However, in many cases, relying on computer algebra software is necessary. To illustrate this situation, let us consider some examples and use Sage to verify our calculations rigorously.*

**5.D.8.** Calculate the series given below and then use Sage to verify your answer.

$$S_1 = \sum_{n=1}^{\infty} \left( \frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}} \right), \quad S_2 = \sum_{n=0}^{\infty} \frac{5}{3^n},$$

$$S_3 = \sum_{n=1}^{\infty} \left( \frac{3}{4^{2n-1}} + \frac{2}{4^{2n}} \right), \quad S_4 = \sum_{n=1}^{\infty} \frac{n}{3^n}.$$

**Solution.** For the first given series we see that

$$\begin{aligned} S_1 &= \lim_{n \rightarrow \infty} \left( \left( \frac{1}{\sqrt{1}} - \frac{1}{\sqrt{2}} \right) + \left( \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{3}} \right) + \cdots \right. \\ &\quad \left. \cdots + \left( \frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}} \right) \right) \\ &= \lim_{n \rightarrow \infty} \left( 1 + \left( -\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} \right) + \cdots \right. \\ &\quad \left. \cdots + \left( -\frac{1}{\sqrt{n}} + \frac{1}{\sqrt{n}} \right) - \frac{1}{\sqrt{n+1}} \right) \\ &= \lim_{n \rightarrow \infty} \left( 1 - \frac{1}{\sqrt{n+1}} \right) = 1. \end{aligned}$$

As we know, a verification by Sage takes the form

```
n=var("n"); sum((1/sqrt(n)-1/sqrt(n+1)), n, 1, oo)
```

For  $S_2$  we see that this is a quintuple of the standard geometric series with the common ratio  $q = 1/3$ . Thus

$$S_2 = \sum_{n=0}^{\infty} \frac{5}{3^n} = 5 \sum_{n=0}^{\infty} \left( \frac{1}{3} \right)^n = 5 \cdot \frac{1}{1 - \frac{1}{3}} = \frac{15}{2}.$$

Or we can directly give in Sage the cell

```
n=var("n"); sum((5/3**n), n, 0, oo)
```

The third infinite series is a series of linear combinations which we can express as a sum of infinite series with factoring out the constants. This is a valid modification, since the obtained series are absolutely convergent. In particular,

$$\begin{aligned} S_3 &= \frac{3}{4} \sum_{n=1}^{\infty} \left( \frac{1}{4^{2n-2}} \right) + \frac{2}{16} \sum_{n=1}^{\infty} \left( \frac{1}{4^{2n-2}} \right) \\ &\stackrel{m:=n-1}{=} \left( \frac{3}{4} + \frac{2}{16} \right) \sum_{m=0}^{\infty} \frac{1}{4^{2m}} \\ &= \frac{14}{16} \sum_{m=0}^{\infty} \left( \frac{1}{16} \right)^m = \frac{14}{16} \cdot \frac{1}{1 - \frac{1}{16}} = \frac{14}{15}. \end{aligned}$$

In Sage after introducing  $n$  as a symbolic variable we can compute this sum as above:

```
sum((3/(4**(2*n-1))+2/(4**(2*n))), n, 1, oo)
```

Finally, for  $S_4$ , notice that from the relation of the partial sums, i.e.,  $s_n = \frac{1}{3} + \frac{2}{3^2} + \frac{3}{3^3} + \dots + \frac{n}{3^n}$  for  $n = 1, 2, \dots$ , we can claim that

$$\frac{s_n}{3} = \frac{1}{3^2} + \frac{2}{3^3} + \dots + \frac{n-1}{3^n} + \frac{n}{3^{n+1}}.$$

Therefore, for all  $n \in \mathbb{Z}_+$  we obtain the relation

$$s_n - \frac{s_n}{3} = \frac{1}{3} + \frac{1}{3^2} + \frac{1}{3^3} + \dots + \frac{1}{3^n} - \frac{n}{3^{n+1}}.$$

This, in combination with the relation  $\lim_{n \rightarrow \infty} \frac{n}{3^{n+1}} = 0$ , gives

$$\begin{aligned} S_4 &= \frac{3}{2} \lim_{n \rightarrow \infty} \left( s_n - \frac{s_n}{3} \right) = \frac{3}{2} \lim_{n \rightarrow \infty} \sum_{k=1}^n \frac{1}{3^k} \\ &= \frac{3}{2} \sum_{k=1}^{\infty} \left( \frac{1}{3} \right)^k \stackrel{(*)}{=} \frac{3}{2} \left( \frac{1}{1 - \frac{1}{3}} - 1 \right) = \frac{3}{4}. \end{aligned}$$

Notice that here our geometric series  $\sum_{k=1}^{\infty} \left( \frac{1}{3} \right)^k$  starts from  $k = 1$  and thus the given replacement in  $(*)$ . A verification in Sage occurs as usual, i.e.,

```
var("n"); sum((n/3**n), n, 1, oo)
```

□

**5.D.9.** Verify the inequality  $\sum_{n=1}^{\infty} \frac{1}{n^2} < \sum_{n=0}^{\infty} \frac{1}{2^n}$ . ○

*Further exercises concerning infinite series are presented in Section E. Let us now describe a beautiful application that highlights the use of infinite series (see 5.E.130 for another fascinated example).*

**5.D.10. Koch snowflake (1904).** Create a “snowflake” by the following procedure: At the beginning, consider an equilateral triangle with sides of length 1. With each of its three sides, do the following: Cut it into three equally long parts, then build another equilateral triangle above the middle part (this is pointing out from the original triangle), and remove the middle part. This transforms the original equilateral triangle into a six-pointed star. Repeating this step ad infinitum, one arrives to the desired snowflake. Prove that the created figure has infinite perimeter. Then determine its area.

**Solution.** The perimeter of the original triangle is equal to 3. In each step, the perimeter increases by one third since three parts of every line segment are replaced with four equally long ones. Thus the snowflake’s perimeter can be expressed as the limit

$$\lim_{n \rightarrow \infty} d_n, \quad d_n := 3 \left( \frac{4}{3} \right)^n,$$

and we see that  $\lim_{n \rightarrow \infty} d_n = +\infty$ . This can be quickly verified in Sage:

```
var("n"); lim(3*((4/3)**n), n=oo)
```

Now, the figure's area is apparently increasing during the construction. For its computation it is sufficient to catch the rise between two consecutive steps. The number of the figure's sides is four times higher at every step (the line segments are divided into thirds and one of them is doubled). Moreover, the new sides are three times shorter. Therefore, the figure's area grows exactly by the equilateral triangles glued to each side (so, there is the same number of them as of the sides). In the first iteration (when creating the six-pointed star from the original triangle), the area grows by the three equilateral triangles with sides of length  $1/3$  (one third of the original sides' length). Let us denote the area of the original equilateral triangle by  $S_0$ . If we realize that shortening an equilateral triangle's sides three times makes its area decrease nine times, we get  $S_0 + 3 \cdot \frac{S_0}{9}$  for the area of the six-pointed star. Similarly, in the next step we obtain the area of the figure as

$$S_0 + 3 \cdot \frac{S_0}{9} + 4 \cdot 3 \cdot \frac{S_0}{9^2}.$$

It is easy now to deduce that the area  $E$  of the resulting snowflake equals the limit

$$\begin{aligned} E &= \lim_{n \rightarrow \infty} \left( S_0 + 3 \frac{S_0}{9} + 4 \cdot 3 \frac{S_0}{9^2} + \dots + 4^n \cdot 3 \frac{S_0}{9^{n+1}} \right) \\ &= S_0 \lim_{n \rightarrow \infty} \left( 1 + \frac{1}{3} + \frac{1}{3} \cdot \frac{4}{9} + \dots + \frac{1}{3} \cdot \left( \frac{4}{9} \right)^n \right) \\ &= S_0 \left( 1 + \frac{1}{3} \lim_{n \rightarrow \infty} \left( 1 + \frac{4}{9} + \dots + \left( \frac{4}{9} \right)^n \right) \right) \\ &= S_0 \left( 1 + \frac{1}{3} \lim_{n \rightarrow \infty} \sum_{k=0}^n \left( \frac{4}{9} \right)^k \right) \\ &= S_0 \left( 1 + \frac{1}{3} \sum_{k=0}^{\infty} \left( \frac{4}{9} \right)^k \right) = S_0 \left( 1 + \frac{1}{3} \cdot \frac{1}{1 - \frac{4}{9}} \right), \end{aligned}$$

that is,  $E = \frac{8}{5} S_0$ . Thus, the snowflake's area is  $8/5$  of the area of the original triangle, i.e.,

$$\frac{8}{5} S_0 = \frac{8}{5} \cdot \frac{\sqrt{3}}{4} = \frac{2\sqrt{3}}{5}.$$

We mention that this snowflake is an example of an infinitely long curve which encloses a finite area.  $\square$

*So far, we have explored the concept of assigning a value to a sum of infinitely many numbers. Now, we shift our focus to sums involving infinitely many functions. Specifically, we can consider such series for each argument  $x$  of the functions  $f_n(x)$ , particularly focusing on sums of polynomials. These are known as "power series", which always converge on an interval (or a disc in the complex plane, for complex polynomials). Moreover, the radius of convergence of these series can be readily determined from their coefficients, which is either a non-negative real number or  $\infty$ .*

Later, in Chapters 6 and 7, we will revisit other types of function series and explore additional concepts of convergence.

**5.D.11.** Consider the series  $S = \sum_{n=1}^{\infty} \frac{(x+4)^n}{n \cdot 5^n}$ . Determine

all  $x \in \mathbb{R}$  for which  $S$  is convergent.

**Solution.** Having the ratio test in mind, let us compute the limit  $\lim_{n \rightarrow \infty} \left| \frac{f_{n+1}(x)}{f_n(x)} \right|$ , that is,

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \frac{\frac{(x+4)^{n+1}}{(n+1) \cdot 5^{n+1}}}{\frac{(x+4)^n}{n \cdot 5^n}} \right| &= \lim_{n \rightarrow \infty} \frac{n |x+4|}{5(n+1)} \\ &= |x+4| \lim_{n \rightarrow \infty} \frac{n}{5(n+1)} = \frac{|x+4|}{5}. \end{aligned}$$

In case you like confirm this conclusion by Sage, give the cell `var("n"); lim(n/(5*(n+1)), n = oo)`.

Now, according to the ratio test the series will converge for  $\frac{|x+4|}{5} < 1$ , that is,  $-9 < x < 1$  and diverges for  $\frac{|x+4|}{5} > 1$ , that is,  $x < -9$  or  $x > 1$ . For  $x = 1$  we see that  $S$  is the harmonic series, i.e.,  $S = \sum_{n=1}^{\infty} \frac{1}{n}$  which diverges by 5.D.1. For  $x = -9$  we get

$$S = \sum_{n=1}^{\infty} \frac{(-5)^n}{n \cdot 5^n} = \sum_{n=1}^{\infty} \frac{(-1)^n}{n} = -1 + \frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \dots$$

which is an alternating series, known as the *alternating harmonic series*. For this series we compute  $\lim_{n \rightarrow \infty} \frac{(-1)^n}{n} = 0$ , hence  $S$  is convergent (see Theorem 5.4.7). As an alternative, in Sage the command `sum((-1)^n/n, n, 1, oo)` provides an explicit evaluation of the alternating harmonic series; it equals to  $-\ln(2)$ . We conclude that the initial series is convergent for all  $x \in [-9, 1)$ .  $\square$

**5.D.12.** Determine the radius  $r$  of convergence of the following power series:

$$\begin{aligned} A(x) &= \sum_{n=1}^{\infty} \frac{2^n}{n} x^n, & B(x) &= \sum_{n=1}^{\infty} \frac{1}{(1+i)^n} x^n, \\ C(x) &= \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n \cdot 8^n} x^n, & D(x) &= \sum_{n=1}^{\infty} (-4n)^n x^n, \\ E(x) &= \sum_{n=1}^{\infty} \left(1 + \frac{1}{n}\right)^{n^2} x^n. \end{aligned}$$

**Solution.** According to the discussion in 5.4.10, for  $A(x)$  we have

$$r = \frac{1}{\limsup_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right|} = \frac{1}{2}.$$

Thus, the power series converges exactly for the real numbers  $x \in (-\frac{1}{2}, \frac{1}{2})$ . Moreover, the series diverges for  $x = \frac{1}{2}$  (since it becomes harmonic), and it converges for  $x = -\frac{1}{2}$  (since then it becomes an alternating harmonic series). However, to determine the convergence for any  $x$  lying in the complex

plane on the circle of radius  $\frac{1}{2}$ , it is a much harder question which goes beyond our lectures.

For  $B(x)$  we compute

$$r = \limsup_{n \rightarrow \infty} \left| \sqrt[n]{\frac{1}{(1+i)^n}} \right| = \limsup_{n \rightarrow \infty} \left| \frac{1}{1+i} \right| = \frac{\sqrt{2}}{2}.$$

For  $C(x)$  we see that

$$\lim_{n \rightarrow \infty} \sqrt[n]{|a_n|} = \lim_{n \rightarrow \infty} \frac{1}{\sqrt[n]{n} \cdot 8} = \frac{1}{8}.$$

Thus the radius is  $r = 8$ . For  $D(x)$  we get  $\lim_{n \rightarrow \infty} \sqrt[n]{|a_n|} = \lim_{n \rightarrow \infty} 4n = +\infty$ , so the radius is  $r = 0$ , while for  $E(x)$  we compute  $\lim_{n \rightarrow \infty} \sqrt[n]{|a_n|} = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n = e$ , so  $r = 1/e$  in this case.  $\square$

**5.D.13.** Calculate the radius  $r$  of convergence of the power series

$$\sum_{n=1}^{\infty} e^{in} \frac{\sqrt[3]{n^3 + n} \cdot 3^n}{\pi^n \cdot \sqrt[3]{n^4 + 2n^3 + 1}} \cdot (x - 2)^n.$$

**Solution.** Here we will apply the following trick: The radius of convergence of any power series does not change if we move its center or alter its coefficients while keeping their absolute values. Therefore, let us determine the radius of convergence of the infinite series

$$\sum_{n=1}^{\infty} \frac{\sqrt[3]{n^3 + n} \cdot 3^n}{\pi^n \sqrt[3]{n^4 + 2n^3 + 1}} \cdot x^n.$$

Since  $\lim_{n \rightarrow \infty} \sqrt[n]{n^a} = \left(\lim_{n \rightarrow \infty} \sqrt[n]{n}\right)^a = 1$  for all  $a > 0$ , we can further move to the series

$$\sum_{n=1}^{\infty} \frac{3^n}{\pi^n} x^n.$$

with the same radius of convergence  $r = \pi/3$ .  $\square$

**5.D.14.** Determine the power series centered at the origin which, determines the function

$$\frac{1}{x^2 - x - 12}, \quad x \in (-3, 3).$$

**Solution.** A quick method relies on the known procedure of partial fraction decomposition, which gives

$$\frac{1}{x^2 - x - 12} = \frac{1}{(x - 4)(x + 3)} = \frac{1}{7} \left( \frac{1}{x - 4} - \frac{1}{x + 3} \right).$$

This expression can be obtained also in Sage, via the `partial_fraction` function, as follows:

```
f(x)=1/(x^2-x-12)
show(f.partial_fraction())
```

Using now appropriately the known formula of geometric series, we see that

$$\begin{aligned}\frac{1}{x-4} &= -\frac{1}{4} \left( 1 + \frac{x}{4} + \frac{x^2}{4^2} + \cdots + \frac{x^n}{4^n} + \cdots \right), \\ \frac{1}{x+3} &= \frac{1}{3} \left( 1 - \frac{x}{3} + \frac{x^2}{3^2} + \cdots + \frac{(-x)^n}{3^n} + \cdots \right).\end{aligned}$$

Thus, altogether we obtain

$$\begin{aligned}\frac{1}{x^2 - x - 12} &= -\frac{1}{28} \sum_{n=0}^{\infty} \frac{x^n}{4^n} - \frac{1}{21} \sum_{n=0}^{\infty} \frac{(-x)^n}{3^n} \\ &= \sum_{n=0}^{\infty} \left( \frac{(-1)^{n+1}}{21 \cdot 3^n} - \frac{1}{28 \cdot 4^n} \right) x^n.\end{aligned} \quad \square$$

**5.D.15.** Determine the radius  $r$  of convergence of the power series  $\sum_{n=0}^{\infty} \frac{2^{2n} \cdot n!}{(2n)!} x^n$ .

**5.D.16.** Calculate the radius of convergence for  $\sum_{n=1}^{\infty} 2^{\sqrt{n}} x^n$ .

**5.D.17.** Find the domain of convergence of the power series  $\sum_{n=1}^{\infty} \frac{\sqrt{n+1}}{3^{\sqrt{n}}} x^n$ .

**5.D.18.** Determine for which  $x \in \mathbb{R}$  the power series  $\sum_{n=1}^{\infty} \frac{(-3)^n}{\sqrt{n^4 + 2n^3 + 111}} (x-2)^n$  converges.

**5.D.19.** Determine for which  $x \in \mathbb{R}$  the series

$$\sum_{i=1}^{\infty} \frac{1}{2^n \cdot n \cdot \ln(n)} x^{3n}$$

converges.

**5.D.20.** Determine all  $x \in \mathbb{R}$  for which the power series  $\sum_{i=1}^{\infty} \frac{x^{2n}}{n^2}$  is convergent.

*The polynomials are functions which we can easily evaluate and thus, the partial sums of power series offer a valuable method for approximating the values of functions. However, as we will see below, to be successful we need some good estimate on the convergence speed.*

*Especially for convergent alternating series*

$$S = \sum_{n=0}^{\infty} (-1)^n a_n = a_0 - a_1 + a_2 - a_3 + \cdots$$

with  $a_0 \geq a_1 \geq a_2 \geq \cdots \geq a_n \geq \cdots \geq 0$  and  $\sum_{n=0}^{\infty} (-1)^n a_n = L$ , where  $L$  is a finite real number, we can prove a very useful estimation error given by

$$|L - S_k| \leq a_{k+1}.$$

Here  $S_k = \sum_{n=0}^k (-1)^n a_n$  denotes the partial sum corresponding to  $S$ . Hence, summing only terms up to the  $k$ th term  $a_k$  and omitting all the remaining terms, the approximation

error will be at most large as  $a_{k+1}$ . Let us illustrate this situation via examples.

**5.D.21.** Approximate  $\cos(1)$  with an error strictly less than  $10^{-8}$ . Then use Sage to find the actual approximation error.

**Solution.** From Section 5.4.12 we know the following expression of  $\cos(x)$  in terms of power series:

$$\cos(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!},$$

for all  $x \in \mathbb{R}$ . Thus

$$\cos(1) = 1 - \frac{1}{2} + \frac{1}{4!} - \frac{1}{6!} + \frac{1}{8!} - \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!}.$$

According to the previous remark on alternating series, stopping at the term  $\frac{1}{(2n)!}$  we will obtain an error which equals at most  $\frac{1}{(2(n+1))!} = \frac{1}{(2n+2)!}$ . Thus, to find the number of terms which we need to approximate  $\cos(1)$  with an error strictly less than  $10^{-8}$ , it suffices to solve the inequality

$$\frac{1}{(2n+2)!} < 10^{-8}. \quad (*)$$

There are many ways to solve this inequality, and perhaps, the simplest one is by testing several values of  $n$ . As a solution, one gets that  $n = 5$  is the smallest positive integer satisfying (\*). For instance, in Sage a solution goes as follows:

```
n=1;
while (1/factorial(2*n+2) >= 10^-8 ):
    n = n+1
print(n)
```

and this answers 5. Here, with the second line we program Sage to try all values until (\*) is true, starting with  $n = 1$ . Hence, the desired solution is

$$\cos(1) \approx 1 - \frac{1}{2} + \frac{1}{4!} - \frac{1}{6!} + \frac{1}{8!} - \frac{1}{10!},$$

with an error less than  $10^{-8}$ . We may find the error of the approximation in Sage as follows:

```
a=1-1/2+1/factorial(4)-1/factorial(6) \
+1/factorial(8)-1/factorial(10)
print(N(cos(1))-N(a))
bool((N(cos(1))-N(a))<(1/factorial(12)))
```

Notice here we used a slash to break the first line. In this cell the print command gives the actual approximation error  $2.07625261428035e - 9$ , which approximately translates to  $2.077 \cdot 10^{-9}$ . The final command returns True, verifying that the error is not larger than the 6th term  $(-1)^n \frac{1}{(2n)!} \stackrel{n=5+1}{=} 1/12!$  (since above we proved that  $n = 5$ ), that is,  $1/12! \approx 2.088 \cdot 10^{-9}$ . For a successful treating of such small numbers one can use again Sage, e.g., by the cell

```
bool(2.077*(10**(-9))<2.088*(10**(-9)))
```

□

**5.D.22.** Approximate  $\sin(1)$  with an error strictly less than  $10^{-8}$ , and then verify your answer in Sage.

**Solution.** In Section 5.4.12 we learned the expression of  $\sin(x)$  in terms of power series:

$$\begin{aligned}\sin(x) &= x - \frac{1}{3!}x^3 + \frac{1}{5!}x^5 - \frac{1}{7!}x^7 + \cdots \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} x^{2n+1}, \quad x \in \mathbb{R}.\end{aligned}$$

Thus

$$\sin(1) = 1 - \frac{1}{3!} + \frac{1}{5!} - \frac{1}{7!} + \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!}$$

and, as before, we are treating an alternating series. Stopping at the term  $\frac{(-1)^n}{(2n+1)!}$  we will obtain an error which equals at most  $\left| \frac{(-1)^{n+1}}{(2n+3)!} \right| = \frac{1}{(2n+3)!}$ . Hence, to locate the number of terms which we need to approximate  $\sin(1)$  with a cost strictly less than  $10^{-8}$ , it suffices to solve the inequality

$$\frac{1}{(2n+3)!} < 10^{-8},$$

and as a solution we get  $n = 5$  (e.g. by applying the same method as in 5.D.21). This means that

$$\sin(1) \approx 1 - \frac{1}{3!} + \frac{1}{5!} - \frac{1}{7!} + \frac{1}{9!} - \frac{1}{11!}$$

with an error less than  $10^{-8}$ . In Sage you may type

```
b=1-1/factorial(3)+1/factorial(5)-1/factorial(7) \
+1/factorial(9) -1/factorial(11)
print(abs(N(sin(1))-N(b)))
print(bool(abs(N(sin(1))-N(b))<1/10**8))
```

which returns the actual approximation error, given by  $1.59828483781155e-10 \approx 1.599 \cdot 10^{-10}$ , and verifies the statement.  $\square$

## E. Additional exercises for the whole chapter

As usual, we will now delve into additional material related to the concepts discussed thus far in Chapter 5. Many of the tasks described below rely on the theory of derivatives, making prior experience with derivatives particularly useful. In some instances, we may need to employ higher-order derivatives, which are formally introduced at the beginning of Chapter 6, see 6.1.1. However, these cases primarily pertain to higher-order derivatives of polynomials, a topic with which the reader is already familiar from our discussion in Section 5.1.6.

## A) MATERIAL ON POLYNOMIAL INTERPOLATION

**5.E.1.** Consider the function  $f(x) = \sin(x)$ . Given three points (nodes)  $x_0, x_1, x_2$ , write a routine in Sage which will return the Hermite interpolation polynomial  $P(x)$  corresponding to these nodes and the values  $y_i = \sin(x_i)$  and  $y'_i = \sin'(x_i) = \cos(x_i)$ , for  $i = 0, 1, 2$ , that is, adapted to the following table (for simplicity you may fix some triple  $(x_0, x_1, x_2)$ , e.g.,  $x_0 = -2\pi, x_1 = 0$  and  $x_2 = 2\pi$ )

$x_i$	$x_0$	$x_1$	$x_2$
$y_i$	$y_0 = \sin(x_0)$	$y_1 = \sin(x_1)$	$y_2 = \sin(x_2)$
$y'_i$	$y'_0 = \cos(x_0)$	$y'_1 = \cos(x_1)$	$y'_2 = \cos(x_2)$

Then, for a variety of different triples  $(x_0, x_1, x_2)$  centered to 0 (that is, with  $x_1 = 0$  and with  $x_0 = -x_2$ ), present the graphs of the corresponding polynomial  $P(x)$  and that of  $f(x)$ , for  $x \in [x_0, x_2]$ .

**Solution.** We present the code in Sage and attach some comments within. Since the Hermite interpolation method includes derivatives, below we will use commands as `derivative(f,x)`, which gives the derivative of a function  $f$  and `derivative(f,x,n)`, returning the  $n$ th derivative of  $f$ . So, let us fix the nodes  $x_0 = -2\pi, x_1 = 0, x_2 = 2\pi$ . Notice the elementary Lagrange polynomials  $\ell_0, \ell_1, \ell_2$  corresponding to these three nodes are all of degree 2. We have:

```
x0=-2*pi; x1=0; x2=2*pi; l(x)=(x-x0)*(x-x1)*(x-x2)
d1l(x)=derivative(l, x) #define first derivative of function l
d2l(x)=derivative(l(x), x, 2) #define second derivative of function l
l0(x)=((x-x1)*(x-x2))/((x0-x1)*(x0-x2)) #elementary Lagrange polynomial l_0
l1(x)=((x-x0)*(x-x2))/((x1-x0)*(x1-x2)) #elementary Lagrange polynomial l_1
l2(x)=((x-x0)*(x-x1))/((x2-x0)*(x2-x1)) #elementary Lagrange polynomial l_2
h01(x)=(1-(d2l(x0)/d1l(x0))*(x-x0))*(l0(x))^2 #1st type Hermite polyn. h^{(1)}_{0}
h11(x)=(1-(d2l(x1)/d1l(x1))*(x-x1))*(l1(x))^2 #1st type Hermite polyn. h^{(1)}_{1}
h21(x)=(1-(d2l(x2)/d1l(x2))*(x-x2))*(l2(x))^2 #1st type Hermite polyn. h^{(1)}_{2}
h02(x)=(x-x0)*(l0(x))^2 #2nd type Hermite polyn. h^{(2)}_{0}
h12(x)=(x-x1)*(l1(x))^2 #2nd type Hermite polyn. h^{(2)}_{1}
h22(x)=(x-x2)*(l2(x))^2 #2nd type Hermite polyn. h^{(2)}_{2}
y0=sin(x0); y1=sin(x1); y2=sin(x2) #introduce the values y_0, y_1, y_2
dy0=derivative(sin(x), x)(x=x0) #introduce the values y'_0
dy1=derivative(sin(x), x)(x=x1) #introduce the values y'_1
dy2=derivative(sin(x), x)(x=x2) #introduce the values y'_2
P(x)=y0*h01(x)+y1*h11(x)+y2*h21(x)+dy0*h02(x)+dy1*h12(x)+dy2*h22(x); show(P(x))
a=plot(sin(x), x, x0, x2, color="red", thickness=8, legend_label="$\sin(x)$")
b=plot(P(x), x, x0, x2, color="blue", thickness=2, linestyle="-.", legend_label="$P(x)$");
show(a+b)
```

This returns the explicit form of the Hermite interpolation polynomial  $P(x)$ , given by

$$P(x) = \frac{(2\pi + x)^2(2\pi - x)^2x}{16\pi^4} - \frac{(2\pi + x)^2(2\pi - x)x^2}{64\pi^4} + \frac{(2\pi + x)(2\pi - x)^2x^2}{64\pi^4},$$

and the following figure

Above, the code is written in such way that one only changes the first line, that is, the initial values of  $x_0, x_1, x_2$ , (and so the triple  $(x_0, x_1, x_2)$ ) and results to a new Hermite interpolation polynomial. Let us present the graphs for the triples  $(-\pi, 0, \pi)$ ,  $(-3\pi/2, 0, 3\pi/2)$ , and  $(-8\pi, 0, 8\pi)$ , centered at 0, but also for other kind of triples, e.g.,  $(-5\pi/2, \pi/2, 3\pi/2)$ ,  $(-e, \sqrt{e}, \ln(3^{12}))$ , etc.

□

**5.E.2.** Determine the natural cubic spline that interpolates the absolute value function  $f(x) = |x|$ , for  $x \in [-1, 1]$ , selecting the points  $x_0 = -1, x_1 = 0, x_2 = 1$ . Then use the “spline” method described in 5.A.16 to verify your result.

**Solution.** By assumption one has  $y_0 = f(x_0) = 1, y_1 = f(x_1) = 0$  and  $y_2 = f(x_2) = 1$ . For  $x \in [-1, 0]$  suppose that  $S(x) = S_1(x) = a_3x^3 + a_2x^2 + a_1x + a_0$  and for  $x \in [0, 1]$  let  $S(x) = S_2(x) = b_3x^3 + b_2x^2 + b_1x + b_0$ , with  $a_i, b_i \in \mathbb{R}$  for all

$i = 0, \dots, 3$ . The conditions that  $S(x)$  must satisfy are eight in total; First, we have  $S_1(x_0) = y_0, S_2(x_1) = y_1, S_1(x_1) = y_1$ , and  $S_2(x_2) = y_2$ , which equivalently are written as  $-a_3 + a_2 - a_1 + a_0 = 1, b_0 = 0 = a_0$  and  $b_3 + b_2 + b_1 + b_0 = 1$ , respectively. Moreover  $S_1'(x_1) = S_2'(x_1)$  and  $S_1''(x_1) = S_2''(x_1)$ , that is,  $a_1 = b_1$  and  $a_2 = b_2$ , respectively. Finally, since  $S$  should be natural, we need  $S_1''(x_0) = 0 = S_2''(x_2)$ , so we also have  $-6a_1 + 2a_2 = 0$  and  $6b_1 + 2b_2 = 0$ . The system of these eight linear equations has non-zero determinant and so unique solution. Using Sage we get  $a_0 = b_0 = 0, a_1 = b_1 = 0, a_2 = b_2 = 3/2, a_3 = 1/2$  and  $b_2 = -(1/2)$ , that is,

$$S(x) = \begin{cases} S_1(x) = (1/2)x^3 + (3/2)x^2, & \text{if } x \in [-1, 0], \\ S_2(x) = -(1/2)x^3 + (3/2)x^2, & \text{if } x \in [0, 1]. \end{cases}$$

Below we include the graphical verification obtained by a combination of the commands `spline` and `plot`, but present the figure that occurs by plotting  $S_1, S_2$  in Sage via the usual way (so one can compare alone in his/her editor).

```
f(x)=abs(x); pts=[(-1, f(-1)), (0, f(0)), (1, f(1))]; S=spline(pts)
A=plot(S, -1, 1, color="steelblue", thickness=2, legend_label="$S(x)$")
B=points(pts, size=50, color="darkgrey")
fpl=plot(f(x), x, -1, 1, color="black", legend_label="$f(x)$")
fpl.set_legend_options(loc=(0.6, 0.8))
tx0=text("$x_0, y_0$", (-0.89, 1), color="darkslategrey", fontsize="12")
tx1=text("$x_1, y_1$", (0.1, -0.03), color="darkslategrey", fontsize="12")
tx2=text("$x_2, y_2$", (0.89, 1), color="darkslategrey", fontsize="12")
show(A+B+fpl+tx0+tx1+tx2)
```

□

**5.E.3.** Without calculation, determine the Hermite interpolation polynomial if the following is given:

$$\begin{aligned} x_0 = 0, \quad x_1 = 2, \quad x_2 = 1, \\ y_0 = 0, \quad y_1 = 4, \quad y_2 = 1, \\ y'_0 = 0, \quad y'_1 = 4, \quad y'_2 = 2. \end{aligned}$$

○

**5.E.4.** Construct the natural cubic interpolation spline for the points  $x_0 = -3, x_1 = 0, x_2 = 3$ , and the values  $y_0 = -3, y_1 = 0, y_2 = 3$ .

○

**5.E.5.** Construct the complete cubic interpolation spline for the points  $x_0 = -3, x_1 = -2, x_2 = -1$  with values  $y_0 = 0, y_1 = 1, y_2 = 2$  and derivatives at the marginal points given by  $y'_0 = 1, y'_2 = 1$ .

○

**5.E.6.** Using Lagrange interpolation, approximate  $\cos^2(1)$ , based on the values of  $\cos^2(x)$  at the points  $\frac{\pi}{4}, \frac{\pi}{3}$ , and  $\frac{\pi}{2}$ .

○

**5.E.7.** Let  $P(x)$  be a polynomial with real non-negative coefficients. Assume that  $P(\frac{1}{x})P(x) \geq 1$  for  $x = 1$ . Show that the same inequality holds for every positive  $x$ .

**Solution.** Let  $P(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$ . From the statement one has  $P(1)^2 \geq 1$ . Thus,

$$\begin{aligned} P(x)P\left(\frac{1}{x}\right) &= (a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0) \cdot (a_n x^{-n} + a_{n-1} x^{-(n-1)} + \dots + a_1 x^{-1} + a_0) \\ &= \sum_{i=0}^n a_i^2 + \sum_{i < j} a_i a_j (x^{j-i} + x^{i-j}) \geq \sum_{i=0}^n a_i^2 + 2 \sum_{i < j} a_i a_j = P(1)^2 \geq 1. \end{aligned}$$

Here we have used the well known inequality  $x + \frac{1}{x} \geq 2$ , which holds for any positive real number  $x$  (equivalent to  $(\sqrt{x} - \frac{1}{\sqrt{x}})^2 \geq 0$ ).  $\square$

**5.E.8.** Determine a polynomial  $P(x)$  of the least degree possible satisfying the conditions  $P(1) = 1$ ,  $P(2) = 28$ ,  $P(0) = 2$ ,  $P'(0) = 1$ ,  $P'(1) = 9$ .  $\circ$

Let us now explore material that focuses on the interpolation error of the Lagrange polynomial, which concerns the accuracy of interpolation. As we will soon demonstrate, Rolle's theorem (see 5.3.8), plays a crucial role in deriving this interpolation error. Later, in Chapter 6, we will observe that the formula for this error closely resembles that of the Taylor polynomial, see 6.1.3.

**5.E.9. Lagrange interpolation error.** Let  $x_0, \dots, x_n$  be  $(n + 1)$  distinct numbers (nodes) in an interval  $I = [a, b] \subset \mathbb{R}$ , and suppose that  $f(x)$  has  $(n + 1)$  derivatives on  $I$ , that is,  $f \in C^{n+1}[a, b]$ .<sup>11</sup> Assume also that  $f(x)$  is interpolated by the Lagrange polynomial  $P(x)$  passing through the  $(n + 1)$  given points. Prove that for each  $x \in I$  there exists a number  $\xi_x$  (generally unknown) in the open interval  $(a, b)$ , such that

$$f(x) - P(x) = \frac{\ell(x)}{(n + 1)!} f^{(n+1)}(\xi_x), \quad (*)$$

where  $f^{(n+1)}$  denotes the  $(n + 1)$ th derivative of  $f$  and by definition  $\ell(x) := (x - x_0)(x - x_1) \dots (x - x_n)$ . The difference  $f(x) - P(x)$  is called the *interpolation error*.

**Solution.** For a proof we will use repeatedly Rolle's theorem. For some  $t \in [a, b]$  distinct from all the numbers  $x_0, \dots, x_n$ , consider the function

$$g(x) := (f(x) - P(x)) - \frac{\ell(x)}{\ell(t)} \cdot (f(t) - P(t)).$$

Since by assumption  $f \in C^{n+1}[a, b]$ , it follows that  $g$  has also  $n + 1$  derivatives on  $I$ . Moreover, it is immediate that

$$g(t) = 0, \quad g(x_0) = 0, \quad \dots, \quad g(x_n) = 0,$$

which means that  $g$  has at least  $n + 2$  zeros in  $I$ . Recall now that Rolle's theorem states that between any two zeros of a differentiable function, exists at least one zero of its derivative. Thus  $g'$  must have at least  $n + 1$  zeros. We can again apply Rolle's theorem, and argue that the second derivative  $g''$  has at least  $n$  zeros if  $n \geq 1$ . Repeatedly we deduce that the third derivative  $g^{(3)}$  of  $g$  has  $n - 1$  zeros if  $n \geq 2$ , and finally  $g^{(n+1)}$  has at least one zero which we denote by  $\xi_t$ . Now,  $P$  is of degree  $n$  and its  $n + 1$  derivative vanishes,  $P^{(n+1)}(x) = 0$  for any  $x \in I$ . Moreover  $\ell(x)$  is polynomial of degree  $n + 1$ , and we see that  $\ell^{(n+1)}(x) = (n + 1)!$ . For instance for  $n = 2$ , that is,  $\ell(x) = (x - x_0)(x - x_1)(x - x_2)$  we have

$$\begin{aligned} \ell'(x) &= (x - x_1)(x - x_2) + (x - x_0)(x - x_1) + (x - x_0)(x - x_1), & \ell''(x) &= \\ &2(x - x_0) + 2(x - x_1) + 2(x - x_2), & \ell^{(3)}(x) &= 6 = (2 + 1)!. \end{aligned}$$

Also  $\ell(t)$  is a constant. Hence, differentiating  $(n + 1)$  times the function  $g(x)$  and evaluating the result at  $\xi_t$  yields the formula

$$0 = g^{(n+1)}(\xi_t) = f^{(n+1)}(\xi_t) - \frac{(n + 1)! (f(t) - P(t))}{\ell(t)}.$$

Upon solving for  $f(t)$  and replacing  $t$  by  $x$  and  $\xi_t$  by  $\xi_x$ , we get the result.  $\square$

Suppose that  $\hat{x}$  is a point at which we want to compute the error estimate. Then  $\xi = \xi_{\hat{x}}$  depends on that point (not in a continuous way in general), and is hardly known. Hence, having small control of  $f^{(n+1)}(\xi)$  one can claim that the formula (\*) is of limited utility. However, it can be used to obtain a bound on the interpolation error, as we explain below via examples.

**5.E.10.** Consider the function  $f(x) = x \ln(x)$  and the points  $x_0 = 8.3$ ,  $x_1 = 8.6$ . Compute the first-order Lagrange interpolation polynomial  $P$  corresponding to this data and next approximate  $f(8.4)$ . Moreover, estimate an upper bound of the absolute value  $|f(8.4) - P(8.4)|$  using the relation (\*), and compare the result with the real interpolation error.

**Solution.** Let us use Sage to compute  $f(x_0)$  and  $f(x_1)$ :

```
x0=8.3; x1=8.6; f(x)=x*ln(x); print([n(f(x0), digits=4), n(f(x1), digits=4)])
```

which returns [17.65, 18.51], that is,  $f(x_0) \approx 17.65$  and  $f(x_1) \approx 18.51$ , respectively. We have

$$\ell_0(x) = \frac{x - 8.6}{8.3 - 8.6} = -\frac{x - 8.6}{3/10} = -\frac{10}{3}(x - 8.6) = \frac{86 - 10x}{3}, \quad \ell_1(x) = \frac{x - 8.3}{8.6 - 8.3} = \frac{x - 8.3}{3/10} = \frac{10x - 83}{3}.$$

<sup>11</sup>Here we follow the notation of the paragraph 6.1.1.

Thus  $P(x) = f(x_0) \cdot \ell_0(x) + f(x_1) \cdot \ell_1(x) \approx 3.13412x + 8.44823$ , and we see that  $P(8.4) \approx 17.87834$ , which gives the required approximation of  $f(8.4)$ . The real value  $f(8.4)$  is approximately given by 17.87716, thus the absolute value of the interpolation error is  $|f(8.4) - P(8.4)| \approx 0.00119$ . These computations can be verified in Sage:

```
x0=8.3; x1=8.6; f(x)=x*ln(x); l0(x)=(x-x1)/(x0-x1); l1(x)=(x-x0)/(x1-x0)
P(x)=f(x0)*l0(x)+f(x1)*l1(x); abs(f(8.4)-P(8.4))
```

Or alternatively, one can proceed using the `lagrange.polynomial` command:

```
x0=8.3; x1=8.6; f(x)=x*ln(x); pt=[(x0, f(x0)), (x1, f(x1))]
R=PolynomialRing(QQ, "x"); p=R.lagrange_polynomial(pt); abs(f(8.4)-p(8.4))
```

Let us now estimate an upper bound of the error. By the formula (\*), and since  $\ell(x) = (x - x_0)(x - x_1) = (x - 8.3)(x - 8.6)$  and  $n = 1$ , we obtain

$$|f(8.4) - P(8.4)| = \left| \frac{f''(\xi)}{2!} (8.4 - 8.3)(8.4 - 8.6) \right| \quad (**)$$

where here  $\xi \equiv \xi_{8.4} \in (8.3, 8.6)$ . By the product rule we see that  $f'(x) = (x)' \cdot \ln(x) + x \cdot (\ln(x))' = \ln(x) + x \cdot \frac{1}{x} = \ln(x) + 1$ , so  $f''(x) = \frac{1}{x}$ . Consequently, we deduce that  $|f''(x)| \leq \frac{1}{8.3}$  for any  $x \in [8.3, 8.6]$  (and hence also for  $x = \xi$ ). Thus (\*\*) gives

$$|f(8.4) - P(8.4)| \leq \frac{1/8.3}{2} |8.4 - 8.3| \cdot |8.4 - 8.6| = \frac{0.1 \cdot 0.2}{16.6} \approx 0.001205.$$

Observe that the actual error  $|f(8.4) - P(8.4)| \approx 0.00119$  computed above, is a bit smaller than this upper bound, as it should be.  $\square$

**5.E.11.** Consider the exponential function  $f(x) = e^x$  and the points  $x_0 = 1, x_1 = 1.3, x_2 = 1.6, x_3 = 1.9, x_4 = 2$ . Suppose that  $P(x)$  is the Lagrange polynomial interpolating  $f$  along these nodes.

(a) What is the degree of the polynomial  $P$ ? Use Sage to determine  $P$ .

(b) Find an upper bound of the absolute value of the interpolation error when we approximate  $f(1.25)$  by  $P(1.25)$ .

**Solution.** (a) The Lagrange polynomial is at most of degree 4. In particular, via Sage and the cell below we see that it has degree exactly 4.

```
x0=1; x1=1.3; x2=1.6; x3=1.9; x4=2; f(x)=e**x
pt=[(x0, f(x0)), (x1, f(x1)), (x2, f(x2)), (x3, f(x3)), (x4, f(x4))]
R=PolynomialRing(RR, "x"); p=R.lagrange_polynomial(pt)
```

(b) Based on the relation (\*) we obtain

$$|f(x) - P(x)| = \left| \frac{f^{(5)}(\xi)}{(4+1)!} \right| |(x-1) \cdot (x-1.3) \cdot (x-1.6) \cdot (x-1.9) \cdot (x-2)|.$$

Since  $f(x) = e^x$ , we have  $f^{(5)}(x) = e^x$ , as well. Moreover we see that  $|f^{(5)}(x)| \leq e^2$  for any  $x \in [0, 2]$ , and hence  $|e^\xi| \leq e^2$ . Thus

$$\begin{aligned} |f(1.25) - P(1.25)| &= \left| \frac{e^\xi}{5!} \right| \cdot |1.25 - 1| \cdot |1.25 - 1.3| \cdot |1.25 - 1.6| \cdot |1.25 - 1.9| \cdot |1.25 - 2| \\ &\leq \frac{e^2}{120} (0.25) \cdot (0.05) \cdot (0.35) \cdot (0.65) \cdot (0.75) \approx \frac{7.38906}{120} \cdot 0.00214 \approx 0.000132. \end{aligned}$$

The absolute value of the actual error is approximately  $|f(1.25) - P(1.25)| \approx 0.0000810$ , and this is smaller of the upper bound given above. One can obtain the actual error in Sage by typing in the end of previous cell `print(abs(f(1.25) - p(1.25)))`.  $\square$

## B) MATERIAL ON REAL NUMBERS AND LIMIT PROCESSES

**5.E.12.** Determine the supremum and infimum of the set  $A = (-3, 0] \cup (1, \pi) \cup \{6\} \subset \mathbb{R}$ .

**Solution.** Clearly,  $\sup A = 6, \inf A = -3$ . One can verify this in Sage by applying the following the cell (notice however that this method applies only for subsets of  $\mathbb{R}$ )

```
A = RealSet.open_closed(-3, 0) + RealSet(1, pi) + RealSet.point(6)
print(A.inf()); print(A.sup())
```

$\square$

**5.E.13.** (a) Find  $\sup A$  and  $\inf A$  for

$$A = \left\{ a_n = \frac{n + (-1)^n}{n} : n \in \mathbb{N}^* \right\} \subset \mathbb{R}.$$

(b) Find a subset of  $\mathbb{R}$  which does not have an infimum in  $\mathbb{R}$ , but has a supremum.

(c) Find a subset of  $\mathbb{R}$  which does not have a supremum in  $\mathbb{R}$ , but has an infimum.

**Solution.** (a) Clearly

$$\begin{aligned} A &= \left\{ a_1 = 0, a_2 = \frac{3}{2}, a_3 = \frac{2}{3}, a_4 = \frac{5}{4}, \dots \right\} \\ &= \left\{ a_1 = 1 - \frac{1}{2 \cdot 1 - 1}, a_2 = 1 + \frac{1}{2 \cdot 1}, a_3 = 1 - \frac{1}{2 \cdot 2 - 1}, a_4 = 1 + \frac{1}{2 \cdot 2}, \dots \right\}. \end{aligned}$$

Therefore, the given sequence  $(a_n = \frac{n+(-1)^n}{n})_{n=1}^\infty$  splits into two subsequences with even and odd indices, that is,

$$(a_n)_{n=1}^\infty = (b_n)_{n=1}^\infty \cup (c_n)_{n=1}^\infty, \quad \text{with } b_n = a_{2n} = 1 + \frac{1}{2n}, \quad \text{and } c_n = a_{2n-1} = 1 - \frac{1}{2n-1},$$

respectively. Clearly  $\frac{3}{2} = b_1 \geq b_n > c_n \geq c_1 = 0$ . Thus,  $\sup A = \frac{3}{2}$  and  $\inf A = 0$ , respectively.

(b) An example is given by the set  $\mathbb{Z} \setminus \mathbb{N}$ .

(c) The set of natural numbers is such an example. □

**5.E.14.** Recall that when the supremum of a subset  $A \subset \mathbb{R}$  belongs to  $A$  is called “*maximum of A*”. Similarly is defined the “*minimum of A*”. Find, if existent, the minimum/maximum of the following sets:  $A = (-1, 2)$ ,  $B = (-1, 2]$ ,  $C = \{(-1)^n : n \in \mathbb{Z}_+\}$ , and  $\mathbb{R}_+ = \{x \in \mathbb{R} : x > 0\}$ .

**Solution.** The set  $A = (-1, 2)$  has 2 as its supremum, but  $2 \notin A$ . So there is no maximum for  $A$ . Neither it has a minimum, since its infimum  $-1 \notin A$ . The set  $B = (-1, 2]$  has 2 as its supremum, which belongs to  $B$ . Hence 2 is the maximum of  $B$ . But it does not have a minimum. For  $C$  both the minimum and maximum elements exist, and are the numbers  $-1$  and  $1$ , respectively. Finally,  $\mathbb{R}_+$  is not bounded above, but does has an infimum which equals to 0. However,  $0 \notin \mathbb{R}_+$  hence in this case there is neither a minimum, nor a maximum. □

**5.E.15.** Find a subset  $X \subset \mathbb{R}$  such that  $\sup X \leq \inf X$ . ○

**5.E.16.** Find sets  $A, B, C \subseteq \mathbb{R}$  such that  $A \cap B = \emptyset$ ,  $A \cap C = \emptyset$ ,  $B \cap C = \emptyset$ , and  $\sup A = \inf B = \inf C = \sup C$ . ○

**5.E.17.** Based on the definition of a convergent sequence, show that  $a_n \rightarrow 1$ , as  $n \rightarrow \infty$ , where  $a_n = \frac{2^n - 1}{2^n}$ .

**Solution.** We have  $|a_n - 1| = \left| \frac{2^n - 1}{2^n} - 1 \right| = \left| \frac{1}{2^n} \right| = \frac{1}{2^n}$ . On the other hand, by induction we get  $n < 2^n$  for any natural number  $n$ , hence we also have  $\frac{1}{2^n} < \frac{1}{n}$  for all  $n \in \mathbb{Z}_+$ . Let  $\varepsilon > 0$ . Using the Archimedean property we can find some  $N$  with  $\frac{1}{N} < \varepsilon$ . Then, for  $n > N$  we get  $\frac{1}{n} < \frac{1}{N} < \varepsilon$  and hence  $|a_n - 1| = \frac{1}{2^n} < \frac{1}{n} < \frac{1}{N} < \varepsilon$ . This shows that  $a_n \rightarrow 1$  as  $n \rightarrow \infty$ . □

**5.E.18.** Use the binomial theorem to prove that  $\lim_{n \rightarrow +\infty} \sqrt[n]{\ln(n)} = 1$ .

**Solution.** For  $x > 0$  the function  $\ln(x)$  is strictly increasing, thus for  $n > 3$  it is true that  $\ln(n) > \ln(e) = 1$  and this implies that  $\sqrt[n]{\ln(n)} > 1$ . Consequently, we may write  $\sqrt[n]{\ln(n)} = 1 + a_n$  for some  $a_n > 0$  for all  $n$ . Taking the  $n$ th power of this relation we arrive to  $\ln(n) = (1 + a_n)^n$ , and here is where the binomial theorem applies:

$$\ln(n) = (1 + a_n)^n = 1 + na_n + \frac{n(n-1)}{2!}a_n^2 + \dots + a_n^n.$$

Thus  $\ln(n) > 1 + na_n$ , from where we deduce that  $a_n < \frac{\ln(n)}{n} - \frac{1}{n}$ . However,  $\frac{\ln(n)}{n} \rightarrow 0$  as  $n \rightarrow +\infty$ , thus  $\lim_{n \rightarrow +\infty} a_n = 0$ . Hence by the relation  $\sqrt[n]{\ln(n)} = 1 + a_n$  the result follows. □

**5.E.19.** Compute the limit  $\lim_{n \rightarrow \infty} (\sqrt{2} \cdot \sqrt[4]{2} \cdot \sqrt[8]{2} \dots \sqrt[2^n]{2})$ . ○

**5.E.20.** Evaluate the limit  $\lim_{n \rightarrow \infty} \left( \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \dots + \frac{1}{(n-1) \cdot n} \right)$ . ○

**5.E.21.** Compute the limit  $\lim_{n \rightarrow \infty} \left( \frac{1}{n^2} + \frac{2}{n^2} + \dots + \frac{n-2}{n^2} + \frac{n-1}{n^2} \right)$  ○

**5.E.22.** Evaluate the limit  $\lim_{n \rightarrow \infty} \left( \frac{1}{\sqrt{n^2+1}} + \frac{1}{\sqrt{n^2+2}} + \cdots + \frac{1}{\sqrt{n^2+n}} \right)$ . Also, use Sage to plot several terms of the given sequence to visually illustrate your answer.

**Solution.** In order to determine this limit, we can invoke the squeeze theorem. The bounds

$$\frac{1}{\sqrt{n^2+1}} + \cdots + \frac{1}{\sqrt{n^2+n}} \geq \frac{1}{\sqrt{n^2+n}} + \cdots + \frac{1}{\sqrt{n^2+n}} = \frac{n}{\sqrt{n^2+n}}$$

and

$$\frac{1}{\sqrt{n^2+1}} + \cdots + \frac{1}{\sqrt{n^2+n}} \leq \frac{1}{\sqrt{n^2+1}} + \cdots + \frac{1}{\sqrt{n^2+1}} = \frac{n}{\sqrt{n^2+1}}$$

for all naturals  $n$ , respectively, imply that

$$1 = \lim_{n \rightarrow \infty} \frac{n}{\sqrt{n^2+n}} \leq \lim_{n \rightarrow \infty} \left( \frac{1}{\sqrt{n^2+1}} + \cdots + \frac{1}{\sqrt{n^2+n}} \right) \leq \lim_{n \rightarrow \infty} \frac{n}{\sqrt{n^2+1}} = 1.$$

Thus  $\lim_{n \rightarrow \infty} \left( \frac{1}{\sqrt{n^2+1}} + \cdots + \frac{1}{\sqrt{n^2+n}} \right) = 1$ . This result can be visually confirmed in Sage by the same method used in 5.B.4.

Thus one can execute the cell

```
var("k")
p=Graphics()
for n in xrange(1, 50+1):
    p=p+points((n, sum(1/sqrt(n^2+k), k, 1, n)), color="black")
show(p)
```

This code produces the figure given below, where indeed one can observe the convergence of the given sequence to the unit.

□

**5.E.23.** Evaluate the limits  $\lim_{n \rightarrow \infty} \left( \frac{n}{n+1} \right)^n$ ,  $\lim_{n \rightarrow \infty} \left( 1 + \frac{1}{n^2} \right)^n$  and  $\lim_{n \rightarrow \infty} \left( 1 - \frac{1}{n} \right)^{n^2}$ .

○

**5.E.24.** Let  $(a_n)$  be a non-negative convergent sequence of real numbers.<sup>12</sup> Show that  $\lim_{n \rightarrow \infty} a_n = a \geq 0$ .

**Solution.** In contrast, suppose that the claim is wrong, i.e., the limit of  $(a_n)$  is a negative number,  $a < 0$ . Since  $a_n \rightarrow a$  as  $n \rightarrow \infty$  and  $\varepsilon = -a$  is a positive real number, there is a natural  $n_0$  such that  $|a_n - a| < \varepsilon$  for all  $n \geq n_0$ , that is,  $a - \varepsilon < a_n < a + \varepsilon$ , for all  $n \geq n_0$ . However,  $a = -\varepsilon$  which gives  $-2\varepsilon < a_n < 0$ , a contradiction as  $(a_n)$  consists only of non-negative terms. Thus  $a \geq 0$ . □

**5.E.25.** Let  $(a_n)$  be a sequence of real numbers and let  $(y_n)$  be a sequence of positive real numbers satisfying  $y_n \rightarrow 0$ , as  $n \rightarrow \infty$ . Suppose that for some  $N \in \mathbb{N}$ , some constant  $\mu > 0$  and some (finite) real number  $a$ , we have  $|a_n - a| < \mu y_n$  for all  $n \geq N$ . Prove that  $(a_n)$  is convergent, in particular,  $\lim_{n \rightarrow \infty} a_n = a$ .

**Solution.** The sequence  $(y_n)$  is by assumption convergent to 0, thus if  $\hat{\varepsilon} > 0$  is given there exists some  $n_0$  (depending in general on  $\hat{\varepsilon}$ ) such that  $|y_n - 0| = |y_n| = y_n < \hat{\varepsilon}$  for all  $n \geq n_0$ . By assumption  $\mu > 0$ , hence we may set  $\hat{\varepsilon} = \varepsilon/\mu$ ,

<sup>12</sup>By the term “non-negative” we mean  $a_n \geq 0$  for all naturals  $n$ .

for some  $\varepsilon > 0$ . Thus we have  $y_n < \frac{\varepsilon}{\mu}$  for all  $n \geq n_0$ . Then, for those  $n$  satisfying both  $n \geq n_0$  and  $n \geq N$  we get  $|a_n - a| \leq \mu y_n < \mu \cdot \frac{\varepsilon}{\mu} = \varepsilon$ . As  $\varepsilon > 0$  is arbitrary, the claim follows.  $\square$

**5.E.26.** (1) Let  $(a_n)$  be a sequence of positive real numbers for which the limit  $\lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n}$  exists and is finite real number  $\ell$ . Show that if  $\ell < 1$ , then  $\lim_{n \rightarrow \infty} a_n = 0$ .

(2) More in general, suppose that  $a_n \neq 0$  for all  $n \in \mathbb{N}$  and that the limit  $\ell = \lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right|$  exists. Show that if  $\ell < 1$ , then  $\lim_{n \rightarrow \infty} a_n = 0$ .

**Solution.** We will prove the first statement and leave the second one for the reader, since the method follows essentially the same ideas. We have  $a_n > 0$  for all  $n \in \mathbb{N}$ , hence the sequence  $(y_n)$  with general term  $y_n = \frac{a_{n+1}}{a_n}$  also satisfies  $y_n > 0$ , for all  $n \in \mathbb{N}$ . Also,  $y_n \rightarrow \ell$  as  $n \rightarrow \infty$  and hence the requirements of the statement in 5.E.24 are satisfied. Thus we have  $\lim_{n \rightarrow \infty} y_n = \ell \geq 0$ . Let  $b$  a real number with  $\ell < b < 1$  and set  $\varepsilon = b - \ell > 0$ . Then, there exists some  $N \in \mathbb{N}$  with  $\left| \frac{a_{n+1}}{a_n} - \ell \right| < \varepsilon$ , provided that  $n \geq N$ . This implies that  $\frac{a_{n+1}}{a_n} < \varepsilon + \ell = b - \ell + \ell = b$ , which in turn gives

$$0 < a_{n+1} < b \cdot a_n < b^2 \cdot a_{n-1} < \dots < b^{n-N+1} a_N.$$

Thus, if  $\mu := a_N b^{-N} > 0$  we obtain  $0 < a_{n+1} < \mu \cdot b^{n+1}$ , for all  $n \geq N$ . In addition, since  $0 < b < 1$  we have  $\lim_{n \rightarrow \infty} b^n = 0$ . Thus the result follows by 5.E.25.

Alternatively, the inequality  $a_{n+1} < b a_n$  for all  $n \geq N$  implies that  $a_{n+1} < a_n$ , for all  $n \geq N$  (since  $0 < b < 1$ ). Therefore, the sequence  $(a_n)$  is monotone (is decreasing starting from the  $N$ th term). Since  $(a_n)$  is also bounded, it is convergent. Let  $L = \lim_{n \rightarrow \infty} a_n$ . Then, using the relation  $a_{n+1} = y_n a_n$  we see that

$$L = \lim_{n \rightarrow \infty} a_{n+1} = \lim_{n \rightarrow \infty} (y_n a_n) = \lim_{n \rightarrow \infty} y_n \cdot \lim_{n \rightarrow \infty} a_n = \ell \cdot L \iff L(1 - \ell) = 0.$$

But  $1 - \ell > 0$ , and thus  $L = 0$ , as it is required.  $\square$

**5.E.27.** (a) Apply the statement in 5.E.25 to prove that  $\lim_{n \rightarrow \infty} \left( \frac{1}{1+na} \right) = 0$ , where  $a > 0$ .

(b) For a real number  $x$  apply the statement 5.E.26 to prove that  $\lim_{n \rightarrow \infty} \frac{x^n}{n!} = 0$ .  $\circ$

**5.E.28.** Recall that if  $(a_n)$  is a Cauchy sequence in  $\mathbb{R}$ , then the difference  $a_{n+1} - a_n$  tends to zero, i.e.,  $(a_{n+1} - a_n) \rightarrow 0$  as  $n \rightarrow \infty$ . Present a counterexample verifying that the converse of this statement is *not* in general true.

**Solution.** Consider the sequence  $(a_n = \sqrt{n})$  with  $n \in \mathbb{N}$ . Then we see that

$$a_{n+1} - a_n = \sqrt{n+1} - \sqrt{n} = \frac{(\sqrt{n+1} - \sqrt{n})(\sqrt{n+1} + \sqrt{n})}{\sqrt{n+1} + \sqrt{n}} = \frac{1}{\sqrt{n+1} + \sqrt{n}},$$

and  $\frac{1}{\sqrt{n+1} + \sqrt{n}} \rightarrow 0$ . However,  $(a_n)$  is *not* a Cauchy sequence (try to verify this claim yourself).  $\square$

**5.E.29.** Based on the definition of a Cauchy sequence, show that  $(a_n = 1/n)_{n=1}^{\infty}$  is such a sequence.

**Solution.** We need to show that for every  $\varepsilon > 0$  there exist  $N \in \mathbb{N}$  such that  $|a_n - a_m| = \left| \frac{1}{n} - \frac{1}{m} \right| < \varepsilon$  for all  $n, m \geq N$ . Indeed, for such  $n, m \geq N$  by the triangle inequality we have

$$\left| \frac{1}{n} - \frac{1}{m} \right| \leq \left| \frac{1}{n} \right| + \left| -\frac{1}{m} \right| = \frac{1}{n} + \frac{1}{m} \leq \frac{1}{N} + \frac{1}{N} = \frac{2}{N}. \quad (*)$$

Now, for  $\varepsilon > 0$  we can find non-zero  $N \in \mathbb{N}$  such that  $\frac{1}{N} < \frac{\varepsilon}{2}$ . Then by (\*) we get the result, i.e.,  $\left| \frac{1}{n} - \frac{1}{m} \right| \leq \frac{2}{N} < \varepsilon$ .  $\square$

**5.E.30.** A sequence  $(x_n)_{n=1}^{\infty}$  of real numbers is called “contractive” if there exists some real  $\alpha$  with  $0 < \alpha < 1$  such that

$$|x_{n+1} - x_n| \leq \alpha |x_n - x_{n-1}|, \quad \text{for all } n \in \mathbb{N}, n \geq 2, \quad (*)$$

Prove that any contractive sequence is Cauchy.

**Solution.** Suppose that  $(x_n)$  is a sequence of real numbers satisfying (\*) for some  $\alpha \in (0, 1)$ . By (\*) we get that

$$\begin{aligned} |x_3 - x_2| &\leq \alpha |x_2 - x_1|, \\ |x_4 - x_3| &\leq \alpha |x_3 - x_2| \leq \alpha \cdot \alpha |x_2 - x_1| = \alpha^2 |x_2 - x_1|, \\ &\dots \quad \dots \end{aligned}$$

$$|x_{n+1} - x_n| \leq \alpha |x_n - x_{n-1}| \leq \alpha^2 |x_{n-1} - x_{n-2}| \leq \dots \leq \alpha^{n-1} |x_2 - x_1|,$$

where the final relation follows by induction over  $n$ . Now, from the geometric series task 5.B.16 recall that

$$1 + \alpha + \alpha^2 + \dots + \alpha^n = \frac{1 - \alpha^{n+1}}{1 - \alpha}.$$

Combining this with our previous observation, for all  $m, n \in \mathbb{N}$  with  $m > n$  we have

$$\begin{aligned} |x_m - x_n| &\leq |x_m - x_{m-1}| + |x_{m-1} - x_{m-2}| + \cdots + |x_{n+1} - x_n| \\ &\leq \alpha^{m-2}|x_2 - x_1| + \alpha^{m-3}|x_2 - x_1| + \cdots + \alpha^{n-1}|x_2 - x_1| \\ &= |x_2 - x_1| (\alpha^{m-2} + \alpha^{m-3} + \cdots + \alpha^{n-1}) = \alpha^{n-1} (1 + \alpha + \cdots + \alpha^{m-n-1}) |x_2 - x_1| \\ &= \alpha^{n-1} \left( \frac{1 - \alpha^{m-n}}{1 - \alpha} \right) |x_2 - x_1| \leq \alpha^{n-1} \left( \frac{1}{1 - \alpha} \right) |x_2 - x_1|. \quad (\#) \end{aligned}$$

If  $x_2 = x_1$  it is easy to see that  $(x_n)$  is a Cauchy sequence, hence we may assume that  $x_2 \neq x_1$ . Recall by 5.B.3 that  $\alpha^{n-1} \rightarrow 0$  as  $n \rightarrow +\infty$ , provided that  $0 < \alpha < 1$ . Therefore, given some  $\varepsilon > 0$  we can find some positive integer  $N$  with  $|\alpha^{n-1} - 0| = |\alpha^{n-1}| < \frac{\varepsilon}{\left(\frac{1}{1-\alpha}\right) \cdot |x_2 - x_1|}$ , for all  $n \geq N$ . Then, for the same  $N$  and for  $m > n \geq N$  by (#) we see that

$$|x_m - x_n| \leq \alpha^{n-1} \left( \frac{1}{1 - \alpha} \right) |x_2 - x_1| < \frac{\varepsilon}{\left(\frac{1}{1-\alpha}\right) |x_2 - x_1|} \left( \frac{1}{1 - \alpha} \right) |x_2 - x_1| = \varepsilon.$$

Thus  $(x_n)$  is a Cauchy sequence. □

**5.E.31.** Consider the sequence  $(x_n)$  of real numbers defined recursively as follows:

$$x_1 = 1, \quad x_{n+1} = \frac{1}{4 + x_n}, \quad n \geq 1.$$

Deduce that  $(x_n)$  is a convergent sequence, by proving that it is contractive (see 5.E.30). ○

**5.E.32.** Let  $(a_n)_{n=1}^\infty$  be a bounded sequence of real numbers. Set  $m_n = \sup\{a_k : k \geq n\}$ , and  $\ell_n = \inf\{a_k : k \geq n\}$ ,  $n \in \mathbb{N}$ . Based on the monotone convergent theorem, show that both  $(m_n)_{n=1}^\infty$  and  $(\ell_n)_{n=1}^\infty$  are convergent. ○

**5.E.33. Equivalent condition for convergence.** Let  $(x_n)$  a sequence of real numbers. Is the following claim true?

$$x_n \text{ is convergent} \iff \lim_{n \rightarrow \infty} \limsup_{m \rightarrow \infty} |x_n - x_m| = 0.$$

**Solution.** The answer is *yes*. Suppose first that  $\lim_{n \rightarrow \infty} x_n = a$  for some (finite) real number  $a$ . Then,  $\lim_{m \rightarrow \infty} |x_n - x_m| = |x_n - a|$  and in turn this implies that

$$\lim_{n \rightarrow \infty} \limsup_{m \rightarrow \infty} |x_n - x_m| = \lim_{n \rightarrow \infty} |x_n - a| = 0.$$

For the opposite direction, we rely on the theory of Cauchy sequence. So, suppose that  $\lim_{n \rightarrow \infty} \limsup_{m \rightarrow \infty} |x_n - x_m| = 0$ . Then, for every  $\varepsilon > 0$  we may fix some natural  $N$  with

$$\limsup_{m \rightarrow \infty} |x_m - x_N| < \frac{\varepsilon}{2}.$$

Therefore, there exist  $m_0 \in \mathbb{N}$  with  $|x_m - x_N| < \frac{\varepsilon}{2}$  for all  $m \geq m_0$ . Combining this with the triangle inequality, for all  $m_1, m_2 \geq m_0$  we obtain

$$|x_{m_1} - x_{m_2}| \leq |x_{m_1} - x_N| + |x_{m_2} - x_N| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$

This show that  $(x_n)$  is a Cauchy sequence, and hence convergent, see the theorem in 5.2.3. □

**5.E.34.** Find the limes superior/inferior of the sequences  $(a_n)$ ,  $(b_n)$  and  $(c_n)$  defined below:

$$a_n = 3 + (-1)^n, \quad b_n = 2 + \frac{1}{n}, \quad c_n = \frac{4n}{n+1} \cos\left(\frac{n\pi}{2}\right), \quad (n \in \mathbb{Z}_+).$$

**Solution.** We recall that superior/inferior of a sequence  $(x_n)$  are essentially the biggest/smallest limits of all the subsequences of  $(x_n)$ . Thus, to compute them it is always sufficient to choose appropriate subsequences of  $(x_n)$ .

Let us begin with  $(a_n)$  and consider its subsequence  $(a_{2n} = 3 + (-1)^{2n})$ . This obviously tends to 4 as  $n \rightarrow +\infty$  and hence  $\limsup_{n \rightarrow \infty} a_n = 4$ . On the other hand, the subsequence  $(a_{2n+1} = 3 + (-1)^{2n+1})$  of  $(a_n)$  tends to 2 as  $n \rightarrow +\infty$  and hence  $\liminf_{n \rightarrow \infty} a_n = 2$ .

Obviously the sequence  $(b_n)$  converges to 2, so any subsequence of  $(b_n)$  will have the same limit and it follows that  $\limsup_{n \rightarrow \infty} b_n = 2 = \liminf_{n \rightarrow \infty} b_n$ .

For  $(c_n)$  we have the expression  $c_n = x_n \cdot y_n$ , where  $x_n = \frac{4n}{n+1}$  and  $y_n = \cos\left(\frac{n\pi}{2}\right)$ . Obviously,  $\lim_{n \rightarrow \infty} x_n = \lim_{n \rightarrow \infty} \frac{4}{1+\frac{1}{n}} = 4$  and so we may focus on  $(y_n)$ . We consider the following four subsequences:

- The subsequence of  $(y_n)$  defined by  $y_{4n} = \cos\left(\frac{4n\pi}{2}\right) = \cos(2n\pi) = 1$ , which satisfies  $\lim_{n \rightarrow \infty} y_{4n} = 1$ . Thus, the

subsequence  $(c_{4n})$  of  $(c_n)$  defined by  $c_{4n} = x_{4n} \cdot y_{4n}$  will tend to  $4 \cdot 1 = 4$ .

• The subsequence of  $(y_n)$  defined by  $y_{4n+1} = \cos(\frac{(4n+1)\pi}{2}) = \cos(2n\pi + \frac{\pi}{2}) = \cos(\pi/2) = 0$ , satisfies  $\lim_{n \rightarrow \infty} y_{4n+1} = 0$ . Hence in this case the subsequence  $(c_{4n+1})$  of  $(c_n)$  defined by  $c_{4n+1} = x_{4n+1} \cdot y_{4n+1}$  tends to  $4 \cdot 0 = 0$ .

• The subsequence of  $(y_n)$  defined by  $y_{4n+2} = \cos(\frac{(4n+2)\pi}{2}) = \cos(2n\pi + \pi) = \cos(\pi) = -1$ , satisfies  $\lim_{n \rightarrow \infty} y_{4n+2} = -1$ . Thus, the subsequence  $(c_{4n+2})$  of  $(c_n)$  defined by  $c_{4n+2} = x_{4n+2} \cdot y_{4n+2}$  tends to  $4 \cdot -1 = -4$ .

• The subsequence of  $(y_n)$  defined by  $y_{4n+3} = \cos(\frac{(4n+3)\pi}{2}) = \cos(2n\pi + \frac{3\pi}{2}) = \cos(\frac{3\pi}{2}) = 0$  tends to 0 and hence the subsequence  $(c_{4n+3})$  of  $(c_n)$  tends to 0 as well.

To summarize, the largest limit of the subsequences  $(c_{4n})$ ,  $(c_{4n+1})$ ,  $(c_{4n+2})$  and  $(c_{4n+3})$  is 4 and the smallest one is  $-4$ . This means that  $\limsup_{n \rightarrow \infty} c_n = 4$  and  $\liminf_{n \rightarrow \infty} c_n = -4$ , respectively.  $\square$

**5.E.35.** Based on the result from 5.B.18 on the Euler number, compute  $\limsup_{n \rightarrow \infty} a_n$  and  $\liminf_{n \rightarrow \infty} a_n$ , where  $(a_n)_{n=1}^{\infty}$  is the sequence defined by  $a_n = \left(1 + \frac{(-1)^n}{n}\right)^n$ , for  $n \in \mathbb{Z}_+$ .

**Solution.** Consider a sequence  $(a_n)$  which its definition involves the expression  $(-1)^n$  (or  $(-1)^{n+1}$  or  $(-1)^{n-1}$ ). Recall that in this case in order to compute the superior/inferior of  $(a_n)$  we can consider the subsequences determined for  $2n$  and  $2n + 1$ , respectively. Hence for the specific task let us consider first the subsequence of  $(a_n)$  defined by  $a_{2n} = \left(1 + \frac{1}{2n}\right)^{2n}$ . We have  $2n \rightarrow +\infty$  as  $n \rightarrow +\infty$ , and hence by 5.B.18 we see that  $\lim_{n \rightarrow +\infty} a_{2n} = e$ . On the other hand, the subsequence of  $(a_n)$  defined by  $a_{2n+1} = \left(1 + \frac{(-1)^{2n+1}}{2n+1}\right)^{2n+1}$  satisfies  $a_{2n+1} = \left(1 - \frac{1}{2n+1}\right)^{2n+1}$  and a combination of 5.B.18 with the exercise 5.E.23 above, gives  $\lim_{n \rightarrow +\infty} a_{2n+1} = e^{-1}$ . As a conclusion we get that  $\limsup_{n \rightarrow \infty} a_n = e$  and  $\liminf_{n \rightarrow \infty} a_n = e^{-1}$ .  $\square$

*Let us now present a few extra tasks on the topological notions that we met so far in Chapter 5.*

**5.E.36.** Is some of the sets  $\mathbb{N}$  or  $\mathbb{Q}$  an open or a closed subset of  $\mathbb{R}$ ?  $\circ$

**5.E.37.** (a) Given the sets  $\mathbb{R}^* = \mathbb{R} \setminus \{0\}$ ,  $\mathbb{R} \setminus \mathbb{Q}$ ,  $\mathbb{R} \setminus \mathbb{Z}$ , and  $(1, 2) \cup \{5\}$ , locate the open one.  $\circ$

(b) Similarly, given the sets  $\mathbb{R} \setminus \mathbb{Q}$ ,  $\mathbb{R} \setminus \mathbb{Z}$  and  $[1, 2] \cup \{5\}$ , locate the closed one.  $\circ$

**5.E.38.** (a) Consider the set  $A = \bigcap_{n \in \mathbb{N}^*} \left(-\frac{1}{n}, 1 + \frac{1}{n}\right)$ , where as usual  $\mathbb{N}^* = \mathbb{N} \setminus \{0\}$ . Show that  $A = [0, 1]$ .

(b) Is the set  $B = \bigcup_{n \in \mathbb{N}^*} \left[\frac{1}{n}, 1 - \frac{1}{n}\right]$  an open or a closed subset of  $\mathbb{R}$ ?

**Solution.** (a) Clearly,  $[0, 1] \subset A$  and we need to prove the opposite inclusion. So assume that  $x \in A$ , that is,  $-\frac{1}{n} < x < 1 + \frac{1}{n}$  for all  $n \in \mathbb{Z}_+$ . Then we have  $x \geq \sup\{-\frac{1}{n} : n \in \mathbb{Z}_+\}$  and  $x \leq \inf\{1 + \frac{1}{n} : n \in \mathbb{Z}_+\}$ . However,  $\sup\{-\frac{1}{n} : n \in \mathbb{Z}_+\} = 0$  and  $\inf\{1 + \frac{1}{n} : n \in \mathbb{Z}_+\} = 1$ , which means that  $x \in [0, 1]$ .

(b) This can be treated similarly, in particular one can show that

$$B = \bigcup_{n \in \mathbb{N}^*} \left[\frac{1}{n}, 1 - \frac{1}{n}\right] = (0, 1),$$

which we leave for practice. Hence  $B$  is open and this shows that the union of infinitely many closed sets is *not* necessary closed.  $\square$

**5.E.39. Compact sets.** Suppose that we define the compactness of a subset  $A \subset \mathbb{R}$  via the Bolzano-Weierstrass theorem (see (4) in Theorem 5.2.8), that is,  $A$  is said to be compact if for any sequence  $(x_n)$  in  $A$  there is a convergent subsequence  $(x_{n_k})$  of  $(x_n)$  whose limit belongs to  $A$ . Under this definition, show that a compact set  $A$  is closed and bounded.

**Solution.** If  $A$  is the empty set, then the result clearly holds, and hence assume that  $A \neq \emptyset$  and that  $A$  is compact. According to our new definition, this means that for any sequence  $(x_n)$  in  $A$  there is a convergent subsequence  $(x_{n_k})$  of  $(x_n)$  whose limit, say  $\ell$ , belongs to  $A$ . Hence if  $(x_n)$  is convergent, then we should have  $\lim_{n \rightarrow \infty} x_n = \lim_{k \rightarrow \infty} x_{n_k} = \ell \in A$ . This shows that  $A$  is closed and it remains to show that  $A$  is bounded. For each  $n \in \mathbb{N}^* = \mathbb{N} \setminus \{0\}$  consider the open sets  $C_n = (-n, n)$ . Obviously,

$$\bigcup_{n \in \mathbb{N}^*} C_n = \mathbb{R}, \quad \text{hence} \quad A \subseteq \bigcup_{n \in \mathbb{N}^*} C_n.$$

Since each  $C_n$  is also open, this means that the family  $\{C_n : n \in \mathbb{N}^*\}$  is an open cover of  $A$ . However,  $A$  is compact and by (5) in Theorem 5.2.8 each of its open covers contains a finite subcover of  $A$ . Thus there exists  $m \in \mathbb{N}^*$  such that

$$A \subseteq \bigcup_{n=1}^m C_n$$

with  $\bigcup_{n=1}^m C_n = (-m, m)$ . This shows that  $A$  is contained in the bounded interval  $(-m, m)$ , therefore  $A$  is bounded. For instance, any interval of the form  $[a, b] \subset \mathbb{R}$  with  $a < b$ ,  $a, b \in \mathbb{R}$ , is closed (and bounded) and hence compact.  $\square$

**5.E.40. An open cover.** Find an open cover, a subcover and a finite subcover of  $A := \{x \in \mathbb{R} : 0 \leq x \leq 1\} = [0, 1]$ .

**Solution.** An open cover of  $A$  is given by the family  $\mathcal{A} := \{\mathcal{A}_a = (a - \varepsilon, a + \varepsilon)\}$  where  $a \in A$  and  $\varepsilon > 0$ . As a subcover, for the same  $\varepsilon$  take the subfamily  $\{\mathcal{A}_b = (b - \varepsilon, b + \varepsilon)\}$ , where  $b \in \{x \in \mathbb{Q} : 0 \leq x \leq 1\}$ . Notice however that this is *not* a finite subcover. To obtain a finite subcover, consider the family

$$\{\mathcal{A}_{0 \cdot \varepsilon}, \mathcal{A}_{1 \cdot \varepsilon}, \mathcal{A}_{2 \cdot \varepsilon}, \dots, \mathcal{A}_{n_0 \cdot \varepsilon}\} = \{\mathcal{A}_0, \mathcal{A}_\varepsilon, \mathcal{A}_{2\varepsilon}, \dots, \mathcal{A}_{n_0\varepsilon}\},$$

where  $n_0 \in \mathbb{N}$  is the largest natural with  $n_0\varepsilon < 1$ . Then this is finite subfamily of  $\{\mathcal{A}_a = (a - \varepsilon, a + \varepsilon) : a \in A\}$  (every set in this family is obviously a member of  $\mathcal{A}$ ), and moreover it covers  $A = [0, 1]$ , i.e.,  $A \subseteq \mathcal{A}_0 \cup \mathcal{A}_\varepsilon \cup \mathcal{A}_{2\varepsilon} \cup \dots \cup \mathcal{A}_{n_0\varepsilon}$ .  $\square$

**5.E.41.** Show that the collection of open intervals  $\mathcal{A} = \{\mathcal{A}_k = (k - 1, k + 1)\}_{k \in \mathbb{N}^*}$  is an open cover of  $\mathbb{N}^* = \mathbb{N} \setminus \{0\}$ . Deduce however that  $\mathbb{N}^*$  is not a compact subset of  $\mathbb{R}$ .

**5.E.42.** Indeed, we see that

$$\bigcup_{k=1}^{\infty} \mathcal{A}_k = (0, +\infty)$$

and  $\mathbb{N}^* \subset (0, +\infty)$ . Observe however that the family  $\{\mathcal{A}_k = (k - 1, k + 1)\}_{k \in \mathbb{N}^*}$  is not a cover of  $\mathbb{N}$ , since its union does not contain 0.<sup>13</sup> On the other hand we see that there is no finite subfamily  $\{\mathcal{A}_{i_1}, \dots, \mathcal{A}_{i_n}\}$  of  $\mathcal{A}$  which covers  $\mathbb{N}^*$ . For, if  $\alpha = \max\{i_1, \dots, i_n\}$  then we see that

$$\bigcup_{k=1}^n \mathcal{A}_{i_k} \subset (0, \alpha + 1),$$

and it is obvious that this union does not contain all naturals. Hence  $\mathbb{N}^*$  is a non-compact set.  $\circ$

**5.E.43.** Suppose that  $A \subset \mathbb{R}$  is a non-empty compact subset of  $\mathbb{R}$  and let  $\varepsilon > 0$ . Specify a finite subset  $B \subset \mathbb{R}$  such that  $\min\{|x - y| : y \in B\} < \varepsilon$  for all  $x \in A$ .

**Solution.** It is easy to see that for any  $\varepsilon > 0$  the set  $\{(x - \varepsilon, x + \varepsilon) : x \in A\}$  is an open cover of  $A$ . On the other hand,  $A$  is by assumption compact. Hence there exist some positive integer  $n$  and  $x_1, \dots, x_n$ , all points of  $A$ , such that

$$A \subset \bigcup_{i=1}^n (x_i - \varepsilon, x_i + \varepsilon).$$

Hence a finite subset  $B \subset \mathbb{R}$  with the required properties is given by these points, i.e.,  $B = \{x_1, \dots, x_n\}$ .  $\square$

*The theory of limits often combines with the theory of matrices, and can be used to solve tasks related to linear algebra.*

For instance, let  $(A_n)_{n=1}^{\infty}$  be a sequence of  $2 \times 2$  matrices, with  $A_n = \begin{pmatrix} a_n & b_n \\ c_n & d_n \end{pmatrix}$ , where  $(a_n)_{n=1}^{\infty}$ ,  $(b_n)_{n=1}^{\infty}$ ,  $(c_n)_{n=1}^{\infty}$  and  $(d_n)_{n=1}^{\infty}$  are sequences of real (or complex) numbers. When  $a_n \rightarrow a$ ,  $b_n \rightarrow b$ ,  $c_n \rightarrow c$  and  $d_n \rightarrow d$  for some real numbers  $a, b, c, d$  we say that  $(A_n)_{n=1}^{\infty}$  converges to the matrix  $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ , i.e.,  $\lim_{n \rightarrow \infty} A_n = A$ .

In this case  $A$  referred to as the “limit matrix” of  $(A_n)_{n=1}^{\infty}$ . Let us illustrate such an example.

**5.E.44.** Given a positive real number  $\varphi$ , consider the matrix sequence  $(A_n)$  whose general term is given by

$$A_n = \begin{pmatrix} 1 & -\frac{\varphi}{n} \\ \frac{\varphi}{n} & 1 \end{pmatrix}^n, \quad n \in \mathbb{Z}_+.$$

Based on the relation  $\lim_{n \rightarrow \infty} \left(1 + \frac{z}{n}\right)^n = e^z$  for all  $z \in \mathbb{C}$ , prove that the limit matrix  $A$  of  $(A_n)$  exists and describes a rotation in the plane by angle  $\varphi$ , i.e.,

$$A = \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix}.$$

<sup>13</sup>Recall that till Chapter 11 we assume that  $\mathbb{N}$  contains 0.

**Solution.** Let us set  $\frac{\varphi}{n} = \tan(\theta_n)$ . Based on basic matrix calculus we can then express the matrix sequence  $(A_n)$  as follows:

$$\begin{aligned} A_n &= \begin{pmatrix} 1 & -\frac{\varphi}{n} \\ \frac{\varphi}{n} & 1 \end{pmatrix}^n = \begin{pmatrix} 1 & -\tan(\theta_n) \\ \tan(\theta_n) & 1 \end{pmatrix}^n = \frac{1}{\cos^n(\theta_n)} \begin{pmatrix} \cos(\theta_n) & -\sin(\theta_n) \\ \sin(\theta_n) & \cos(\theta_n) \end{pmatrix}^n \\ &= \frac{1}{\cos^n(\theta_n)} \begin{pmatrix} \cos(n\theta_n) & -\sin(n\theta_n) \\ \sin(n\theta_n) & \cos(n\theta_n) \end{pmatrix} = \begin{pmatrix} \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} & -\frac{\sin(n\theta_n)}{\cos^n(\theta_n)} \\ \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} & \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} \end{pmatrix}. \end{aligned}$$

Notice above we used the relations

$$\begin{pmatrix} 1 & -\tan(\theta_n) \\ \tan(\theta_n) & 1 \end{pmatrix} = \frac{1}{\cos(\theta_n)} \begin{pmatrix} \cos(\theta_n) & -\sin(\theta_n) \\ \sin(\theta_n) & \cos(\theta_n) \end{pmatrix}, \quad \begin{pmatrix} \cos(\theta_n) & -\sin(\theta_n) \\ \sin(\theta_n) & \cos(\theta_n) \end{pmatrix}^n = \begin{pmatrix} \cos(n\theta_n) & -\sin(n\theta_n) \\ \sin(n\theta_n) & \cos(n\theta_n) \end{pmatrix}.$$

Although the first is obvious, you may like to confirm the second one by induction. Hence we can write

$$\lim_{n \rightarrow \infty} A_n = \begin{pmatrix} \lim_{n \rightarrow \infty} \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} & -\lim_{n \rightarrow \infty} \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} \\ \lim_{n \rightarrow \infty} \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} & \lim_{n \rightarrow \infty} \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} \end{pmatrix}, \quad (*)$$

and  $A = \lim_{n \rightarrow \infty} A_n$  will exist if and only if the limits inside the matrix in  $(*)$  exist. To examine these limits we rely on de Moivre's theorem, as follows:

$$\frac{\cos(n\theta_n)}{\cos^n(\theta_n)} + i \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} = \frac{\cos(n\theta_n) + i \sin(n\theta_n)}{\cos^n(\theta_n)} = \left( \frac{\cos(\theta_n) + i \sin(\theta_n)}{\cos(\theta_n)} \right)^n = \left( 1 + i \tan(\theta_n) \right)^n = \left( 1 + \frac{i\varphi}{n} \right)^n.$$

Recalling that  $\lim_{n \rightarrow \infty} \left( 1 + \frac{i\varphi}{n} \right)^n = e^{i\varphi} = \cos(\varphi) + i \sin(\varphi)$ , we deduce that

$$\lim_{n \rightarrow \infty} \left( \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} + i \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} \right) = \cos(\varphi) + i \sin(\varphi) \iff \lim_{n \rightarrow \infty} \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} + i \lim_{n \rightarrow \infty} \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} = \cos(\varphi) + i \sin(\varphi).$$

Comparing the real and imaginary parts, we obtain  $\lim_{n \rightarrow \infty} \frac{\cos(n\theta_n)}{\cos^n(\theta_n)} = \cos(\varphi)$ ,  $\lim_{n \rightarrow \infty} \frac{\sin(n\theta_n)}{\cos^n(\theta_n)} = \sin(\varphi)$ , and the result follows by  $(*)$ .  $\square$

Let's now discuss additional content concerning the limits of functions and the concept of continuity. This will involve various computational and theoretical examples, as well as notable applications of the intermediate value theorem. However, we will first address tasks involving sequences defined recursively, such as in the problem 5.E.31 above.

Let  $f : A \subset \mathbb{R} \rightarrow \mathbb{R}$  be a continuous function defined on a subset  $A$  of real numbers. Suppose that exists a sequence  $(x_n)$  in  $A$  satisfying  $x_{n+1} = f(x_n)$ , for all  $n$ . Moreover, assume that the  $\lim_{n \rightarrow \infty} x_n$  exists, and that is equal to some (limit point)  $a \in A$ . In this situation it is not hard to see that  $\lim_{n \rightarrow \infty} f(x_n) = f(a)$  and  $f(a) = a$ . This shows how useful can be continuous functions and provides a very common way to define sequences, that is, by iterating some function  $f$  (recursive definition).

**5.E.45. Iterations.** Consider the sequence  $(a_n)_{n=1}^{\infty}$  with  $a_1 = 0$ ,  $a_2 = 1$ ,  $a_3 = \sqrt{3}$ ,  $\dots$ ,  $a_n = \sqrt{1 + 2a_{n-1}}$ .

(a) Show that  $(a_n)_{n=1}^{\infty}$  is strictly increasing.

(b) Is this a convergent sequence? In the positive case, find the limit  $\lim_{n \rightarrow \infty} a_n$ .

(c) Use Sage to plot some terms of  $(a_n)$  and obtain a graphical confirmation of your conclusion in (b).

**Solution.** We should prove that  $a_{n+1} > a_n$  for all  $n$ . Observe that  $a_2 = 1 > 0 = a_1$ . Assuming that  $a_n > a_{n-1}$  for  $n \geq 2$  and proceeding by induction over  $n$  one gets  $a_{n+1} = \sqrt{1 + 2a_n} > \sqrt{1 + 2a_{n-1}} = a_n$ . Using mathematical induction over  $n$  we can also show that  $(a_n)$  is bounded above, that is,  $a_n < 3$  for all naturals  $n \geq 1$ . This is because  $a_1 = 0 < 3$  and hence assuming  $a_n < 3$  for  $n \geq 2$ , we can arrive to the claim:  $a_{n+1} = \sqrt{1 + 2a_n} < \sqrt{1 + 2 \cdot 3} < \sqrt{9} = 3$ . Since the sequence  $(a_n)$  is strictly increasing and bounded above, by the monotone sequence theorem it should be convergent.

To determine its limit we rely on the continuity of the square root function  $\sqrt{x}$ , as follows: Suppose that  $a = \lim_{n \rightarrow \infty} a_n$ . Then  $a$  must satisfy the relation  $a = \sqrt{1 + 2a}$ , thus  $a^2 = 1 + 2a$  with solutions  $a = 1 \pm \sqrt{2}$ . However,  $a_n \geq 0$  for all  $n$ , from where one can neglect the negative solution, that is,  $\lim_{n \rightarrow \infty} a_n = 1 + \sqrt{2}$ .

Let us now use Sage to plot some terms of  $(a_n)$ . To do so we will first use the `def` command to introduce our sequence. This can be done as follows:

```

def a(n, D={}):
    if n in D.keys():
        return D[n]
    if (n==1):
        sol = 0
    else:
        sol = sqrt(1+2*a(n-1))
    D[n] = sol
    return sol
    
```

In this way to test different values of  $(a_n)$  one can simply type

```
a(2).n(); a(3).n(); a(10).n()
```

etc. Notice however that the definition of  $(a_n)$  via the `def` method, does not allow us to compute the limit of  $(a_n)$ , which means that typing `lim(a(n), n = oo)` returns an error (even if we add before the `def` command the variable  $n$  as symbolic).

Now we can use this routine to plot  $(a_n)$ . Together we will sketch the line  $y = 1 + \sqrt{2}$  so that the visualization of our conclusion about the limit to be easier.

```

N=50
pts = [(n, a(n)) for n in range(1, N)]
p=points(pts, color="slategray", size=25)
p+=line([(0, 1+sqrt(2)), (51, 1+sqrt(2))], rgbcolor=(0.7,0.2,0.3), linestyle="--")
p+=point([0, 1+sqrt(2)], size=20, color="darkblue")
p+=text(r"$1+\sqrt{2}$", (-4, 1+sqrt(2)), color="darkblue", fontsize="14")
p.show(figsize=6)
    
```

The figure that Sage returns is here:

□

**5.E.46.** Consider the sequence  $(a_n)_{n=1}^{\infty}$  defined by the relation  $a_{n+1} = \frac{1}{2} \left( a_n + \frac{a^2}{a_n} \right)$  for all positive integers  $n$ , with  $a_1 > a$ , for some  $a > 0$ . Show that  $\lim_{n \rightarrow +\infty} a_n = a$ .

**Solution.** For all naturals  $n > 1$  by the AM-GM-inequality presented in Chapter 1, we have

$$a_n = \frac{1}{2} \left( a_{n-1} + \frac{a^2}{a_{n-1}} \right) \geq \sqrt{a_{n-1} \cdot \frac{a^2}{a_{n-1}}} = a > 0.$$

Thus, together with the condition  $a_1 > a$  this gives  $a_n \geq a$  for all  $n$  and hence  $(a_n)$  is bounded. It is also decreasing, since

$$a_{n+1} - a_n = \frac{a^2 - a_n^2}{2a_n} \leq 0. \quad (b)$$

One may like to confirm the equality appearing in (b) also via Sage, which can be done quickly by the block

```

var("n, c"); function("a")(n)
bool((1/2)*(a(n)+(c^2/a(n)))-a(n)==(c^2-a(n)*a(n))/(2*a(n)))
    
```

In this way one proves that  $(a_n)$  is bounded and monotone, hence its limit  $\lim_{n \rightarrow +\infty} a_n$  exists and equals to  $\inf\{a_n : n \in \mathbb{N}\}$ .

Let us set  $b = \inf\{a_n : n \in \mathbb{N}\}$ . Then we should have

$$b = \frac{1}{2} \left( b + \frac{a^2}{b} \right),$$

which can be equivalently expressed as  $b^2 = a^2$ . However, by assumption  $a > 0$  and thus we get  $b = a$ . □

**5.E.47.** Consider the sequence  $(a_n)_{n=1}^{\infty}$  with  $a_1 = \sqrt{2}$  and  $a_n = \sqrt{2 + a_{n-1}}$  for all naturals  $n$  with  $n \geq 2$ . Show that  $(a_n)$  is convergent, and in particular compute  $\lim_{n \rightarrow +\infty} a_n$ . ○

**5.E.48.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a continuous function satisfying the relation  $x^2 f(x) = 1 - \cos(2x)$ , for all  $x \in \mathbb{R}$ . Using the result of 5.B.31, find the explicit form of  $f$ .

**Solution.** Obviously, for  $x \neq 0$  the function at hand satisfies  $f(x) = \frac{1 - \cos(2x)}{x^2}$ . For  $x = 0$ , by the continuity of  $f$  we should have  $f(0) = \lim_{x \rightarrow 0} f(x)$ . To compute this limit one can use the known identity  $\sin^2\left(\frac{\theta}{2}\right) = \frac{1 - \cos(\theta)}{2}$  (half-angle formula), which can be rephrased as  $2 \sin^2(\theta) = 1 - \cos(2\theta)$ . This is a very useful trigonometric identity, which for our case applies as follows:

$$f(0) = \lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} \frac{1 - \cos(2x)}{x^2} = 2 \lim_{x \rightarrow 0} \frac{\sin^2(x)}{x^2} = 2 \left( \lim_{x \rightarrow 0} \frac{\sin(x)}{x} \right)^2 = 2 \cdot 1^2 = 2.$$

Therefore one can now present the full type of  $f$ , namely

$$f(x) = \begin{cases} \frac{1 - \cos(2x)}{x^2}, & \text{for } x \neq 0, \\ 2, & \text{for } x = 0. \end{cases}$$

□

**5.E.49.** Using the result of 5.B.31, when adequate, evaluate the following limits:

$$\lim_{x \rightarrow 0} \frac{\sin^2(x)}{x}, \quad \lim_{x \rightarrow 0} \frac{x}{\sin^2(x)}, \quad \lim_{x \rightarrow 0} \frac{\arcsin(x)}{x}, \quad \lim_{x \rightarrow 0} \frac{3 \tan^2(x)}{5x^2}, \quad \lim_{x \rightarrow 0} \frac{\sin(3x)}{\sin(5x)}, \quad \lim_{x \rightarrow 0} \frac{\tan(3x)}{\sin(5x)}.$$

○

**5.E.50.** Confirm that

$$\lim_{x \rightarrow 0} \frac{e^{5x} - e^{2x}}{x} = 3 = \lim_{x \rightarrow 0} \frac{e^{5x} - e^{-x}}{\sin(2x)}.$$

(Hint: Recall that  $\lim_{x \rightarrow 0} \frac{e^x - 1}{x} = 1$ ). Next use Sage to sketch the graphs of the involved functions. ○

**5.E.51.** Compute the limit  $\lim_{x \rightarrow +\infty} \left( \frac{3x+1}{3x-2} \right)^{4x}$  with the aid of the relation  $\lim_{x \rightarrow +\infty} \left( 1 + \frac{1}{x} \right)^x = e$ . Next verify your answer via Sage.

**Solution.** Based on the properties of powers, we see that

$$\left( \frac{3x+1}{3x-2} \right)^{4x} = \frac{[3x(1 + \frac{1}{3x})]^{4x}}{[3x(1 - \frac{2}{3x})]^{4x}} = \frac{(1 + \frac{1}{3x})^{4x}}{(1 - \frac{2}{3x})^{4x}} = \frac{\left[ \left( 1 + \frac{1}{3x} \right)^{3x} \right]^{\frac{4}{3}}}{\left[ \left( 1 + \frac{-2}{3x} \right)^{3x} \right]^{\frac{4}{3}}} = \frac{\left[ \left( 1 + \frac{1}{3x} \right)^{3x} \right]^{\frac{4}{3}}}{\left[ \left( 1 + \frac{-\frac{2}{3}x}{x} \right)^{-\frac{3}{2}x} \right]^{\frac{4}{3}}}.$$

Thus

$$\lim_{x \rightarrow +\infty} \left( \frac{3x+1}{3x-2} \right)^{4x} = \frac{\lim_{x \rightarrow +\infty} \left[ \left( 1 + \frac{1}{3x} \right)^{3x} \right]^{\frac{4}{3}}}{\lim_{x \rightarrow +\infty} \left[ \left( 1 + \frac{-\frac{2}{3}x}{x} \right)^{-\frac{3}{2}x} \right]^{\frac{4}{3}}} = \frac{\left[ \lim_{x \rightarrow +\infty} \left( 1 + \frac{1}{3x} \right)^{3x} \right]^{\frac{4}{3}}}{\left[ \lim_{x \rightarrow +\infty} \left( 1 + \frac{-\frac{2}{3}x}{x} \right)^{-\frac{3}{2}x} \right]^{\frac{4}{3}}} = \frac{e^{\frac{4}{3}}}{e^{-\frac{8}{3}}} = e^{\frac{4}{3} + \frac{8}{3}} = e^4.$$

For a confirmation via Sage just give the cell `limit(((3 * x + 1)/(3 * x - 2))**(4 * x), x = oo)`. □

**5.E.52.** Evaluate the limits  $\lim_{x \rightarrow +\infty} \left( 2 + \frac{1}{x} \right)^{\frac{1}{x}}$ ,  $\lim_{x \rightarrow +\infty} x^{-x}$  and  $\lim_{x \rightarrow 0} e^{\frac{1}{x}}$ . ○

**5.E.53.** Evaluate the following limits:

$$\lim_{x \rightarrow 0} \frac{\sin(x)}{x^3}, \quad \lim_{x \rightarrow +\infty} \left( \sqrt{x^2 + x} - x \right), \quad \lim_{x \rightarrow +\infty} \left( x \sqrt{1 + x^2} - x^2 \right), \quad \lim_{x \rightarrow 0^-} \frac{\sqrt{1 + \tan(x)} - \sqrt{1 - \tan(x)}}{\sin(x)}.$$

**5.E.54.** Use the binomial theorem to compute the limit  $\lim_{x \rightarrow 0} \frac{(1 + 2nx)^n - (1 + nx)^{2n}}{x^2}$ , for all  $n \in \mathbb{N}^*$ . Next confirm your computation via Sage. ○

**5.E.55.** Exam the convergence of the sequence  $(a_n)$  with general term ○

$$a_n = \sum_{k=1}^n \frac{\cos(k)}{2^k}, \quad n = 1, 2, \dots$$

**5.E.56.** Compute the limit  $\lim_{n \rightarrow +\infty} \frac{\lfloor xn \rfloor}{n}$ , where  $x \in \mathbb{R}$  and  $\lfloor \cdot \rfloor$  is the floor function introduced in 5.B.48. ○

**Solution.** Recall from 5.B.48 that for any  $x \in \mathbb{R}$  we have  $\lfloor x \rfloor \leq x < \lfloor x \rfloor + 1$ . Since in general we have  $nx \in \mathbb{R}$  for all  $n \in \mathbb{Z}$  and  $x \in \mathbb{R}$  we also get  $\lfloor nx \rfloor \leq nx < \lfloor nx \rfloor + 1$ , which we may rewrite as  $0 \leq x - \frac{\lfloor xn \rfloor}{n} < \frac{1}{n}$ , for all  $n \neq 0$ . Combining this with the squeeze theorem we deduce that  $\lim_{n \rightarrow +\infty} \frac{\lfloor xn \rfloor}{n} = x$ , for all  $x \in \mathbb{R}$ . □

**5.E.57. The ceiling function and the fractional part function.** (1) Use the command `ceil` in Sage to compute  $\lceil -1.4 \rceil$ ,  $\lceil -0.5 \rceil$ ,  $\lceil 2 \rceil$ ,  $\lceil 2.1 \rceil$ ,  $\lceil \sqrt{7} \rceil$ ,  $\lceil \pi \rceil$  and  $\lceil 9/2 \rceil$ .  
 (2) Construct in Sage the fractional part function and then compute its evaluation on the values mentioned in (1).  
 (3) Show that  $\lceil x \rceil = -\lfloor -x \rfloor$ , for all  $x \in \mathbb{R}$ .  
 (4) If  $x = n + d$ , with  $n \in \mathbb{Z}$  and  $0 \leq d < 1$ , show that  $n = \lfloor x \rfloor$  and  $d = \{x\}$ .  
 (5) Show that the fractional part function is discontinuous at any integer.  
 (6) Use Sage to sketch the graph of the ceiling function for  $-5 \leq x \leq 5$  and of the fractional part function for  $0 \leq x \leq 5$ .

**Solution.** (1) It is not hard to compute

$$\lceil -1.4 \rceil = -1, \quad \lceil -0.5 \rceil = 0, \quad \lceil 2 \rceil = 2, \quad \lceil 2.1 \rceil = 3 = \lceil \sqrt{7} \rceil, \quad \lceil \pi \rceil = 4, \quad \lceil 9/2 \rceil = 5.$$

A confirmation in Sage occurs by the command `ceil`, as follows:

```
print(ceil(-1.4)); print(ceil(-0.5)); print(ceil(2)); print(ceil(2.1))
print(ceil(sqrt(7))); print(ceil(pi)); print(ceil(9/2))
```

(2) In Sage to introduce the fractional part function  $x \mapsto \{x\} = x - \lfloor x \rfloor$ , use the floor function `floor` and type the syntax: `fractal(x) = x - floor(x)` Then, to compute the required evaluations type `print(fractal(-1.4))`, `print(fractal(-0.5))`, etc. Notice that Sage has a build-in function for the fractional part function, called `frac` but this agrees with ours only for positive reals. In this way you can quickly verify the following answers:

$$\begin{aligned} \{-1.4\} &= -1.4 - \lfloor -1.4 \rfloor = -1.4 - (-2) = 0.6, & \{-0.5\} &= -0.5 - \lfloor -0.5 \rfloor = -0.5 - (-1) = 0.5, \\ \{2\} &= 2 - \lfloor 2 \rfloor = 2 - 2 = 0, & \{2.1\} &= 2.1 - \lfloor 2.1 \rfloor = 2.1 - 2 = 0.1, \\ \{\sqrt{7}\} &= \sqrt{7} - \lfloor \sqrt{7} \rfloor \approx 2.645752 - 2 \approx 0.645752, & \{\pi\} &= \pi - \lfloor \pi \rfloor \approx 0.141593, & \{9/2\} &= 4.5 - \lfloor 4.5 \rfloor = 0.5. \end{aligned}$$

(3) We leave this to the reader.

(4) Consider a real  $x$  such that  $x = n + d$  with  $n \in \mathbb{Z}$  and  $0 \leq d < 1$ . By (2) in 5.B.48 we know that  $\lfloor x + n \rfloor = \lfloor x \rfloor + n$  for all  $x \in \mathbb{R}$  and  $n \in \mathbb{Z}$ . Thus we have  $\lfloor x \rfloor = \lfloor n + d \rfloor = n + \lfloor d \rfloor = n$ , since  $\lfloor d \rfloor = 0$ . Consequently,

$$x = n + d = \lfloor x \rfloor + d = \lfloor x \rfloor + \{x\},$$

that is,  $\{x\} = d$ . This proves (4).

(5) Let  $n \in \mathbb{Z}$  be an integer. We see that

$$\lim_{x \rightarrow n^+} \{x\} = \lim_{h \rightarrow 0} \{n + h\} = \lim_{h \rightarrow 0} (n + h - \lfloor n + h \rfloor) = \lim_{h \rightarrow 0} (n + h) - \lim_{h \rightarrow 0} (\lfloor n + h \rfloor) = n - \lim_{h \rightarrow 0} (n + \lfloor h \rfloor) = n - n = 0.$$

On the other hand, we compute

$$\lim_{x \rightarrow n^-} \{x\} = \lim_{h \rightarrow 0} \{n - h\} = \lim_{h \rightarrow 0} (n - h - \lfloor n - h \rfloor) = \lim_{h \rightarrow 0} (n - h) - \lim_{h \rightarrow 0} (\lfloor n - h \rfloor) = n - (n - 1) = 1.$$

It follows that the function  $x \mapsto \{x\}$  is not continuous at any integer (see also its graph below).

(6) For this task and for the ceiling function you may proceed in analogous way with the floor function, presented in 5.B.48. This method includes the jump discontinuities, and is encoded by the following block:

```
g=ceil(x)
p=plot(g, x, -5, 5, ticks=[1,1])
for x in [-5..5] :
```

```
p+=point([x,x], size=30, color="black")
for x in [-4..5]:
    p+=circle((x-1,x),0.08, color="black")
show(p)
```

In a similar way we can sketch the graph of the fractional part function (together with the jump discontinuities).

```
fractal(x)=x-floor(x)
q=plot(fractal, x, 0, 5)
for x in [0..5]:
    q+=point([x,0], size=30, color="black")
for x in [1..5]:
    q+=circle((x,1),0.03, color="black")
show(q)
```

Let us present the figures that Sage constructs: At left is the graph of the ceiling function and at right those of the fractional part function (again, in both figures one should ignore the vertical lines). Notice that the fractional part function is non-negative.

□

**5.E.58.** Examine the continuity of the function  $f(x) = (x - 1)^{-\operatorname{sgn}(x)}$ , at the points 0 and 1.

○

**5.E.59.** Given the points  $-\pi, 0, 1, 2, 3, \pi$ , determine whether the function

$$f(x) = \begin{cases} x, & x < 0; \\ 0, & 0 \leq x < 1; \\ x, & x = 1; \\ 0, & 1 < x < 2; \\ x, & 2 \leq x \leq 3; \\ \frac{1}{x-3}, & x > 3 \end{cases}$$

is continuous; left-continuous or right-continuous at these points.

○

**5.E.60.** Find all  $p \in \mathbb{R}$  for which the function

$$f(x) = \frac{\sin(6x)}{3x}, \quad x \in \mathbb{R}^* = \mathbb{R} \setminus \{0\}; \quad f(0) = p,$$

is continuous at the origin.

○

**5.E.61.** Choose a real number  $a$  so that the function

$$h(x) = \frac{x^4 - 1}{x - 1}, \quad x > 1; \quad h(x) = a, \quad x \leq 1,$$

is continuous on  $\mathbb{R}$ .

○

**5.E.62.** By defining the values at the points  $-1$  and  $1$ , extend the function

$$f(x) = (x^2 - 1) \sin \frac{2x - 1}{x^2 - 1}, \quad x \in \mathbb{R} \setminus \{\pm 1\},$$

so that the resulting function is continuous on the whole  $\mathbb{R}$ .

○

**5.E.63.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a function satisfying the relation

$$f^3(x) + 3f^2(-x)f(x) = 4x^2, \quad x \in \mathbb{R}. \quad (\#)$$

(a) Prove that  $f$  is even and next show that  $\lim_{x \rightarrow 0} f(x) = 0$ .

(b) Show that  $\lim_{x \rightarrow 0} \frac{\ln(f(x))}{\ln(\sqrt{x^3})} = 4/9$ .

**Solution.** (a) In the defining equation (#) replace  $x$  by  $-x$ . This gives  $f^3(-x) + 3f^2(x)f(-x) = 4x^2$  and by subtracting this relation from (#) (by parts), we get

$$f^3(x) - 3f^2(x)f(-x) + 3f(x)f^2(-x) - f^3(-x) = 4x^2 - 4x^2 = 0 \iff (f(x) - f(-x))^3 = 0, \quad x \in \mathbb{R},$$

where we used the identity  $(a - b)^3 = a^3 - 3a^2b + 3ab^2 - b^3$ , with  $a, b \in \mathbb{R}$ . Therefore, we deduce that  $f(x) - f(-x) = 0$ , for all  $x \in \mathbb{R}$ , i.e.,  $f$  is even.

Now, because  $f$  is even the defining equation takes the form  $f^3(x) + 3f^2(x)f(x) = 4x^2$  or  $4f^3(x) = 4x^2$ , that is,  $f^3(x) = x^2$  for all  $x \in \mathbb{R}$ , from where we get  $f(x) = \sqrt[3]{x^2} = x^{\frac{2}{3}}$ ,  $x \in \mathbb{R}$ . As for the limit, recall that the function  $f(x) = x^{\frac{2}{3}}$  is everywhere continuous on  $\mathbb{R} = (-\infty, \infty)$ , see also the Problem 6.A.21 where the graph of  $f$  is presented. Therefore,  $\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} x^{\frac{2}{3}} = f(0) = 0$ .

(b) The type of  $f$  is known by the first part, thus one can easily prove the claim, i.e.,

$$\lim_{x \rightarrow 0} \frac{\ln(f(x))}{\ln(\sqrt{x^3})} = \lim_{x \rightarrow 0} \frac{\ln(x)^{2/3}}{\ln(x)^{3/2}} = \lim_{x \rightarrow 0} \frac{(2/3)\ln(x)}{(3/2)\ln(x)} = \frac{4}{9} \cdot \lim_{x \rightarrow 0} \frac{\ln(x)}{\ln(x)} = \frac{4}{9}. \quad \square$$

**5.E.64.** Let  $f : \mathbb{R} \rightarrow (-\infty, 1)$  and  $g : \mathbb{R} \rightarrow (1, +\infty)$  be continuous functions satisfying  $f(a) = na$  and  $g(b) = nb$  for certain reals  $0 < a < b$  and some positive integer  $n$ . Prove the existence of some  $\xi \in (a, b)$  satisfying the equation

$$\xi = \frac{f(\xi)g(\xi)}{n}.$$

**Solution.** Observe that  $f(a) = na < 1$  since  $f(a) \in (-\infty, 1)$ , and hence  $a < \frac{1}{n}$ , while  $g(b) = nb > 1$  since  $g(b) \in (1, +\infty)$  and hence  $b > \frac{1}{n}$ . Thus, we can indeed form the interval  $[a, b]$  and consider the function

$$\ell(x) = f(x)g(x) - nx, \quad x \in [a, b].$$

Then we see that:

- $\ell(a) = f(a)g(a) - na = na(g(a) - 1) > 0$ , since  $g(a) > 1$  and so  $g(a) - 1 > 0$  and  $0 < a < 1/n$ .
  - $\ell(b) = f(b)g(b) - nb = nb(f(b) - 1) < 0$ , since  $f(b) < 1$  and hence  $f(b) - 1 < 0$  while  $0 < \frac{1}{n} < b$ .
- Thus,  $\ell(a)\ell(b) < 0$  and by Bolzano's theorem there exists some  $\xi \in (a, b)$  with  $\ell(\xi) = 0$ , that is,  $n\xi = f(\xi)g(\xi)$ .  $\square$

**5.E.65.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a periodic function with period  $T > 0$ , that is,  $f(x+T) = f(x)$  for all  $x \in \mathbb{R}$ . If  $\lim_{x \rightarrow +\infty} f(x)$  exists and is a real number  $\alpha$ , show that  $f(x) = \alpha$  for all  $x \in \mathbb{R}$ , i.e.,  $f$  is constant.<sup>14</sup>

**Solution.** By assumption  $f$  is periodic with period  $T$ , hence it suffices to prove the  $f$  is constant on  $[0, T]$ . Since  $\lim_{x \rightarrow +\infty} f(x) = \alpha \in \mathbb{R}$ , for every  $\varepsilon > 0$  there exist  $C > 0$  such that  $|f(x) - \alpha| < \varepsilon$ , for all  $x \geq C$ . Moreover, for all  $x \in [0, T]$  we can find some positive integer  $n$  such that  $x + nT \geq C$ . Thus we get  $|f(x) - \alpha| = |f(x + nT) - \alpha| < \varepsilon$ . This shows that  $|f(x) - \alpha| < \varepsilon$ , for all  $x \in [0, T]$  and  $\varepsilon > 0$ , and hence  $f(x) = \alpha$  for all  $x \in \mathbb{R}$ .  $\square$

**5.E.66.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a continuous function which is periodic with period  $T > 0$ . Show that there exists  $x_0 \in \mathbb{R}$  such that  $f(x_0 + \frac{T}{2}) = f(x_0)$ . Then use Sage to compute  $x_0$  for  $f(x) = \cos(x)$ .

**Solution.** It is sufficient to consider the function  $g(x) = f(x + \frac{T}{2}) - f(x)$  which is continuous on  $\mathbb{R}$  (since  $f$  is continuous) and satisfies

$$g(0) = f\left(\frac{T}{2}\right) - f(0), \quad g\left(\frac{T}{2}\right) = f(0) - f\left(\frac{T}{2}\right) = -g(0).$$

Recall that if a continuous function has values of opposite sign inside an interval, then it admits a root in that interval (Bolzano's theorem, see 5.2.19). In particular, the result follows by the intermediate value theorem applied to  $g$ , the latter restricted on  $[0, \frac{T}{2}]$ .

The  $\cos$  function  $f(x) = \cos(x)$  has period  $T = 2\pi$ , thus it suffices to focus on the interval  $(0, \frac{T}{2} = \pi)$ . The equation  $\cos(x_0 + \pi) = \cos(x_0)$  is equivalent to  $\cos(x_0) = 0$  (since  $\cos(x + \pi) = -\cos(x)$  for all  $x$ ). Hence obviously  $x_0 = \frac{\pi}{2} \in (0, \pi)$  (see also the table in 5.A.3).<sup>15</sup> In Sage just type `solve(cos(x + pi) == cos(x), x)`.  $\square$

<sup>14</sup>Later we will see that the condition  $\lim_{x \rightarrow +\infty} f(x) = \alpha \in \mathbb{R}$ , means that the line  $y = \alpha$  is a horizontal asymptote of  $y = f(x)$ .

<sup>15</sup>Recall that the equation  $\cos(x) = 0$  has general solution  $\frac{\pi}{2} + k\pi$ , with  $k \in \mathbb{N}$ .

**5.E.67.** Let  $f, g, h, k : \mathbb{R} \rightarrow \mathbb{R}$  continuous functions on  $\mathbb{R}$  satisfying the following conditions:

- $f(x) > 0$  and  $k(x) > 0$  for all  $x \in \mathbb{R}$ ;
- $f(a) = g(a)$  and  $h(b) = k(b)$  for some  $a \neq b \in \mathbb{R}$ ;
- $g(x) < f(x)$  for all  $x \in \mathbb{R} \setminus \{a\}$  and  $k(x) < h(x)$  for all  $x \in \mathbb{R} \setminus \{b\}$ .

Prove the existence of (at least) one  $x_0 \in (a, b)$  for which the vectors  $\vec{u} = (g(x_0), f(x_0))^T$  and  $\vec{v} = (k(x_0), h(x_0))^T$  (of  $\mathbb{R}^2$ ) are parallel.

**Solution.** The vectors  $\vec{u}$  and  $\vec{v}$  are parallel if and only if the determinant  $\begin{vmatrix} g(x_0) & f(x_0) \\ k(x_0) & h(x_0) \end{vmatrix}$  vanishes, i.e.,  $g(x_0)h(x_0) = k(x_0)f(x_0)$ . Consider the function  $\varphi(x) = g(x)h(x) - k(x)f(x)$ . This function is continuous on  $[a, b]$  and by the assumptions it follows that

$$\begin{aligned} \varphi(a)\varphi(b) &= (g(a)h(a) - k(a)f(a)) \cdot (g(b)h(b) - k(b)f(b)) \\ &= g(a)h(a)g(b)h(b) - g(a)h(a)k(b)f(b) - k(a)f(a)g(b)h(b) + k(a)f(a)k(b)f(b) \\ &= f(a)h(a)g(b)k(b) - f(a)h(a)k(b)f(b) - k(a)f(a)g(b)k(b) + k(a)f(a)k(b)f(b) \\ &= f(a)(h(a) - k(a)) \cdot k(b)(g(b) - f(b)) < 0. \end{aligned}$$

Thus, by the Bolzano's theorem there exists  $x_0 \in (a, b)$  with  $\varphi(x_0) = 0$  and the claim follows. □

**5.E.68.** Show that the equation  $x^{2024} + 3x - e^x - 1 = 0$  has at least a real solution in the open interval  $(0, 1)$ .

**Solution.** The function  $f(x) = x^{2024} + 3x - e^x - 1$  is sum of the polynomial  $x^{2024} + 3x - 1$  with the negative of the exponential function, hence by 5.2.17 it should be continuous on  $\mathbb{R}$  and hence also on the closed interval  $[0, 1]$ . Moreover, we have  $f(0) = -2 < 0$  and  $f(1) = 3 - e > 0$ . Therefore, the claim follows by the Bolzano's theorem. □

**5.E.69.** Let  $f$  be a real-valued continuous function defined on the closed interval  $[1, 4]$ .

- (a) Explain why the function  $g(x) = f(x) + e^{2x-1}$  with the same domain as  $f$  has a minimal and a maximal value there.
- (b) Prove the existence of some  $x_0 \in [1, 4]$  such that  $f(x) < f(x_0) + e^{2x_0}$ , for all  $x \in [1, 4]$ .

**Solution.** (a) The function  $g$  is continuous for all  $x \in [1, 4]$ , as the sum of two continuous function defined there, see the basic limit properties in 5.2.17. Thus  $g$  should take all the values between the maximal and the minimal one on the closed interval  $[1, 4]$ , by the Corollary in 5.2.19.

(b) Using the conclusion from the first part, we can find  $x_0 \in [1, 4]$  such that  $g(x) \leq g(x_0)$  for all such  $x$  (i.e., at  $x_0$  the function  $g$  attains its maximal value). This induces the result, i.e.,

$$f(x) \leq f(x_0) + e^{2x_0-1} - e^{2x-1} < f(x_0) + e^{2x_0-1} < f(x_0) + e^{2x_0}, \quad x \in [1, 4].$$

□

**5.E.70.** Let  $f : I \rightarrow \mathbb{R}$  be a continuous function defined on the interval  $I = [a, b]$ , where  $a, b \in \mathbb{R}$  with  $a < b$ . If  $f$  is injective, prove that  $f$  is strictly monotone. ○

**5.E.71.** Compute the following limits or explain why they do not exist:

$$\lim_{x \rightarrow +\infty} (\arccos(1/(x+1)))^3, \quad \lim_{x \rightarrow -\infty} \arctan(1/x), \quad \lim_{x \rightarrow -\infty} \arctan(x^4), \quad \lim_{x \rightarrow -\infty} \arctan(\sin(x)).$$

Next, use Sage to verify your conclusions.

**Solution.** The function  $\arccos(x)$  is continuous on its domain  $[-1, 1]$ , while the function  $x^3$  is continuous everywhere. Moreover,  $\lim_{x \rightarrow +\infty} (1/(x+1)) = 0$ , and  $\arccos(0) = \pi/2$ . Thus,

$$\lim_{x \rightarrow +\infty} (\arccos(1/(x+1)))^3 = [\arccos(\lim_{x \rightarrow +\infty} 1/(x+1))]^3 = (\pi/2)^3.$$

The same conclusion occurs graphically, via the graph of the function  $f(x) = (\arccos(1/(1+x)))^3$ , see below at the left-hand-side for an illustration for  $x > 0$ :

Similarly, the function  $\arctan(x)$  is continuous and injective on its domain. Thus, according to 5.E.70 it should be strictly monotone, and indeed it is easy to verify that it is strictly increasing. This is also illustrated by the graph of  $\arctan(x)$ , as we see above at the right-hand-side. Now, according to the discussion in 5.2.16 these properties allow us to move the examined limit into the argument of such a function. Therefore, it is possible to write

$$\begin{aligned} \lim_{x \rightarrow -\infty} \arctan(1/x) &= \arctan\left(\lim_{x \rightarrow -\infty} (1/x)\right), \\ \lim_{x \rightarrow -\infty} \arctan(x^4) &= \arctan\left(\lim_{x \rightarrow -\infty} x^4\right), \\ \lim_{x \rightarrow -\infty} \arctan(\sin(x)) &= \arctan\left(\lim_{x \rightarrow -\infty} \sin(x)\right). \end{aligned}$$

However, we see that  $\lim_{x \rightarrow -\infty} (1/x) = 0$ ,  $\lim_{x \rightarrow -\infty} x^4 = +\infty$ , and  $\lim_{x \rightarrow -\infty} \sin(x)$  does not exist. Therefore, using the relations above we obtain  $\lim_{x \rightarrow -\infty} g(x) = \arctan(0) = 0$ ,  $\lim_{x \rightarrow -\infty} h(x) = \pi/2$ , while the last limit does not exist. Finally, to describe a confirmation via Sage just type

```
f(x)=(arccos(1/(1+x)))^3; print(lim(f(x), x=+oo))
g(x)=arctan(1/x); print(lim(g(x), x=-oo))
h(x)=arctan(x^4); print(lim(h(x), x=-oo))
k(x)=arctan(sin(x)); print(lim(k(x), x=-oo))
```

□

**5.E.72.** Show by an example that, in general, the intermediate value theorem fails for discontinuous functions.

**Solution.** For some positive real numbers  $\alpha, \delta$ , consider the function  $f : [-\delta, \delta] \rightarrow \mathbb{R}$  with

$$f(x) = \begin{cases} \alpha & \text{if } -\delta \leq x < 0, \\ -\alpha & \text{if } 0 \leq x \leq \delta. \end{cases}$$

Obviously, this function is discontinuous at  $x = 0$  since  $\lim_{x \rightarrow 0^-} f(x) = \alpha \neq \lim_{x \rightarrow 0^+} f(x) = -\alpha = f(0)$ . On the other hand we see that  $f(-\delta) = \alpha > 0$  and  $f(\delta) = -\alpha < 0$ , so that  $f(-\delta)f(\delta) < 0$ , but  $f(x) \neq 0$  for any  $x \in [-\delta, \delta]$ . □

Let us now present some further applications related to the intermediate value theorem. We first describe the 1-dimensional case of the so called Borsuk–Ulam theorem. We then study an application related to the temperature of antipodal points on the earth.

**5.E.73. 1-dimensional Borsuk–Ulam theorem.** Let  $S^1$  be the unit circle. Show that for any continuous function  $f : S^1 \rightarrow \mathbb{R}$  there exists some  $x \in S^1$  with  $f(-x) = f(x)$ .<sup>16</sup>

**Solution.** Consider the function  $g : S^1 \rightarrow \mathbb{R}$  defined by  $g(x) := f(x) - f(-x)$ . If  $g(x_0) = 0$  for some arbitrary  $x_0 \in S^1$ , we are done. Otherwise we may assume that  $g(x) > 0$  (and similarly is treated the case with  $g(x) < 0$ ). Then  $g(-x) = f(-x) - f(x) = -(f(x) - f(-x)) = -g(x) < 0$ . Thus, Bolzano’s theorem certifies the existence of some  $x_0 \in S^1$  with  $-x < x_0 < x$  satisfying  $g(x_0) = 0$ . This proves the claim.

We should mention that the result extends to  $n$  dimensions, as follows: Let

$$S^n = \left\{ (x_1, \dots, x_{n+1}) \in \mathbb{R}^{n+1} : \sum_{k=1}^{n+1} x_k^2 = 1 \right\} \subset \mathbb{R}^{n+1}$$

<sup>16</sup>Prove that this is equivalent to say that any continuous odd function  $S^1 \rightarrow \mathbb{R}$  has a zero.

be the  $n$ -sphere. Then, for any continuous map  $f : S^n \rightarrow \mathbb{R}^n$  there exists  $x \in S^n$  such that  $f(-x) = f(x)$ .<sup>17</sup>  $\square$

**5.E.74. Earth's temperature and antipodal pints.** Prove that at any time there is a point on the globe where the temperature agrees with the temperature on the antipode, assuming that the temperature varies continuously.<sup>18</sup>

**Solution.** Consider the equator (or any meridian of the globe), and denote by  $T : [0, 2\pi] \rightarrow \mathbb{R}$  the temperature, so that  $T(x)$  is the temperature of a point  $x$  on this great circle. Notice that every great circle through any point also passes through its antipodal point, so there are infinitely many great circles through two antipodal points. Define the function  $f(x) = T(x) - T(x + \pi)$ , which is also continuous on  $[0, 2\pi]$ , since  $T$  is assumed to be continuous. If  $f(0) = 0$  we have found our antipodal points with equal temperature. Otherwise we may assume that  $f(0) \neq 0$ . We see that  $f(0) = T(0) - T(\pi)$ ,  $f(\pi) = T(\pi) - T(2\pi)$ , and since  $T$  is periodic with period  $2\pi$ , we finally get  $f(\pi) = T(\pi) - T(2\pi) = T(\pi) - T(0) = -f(0)$ . By Bolzano's theorem this implies that there exists some point  $x_0 \in (0, \pi)$  such that  $f(x_0) = 0$  (notice that  $T$  is also continuous on  $[0, \pi]$ ). Thus  $T(x_0) = T(x_0 + \pi)$ , which proves the claim.  $\square$

C) MATERIAL ON DERIVATIVES

*For convenience, we divide this paragraph into two subsections: one containing technical exercises for additional practice on derivatives, and the other focusing on applications of derivatives.*

C1) MATERIAL ON DERIVATIVES - PRACTICE

**5.E.75.** Show that the function  $f(x) = x|x|$  is differentiable for all  $x \in \mathbb{R}$ .

**Solution.** Based on the definition of the absolute value function, one deduces that  $f(x) = x^2$  for  $x > 0$  and  $f(x) = -x^2$  for  $x < 0$ , so for all  $x \in \mathbb{R} \setminus \{0\}$  the function  $f$  is differentiable (it is easy to see that  $(x^2)' = 2x$ , see also below). We need to check the differentiability of  $f$  at  $x_0 = 0$ , where  $f(0) = 0$ . We should compute the left and right derivatives,  $f'_-(0)$  and  $f'_+(0)$ , respectively. We see that

$$f'_-(0) = \lim_{x \rightarrow 0^-} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^-} \frac{-x^2 - 0}{x} = 0, \quad f'_+(0) = \lim_{x \rightarrow 0^+} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^+} \frac{x^2 - 0}{x} = 0,$$

that is, the left and right derivative exist and are equal. Hence,  $f$  is also differentiable at  $x_0 = 0$ , with  $f'(0) = 0$ .  $\square$

**5.E.76.** Compute the derivatives of the functions  $f(x) = (\tan(x))^x$  and  $g(x) = (\sin(x))^{\ln(x)}$ .

**Solution.** By the quotient rule and since  $\tan(x) = \frac{\sin(x)}{\cos(x)}$ , we easily get

$$\tan'(x) \equiv (\tan(x))' \equiv \frac{d}{dx} \tan(x) = \left( \frac{\sin(x)}{\cos(x)} \right)' = \frac{1}{\cos^2(x)}.$$

Moreover, we have  $f(x) = \tan(x) = e^{\ln(\tan(x))}$ , and hence we deduce that

$$f(x) = (e^{\ln(\tan(x))})^x = e^{x \ln(\tan(x))}.$$

Combining this with the relations  $(e^{h(x)})' = h'(x) \cdot e^{h(x)}$  and  $(\ln(h(x)))' = h'(x)/h(x)$ , we get

$$\begin{aligned} f'(x) &= \left( e^{x \ln(\tan(x))} \right)' = (x \ln(\tan(x)))' \cdot e^{x \ln(\tan(x))} = (x \ln(\tan(x)))' \cdot f(x) \\ &= \left( \ln(\tan(x)) + x \cdot \frac{\tan'(x)}{\tan(x)} \right) \cdot f(x) = \left( \ln(\tan(x)) + x \cdot \frac{1}{\tan(x)} \cdot \frac{1}{\cos^2(x)} \right) \cdot f(x) \\ &= \left( \ln(\tan(x)) + x \cdot \frac{(1 + \tan^2(x))}{\tan(x)} \right) \cdot f(x), \end{aligned}$$

where in the final relation one replaces  $1/\cos^2(x)$  by  $1 + \tan^2(x)$ . In Sage a verification is given as usual:

```
f(x)=tan(x)**x; df=diff(f, x); show(df)
```

In a similar vein, for the function  $g$  we get

$$g(x) = (\sin(x))^{\ln(x)} = (e^{\ln(\sin(x))})^{\ln(x)} = e^{\ln(x) \cdot \ln(\sin(x))}.$$

<sup>17</sup>Another famous result in topology with a very similar flavor is the so called "Brouwer fixed point theorem" which we will analyze in Chapter 9.

<sup>18</sup>Observe that the same result applies for the barometric pressure of antipodal points on the globe.

Thus,

$$\begin{aligned} g'(x) &= \left( (\sin(x))^{\ln(x)} \right)' = \left( e^{\ln(x) \cdot \ln(\sin(x))} \right)' = (\ln(x) \cdot \ln(\sin(x)))' \cdot g(x) \\ &= \left( \frac{1}{x} \cdot \ln(\sin(x)) + \ln(x) \cdot \cos(x) \cdot \frac{1}{\sin(x)} \right) \cdot g(x) = \left( \frac{\ln(\sin(x))}{x} + \ln(x) \cdot \cot(x) \right) \cdot g(x). \end{aligned}$$

For a verification in Sage type

```
g(x)=sin(x)**ln(x); show(g.derivative(x))
```

Observe that for your convenience the given solution in this task highlights two different, but familiar, methods in Sage that we can always use to compute derivatives. □

**5.E.77.** Differentiate the expression  $\frac{\sqrt[4]{x-1} \cdot (x+2)^3}{e^x(x+132)^2}$ , with  $x > 1$ . ○

**5.E.78.** Calculate the first derivative of the functions given below:

- (1)  $a(x) = (2 - x^2) \cos(x) + 2x \sin(x)$  with  $x \in \mathbb{R}$ ;
- (2)  $b(x) = \sin(\sin(x))$  with  $x \in \mathbb{R}$ ;
- (3)  $c(x) = \sin(\ln(x^3 + 2x))$  with  $x \in (0, +\infty)$ ;
- (4)  $d(x) = (1 + x - x^2)/(1 - x + x^2)$  with  $x \in \mathbb{R}$ ;
- (5)  $\varepsilon(x) = \sqrt{x \sqrt{x \sqrt{x}}}$  with  $x \in (0, +\infty)$ ;
- (6)  $f(x) = \sin(\sin(\sin(x)))$  with  $x \in \mathbb{R}$ ;
- (7)  $g(x) = \sqrt[3]{\sin(x)}$  with  $x \in \mathbb{R} \setminus \{n\pi : n \in \mathbb{Z}\}$ ;
- (8)  $h(x) = \sqrt[3]{\frac{1+x^3}{1-x^3}}$  with  $x \in \mathbb{R} \setminus \{\pm 1\}$ . ○

**5.E.79.** Recall that a function  $f$  is called *odd* if  $f(-x) = -f(x)$  for all  $x$  in its domain, and *even* if  $f(-x) = f(x)$  for all such  $x$ . Therefore, an odd function is symmetric about the origin, and an even function is symmetric with respect to the  $y$ -axis.

(a) Present a function defined on  $\mathbb{R}$  which is neither even, nor odd.

(b) Show that the derivative of an even (respectively odd) function is an odd (respectively even) function. ○

**5.E.80.** Extend the discussion of real polynomials of degree at most three, initiated in Problem 5.A.2, using derivatives. ○

So far we have discussed most of the transcendental functions, as the exponential, the logarithms, the trigonometric and their inverse. Another remarkable class consists of the so called “hyperbolic functions”, defined by

$$\sinh(x) = \frac{e^x - e^{-x}}{2}, \quad \cosh(x) = \frac{e^x + e^{-x}}{2}, \quad \tanh(x) = \frac{\sinh(x)}{\cosh(x)}, \quad \coth(x) = \frac{\cosh(x)}{\sinh(x)},$$

where  $x \in \mathbb{R}$  for the first three cases, while the domain of  $\coth$  is  $\mathbb{R}^* = \mathbb{R} \setminus \{0\}$ . Notice that

$$\cosh^2(x) - \sinh^2(x) = 1, \quad x \in \mathbb{R}.$$

The hyperbolic functions come at handy at times (especially in physics), and the next task is devoted to them, see also 5.4.12.

**5.E.81. Hyperbolic functions.** (a) Show that  $\sinh$  (respectively,  $\cosh$ ) is the odd (respectively, even) part of the exponential function. Moreover, prove that  $\tanh(-x) = -\tanh(x)$  for all  $x \in \mathbb{R}$  and  $\coth(x) = -\coth(x)$  for all  $x \in \mathbb{R}^*$ .

(b) Determine the derivatives of the hyperbolic functions on their domains.

(c) Confirm your answer in Sage and next sketch the graphs of  $\sinh$  and  $\cosh$  in the interval  $I = [-\pi, \pi]$ .

**Solution.** (a) Obviously, one has the relation

$$e^x = \frac{e^x - e^{-x}}{2} + \frac{e^x + e^{-x}}{2} = \sinh(x) + \cosh(x),$$

and is easy to see that  $\sinh(-x) = -\sinh(x)$ , while  $\cosh(-x) = \cosh(x)$  for all  $x \in \mathbb{R}$ . The rest two relations are now direct.

(b) This is really easy and relies on the basic rules of differentiation, see 5.3.4, in combination with the formula  $(e^x)' = e^x$ ,

for all  $x \in \mathbb{R}$ . Thus

$$(\sinh(x))' = \left( \frac{e^x - e^{-x}}{2} \right)' = \frac{1}{2} (e^x + e^{-x}) = \cosh(x),$$

$$(\cosh(x))' = \left( \frac{e^x + e^{-x}}{2} \right)' = \frac{1}{2} (e^x - e^{-x}) = \sinh(x),$$

$$(\tanh(x))' = \left( \frac{\sinh(x)}{\cosh(x)} \right)' = \frac{\cosh^2(x) - \sinh^2(x)}{\cosh^2(x)} = \frac{1}{\cosh^2(x)} = 1 - \tanh^2(x),$$

$$(\coth(x))' = \left( \frac{\cosh(x)}{\sinh(x)} \right)' = \frac{\sinh^2(x) - \cosh^2(x)}{\sinh^2(x)} = -\frac{1}{\sinh^2(x)}.$$

(c) As one could expect in Sage the hyperbolic functions are built-in and correspond to the commands `sinh`, `cosh`, `tanh` and `coth`. Therefore, to confirm the previous computations in Sage one can combine these functions with either the command `diff`, or the command `derivative`, as follows

```
show(sinh(x).derivative()); show(cosh(x).derivative())
show(tanh(x).derivative()); show(coth(x).derivative())
```

Let us finally present the graphs of `sinh` and `cosh`, but leave for practice the corresponding coding in Sage.

□

**5.E.82.** Find the inverse of the hyperbolic sine function  $f(x) = \sinh(x)$ , determine its domain and its range, and next compute its first derivative. ○

**5.E.83.** Prove that the following function is differentiable at  $x = 0$ ,

$$f(x) = \begin{cases} x^2, & \text{if } x \in \mathbb{Q}, \\ 0, & \text{if } x \in \mathbb{R} \setminus \mathbb{Q}. \end{cases}$$

**Solution.** Notice that  $f(0) = 0$ . Thus,  $\lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0} \frac{f(x)}{x}$ . However, we see that  $0 \leq \left| \frac{f(x)}{x} \right| \leq \frac{|x^2|}{|x|} = |x|$ , and thus by the squeeze theorem we get  $\lim_{x \rightarrow 0} \frac{f(x)}{x} = 0$ . □

**5.E.84.** Show that the function  $f(x) = \sqrt{|x|}$  is *not* differentiable for all  $x \in \mathbb{R}$ . Which is the problematic point?

**Solution.** We see that  $f(x) = \sqrt{x}$  for  $x \geq 0$  and  $f(x) = \sqrt{-x}$  for  $x < 0$ . Thus for  $x \neq 0$  we may write

$$f'(x) = \begin{cases} \frac{1}{2\sqrt{x}}, & x > 0; \\ -\frac{1}{2\sqrt{-x}}, & x < 0. \end{cases}$$

However, at  $x_0 = 0$  the given function is not differentiable since for the left and right derivative one computes  $f'_-(0) = -\infty$  and  $f'_+(0) = +\infty$ , respectively (you should be able to verify the last claim by a formal computation, but also in Sage). □

**5.E.85.** Provide an example of a continuous function  $f : \mathbb{R} \rightarrow \mathbb{R}$  which is differentiable for all  $x \in \mathbb{R}$  but whose first derivative  $f'(x)$  is not continuous at  $x_0 = 0$ . Next use Sage to present the graph of your example.

**Solution.** An example is given by the piecewise function  $f : [-1, 1] \rightarrow \mathbb{R}$ , defined by

$$f(x) = \begin{cases} x^2 \sin\left(\frac{1}{x}\right), & x \neq 0; \\ 0, & x = 0. \end{cases}$$

We know that  $\lim_{x \rightarrow 0} f(x) = 0$  and since  $f(0) = 0$ , the function  $f$  is continuous. A short computation shows that its first derivative is given by

$$f'(x) = \begin{cases} 2x \sin\left(\frac{1}{x}\right) - \cos\left(\frac{1}{x}\right), & x \neq 0; \\ 0, & x = 0. \end{cases}$$

Above, the first expression follows by the chain and product rule, while to verify that  $f'(0) = 0$ , notice that

$$\lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x} = \lim_{x \rightarrow 0} x \sin\left(\frac{1}{x}\right) = 0$$

(since  $0 \leq |x \sin(\frac{1}{x})| \leq |x|$ ). On the other hand, we see that the limit  $\lim_{x \rightarrow 0} (2x \sin(\frac{1}{x}) - \cos(\frac{1}{x}))$  does not exist, so  $f'(x)$  is not continuous at the origin. For another similar example see the description in 5.3.3.

Now, to present the graph of  $f$  one can apply the `piecewise` method described in 5.C.5. Thus we can proceed with the cell

```
f1(x)=(x^2)*sin(1/x); f2(x)=0
S=RealSet(x==0)
S1=RealSet.closed_open(-1,0)
S2=RealSet.open_closed(0,1)
S3=S1.union(S2)
F=piecewise([[S, f2(x)], [S3, f1(x)]])
p=plot(F(x), x, -1, 1, ymin=-0.1, ymax=0.1, color="black")
show(p)
```

In this block we appropriately used the command `RealSet` to produce the sets  $\{0\}$ ,  $[-1, 0)$ , and  $(0, 1]$ , and next the command `union` to introduce the set  $[-1, 0) \cup (0, 1]$ . Below, on the left is the figure produced by this block, while on the right we see a zoomed version of the graph of  $f$  near the origin. Can you realize the changes that we did in our code to get the zoomed version?

□

**5.E.86.** (1) Consider the function  $f : \mathbb{R} \rightarrow \mathbb{R}$  defined by  $f(0) = 0$  and  $f(x) = x \arctan\left(\frac{1}{x}\right)$  for all  $x \in \mathbb{R} \setminus \{0\}$ . Determine whether the derivative of  $f$  exists at  $x_0 = 0$ .

(2) Consider the function  $f : \mathbb{R} \rightarrow \mathbb{R}$  defined by  $f(-1) = 0$  and  $f(x) = (x^2 - 1) \sin\left(\frac{1}{x+1}\right)$  for all  $x \in \mathbb{R} \setminus \{-1\}$ . Determine whether the derivative of  $f$  exists at  $x_0 = -1$ .

(3) Present an example of a function  $f : \mathbb{R} \rightarrow \mathbb{R}$  which is continuous on  $\mathbb{R}$  but does not have derivatives at the points  $x_1 = 5$  and  $x_2 = 9$ .

(4) Find functions  $f$  and  $g$  which are not differentiable anywhere, yet their composition  $f \circ g$  is differentiable everywhere on

$\mathbb{R}$ .

(5) For  $x > e$ , determine the sign of the derivative of the function  $f(x) = \arctan\left(\frac{\ln(x)}{-1 + \ln(x)}\right)$ . ○

**5.E.87.** If  $f(x) = 5x + 4 \sin(x)$ , then compute  $(f^{-1})'(4)$  by means of the formula of the derivative of the inverse function presented in 5.3.6. ○

**5.E.88.** (a) Let  $P(x)$  be a polynomial of order  $n \geq 2$ . Prove that  $P(x)$  is divided by  $(x - \rho)^2$  with quotient  $\pi(x)$ , i.e.,  $P(x) = (x - \rho)^2\pi(x)$ , if and only if  $P(\rho) = P'(\rho) = 0$ .

(b) Show that  $(x - 1)^2$  is a factor of the polynomial  $P(x) = nx^{n+1} - x^{n-1} - (n^2 + 1)x + n^2 - n + 2$ , with  $n \geq 2$ .

**Solution.** (a) If  $P(x) = (x - \rho)^2\pi(x)$  then by differentiation we get  $P'(x) = 2(x - \rho)\pi(x) + (x - \rho)^2\pi'(x)$ . Thus  $P'(\rho) = 0 = P(\rho)$ . Conversely, assume that  $P(\rho) = 0 = P'(\rho)$ . From the first relation we get  $P(x) = (x - \rho)\nu(x)$  for some polynomial  $\nu(x)$ , and hence  $P'(x) = \nu(x) + (x - \rho)\nu'(x)$ . But then the second relation can be equivalently written as  $\nu(\rho) + (\rho - \rho)\nu'(\rho) = 0$ , that is  $\nu(\rho) = 0$ . Therefore  $\rho$  is a root of  $\nu(x)$  and hence  $\nu(x) = (x - \rho)\pi(x)$  for some polynomial  $\pi(x)$ . It follows that  $P(x) = (x - \rho)^2\pi(x)$ , as it is required.

(b) We see that  $P(1) = n - 1 - n^2 - 1 + n^2 - n + 2 = 0$ . Moreover, the first derivative of  $P$  is given by  $P'(x) = n(n + 1)x^n - (n - 1)x^{n-2} - (n^2 + 1)$ , and thus  $P'(1) = n(n + 1) - (n - 1) - n^2 - 1 = n^2 + n - n + 1 - n^2 - 1 = 0$ . The claim now follows from the statement in (a). □

**5.E.89.** Let  $P$  be a cubic polynomial satisfying the conditions  $P(0) = 1$ ,  $P'(0) = 1$ ,  $P(1) = 2a + 2$ ,  $P'(1) = 5a + 1$ . Find the values of the parameter  $a \in \mathbb{R}$  for which the polynomial  $P$  is strictly monotonic on the whole real line. ○

**5.E.90.** Suppose that  $f, g : \mathbb{R} \rightarrow \mathbb{R}$  are two functions differentiable at  $a \in \mathbb{R}$ . Prove that  $\lim_{x \rightarrow a} \frac{x^2 f(a) - a^2 f(x)}{x - a} = 2af(a) - a^2 f'(a)$ , and more in general

$$\lim_{x \rightarrow a} \frac{g(x)f(a) - g(a)f(x)}{x - a} = g'(a)f(a) - f'(a)g(a).$$

**Solution.** For the first limit we have

$$\begin{aligned} \lim_{x \rightarrow a} \frac{x^2 f(a) - a^2 f(x)}{x - a} &= \lim_{x \rightarrow a} \frac{x^2 f(a) - a^2 f(x) - a^2 f(a) + a^2 f(a)}{x - a} = \lim_{x \rightarrow a} \frac{(x^2 - a^2)f(a) - a^2(f(x) - f(a))}{x - a} \\ &= f(a) \lim_{x \rightarrow a} \frac{x^2 - a^2}{x - a} - a^2 \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} = f(a) \lim_{x \rightarrow a} (x + a) - a^2 f'(a) \\ &= 2af(a) - a^2 f'(a). \end{aligned}$$

For the general case we apply the same trick:

$$\begin{aligned} \lim_{x \rightarrow a} \frac{g(x)f(a) - g(a)f(x)}{x - a} &= \lim_{x \rightarrow a} \frac{g(x)f(a) - g(a)f(x) - g(a)f(a) + g(a)f(a)}{x - a} \\ &= \lim_{x \rightarrow a} \frac{(g(x) - g(a))f(a) - g(a)(f(x) - f(a))}{x - a} \\ &= f(a) \lim_{x \rightarrow a} \frac{g(x) - g(a)}{x - a} - g(a) \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} = f(a)g'(a) - g(a)f'(a). \end{aligned}$$

□

**5.E.91.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a differentiable function at 0, satisfying  $f(x)f(y) \neq 1$  for all  $x, y \in \mathbb{R}$  and

$$f(x + y)(1 - f(x)f(y)) = f(x) + f(y), \quad x, y \in \mathbb{R}.$$

Show that  $f$  is differentiable on the whole real line. ○

**5.E.92. Interactive tangent lines via Sage.** For the polynomial  $P(x) = x^4 - 2x$  use Sage to produce an interactive graph for the tangent line of  $P$  at a random point  $x_0$ , lying in the interval  $[-2, 2]$ . (Hints: Combine the routine constructed in 5.C.14 with the method presented in ?? for creating an interactive plot).

**Solution.** Let us use the routing introduced in 5.C.14 for the construction of the tangent line and combine this with the commands `@interact` and `slider`, which are responsible for the creation and the control of the interactive environment, respectively. In particular, the command `@interact` appears always in a separate line inside the syntax, usually before the `def` command that our subroutine starts. On the other hand, the `slider` command converts the `x0` input from a numerical input into a slider. The coding goes as follows

```
P(x)=x^4-2*x; P1(x)=diff(P(x), x)
@interact
```

```
def Tangentat(x_0 = slider(-2, 2, 0.1, -1.5, label="x-coordinate")) :
    y_0=P(x_0)
    m=P1(x_0)
    c=y_0 - m*x_0
    l(x)=m*x+c
    Q = plot(P(x), -2, 2, color="blue", ymin=-2, ymax=20)
    Q+=plot(l(x), -2, 2, color="black", ymin=-2, ymax=20)
    Q+=point((x_0, y_0), color="black", size=50)
    Q.show()
    show("x_0=" , x_0)
    show("tang. line: l(x) = (" , m, ") * x + (" , c, ")")
    return
```

Recall inside the command `slider` the first two parameters determine the interval where that variable  $x_0$  is defined, in our case  $-2 \leq x \leq 2$ . The third parameter determines the granularity of the slider, and our choice represents a movement with step 0.1. Notice in CoCalc.com one should call the subroutine by typing `Tangentat()` in the very end of the block presented above (without specifying  $x_0$  inside the parenthesis). However, in <https://sagecell.sagemath.org> this is not necessary and one can simply move the slider around. Test yourself Sage's output.  $\square$

**5.E.93.** Consider the functions  $f(x) = 2 + \ln(x - 1)$  and  $g(x) = 2 - \ln(x - 1)$ , with  $x \in A = (1, +\infty)$ .

(a) Use Sage to find the common points of the graphs of  $f, g$ , respectively.

(b) Deduce about the monotonicity of  $f, g$ , and show that  $x = 1$  is an asymptote without slope (vertical asymptote) both of  $C_f$  and  $C_g$ . Moreover, deduce that  $f(A) = g(A) = \mathbb{R}$ .

(c) Show that the tangent lines of  $f, g$  at points with the same  $y$ -coordinate are perpendicular.

**Solution.** (a) This can be done by solving the equation  $f(x) = g(x)$ , which is equivalent to  $\ln(x - 1) = 0$  and has  $x = 2$  as a unique solution. There we see that  $f(2) = g(2) = 2$ , hence the common point of  $C_f$  and  $C_g$  is the point  $P = [2, 2]$ . A solution via Sage occurs by the cell

```
f(x)=2+ln(x-1); g(x)=2-ln(x-1); solve(f(x)==g(x), x)
```

(b) We see that  $f'(x) = \frac{1}{x-1} > 0$  and  $g'(x) = -\frac{1}{x-1} < 0$  for all reals  $x > 1$ . Thus  $f$  is strictly increasing on  $A$ , while  $g$  is strictly decreasing on  $A$ . Moreover, you can compute  $a = \lim_{x \rightarrow 1^+} f(x) = -\infty, b = \lim_{x \rightarrow \infty} f(x) = +\infty, c = \lim_{x \rightarrow 1^+} g(x) = +\infty$  and  $d = \lim_{x \rightarrow \infty} g(x) = -\infty$ . These limits can be confirmed in Sage, as usual:

```
f(x)=2+ln(x-1); g(x)=2-ln(x-1);
a=lim(f(x), x=1, dir="right"); b=lim(f(x), x=oo);
c=lim(g(x), x=1, dir="right"); d=lim(g(x), x=oo)
show(a, ", ", b, ", ", c, ", ", d)
```

Both functions  $f, g$  are continuous, hence by the limits above we deduce that  $f(A) = \mathbb{R}$  and  $g(A) = \mathbb{R}$ . Moreover, the limits  $a, c$  presented above show that the graphs of  $f, g$ , respectively, tend toward  $\mp\infty$  as the inputs approach 1, and hence the line  $x = 1$  is a vertical asymptote for both  $C_f, C_g$  (we will discuss more details on asymptotes in 6.1.8). To illustrate the behaviour of  $f, g$ , we used Sage to sketch the graphs  $C_f, C_g$ , for  $1 \leq x \leq 50$ , which we present together here:

(c) To get points on  $C_f, C_g$  with the same  $y$ -coordinate it is sufficient to draw horizontal lines  $y = c, c \in \mathbb{R}$ . This happens due to the type of monotonicity of  $f, g$ . Let  $Q, R$  be the corresponding intersection points of the line  $y = c$  with  $C_f$  and  $C_g$ , respectively. We may assume that  $Q = [a, f(a)] = [a, c]$  and  $R = [b, g(b)] = [b, c]$ . Notice for  $a = 2 = b$  we have  $P = Q = R$ . The getter a better view around the intersection point of  $C_f$  and  $C_g$ , see the figure below (at the l.h.s). In this figure, to become more precise, we fix the points  $Q, R$  to be elements of the line  $y = 2.5$  (hence one can specify  $Q, R$  explicitly, as we did).

From the mathematical point of view it is not necessary to fix  $c$ . At the the points  $Q = [a, c] \in C_f$  and  $R = [b, c] \in C_g$  we have  $f'(a) = \frac{1}{1-a}$  and  $g'(b) = -\frac{1}{1-b}$ , and to prove the claim it is sufficient to show hat  $f'(a)g'(b) = -1$ . Because  $f(a) = c = g(b)$  we get  $a - 1 = e^{c-2}, b - 1 = e^{2-c}$  and the result follows (for an illustration see the picture at the r.h.s, which includes the tangent lines of  $C_f, C_g$ , at the points  $Q, R$ , respectively), i.e.,

$$f'(a)g'(b) = -\frac{1}{(1-a)(1-b)} = -\frac{1}{e^{c-2} e^{2-c}} = -\frac{1}{e^0} = -1.$$

For your convenience, let us finally present the code used to construct the figure including the tangent lines.

```

□

**5.E.94.** Consider the function  $f(x) = e^{\sqrt{\alpha} \cos(x)}$ , where  $\alpha > 0$  is some fixed constant. Provide a proof of the following facts::

- $f$  is continuous, even, and periodic with period independent of  $\alpha$ . Sketch the graph of  $f$  for  $\alpha = 3$  and  $x \in [-2\pi, 2\pi]$ ;
- $f$  is differentiable for all  $x \in \mathbb{R}$ . Find the formula of  $f'(x)$ ;
- $f$  is (strictly) decreasing in  $(0, \pi)$  and (strictly) increasing in  $(\pi, 2\pi)$ , in particular, the point  $x_0 = \pi$  provides a local minimum of  $f$ .

**Solution.** (a) The domain of  $f$  is the whole real line  $\mathbb{R}$ . Since  $f$  is the composition of continuous functions, it is also continuous. It is even since  $\cos(-x) = \cos(x)$  which implies that  $f(-x) = f(x)$  for all  $x \in \mathbb{R}$ . Suppose that  $T \in \mathbb{R} \setminus \{0\}$  satisfies  $f(x+T) = f(x)$ , for all  $x \in \mathbb{R}$ . Since the exponential map is an injection this gives  $\sqrt{\alpha} \cos(x+T) = \sqrt{\alpha} \cos(x)$ , that is,  $\cos(x+T) = \cos(x)$  for all  $x \in \mathbb{R}$ . Thus

$$x+T = 2k\pi + x, \quad \text{or} \quad x+T = 2k\pi - x,$$

which implies that  $T = 2k\pi$  or  $T = 2k\pi - 2x$  for all  $x \in \mathbb{R}$  and some  $k \in \mathbb{Z}$ . This means that  $f$  is periodic with period  $2k\pi$ , so for  $k = 1$  we obtain  $T = 2\pi$  which is the smallest (positive) period of  $f$ . A visual verification of this fact occurs by sketching the graph of  $f$ , for some fixed  $\alpha$ . Below we present the case for  $\alpha = 3$ .

- The function  $f$  is differentiable on  $\mathbb{R}$  as the composition of differentiable functions. By the chain rule we see that

$$f'(x) = (\sqrt{\alpha} \cos(x))' e^{\sqrt{\alpha} \cos(x)} = -\sqrt{\alpha} \sin(x) \cdot e^{\sqrt{\alpha} \cos(x)}, \quad x \in \mathbb{R}.$$

Or we can compute this in Sage, via the cell

```
a=var("a"); f(x)=e**(sqrt(a)*cos(x)); show(diff(f, x))
```

- In  $[0, 2\pi]$  the equation  $f'(x) = 0$  has three solutions, namely the points  $x = 0$ ,  $x = \pi$  and  $x = 2\pi$ , see also the figure in the r.h.s. where we have included the graph of  $f'(x)$ . Moreover we see that  $f'(x) < 0$  for all  $x \in (0, \pi)$  and  $f'(x) > 0$  for all

$x \in (\pi, 2\pi)$ . It follows that  $f(x)$  is decreasing in the first interval, and increasing in the second one. Hence  $x_0 = \pi$  is a local minimum of  $f$  giving the minimal value  $f(\pi) = e^{-\sqrt{\alpha}}$  (the other two stationary points are local maxima of  $f$  in  $[0, 2\pi]$ ).  $\square$

- 5.E.95.** (a) Determine all local extrema of the function  $f(x) = x \ln^2(x)$  with domain  $(0, +\infty)$ ;  
 (b) Determine the maximum value of the function  $f(x) = e^{-x} \cdot \sqrt[3]{3x}$ , with  $x \in \mathbb{R}$ .  
 (c) Find the absolute extrema of the polynomial  $p(x) = x^3 - 3x + 2$  on the interval  $[-3, 2]$ .  
 (d) Is there any  $\alpha \in \mathbb{R}$  such that the function  $h(x) = \alpha x + \sin(x)$ ,  $x \in [0, 2\pi]$  has a global minimum at  $x_0 = 5\pi/4$ ?  $\circ$

**5.E.96.** Show that the function  $f(x) = e^{-x}$  is strictly decreasing for any  $x \in \mathbb{R}$ .  $\circ$

**5.E.97.** Find all the solutions of the equation  $x^{2025} + 2024x = 2025 - \ln(x)$ .  $\circ$

**5.E.98.** Let  $I = [a, b] \subset \mathbb{R}$  be a closed subset of  $\mathbb{R}$  and let  $f : I \rightarrow \mathbb{R}$  be a continuous function. Suppose that  $f$  is differentiable on the open interval  $(a, b)$  and satisfies  $f(a) = f(b) = 0$ . Show that for given  $\kappa \in \mathbb{R}$  there exists  $x_0 \in (a, b)$  such that  $\kappa f(x_0) + f'(x_0) = 0$ .

**Solution.** For fixed  $\kappa \in \mathbb{R}$  consider the function  $g(x) = e^{\kappa x} f(x)$ , with  $x \in [a, b]$ . By assumption  $f$  is continuous on  $[a, b]$ , differentiable on  $(a, b)$ , and the same is  $g$ . We see that

$$g'(x) = \kappa e^{\kappa x} f(x) + e^{\kappa x} f'(x) = e^{\kappa x} (\kappa f(x) + f'(x)), \quad x \in (a, b). \quad (*)$$

Moreover,  $g(a) = 0 = g(b)$  and by Rolle's theorem (see 5.3.8) one can find some  $x_0 \in (a, b)$  such that  $g'(x_0) = 0$ . Then the result is a simple consequence of (\*).  $\square$

**5.E.99.** Let  $f : [0, 4] \rightarrow \mathbb{R}$  be a differentiable function with  $f(0) = f(4) = 0$ , and set  $g(x) := \frac{x(4-x)}{4} f(2)$ , for any  $x \in [0, 4]$ . Show that there exist  $x_1, x_2 \in (0, 4)$  with  $x_1 \neq x_2$  satisfying  $f'(x_1) = g'(x_1)$  and  $f'(x_2) = g'(x_2)$ .

**Solution.** The functions  $f, g$  are both differentiable on  $[0, 4]$ , so the same is their difference  $h(x) := f(x) - g(x) = f(x) - \frac{x(4-x)}{4} f(2)$ . Moreover, we see that  $h(0) = f(0) - g(0) = 0$ ,  $h(4) = f(4) - g(4) = 0$  and  $h(2) = f(2) - \frac{2 \cdot 2}{4} f(2) = 0$ . Thus,  $h$  satisfies the Rolle's theorem conditions on the intervals  $[0, 2]$  and  $[2, 4]$ . This means that there exist  $x_1 \in (0, 2)$  such that  $h'(x_1) = 0$ , which is equivalent to  $f'(x_1) = g'(x_1)$  and  $x_2 \in (2, 4)$  such that  $h'(x_2) = 0$ , that is,  $f'(x_2) = g'(x_2)$ .  $\square$

**5.E.100.** Suppose that  $f : I \rightarrow \mathbb{R}$  is a continuous function on  $I = [a, b]$ , differentiable on  $(a, b)$  and such that  $\lim_{x \rightarrow a} f'(x) = \kappa \in \mathbb{R}$ . Show that  $f$  is also differentiable at  $x = a$  with  $f'(a) = \kappa$ .

**Solution.** We can apply the mean value theorem on  $f$  on the interval  $(a, a+h)$  for some small enough  $h$ . Hence there exists  $c_h \in (a, a+h)$  such that

$$f'(c_h) = \frac{f(a+h) - f(a)}{h}. \quad (*)$$

Moreover, we see that  $c_h \rightarrow a$  as  $h \rightarrow 0$  and hence

$$f'(a) = \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} \stackrel{(*)}{=} \lim_{h \rightarrow 0} f'(c_h) = \lim_{x \rightarrow a} f'(x) = \kappa. \quad \square$$

**5.E.101.** Show that the polynomial  $P(x) = x^5 - x^4 + 2x^3 - x^2 + x + 1$  has exactly one real root. Next use Sage to approximate this root.

**Solution.** It is easy to prove that any odd degree polynomial has at least one real root. For instance, the polynomial at hand has degree 5, hence by the fundamental theorem of algebra (see 12.4.20),  $P$  has to have five roots over  $\mathbb{C}$ . Moreover, the complex roots with real coefficients come in pairs of conjugated numbers. Therefore,  $P$  has to have at least one real root, say  $x_0$ .

Suppose now that there exists a second real root  $x'_0$ . Then, according to the Rolle's theorem there must be some  $c \in (x_0, x'_0)$ , such that  $P'(c) = 0$ . But  $P'(x) = 5x^4 - 4x^3 + 6x^2 - 2x + 1 = 2x^2(x-1)^2 + 3x^4 + 3x^2 + (x-1)^2 > 0$ , for all  $x \in \mathbb{R}$ , a contradiction. Therefore,  $P$  admits exactly one real root. In other words,  $P$  is strictly increasing and thus its graph should cross the  $x$ -axis just once.

From the graph of  $P$  given below we see that the unique root of  $P$  should be near to  $-0.5$ . In Sage to obtain this root we can use the `find_root` function, as follows:

```
find_root(x^5-x^4+2*x^3-x^2+x+1, -1, 1)
```

According to Sage's answer, the unique root of  $P$  is given by  $x_0 \approx -0.47748$ .

□

**5.E.102.** Let  $f : \mathbb{R} \rightarrow (0, +\infty)$  be a continuously differentiable function with  $f(0) \neq 0$ . Prove that there exists  $\xi \in (0, 1)$  satisfying the relation  $e^{f'(\xi)} f(0)^{f(\xi)} = f(1)^{f(\xi)}$ .

**Solution.** Let us rewrite the equation as  $e^{f'(\xi)} = \left(\frac{f(1)}{f(0)}\right)^{f(\xi)}$ . By applying the logarithm in both sides we get

$$\ln\left(e^{f'(\xi)}\right) = f'(\xi) = \ln\left(\frac{f(1)}{f(0)}\right)^{f(\xi)} \iff f'(\xi) = f(\xi) \ln\left(\frac{f(1)}{f(0)}\right) \iff \frac{f'(\xi)}{f(\xi)} = \ln(f(1)) - \ln(f(0)).$$

It is now obvious that the existence of such a  $\xi$  is guaranteed by applying the Lagrange mean value theorem to the function  $f(x) = \ln(f(x))$ , which is continuous on  $[0, 1]$  and differentiable at all points inside this interval. □

**5.E.103.** Show that any real  $x \geq 0$  satisfies  $x \geq \ln(x + 1)$ . ○

**5.E.104.** Let  $\alpha, \beta$  be reals satisfying  $0 < \alpha < \beta$ . Show that  $\alpha x^\beta - \beta x^\alpha > \alpha - \beta$ , for all  $x > 1$ . ○

**5.E.105.** Show that all  $x \in \mathbb{R}$  satisfy  $e^x - x \geq 1$ .

**Solution.** Consider the function  $f(x) = e^x - x + 1$ . This is differentiable in  $\mathbb{R}$  with  $f'(x) = e^x - 1$ . We see that the equation  $f'(x) = 0$  has a unique solution given by  $x = 0$ . In particular, having in mind the graph of  $e^x$  we see that  $e^x < 1$  for  $x < 0$ , so  $f'(x) < 0$  for  $x \in (-\infty, 0)$  and  $e^x > 1$  for  $x > 0$  which means that  $f'(x) > 0$  for  $x \in (0, +\infty)$ . Hence  $f$  is strictly decreasing in the first interval and strictly increasing in the second one, see the figure below. Thus, for  $x > 0$  we have  $f(x) > f(0)$  and so  $e^x - x + 1 > 2$ , that is  $e^x - x > 1$ , while for  $x < 0$  we have  $f(x) > f(0)$  and so again  $e^x - x + 1 > 2$ . So for  $x \neq 0$  we get  $e^x - x > 1$ . Since for  $x = 0$  this holds as an equality we have finally proved  $e^x - x \geq 1$  for all  $x \in \mathbb{R}$ .

**Remark:** The graphs of  $f, g$  sketched below indicate that one may use the function  $g(x) = e^x - x - 1$ , instead of  $f$ , and apply the same procedure. Try to verify this claim.

□

**5.E.106.** For  $x > y > 0$  prove the inequality

$$\frac{x + y}{2} > \frac{x - y}{\ln(x) - \ln(y)}.$$

**Solution.** Rewrite the given inequality as  $\frac{\ln(x) - \ln(y)}{x - y} > \frac{2}{x + y}$  and set  $t = x - y > 0$ . Then we get

$$\frac{\ln(t + y) - \ln(y)}{t} > \frac{2}{t + 2y} \iff \frac{\ln\left(\frac{t+y}{y}\right)}{t} > \frac{2}{t + 2y} \iff \ln\left(1 + \frac{t}{y}\right) > \frac{2t}{t + 2y} \iff \ln\left(1 + \frac{t}{y}\right) > \frac{2\frac{t}{y}}{2 + \frac{t}{y}}.$$

Putting now  $\psi = \frac{t}{y}$  we have  $\psi > 0$  and the initial inequality can be equivalently transformed to

$$\ln(1 + \psi) > \frac{2\psi}{2 + \psi}, \quad \psi > 0. \quad (b)$$

Thus now you may consider the function  $f(\psi) = \ln(1 + \psi) - \frac{2\psi}{2 + \psi}$ , with  $\psi > -1$ . Its first derivative is given by

$$f'(\psi) = \frac{1}{\psi + 1} - \frac{2(2 + \psi) - 2\psi}{(2 + \psi)^2} = \frac{\psi^2}{(\psi + 1)(2 + \psi)^2} > 0,$$

that is,  $f'(\psi) > 0$  for all  $\psi > -1$ . Hence for example we should have  $f(\psi) > f(0) = 0$ , which gives us the inequality presented in (b).  $\square$

**5.E.107.** If  $p, q \in \mathbb{R}$  are such that  $0 < p < q$  show that

$$\ln\left(\frac{p+q}{2}\right) < \frac{p}{p+q} \ln(p) + \frac{q}{p+q} \ln(q). \quad (\#)$$

**Solution.** Consider the 1-parameter family  $f_q(x) = \ln\left(\frac{x+q}{2}\right) - \frac{x}{x+q} \ln(x) - \frac{q}{x+q} \ln(q)$  with  $q > 0$  and domain  $A = (0, +\infty)$ . Notice that  $f_q(q) = 0$ . We will prove that  $f_q$  is strictly increasing for all  $x \in (0, q]$ , which for  $0 < p < q$  gives the inequality  $f_q(p) < f_q(q)$ . Then, it is easy to see that the latter is equivalent to (#). Therefore let us compute the first derivative of  $f$ :

$$\begin{aligned} f'_q(x) &= \frac{1}{2} \cdot \frac{2}{x+q} - \frac{(x+q) - x}{(x+q)^2} \ln(x) - \frac{x}{x+q} \cdot \frac{1}{x} + \frac{q}{(x+q)^2} \ln(q) = \frac{1}{x+q} - \frac{q \ln(x)}{(x+q)^2} - \frac{1}{x+q} + \frac{q \ln(q)}{(x+q)^2} \\ &= \frac{q(\ln(q) - \ln(x))}{(x+q)^2} = \frac{q \ln\left(\frac{q}{x}\right)}{(x+q)^2}. \end{aligned}$$

The critical points of  $f_q$  are the solutions of  $f'_q(x) = 0$ , and we see that

$$f'_q(x) = 0 \iff \ln\left(\frac{q}{x}\right) = 0 \iff \frac{q}{x} = 1 \iff q = x.$$

Now, for  $x > q$  we have  $\ln\left(\frac{q}{x}\right) < 0$ , hence  $f'_q(x) < 0$  and  $f_q$  is strictly decreasing in  $[q, +\infty)$  for all  $q > 0$ . On the other hand for  $0 < x < q$  we get  $f'_q(x) > 0$ , therefore  $f_q$  is strictly increasing on  $(0, q]$  for all  $q > 0$ . Thus, in fact, at  $x_0 = q$  our family  $f_q$  attains its unique maximum which equals to  $f_q(q) = 0$  (hence,  $f_q$  is non-positive all along its domain, for all  $q > 0$ ). Let us finally sketch the graph of  $f_q$  for  $q = 1, 2, \dots, 5$ , so that we have an illustrated confirmation of the monotonicity of  $f_q$  for these values of the parameter  $q$ .

To obtain this figure, we have used Sage and a bit of programming (relying on the command `for`), which goes as follows:

```
var("q"); f(x, q)=ln((x+q)/2)-(x/(x+q))*ln(x)-(q/(x+q))*ln(q)
a=plot([f(x, q) for q in [1,2,..,5]], (x, 0, 10), ymax=0.05, ymin=-0.4)
a+=point([(q, f(q, q)) for q in [1,2,..,5]], size=20, color="black")
a+=text(r"$q=1$", (1, 0+0.02), fontsize=12, color="black")
a+=text(r"$q=2$", (2, 0+0.02), fontsize=12, color="black")
a+=text(r"$q=3$", (3, 0+0.02), fontsize=12, color="black")
a+=text(r"$q=4$", (4, 0+0.02), fontsize=12, color="black")
a+=text(r"$q=5$", (5, 0+0.02), fontsize=12, color="black"); show(a)
```

□

When applying the l'Hopital's rule, caution is always necessary. For instance, the l'Hopital's rule can yield a non-existent limit even when the original limit exists. Let's illustrate this remarkable scenario with an example.

**5.E.108.** Consider the function  $f(x) = \frac{x + \sin x}{x}$ .

(a) Which is the type of indeterminate form corresponding to the limit  $\lim_{x \rightarrow +\infty} f(x)$ ?

(b) Show that in this case the l'Hopital's rule leads to a non-existing limit, although  $\lim_{x \rightarrow +\infty} f(x) = 1$ . ○

**5.E.109.** Using the L'Hospital's rule provide an alternative proof of the relation  $\lim_{n \rightarrow +\infty} \sqrt[n]{n} = 1$  (see 5.B.8). Moreover, apply the same method to prove that  $\lim_{n \rightarrow +\infty} \sqrt[n]{\ln(n)} = 1$  (see 5.E.18), and  $\lim_{n \rightarrow +\infty} (n \sin(\frac{1}{n})) = 1$ .

**Solution.** Recall that  $\sqrt[n]{n} = n^{1/n}$ . Thus, as  $n \rightarrow +\infty$  this gives the indeterminate form  $(+\infty)^0$ . Consider the function  $f(x) = x^{1/x}$  with  $x > 0$ . Taking the logarithm in both sides we get  $\ln(f(x)) = \ln(x^{1/x}) = \frac{1}{x} \ln(x)$ . Thus  $f(x) = e^{\frac{\ln(x)}{x}}$ .

Notice that by the L'Hospital's rule we get  $\lim_{x \rightarrow +\infty} \frac{\ln(x)}{x} \stackrel{\frac{+\infty}{+\infty}}{=} \lim_{x \rightarrow +\infty} \frac{1}{x} = 0$ . Therefore

$$\lim_{x \rightarrow +\infty} f(x) = \lim_{x \rightarrow +\infty} e^{\frac{\ln(x)}{x}} = e^{\lim_{x \rightarrow +\infty} \frac{\ln(x)}{x}} = e^0 = 1,$$

and applying this to our sequence we get the result:

$$\lim_{n \rightarrow +\infty} \sqrt[n]{n} = \lim_{n \rightarrow +\infty} n^{\frac{1}{n}} = \lim_{n \rightarrow +\infty} e^{\frac{\ln(n)}{n}} = 1.$$

Let us use the L'Hospital's rule to prove also that  $\lim_{n \rightarrow +\infty} \sqrt[n]{\ln(n)} = 1$  and leave the third limit for practice. Since we have  $\sqrt[n]{\ln(n)} = (\ln(n))^{\frac{1}{n}}$ , we see that the limit  $\lim_{n \rightarrow +\infty} \sqrt[n]{\ln(n)} = 1$  has the indeterminate form  $(+\infty)^0$ . So, let us consider the function  $g(x) = (\ln(x))^{\frac{1}{x}}$ . Then, we can write  $g(x) = e^{\frac{1}{x} \cdot \ln(\ln(x))}$ . Hence, to compute  $\lim_{x \rightarrow +\infty} g(x)$  it is sufficient to compute  $\lim_{x \rightarrow +\infty} \frac{\ln(\ln(x))}{x}$ . This has the indeterminate form  $\frac{+\infty}{+\infty}$ , so by applying the L'Hospital's rule we get

$$\lim_{x \rightarrow +\infty} \frac{\ln(\ln(x))}{x} = \lim_{x \rightarrow +\infty} \frac{(\ln(\ln(x)))'}{x'} = \lim_{x \rightarrow +\infty} \frac{\frac{(\ln(x))'}{\ln(x)}}{1} = \lim_{x \rightarrow +\infty} \frac{1}{x \ln(x)} = \frac{1}{+\infty} = 0.$$

Therefore,  $\lim_{x \rightarrow +\infty} g(x) = e^0 = 1$  and this implies that  $\lim_{n \rightarrow +\infty} \sqrt[n]{\ln(n)} = 1$ . □

**5.E.110.** Use the l'Hospital's rule to evaluate the limit  $\lim_{x \rightarrow 0} (\cot(x) - \frac{1}{x})$ .

**Solution.** Since  $\cot(x) = \frac{\cos(x)}{\sin(x)}$ , by applying repeatedly the l'Hospital's rule one has

$$\begin{aligned} \lim_{x \rightarrow 0} \left( \cot(x) - \frac{1}{x} \right) &= \lim_{x \rightarrow 0} \frac{x \cos(x) - \sin(x)}{x \sin(x)} \stackrel{\frac{0}{0}}{=} \lim_{x \rightarrow 0} \frac{(x \cos(x) - \sin(x))'}{(x \sin(x))'} = \lim_{x \rightarrow 0} \frac{\cos(x) - x \sin(x) - \cos(x)}{\sin(x) + x \cos(x)} \\ &= \lim_{x \rightarrow 0} \frac{-x \sin(x)}{\sin(x) + x \cos(x)} \stackrel{\frac{0}{0}}{=} \lim_{x \rightarrow 0} \frac{(-x \sin(x))'}{(\sin(x) + x \cos(x))'} = \lim_{x \rightarrow 0} \frac{-\sin(x) - x \cos(x)}{\cos(x) + \cos(x) - x \sin(x)} \\ &= \frac{0 - 0}{1 + 1 - 0} = 0. \end{aligned}$$

□

**5.E.111.** Using the l'Hospital's rule, when adequate, determine the limits

$$a = \lim_{x \rightarrow 1^-} (1 - x) \tan\left(\frac{\pi x}{2}\right), \quad b = \lim_{x \rightarrow \frac{\pi}{2}^-} \left(\frac{\pi}{2} - x \tan(x)\right), \quad c = \lim_{x \rightarrow 1} \left(\frac{1}{2 \ln(x)} - \frac{1}{x^2 - 1}\right), \quad d = \lim_{x \rightarrow +\infty} \left(\cos \frac{2}{x}\right)^{x^2}.$$

○

Next we present a result which analogous to l'Hopital's rule, which can be used in establishing the monotonicity of a ratio  $f/g$  of two functions  $f, g : [a, b] \rightarrow \mathbb{R}$ , which are both differentiable on  $(a, b)$ , with  $g'(x) \neq 0$  for all  $x \in (a, b)$ . In the literature, it is commonly referred to as the "l'Hopital's Monotone Rule" or for short by "LMR", and, despite its numerous applications in various contexts, it often seems to be overlooked. Notice the rule holds true even in cases where  $a$  or  $b$  is infinite, and in particular when  $f, g$  are defined only on the open interval  $(a, b)$  (provided that  $g'$  has constant sign).

**5.E.112.** Suppose that  $a, b$  are such that  $-\infty \leq a < b \leq \infty$  and let  $f, g : (a, b) \rightarrow \mathbb{R}$  be continuous functions which are differentiable on  $(a, b)$ . Suppose also that  $\lim_{x \rightarrow a^+} f(x) = \lim_{x \rightarrow a^+} g(x) = 0$  (or  $\lim_{x \rightarrow b^-} f(x) = \lim_{x \rightarrow b^-} g(x) = 0$ ), and that the derivative  $g'$  is nonzero (and does not change sign on  $(a, b)$ ). Prove that if  $f'/g'$  is (strictly) increasing or (strictly) decreasing on  $(a, b)$ , then so is  $f/g$ .

**Solution.** We will analyze the case with  $\lim_{x \rightarrow a^+} f(x) = \lim_{x \rightarrow a^+} g(x) = 0$ , and similarly one can treat the case  $f(b^-) = g(b^-) = 0$ . Assume also that  $f'/g'$  is strictly increasing, and the proof for the rest cases is analogous. We will prove that

$$\left(\frac{f}{g}\right)' > 0, \quad \text{for all } x \in (a, b),$$

and hence the ratio  $f/g$  is strictly increasing. Fix some arbitrary  $x \in (a, b)$  and consider the function  $h_x : (a, b) \rightarrow \mathbb{R}$ , defined by

$$h_x(y) = f'(x)g(y) - f(y)g'(x), \quad y \in (a, b).$$

Obviously,  $h_x$  is differentiable on  $(a, b)$  (and hence also continuous), with

$$h'_x(y) = f'(x)g'(y) - f'(y)g'(x) = g'(x)g'(y) \left(\frac{f'(x)}{g'(x)} - \frac{f'(y)}{g'(y)}\right). \quad (*)$$

By the hypothesis,  $g'(x)$  is non-zero and it has constant sign, that is, only one of the following relations is possible:  $g'(x) > 0$  or  $g'(x) < 0$  for all  $x \in (a, b)$ . Moreover  $f'/g'$  is strictly increasing, so for  $x > y$  the inequality  $\frac{f'(x)}{g'(x)} > \frac{f'(y)}{g'(y)}$  makes sense. Therefore, by (\*) we deduce that  $h'_x(y) > 0$  for all  $y \in (a, x)$ , which means that the function  $h_x$  is strictly increasing on  $(a, x)$ . In fact, by continuity,  $h_x$  should be strictly increasing on  $(a, x]$ . Moreover, by our hypothesis we get

$$\lim_{x \rightarrow a^+} h_x(x) = \lim_{x \rightarrow a^+} (f'(x)g(x) - f(x)g'(x)) = 0,$$

and hence, all together, this implies that  $h_x(x) > 0$ . Thus

$$\left(\frac{f}{g}\right)'(x) = \frac{f'(x)g(x) - f(x)g'(x)}{g^2(x)} = \frac{h_x(x)}{g^2(x)} > 0$$

and since  $x \in (a, b)$  is arbitrary, our claim follows.  $\square$

**5.E.113.** (a) Based on the l'Hopital monotone rule study the monotonicity of  $k = f/g$  on the specified domain  $A$ , when  $f, g, A$  are given as follows:

(1)  $f(x) = e^{2x} - 1, g(x) = \ln(x + 1), A = (-1, 0) \cup (0, +\infty)$ ;

(2)  $f(x) = e^x - 1, g(x) = 2x + e^x - 1, A = (-\infty, 0) \cup (0, \infty)$ .

Then, confirm your conclusions by specifying the sign of the first derivative  $\kappa'$  of  $\kappa = f/g$ , and rely on Sage to verify all your computations.

(b) For both cases confirm that  $\lim_{x \rightarrow 0} \kappa(x) = \lim_{x \rightarrow 0} K(x)$ , where  $K(x) = f'(x)/g'(x)$ .

**Solution.** (a) Let us begin with (1). We have

$$\kappa(x) = \frac{f(x)}{g(x)} = \frac{e^{2x} - 1}{\ln(x + 1)}, \quad \text{and} \quad K(x) = \frac{f'(x)}{g'(x)} = 2(x + 1)e^{2x},$$

where  $\kappa$  is defined on  $A = (-1, 0) \cup (0, +\infty)$  (and we assume the same for both  $f, g$ ). Moreover, the given functions satisfy  $\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} g(x) = 0$ , hence one can apply the LMR (5.E.112). A direct computation shows that

$$K'(x) = 2e^{2x}(3 + 2x) > 0, \quad \text{for all } x \in A.$$

Because  $K = f'/g'$  is differentiable, this implies that  $K$  strictly increases on  $A$  and according to LMR the same monotonicity pattern we should get for the function  $\kappa = f/g$ . To confirm this result, and because  $\kappa$  is differentiable on  $A$ , we will use its first derivative:

$$\frac{d\kappa(x)}{dx} = \kappa'(x) = \left(\frac{f(x)}{g(x)}\right)' = \left(\frac{e^{2x} - 1}{\ln(x + 1)}\right)' = \frac{2e^{2x} \cdot \ln(x + 1) - (e^{2x} - 1) \cdot \frac{1}{x+1}}{(\ln(x + 1))^2} = \frac{2(x + 1)e^{2x} \ln(x + 1) - e^{2x} + 1}{(x + 1)(\ln(x + 1))^2}.$$

To determine the sign of  $\kappa'(x)$  it is sufficient to determine the sign of the numerator  $h(x) := 2(x + 1)e^{2x} \ln(x + 1) - e^{2x} + 1$ . A direct computation shows that  $h'(x) = 2e^{2x} \ln(x + 1)(2x + 3)$ , so for all  $x \in A$  we have  $h'(x) > 0$ . Therefore  $h$  is increasing on  $A$ . Moreover  $h(0) = 0$ , and thus it should be  $h(x) > 0$  for all  $x \in A$ , which implies that  $\kappa'(x) > 0$ . As a side remark observe that it is easier to deduce that the ratio  $K = f'/g'$  is increasing, than determining the sign of  $k' = (f/g)'$ .

Now, let's perform all computations in Sage, including necessary explanations within the code:

```
f(x)=e^(2*x)-1; g(x)=ln(x+1); k(x)=f(x)/g(x) #declare the ratio k=f/g
A=RealSet((-1, 0), x>0); show(A) #declare the domain A of k
K(x)=diff(f, x)/diff(g, x); show(K(x)) #declare and show the ratio K=f'/g'
Kprime(x)=diff(K, x).factor(); show(Kprime(x)) #declare and show the derivative K'
```

```

print(bool(Kprime(x)>0 for x in A)) #confirm that K'>0 for all the elements of A
kprime(x)=diff(k, x).factor(); show(kprime(x)) #declare and show the derivative k'
print(bool(kprime(x)>0 for x in A)) #confirm that k'>0 for all the elements of A
h(x)=2*(x+1)*e^(2*x)*ln(x+1)-e^(2*x)+1; show(diff(h, x).factor()) #declare the numerator h
print(bool(diff(h, x)>0 for x in A)) #confirm that the derivative of h is positive in A
print(bool(h(x)>0 for x in A)) #confirm that h is positive in A

```

(2) In this case we have

$$\kappa(x) = \frac{f(x)}{g(x)} = \frac{e^x - 1}{2x + e^x - 1}, \quad \text{and} \quad K(x) = \frac{f'(x)}{g'(x)} = \frac{e^x}{2 + e^x},$$

where  $\kappa$  is defined on  $A = (-\infty, 0) \cup (0, +\infty)$  (and we assume the same for both  $f, g$ ). We also have  $\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} g(x) = 0$  and hence we can apply the LMR. In particular, the ratio  $K(x) = \frac{e^x}{2+e^x}$  is strictly increasing on  $A$  (e.g., its first derivative satisfies  $K'(x) = \frac{2e^x}{(2+e^x)^2} > 0$  for all  $x \in A$ ), and hence the same monotonicity pattern must have the ratio  $\kappa = f/g$ . It is an easy exercise to see that the first derivative of  $\kappa$  satisfies

$$\kappa'(x) = \frac{2(xe^x - 1 - e^x + 1)}{(2x + e^x - 1)^2} > 0, \quad \forall x \in A.$$

On the other hand, a confirmation via Sage occurs in a very similar way as in (a), i.e.,

```

f(x)=e^x-1; g(x)=2*x+e^x-1; k(x)=f(x)/g(x)
A=RealSet(x>0, x<0); show(A) #declare the domain A
K(x)=diff(f, x)/diff(g, x); show(K(x)) #declare and show the ratio K=f'/g'
Kprime(x)=diff(K, x).factor(); show(Kprime(x)) #declare and show the derivative K'
print(bool(Kprime(x)>0 for x in A)) #confirm that K'>0 for all the elements of A
kprime(x)=diff(k, x).factor(); show(kprime(x)) #declare and show the derivative k'
print(bool(kprime(x)>0 for x in A)) #confirm that k'>0 for all the elements of A

```

(b) The objective of this question is to illustrate that the LMR operates similarly to the l'Hospital's rule for limits. According to the latter rule we get

$$\lim_{x \rightarrow 0} \kappa(x) = \lim_{x \rightarrow 0} \frac{f(x)}{g(x)} = \lim_{x \rightarrow 0} \frac{e^{2x} - 1}{\ln(x + 1)} \stackrel{\frac{0}{0}}{=} \lim_{x \rightarrow 0} \frac{f'(x)}{g'(x)} = \lim_{x \rightarrow 0} K(x) = \lim_{x \rightarrow 0} 2(x + 1)e^{2x} = 2.$$

Verify yourself that in a similar way in (2) we get  $\lim_{x \rightarrow 0} \kappa(x) = \lim_{x \rightarrow 0} K(x) = 1/3$ . □

C2) MATERIAL ON DERIVATIVES - APPLICATIONS

**5.E.114. Thales theorem and the shadow problem.** (a) A man who is 1.7 meters tall walks away from a 4-meter-tall lamppost at a speed of 1.4 m/sec (see also the figure given below). Find the rate at which his shadow is increasing in length. (b) Suppose now that as a man walks away from a lamppost with height 380 cm, the tip of his shadow moves twice as fast as he does. What is man's height?

**Solution.** (a) Let us denote by  $x$  the distance of the man from the base of the lamppost at time  $t$ , and by  $y$  the length of his shadow, both measured as meters. By assumption the man is moving at a rate of 1.4m/sec, that  $x = 1.4t$ . Consider the triangles  $OLB$  and  $AMB$ .

These triangles are similar, so by Thales theorem we have

$$\frac{x + y}{4} = \frac{y}{1.7} \iff \frac{1.4t + y}{4} = \frac{y}{1.7} \iff y = 1.03478 \cdot t = \frac{119}{115} \cdot t.$$

One may like to solve this equation via Sage and take the final equality presented here, which can be done by the syntax

```
var("t"); solve(4*x==1.7*(1.4*t+x), x)
```

It follows that the length of man's shadow increases with rate  $\frac{dy}{dt} = \frac{119}{115}$  m/sec.

(b) Let us denote by  $\alpha$  the whole distance from lamppost's base to the tip of man's shadow (hence in terms of the previous figure we have  $\alpha = x + y$ ), and by  $h$  the man's height (which we now enumerate in centimeters and is the unknown of the problem). Notice that both  $\alpha, x$  are functions of the time  $t$ , but  $h$  is constant. In this case Thales theorem tells us that

$$\frac{\alpha(t)}{380} = \frac{\alpha(t) - x(t)}{h} \iff 380 \cdot (\alpha(t) - x(t)) = h \cdot \alpha(t)$$

which we need to differentiate with respect to  $t$ , based on the statement of the assumption, that is  $\frac{d\alpha}{dt} = 2\frac{dx}{dt}$ . This gives

$$380\left(\frac{d\alpha}{dt} - \frac{dx}{dt}\right) = 2 \cdot h \frac{dx}{dt} \iff 380\left(2\frac{dx}{dt} - \frac{dx}{dt}\right) = 2 \cdot h \frac{dx}{dt},$$

which is equivalent to  $h = \frac{380}{2} = 190$  cm. □

**5.E.115. Inscribed rectangle with maximal area.** (1) Find the rectangle with the largest area that can be inscribed inside the graph of the parabola  $y = x^2$  and below the line  $y = a$ , where  $a > 0$  is some fixed constant (see the figure below).

(2) Which is the maximum area for the values 1, 2 and 3 of  $a$ ?

**Solution.** (1) Let  $[x, x^2]$  be the point representing the lower right corner of the rectangle. As we indicate in the figure, the upper right corner should be the point  $[x, a]$ , in particular the height of the rectangle is the function  $h_a(x) = a - x^2$  with  $x \in [0, \sqrt{a}]$ . Notice  $h_a(\sqrt{a}) = 0$ , and  $h_a(0) = a$  which are two cases that we may exclude for obvious reasons (these correspond to zero height and zero width ( $x = 0$ ) respectively, hence they do not determine a rectangle). Thus, the function representing the area of the rectangle is

$$E_a(x) = 2 \cdot x \cdot h_a(x) = 2x(a - x^2) = 2xa - 2x^3,$$

which we want to maximize on the interval  $(0, \sqrt{a})$ .

A differentiation of the defining equation of  $E_a$  with respect to  $x$  gives  $E'_a(x) = 2a - 6x^2$ . The equation  $E'_a(x) = 0$  has a unique solution in  $(0, \sqrt{a})$  given by  $x_a := \sqrt{\frac{a}{3}}$ , with

$$E_a(x_a) = \frac{4\sqrt{3}}{9}a^{\frac{3}{2}} = \frac{4\sqrt{3}a^3}{9}, \quad a > 0. \quad (*)$$

There are many ways to prove that  $x_a$  maximizes the area. For instance the second derivative of the area function  $E_a$  is given by  $E''_a(x) = (E'_a(x))' = -12x$  and hence obviously  $E''_a(x_a) < 0$  (since  $x_a > 0$  for all  $a > 0$ ). You can easily confirm these conclusions in Sage by applying the cell

```
var("a"); assume(a>0)
h(a, x)=a-x^2; E(a, x)=2*x*h(a, x)
show(diff(E(a, x), x)); show(solve(diff(E(a, x), x)==0, x))
bool(diff(E(a, x), x, 2)(x=sqrt(a/3))<0)
```

(2) It is sufficient to replace in (\*) the required values. This gives  $E_1(x_1) = \frac{4\sqrt{3}}{9}$ ,  $E_2(x_2) = \frac{4\sqrt{24}}{9} = \frac{8\sqrt{6}}{9}$  and  $E_3(x_3) = \frac{4\sqrt{81}}{9} = 4$ . In Sage to confirm these values add in the previous block the cell

```
show(E(1, sqrt(1/3)).factor()); show(E(2, sqrt(2/3)).factor()); show(E(3, sqrt(3/3)).factor())
```

Let us finalize this task by illustrating these three solutions:

□

**5.E.116.** Inscribe a rectangle with the greatest perimeter possible into a semidisc with radius  $r$ . Determine the rectangle's perimeter.

○

**5.E.117.** Among the rectangles with perimeter  $4c$ , find the one having the greatest area (if such one exists) and determine the lengths of its sides.

○

**5.E.118.** Find the height  $h$  and the radius  $r$  of the largest (greatest volume) cone which fits into a ball of radius  $R$ .

○

**5.E.119.** From all triangles with given perimeter  $p$ , select the one with the greatest area.

**5.E.121. Regiomontanus' angle maximization problem (1471).** In the museum, there is a painting on the wall. Its lower edge is  $a$  meters above the ground and its upper edge is  $b$  meters, that is, its height equals to  $b - a$ . A tourist is looking at the painting, her eyes being at height  $h < a$  meters above ground (see the figure below). How far from the wall should the tourist stand if she wants to maximize her angle of view at the painting? This is the so-called "Regiomontanus' angle maximization problem" from 14th century.<sup>19</sup>

**Solution.** First observe that because the tourist is below the lowest level of the painting, her viewing angle very close to the wall of very far from the wall becomes small, so the largest viewing angle is somewhere in between. We will use the picture above (at the left) to illustrate the situation. Let us denote by  $x$  the distance (in meters) of the tourist from the wall and the angle of her view at the painting by  $\varphi$ . For the angles  $\alpha, \beta \in (0, \pi/2)$  we have

$$\tan(\alpha) = \frac{b-h}{x}, \quad \tan(\beta) = \frac{a-h}{x},$$

with  $h < a < b$ . Our task is to maximize  $\varphi = \alpha - \beta$ . Let us add that for  $h > b$ , one can proceed analogously and for  $h \in [a, b]$ , the angle  $\varphi$  increases as  $x$  decreases ( $\varphi = \pi$  for  $x = 0$  and  $h \in (a, b)$ ). From the condition  $h < a$  it follows that the angle  $\varphi$  is acute, that is,  $\varphi \in (0, \pi/2)$ . Since the function  $y = \tan(x)$  is increasing on the interval  $(0, \pi/2)$ , we can turn our attention on maximizing the value  $\tan(\varphi)$ . We have that

<sup>19</sup> This optimization problem was first posed and solved in 1471 by the German astronomer Johannes Müller von Königsberg (1436–1476), known as Regiomontanus. Müller solved the problem based on elementary geometry, but the solution presented here relies on differentiation.

$$\tan(\varphi) = \tan(\alpha - \beta) = \frac{\tan(\alpha) - \tan(\beta)}{1 + \tan(\alpha)\tan(\beta)} = \frac{\frac{b-h}{x} - \frac{a-h}{x}}{1 + \frac{b-h}{x} \cdot \frac{a-h}{x}} = \frac{x(b-a)}{x^2 + (b-h)(a-h)}.$$

So it suffices to find the global maximum of the function

$$f(x) = \frac{x(b-a)}{x^2 + (b-h)(a-h)}, \quad x \in [0, +\infty),$$

whose first derivative is given by

$$f'(x) = \frac{(b-a)[(b-h)(a-h) - x^2]}{[x^2 + (b-h)(a-h)]^2}, \quad (*)$$

for all  $x \in (0, +\infty)$ . This expression can be quickly verified via the following cell in Sage:

```
var("a, b, h"); f(x)=x*(b-a)/(x^2+(b-h)*(a-h))
df1=diff(f(x), x).factor(); show(df1)
```

From (\*) one can see that

$$f'(x) > 0, \quad \text{for } x \in (0, \sqrt{(b-h)(a-h)}), \quad \text{and } f'(x) < 0, \quad \text{for } x \in (\sqrt{(b-h)(a-h)}, +\infty),$$

and hence  $f$  attains its global maximum at the point  $x_0 = \sqrt{(b-h)(a-h)}$ . This is the desired point and the corresponding angle is given by

$$\varphi_0 = \arctan\left(\frac{x_0(b-a)}{x_0^2 + (b-h)(a-h)}\right) = \arctan\left(\frac{b-a}{2\sqrt{(b-h)(a-h)}}\right).$$

Let us describe two examples:

- Suppose an ant looks at the painting, so in this case we have  $h = 0$ ,  $x_0 = \sqrt{ab}$  and  $\varphi_0 = \arctan\left(\frac{b-a}{2\sqrt{ab}}\right)$ . If the painting is 1 meter high and its lower edge is 2 meters above ground, i.e.,  $a = 2$  and  $b = 3$ , then the ant will see the painting at the largest angle  $\varphi_0 \doteq 0.201\text{rad} \approx 11.5^\circ$  at the distance  $x_0 = \sqrt{6} \approx 2.45$  meters from the wall.

- As for another example, look in the left picture above, where the painting is viewed by a man whose eyes are at the height of 1.8 meters, together with his son whose eyes are 1 meter above ground. In this case the father should stand at  $x_0 \doteq 0.49$  meters from the wall, and his son at  $x_0 \doteq 1.41$  meters from the wall. Thus the father has viewing angle  $\varphi_0 \doteq 0.795\text{rad} \approx 45.6^\circ$  whereas his son has  $\varphi_0 \doteq 0.339\text{rad} \approx 19.5^\circ$ , and the quotient  $\frac{0.795}{0.339} \approx 2.3$  proves what a strongly better view the father has. □

**5.E.122.** Determine the point  $x_0$  of the previous problem 5.E.121 by an alternative method. ○

**5.E.123. Snell's law.** This task is about the light rays which bend when traveling from one (optical) medium to another, such as air to water. This causes items placed in or behind water to look shifted and there is a rule which can be applied to evaluate the bending of a light ray, called the “*Snell's law*”.<sup>20</sup> Having as reference the figure given below, determine the refracted light ray between the point  $A$  in a homogeneous medium with speed of light  $v_1$  and the point  $B$  in a homogeneous medium with speed of light  $v_2$ .

**Solution.**

We can assume that distances are given in meters, the speeds  $v_1, v_2$  in meters per second, and the time in seconds. But for convenience we will omit the units of measurement in our notation. The ray is determined by “*Fermat's principle of least time*”, which states that “from all the paths between the points  $A$  and  $B$ , the light will go along the one which can be traversed in the least time”. In homogeneous mediums the ray will be a straight line and in our case we will consider its segment. So it suffices to determine the point  $R$  (given by the value  $x$ ) where the ray refracts. The distance between the points  $A$  and  $R$  is  $\sqrt{h_1^2 + x^2}$ , while the distance between  $R$  and  $B$  is  $\sqrt{h_2^2 + (d-x)^2}$ . We deduce that the total time which needs the energy to be transmitted between the points  $A$  and  $B$  is represented by the function

$$T(x) = \frac{\sqrt{h_1^2 + x^2}}{v_1} + \frac{\sqrt{h_2^2 + (d-x)^2}}{v_2},$$

<sup>20</sup>An optical medium is material through which light (and other electromagnetic waves) propagate.

with  $x \in [0, d]$ . We want to locate the point  $x \in [0, d]$  at which the value  $T(x)$  is minimal. The derivative of  $T$  is the continuous function  $T'(x) = \frac{x}{v_1 \sqrt{h_1^2 + x^2}} - \frac{d-x}{v_2 \sqrt{h_2^2 + (d-x)^2}}$  for all  $x \in [0, d]$ , and thus the critical point equation

$T'(x) = 0$  is equivalent to  $\frac{x}{v_1 \sqrt{h_1^2 + x^2}} = \frac{d-x}{v_2 \sqrt{h_2^2 + (d-x)^2}}$ , from where we deduce that

$$\frac{f_1(x)}{f_2(x)} = \frac{v_1}{v_2}, \quad \text{with} \quad f_1(x) = \frac{x}{\sqrt{h_1^2 + x^2}}, \quad f_2(x) = \frac{d-x}{\sqrt{h_2^2 + (d-x)^2}}.$$

This expression is useful for us because (see the picture)

$$\sin(\varphi_1) = \frac{x}{\sqrt{h_1^2 + x^2}}, \quad \sin(\varphi_2) = \frac{d-x}{\sqrt{h_2^2 + (d-x)^2}}.$$

Thus there is at most one stationary point, determined by the relation

$$\frac{\sin(\varphi_1)}{\sin(\varphi_2)} = \frac{v_1}{v_2}. \quad (\#)$$

This is the so called “Snell’s law” in physics. As  $\varphi_1 \in [0, \pi/2]$  increases the angle  $\varphi_2 \in [0, \pi/2]$  decreases. On the other hand, on the interval  $[0, \pi/2]$  the sine function is non-negative and increasing, so the quotient  $(\sin \varphi_1)/(\sin \varphi_2)$  is increasing with respect to  $x$ . Since  $T'(0) < 0$  and  $T'(d) > 0$ , there is exactly one stationary point  $x_0$ . From the inequalities  $T'(x) < 0$  for  $x \in [0, x_0)$  and  $T'(x) > 0$  for  $x \in (x_0, d]$ , it follows that at the stationary point  $x_0$  there is the global minimum.

Let us summarize as follows: The ray is given by the point  $R$  of refraction (i.e., the value  $x_0$ ), and the point  $R$  is determined by the Snell’s law (#). The ration  $v_1/v_2$  is constant for the given homogeneous mediums, and determines an important quantity which describes the interface of optical spaces. It is called “refractive index” and denoted by  $\mathbf{n}$ . Usually, the first optical medium (space) is vacuum, that is,  $v_1 = c$ , where  $c =$  speed of light and  $v_2 = v$ , such that  $\mathbf{n} = c/v$ . For vacuum, we get  $\mathbf{n} = 1$ , of course. This value is also used for the air since its refractive index at standard conditions is  $\mathbf{n} \doteq 1.000272$ . Other mediums have  $\mathbf{n} > 1$  ( $\mathbf{n} = 1.31$  for ice,  $\mathbf{n} = 1.33$  for water,  $\mathbf{n} = 1.5$  for glass). However, the refractive index also depends on the wave length of the electromagnetic radiation in question (for example, for water and light, it ranges from  $\mathbf{n} \doteq 1.331$  to  $\mathbf{n} \doteq 1.344$ ), where the index ordinarily decreases as the wave length increases. The speed of light in an optical space having  $\mathbf{n} > 1$  depends on its frequency, and hence we talk about the “dispersion of light”. The dispersion causes rays of different colors to refract at different angles. The violet ray refracts the most and the red ray refracts the least. This is also the origin of a rainbow.  $\square$

**5.E.124.** You are in a boat on a lake at distance  $d$  km from the shore. You want to get to a given place on the shore whose straight-line distance is  $\sqrt{d^2 + \ell^2}$  from you, see the figure below. What path will you take if you want to be there as soon as possible, supposing you can row at  $v_1$  kph and run along the shore at  $v_2$  kph? How long will the journey take?

**Solution.** The optimal strategy is given by first rowing in a straight line to the shore at some point  $[0, x]$  for  $x \in [0, \ell]$ , and then running along the shore to the target point  $[0, \ell]$ , see the diagram. So the trajectory consists of two line segments, or only one segment, in the case when  $x = \ell$ . The voyage to the point  $[0, x]$  on the shore takes  $\frac{\sqrt{d^2+x^2}}{v_1}$  hours, and the final run takes  $\frac{\ell-x}{v_2}$  hours. Thus, the total time is the function

$$t(x) = \frac{\sqrt{d^2 + x^2}}{v_1} + \frac{\ell - x}{v_2}, \quad x \in [0, \ell].$$

It can be assumed that  $v_1 < v_2$ , for if  $v_1 \geq v_2$ , the optimal strategy is to row straight to the target point, which corresponds to  $x = \ell$ . Now, the first and the second derivative of  $t(x)$  are given by  $t'(x) = \frac{x}{v_1 \sqrt{d^2+x^2}} - \frac{1}{v_2}$  and  $t''(x) = \frac{d^2}{v_1 \sqrt{(d^2+x^2)^3}}$ , respectively, with  $x \in (0, \ell)$ . You may confirm these relations in Sage as follows:

```
var("d, l, v1, v2"); assume(v1<v2)
t(x)=(sqrt(d^2+x^2))/(v1) + (l-x)/(v2)
d1t(x)=diff(t, x); show(d1t(x))
d2t(x)=diff(t, x, 2); show(d2t(x).factor())
```

In this block for the second derivative we used the command `diff(t, x, 2)`, where recall that `diff(f, x, k)` computes the  $k$ th derivative of some function  $f$  (see also Chapter 6). As an alternative one could simply type `d2t(x) = diff(d1t, x)`, since in our code `d1t` represents the first derivative of  $t(x)$ .

Let us now focus on the stationary point equation  $t'(x) = 0$ , or equivalently  $\frac{x}{\sqrt{d^2+x^2}} = \frac{v_1}{v_2}$ , whose solution is given by

$$x_0 = \frac{v_1 d}{\sqrt{v_2^2 - v_1^2}}.$$

You can confirm this expression via Sage by adding in the previous block the command

```
show(solve(d1t(x)==0, x))
```

We see that if  $x_0 < \ell$ , then  $t(x)$  has a global minimum at  $x_0$  on the interval  $[0, \ell]$ . This is because  $t''(x) > 0$  for all  $x$  in that interval. If  $x_0 \geq \ell$ , then  $t'(x) \leq 0$  for all  $x \in [0, \ell]$  and so the global minimum of  $t(x)$  occurs at  $\ell$ . In the former case, the fastest journey in hours takes

$$t(x_0) = \frac{\sqrt{d^2 + x_0^2}}{v_1} + \frac{\ell - x_0}{v_2} = \frac{d \sqrt{v_2^2 - v_1^2}}{v_1 v_2} + \frac{\ell}{v_2}.$$

In the latter case, the fastest journey in hours takes  $t(\ell) = \frac{\sqrt{d^2 + \ell^2}}{v_1}$ .

Notice one could follow an even simpler approach for doing the calculations, using the variable  $\theta$ , instead of the variable  $x$ , where  $x = d \tan(\theta)$ . The fastest journey occurs when  $\sin(\theta) = v_1/v_2$ , which is the limiting case of Snell's law.  $\square$

### 5.E.125. L'Hospital's pulley.

A rope of length  $r$  is tied at one of its ends to the ceiling at a point  $A$ . A small pulley is attached to its other end. A point  $B$  is also on the ceiling at distance  $d$ ,  $d > r$ , from  $A$ . Another rope of length  $\ell > \sqrt{d^2 + r^2}$ , is tied to  $B$  at one end, passes over the pulley, and has a weight is attached to its other end, see the figure presented below. Omit the mass and the size of the ropes and the pulley. In what position does the weight stabilize so that the system is in a stationary position?

**Solution.** The system is in stationary position when its potential energy is minimized. This is when the distance between the weight and the ceiling is maximal. Let  $x$  be the distance between  $A$  and the point  $P$  on the ceiling vertically above the weight and the pulley. By the Pythagorean theorem, the distance between the pulley and the ceiling is  $\sqrt{r^2 - x^2}$ . Similarly, the distance between the weight and the pulley is  $\ell - \sqrt{(d-x)^2 + r^2 - x^2}$ . Hence if  $f(x)$  is the distance between the weight and the ceiling, then

$$f(x) = \sqrt{r^2 - x^2} + \ell - \sqrt{(d-x)^2 + r^2 - x^2}.$$

The state of the system is fully determined by the value  $x \in [0, r]$ . Therefore, it suffices to find the global maximum of  $f$  on the interval  $[0, r]$ . The first derivative of  $f$  is given by

$$f'(x) = \frac{-x}{\sqrt{r^2 - x^2}} - \frac{-(d-x) - x}{\sqrt{(d-x)^2 + r^2 - x^2}} = \frac{-x}{\sqrt{r^2 - x^2}} + \frac{d}{\sqrt{(d-x)^2 + r^2 - x^2}}, \quad x \in (0, r).$$

Let us use once more Sage to confirm this expression:

```
var("r, d, l"); f(x)=sqrt(r^2-x^2)+l-sqrt((d-x)^2+r^2-x^2)
df1(x)=diff(f, x); show(df1(x))
```

Now, instead of solving the equation  $f'(x) = 0$ , it is easier to solve the equation  $(f'(x))^2 = 0$ , which is equivalent to the polynomial

$$2dx^3 - (2d^2 + r^2)x^2 + d^2r^2 = 0, \quad x \in (0, r).$$

This has  $x = d$  as an obvious solution and hence we get the factorization  $(x - d)(2dx^2 - r^2x - dr^2) = 0$ . Thus, with a bit of try we see that the equation  $f'(x) = 0$  has three solutions. The solution  $x = d$  does not lie on the interval  $[0, r]$  since  $d > r$ . The solution  $x = \frac{r^2 - r\sqrt{r^2 + 8d^2}}{4d}$  is also outside the interval  $[0, r]$ , since  $x_1 < 0$ . But the solution

$$x_0 = \frac{r^2 + r\sqrt{r^2 + 8d^2}}{4d}$$

is positive and since  $r < d$  it satisfies  $x_0 < r$ , i.e.,  $x_0 < \frac{r}{4} + \frac{3r}{4} = r$ . Now, because  $f'$  is continuous on the open interval  $(0, r)$  it changes sign only at  $x_0$ . Based on the limits  $\lim_{x \rightarrow 0^+} f'(x) = \frac{d}{\sqrt{d^2 + r^2}}$  and  $\lim_{x \rightarrow r^-} f'(x) = -\infty$ , we deduce that  $f'(x) > 0$  for all  $x \in (0, x_0)$ , while  $f'(x) < 0$  for all  $x \in (x_0, r)$ . This implies that at  $x_0$  the function  $f$  attains its global maximum.  $\square$

**5.E.126.** A rectangle is inscribed into an equilateral triangle with sides of length  $a$  so that one of its sides lies on one of the triangle's sides and the other two of the rectangle's vertices lie on the remaining sides of the triangle. What is the maximum possible area of the rectangle?

**5.E.127.** Determine the dimensions of an (open) swimming pool whose volume is  $32 \text{ m}^3$  and whose bottom has the shape of a square, so that one would use the least amount of paint possible to prime its bottom and its walls.

**5.E.128.** Express the number 28 as a sum of two non-negative numbers such that the sum of the first summand squared and the second summand cubed is as small as possible.

**5.E.129.** With the help of the first derivative, find the real number  $a > 0$  for which the sum  $a + 1/a$  is minimal. Next solve this problem without using differential calculus.

D) MATERIAL ON INFINITE SUMS AND POWER SERIES

Recall by Section D that infinite sums may have several beautiful applications. Below we describe an application, strongly related with the compelling notion of fractals, the so called Sierpiński carpet.

**5.E.130. Sierpiński carpet.** The unit square is divided into nine equal squares, and then the middle one is removed. Each of the eight remaining squares is again divided into nine equal sub-squares and then the middle sub-square, corresponding to each of these eight squares, is removed again. Having applied this procedure ad infinitum, determine the area of the resulting figure.

**Solution.** In the first step, a square having the area of  $1/9$  is removed. In the second step, eight squares are removed, each having the area of  $9^{-2}$ , so in total we remove  $8 \cdot 9^{-2}$ . Every further iteration removes eight times more squares than in the previous steps, but the squares are nine times smaller. Thus, the sum of areas of all the removed squares is encoded by the following infinite sum:

$$\frac{1}{9} + \frac{8}{9^2} + \frac{8^2}{9^3} + \dots = \sum_{n=0}^{\infty} \frac{8^n}{9^{n+1}}.$$

Now, to compute the area of the remaining figure (known as the *Sierpiński carpet*) it is sufficient to consider the difference

$$1 - \sum_{n=0}^{\infty} \frac{8^n}{9^{n+1}} = 1 - \frac{1}{9} \sum_{n=0}^{\infty} \left(\frac{8}{9}\right)^n = 1 - \frac{1}{9} \cdot \frac{1}{1 - \frac{8}{9}} = 0,$$

where we used the result from 5.B.16 on geometric series. Thus, the Sierpiński carpet has zero area.

**5.E.131.** Decide whether the following implications hold:

(a) Convergence of series  $\sum_{n=1}^{\infty} a_n, \sum_{n=1}^{\infty} b_n$  implies that the series  $\sum_{n=1}^{\infty} (6a_n - 5b_n)$  converges as well.

(b) If a series  $\sum_{n=0}^{\infty} a_n$  satisfies  $\lim_{n \rightarrow \infty} a_n^2 = 0$ , then it is convergent.

(c) If a series  $\sum_{n=1}^{\infty} a_n^2$  converges, then the series  $\sum_{n=1}^{\infty} \frac{a_n}{n}$  converges absolutely.

**5.E.132.** Prove that the series below diverge to  $+\infty$ :

$$T_1 = \sum_{n=2}^{\infty} \frac{1}{\sqrt[n]{\ln(n)}}, \quad T_2 = \sum_{n=1}^{\infty} \frac{1}{n - \ln(n)}.$$

**Solution.** The two enlisted series consist of non-negative terms only. So the series either converge, or diverge to  $+\infty$ . For  $T_1$  it is useful to recall that  $\lim_{n \rightarrow \infty} \sqrt[n]{\ln(n)} = 1$  (see for example 5.E.18), and hence we also get

$$\lim_{n \rightarrow \infty} \frac{1}{\sqrt[n]{\ln(n)}} = \frac{1}{\lim_{n \rightarrow \infty} \sqrt[n]{\ln(n)}} = 1.$$

Thus, by (1) in Theorem 5.1.9 we deduce that  $T_1$  is not convergent, and in particular it diverges to  $+\infty$ . For  $T_2$  we have  $\lim_{n \rightarrow \infty} \frac{1}{n - \ln(n)} = 0$ . However, we see that

$$\sum_{n=1}^{\infty} \frac{1}{n - \ln(n)} \geq \sum_{n=1}^{\infty} \frac{1}{n} = +\infty.$$

Hence  $T_2$  also diverges to  $+\infty$ .

**5.E.133.** Prove that the series

$$S = \sum_{n=0}^{\infty} \arctan\left(\frac{n^2 + 2n + 3\sqrt{n} + 4}{n+1}\right), \quad T = \sum_{n=1}^{\infty} \frac{3^n + 1}{n^3 + n^2 - n}$$

are both divergent.

**Solution.** For the first case we have

$$\lim_{n \rightarrow \infty} \arctan\left(\frac{n^2 + 2n + 3\sqrt{n} + 4}{n+1}\right) = \lim_{n \rightarrow \infty} \arctan\left(\frac{n^2}{n}\right) = \frac{\pi}{2}.$$

We can do this computation in Sage by typing

```
var("n"); lim(arctan((n^2+2*n+3*sqrt(n)+4)/(n+1)), n=oo)
```

For the second one we compute

$$\lim_{n \rightarrow \infty} \frac{3^n + 1}{n^3 + n^2 - n} = \lim_{n \rightarrow \infty} \frac{3^n}{n^3} = +\infty.$$

Thus, the necessary condition  $\lim_{n \rightarrow \infty} a_n = 0$  for the series  $\sum_{n=n_0}^{\infty} a_n$  to converge does not hold, and so none of  $S, T$  converges.  $\square$

**5.E.134.** Compute explicitly the sum  $\sum_{n=0}^{\infty} \frac{1}{(3n+1)(3n+4)}$ .

**Solution.** It suffices to use the form (this is the so-called partial fraction decomposition)

$$\frac{1}{(3n+1)(3n+4)} = \frac{1}{3} \cdot \frac{1}{3n+1} - \frac{1}{3} \cdot \frac{1}{3n+4}, \quad n = 0, 1, 2, \dots$$

This gives

$$\sum_{n=0}^{\infty} \frac{1}{(3n+1)(3n+4)} = \lim_{n \rightarrow \infty} \frac{1}{3} \left(1 - \frac{1}{4} + \frac{1}{4} - \frac{1}{7} + \frac{1}{7} - \frac{1}{10} + \dots + \frac{1}{3n+1} - \frac{1}{3n+4}\right) = \lim_{n \rightarrow \infty} \frac{1}{3} \left(1 - \frac{1}{3n+4}\right) = \frac{1}{3}.$$

$\square$

**5.E.135.** (a) Using the ratio test show that  $S = \sum_{n=1}^{\infty} \frac{(-2)^{n^2}}{n!}$  is not convergent.

(b) Exam the convergence of the series  $T = \sum_{n=1}^{\infty} (-1)^{n+1} \arctan\left(\frac{2}{\sqrt{3n}}\right)$ .  $\circ$

**5.E.136.** Let  $S = \sum_{n=0}^{\infty} f(n)$  be an infinite series for which the limit  $\lim_{n \rightarrow \infty} \sqrt[n]{|f(n)|}$  exists, and equals to  $q$ . Present in Sage a syntax based on the root test to deduce, if possible, for the absolute convergence/divergence of  $S$ . Then apply your program for the following series and state Sage's output.

$$S_1 = \sum_{n=1}^{\infty} 2^n \left(\frac{4}{5}\right)^{n^2}, \quad S_2 = \sum_{n=1}^{\infty} \left(\frac{\ln(n)}{n}\right)^n, \quad S_3 = \sum_{n=1}^{\infty} \left(\frac{2n}{4n^2 + 1}\right)^{\frac{1}{n}}, \quad S_4 = \sum_{n=1}^{\infty} (-1)^{n-1} \left(\frac{3n}{n+1}\right)^n.$$

**Solution.** Here one can use once more the command `def` to creating a subroutine, as we did in 5.D.5. This time we will call it `roottest`. Recall that according to the root test the series  $S$  will converge absolutely if  $q < 1$ , will not converge absolutely for  $q > 1$ , while for  $q = 1$  the root test is inconclusive. Thus one can give the cell

```
var("n")
def roottest(f):
    q=lim(abs(f(n))**(1/n), n=oo)
    if q<1:
        return "converges absolutely"
    elif q==1:
        return "no conclusion"
    else:
        return "does not converge absolutely"
    return
```

Now to test our routine via the given series, one can simply introduce first the sequence inside the series, and then apply the command `roottest(f)`. For instance for the second series, type in your editor

`f(n) = (ln(n)/n)^n; roottest(f)`

Sage informs us that the series converges absolutely. Check yourself that the same is true for the first series (see also 5.D.4). On the other hand, the series  $S_4$  does not converge absolutely, while the root test does not provide a result for  $S_3$ .  $\square$

5.E.137. Prove the convergence of the series  $\sum_{n=1}^{\infty} \frac{3^n + 2^n}{6^n}$ , and find its value.  $\circ$

5.E.138. Calculate the series  $\sum_{n=1}^{\infty} \frac{2n-1}{2^n}$  and  $\sum_{n=0}^{\infty} \frac{n+1}{3^n}$ .  $\circ$

5.E.139. Determine those  $\alpha \in \mathbb{R}$ ,  $\beta \in \mathbb{Z}$  and  $\gamma \in \mathbb{R} \setminus \{0\}$  which establish the following series as convergent:

$$\sum_{n=120}^{\infty} \frac{e^{-\alpha n}}{n}, \quad \sum_{n=240}^{\infty} \frac{\beta^n \cdot n!}{n^n}, \quad \sum_{n=360}^{\infty} \frac{n}{\gamma^n}.$$

5.E.140. Determine whether the series  $\sum_{n=21}^{\infty} (-1)^n \frac{n^8 - 5n^6 + 2n}{2^n}$  converges absolutely, converges conditionally, or does not converge at all.  $\circ$

5.E.141. Find all real numbers  $\alpha \geq 0$  for which the series  $\sum_{n=1}^{\infty} (-1)^n \ln(1 + \alpha^{2n})$  is convergent.  $\circ$

5.E.142. Explain, why the convergence interval of the power series expressing the function  $\frac{1}{1+x^2}$  with the center at origin is one.

**Solution.** Recall by 5.B.16 that the geometric series  $\sum_{n=0}^{\infty} x^n = \frac{1}{1-x}$  converges for  $|x| < 1$ . Thus  $\frac{1}{1+x} = \sum_{n=0}^{\infty} (-1)^n x^n$  and substituting  $x^2$  instead of  $x$ , we arrive at  $\frac{1}{1+x^2} = \sum_{n=0}^{\infty} (-1)^n x^{2n}$ , again converging for  $|x| < 1$ . At the same time, viewing the same sum over complex  $x$ , the sum explodes towards infinite absolute value if  $x$  approaches the imaginary unit  $i$ . Thus the power series cannot converge for  $|x| > 1$ .  $\square$

5.E.143. Express the function  $y = e^x$ , defined on the whole real line, as an infinite polynomial whose terms are of the form  $a_n(x-1)^n$ . Then express the function  $y = 2^x$  defined on  $\mathbb{R}$  as an infinite polynomial with terms  $a_n x^n$ .

**Solution.** We know the series for  $e^x$ , thus writing  $e^{x-1} = e^{-1} e^x$  leads to  $e^x = \sum_{n=0}^{\infty} \frac{e}{n!} (x-1)^n$ . The second task is even simpler, since  $2^x = e^{x \ln(2)} = \sum_{n=0}^{\infty} \frac{\ln^n(2)}{n!} x^n$ .  $\square$

5.E.144. Supposing  $|x| < 1$ , determine the series

$$A(x) = \sum_{n=1}^{\infty} \frac{1}{2n-1} x^{2n-1}, \quad B(x) = \sum_{n=1}^{\infty} n^2 x^{n-1}.$$

5.E.145. Give an example of two divergent series  $\sum_{n=1}^{\infty} a_n$ ,  $\sum_{n=1}^{\infty} b_n$  with positive numbers for which the series  $\sum_{n=1}^{\infty} (3a_n - 2b_n)$  converges absolutely.

5.E.146. Determine whether the series  $\sum_{n=1}^{\infty} (-1)^n \frac{(n!)^2}{(2n)!}$  and  $\sum_{n=1}^{\infty} (-1)^n \frac{n^7 - n^4 + n}{n^8 + 2n^6 + n}$  converge absolutely, converge conditionally, or do not converge at all.

5.E.147. Does the series  $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{\sqrt[3]{n} + \sqrt[5]{n} + 1}{n + \sqrt[5]{n}}$  converge?

5.E.148. Find the values of the parameter  $p \in \mathbb{R}$  for which the series  $\sum_{n=1}^{\infty} (-1)^n \sin^n \frac{p}{n}$  converges.

5.E.149. Determine whether the series  $\sum_{n=0}^{\infty} \frac{2^n + (-2)^n}{5^n}$  converges.

5.E.150. Using the power series  $F(x) = \sum_{n=0}^{\infty} (-1)^n (2n + 1)x^{2n}$  with  $x \in (-1, 1)$ , calculate the infinite sum  $S =$

$\sum_{n=1}^{\infty} \frac{2n - 1}{(-2)^{n-1}}$ .

## Solutions to the exercises

**5.A.7.** As usual, we have a taste for Sage, where an appropriate cell reads as follows:

```
g(x)=(x/(1+8*x**2))
figg=plot(g(x), (x, -1, 1), figsize=4, color="black"); show(figg)
R=PolynomialRing(QQ, "x")
n=20
points=[(-1+k*(2/n), g(-1+k*2/n)) for k in [0, 1, ..., n]]
P(x)=R.lagrange_polynomial(points); show(P(x))
figg+=plot(P(x), (x, -1, 1), color="purple")
figg+=list_plot(points, size=20, figsize=4, color="blue"); figg
```

This returns the interpolation polynomial  $P(x)$  under question, and also the plots of  $g(x)$  and of  $P(x)$ , along with the given set of points.

Note that the polynomial oscillates wildly near the endpoints, getting worse and worse as  $n$  increases.

**5.A.8.** An implementation of the following cell in Sage prints out the explicit for of  $P$ , given by  $P(x) = 3x^2 - 2x - 4$ .

```
R = PolynomialRing(QQbar, "x")
R.lagrange_polynomial([( -1, 1), (1, -3), (2, 4)])
```

For further practicing with the method of elementary Lagrange polynomials, we suggest to the reader to verify this answer also by a formal computation.

**5.A.9.** Assume that that  $P(x) = ax^3 + bx^2 + cx + d$  for some reals  $a, b, c, d$  to be specified. By the given conditions one gets the following system (we present this directly in Sage)

```
var("a, b, c, d")
eq1=d-1; eq2=a+b+c+d
eq3=8*a+4*b+2*c+d-1; eq4=27*a+9*b+3*c+d-10
solve([eq1==0, eq2==0, eq3==0, eq4==0], a, b, c, d)
```

This blocks returns the answer  $a = 1, b = -2, c = 0, d = 1$ , that is,  $P(x) = x^3 - 2x^2 + 1$ . Alternatively, one may apply the previous method of Lagrange polynomials:

```
R = PolynomialRing(QQbar, "x")
R.lagrange_polynomial([(0, 1), (1, 0), (2, 1), (3, 10)])
```

which verifies the previous answer:  $x^3 - 2 * x^2 + 1$ .

**5.A.13.** The polynomial  $Q$  is given by  $Q(x) = x^3 - 2x^2 + 3x - 3$ .

**5.A.14.** An answer is given by  $x^5 - 2x^4 - 5x + 2$ .

**5.A.17.** Sought spline differs from the one in 5.A.15 only in the values of the derivatives at the points  $-1$  and  $1$ . Similarly to the previous task, we get that the parts  $S_1$  and  $S_2$  of our spline have the forms  $S_1(x) = ax^3 + bx^2 + 1$  and  $S_2(x) = -ax^3 + bx^2 + 1$ , respectively, where  $a, b, c, d$  are unknown real parameters. Confronting this with the conditions  $S_1(-1) = 0, S_1'(-1) = 1, S_2(1) = 0$ , and  $S_2'(1) = 1$  yields the system  $\{-a + b + 1 = 0, 3a - 2b = -1\}$ , having the solution  $a = -3, b = -4$ . Hence,

$$S(x) = \begin{cases} -3x^3 - 4x^2 + 1, & \text{if } x \in [-1, 0], \\ 3x^3 - 4x^2 + 1, & \text{if } x \in [0, 1]. \end{cases}$$

**5.A.20.**  $S_1(x) = 1 - \frac{11}{20}x + \frac{1}{20}x^3; S_2(x) = \frac{1}{2} - \frac{2}{5}(x-1) + \frac{3}{20}(x-1)^2 - \frac{1}{40}(x-1)^3$ .

**5.B.1.** The set  $\mathbb{Z}_+$  is unbounded above, hence  $A$  is also unbounded and in particular  $\sup A$  cannot exist. Observe also that  $\left| \frac{(-1)^n}{n} \right| = \frac{1}{n} \leq 1$  and thus we have the inequalities  $n + \frac{(-1)^n}{n} \geq n - \left| \frac{(-1)^n}{n} \right| \geq n - 1$  for all  $n \in \mathbb{Z}_+$ . This implies that  $n + \frac{(-1)^n}{n} \geq 0$  for all  $n \in \mathbb{Z}_+$ , and hence 0 is a lower bound of  $A$ . In particular,  $0 \in A$  and  $A$  is non-empty, thus we deduce that  $\inf A = 0$ .

**5.B.2.** For the set  $B$  we get  $\sup B = \frac{1}{4} \in B$  and  $\inf B = -1 \in B$ . For  $C$  we see that  $\sup C = 9 \notin C$ ,  $\inf C = -9 \notin C$ . For the set  $X$ ,  $\inf X = -1 \in X$ , while  $\sup X = 0 \notin X$ . Further,  $\inf Y = 0 \notin Y$ , while  $\sup Y = 5 \in Y$ .

**5.B.6.** (a) By 5.B.3 we know that  $\frac{1}{n} \rightarrow 0$  and  $3^n \rightarrow +\infty$ . Thus their sum will diverge to  $+\infty$ .  
 (b) Here we are based on fact that if  $a_n \rightarrow +\infty$  and  $b_n \rightarrow +\infty$ , then also  $a_n + b_n = +\infty$ . We have  $n^2 \rightarrow +\infty$  and  $2^n \rightarrow +\infty$ , so  $(n^2 + 2^n) \rightarrow +\infty$ , as well.  
 (c) For this use the first assertion in Problem 5.B.5: Since  $n^2 \rightarrow +\infty$ , and  $3^n \rightarrow +\infty$ , also their product  $n^2 \cdot 3^n \rightarrow +\infty$ .  
 (d) For this use the second assertion in Problem 5.B.5: Since  $\frac{n}{n+1} \rightarrow 1 > 0$  and  $4^n \rightarrow +\infty$ , their product will tend to  $+\infty$  as well.

**5.B.7.** (a) For any  $\varepsilon > 0$  the inequality  $1/2^n < \varepsilon$  is equivalent to  $2^n > 1/\varepsilon$ . Thus, taking  $N > 1/\varepsilon$  we see that  $n \geq N$  implies  $2^n \geq 2^N > N > 1/\varepsilon$ . Hence  $1/2^n < \varepsilon$ , and this proves the claim.  
 (b) Observe that the terms of  $(b_n = (-1)^{n+1})$  interchange between 1 and  $-1$ . Such a sequence is said to be an *alternating sequence*, and since its  $n$ th term is either 1 or  $-1$ , it must diverge by oscillation. For instance, taking  $\varepsilon$  with  $0 < \varepsilon < 1/2$  we see that infinitely many terms of  $(b_n)$  do *not* sit in the open interval  $(x - \varepsilon, x + \varepsilon)$ , for any  $x \in \mathbb{R}$ . Hence the inequality  $|b_n - x| < \varepsilon$  will not make sense for infinitely many  $n$ .  
 (c) The sequence  $(c_n = \sin(n\pi/2))$  ( $n \geq 1$ ) is of the form  $(1, 0, -1, 0, 1, 0, \dots)$ . Therefore, by the same reasoning as in the previous case (b) one deduces that  $(c_n)$  diverges.  
 (d) In this case a solution is given by  $x_n = n, y_n = -n + 1$ , with  $n \in \mathbb{Z}_+$ .

**5.B.12.** We have to prove the *incorrectness* of the statement: “Any convergent sequence is bounded and monotone.” Take for example the sequence  $((-1)^n/n)_{n \geq 1}$ . It converges to 0 but is not monotone, as we can see in the figure below.

For the second question, an example is given by  $(a_n = n)_{n \geq 1}$ . Clearly, this sequence is strictly increasing, but is not bounded and so it cannot be convergent (it is not hard to prove that any convergent sequence is bounded).

**5.B.13.** Recall that  $|\sin(x)| \leq 1$  for any  $x \in \mathbb{R}$ . Thus  $|a_n| = \left| \frac{1}{n} \sin(n) \right| \leq \left| \frac{1}{n} \right| = \frac{1}{n}$ , which implies that  $|a_n| \leq 1/n \leq 1$ , for any natural  $n \geq 1$ . This is equivalent to say that  $-1 \leq a_n \leq 1$ , and so the sequence  $(a_n)$  is bounded. Next, it is easy to see that  $(b_n = n^2 + 1)$  is bounded below,  $b_n \geq 2$  for any  $n$  (since  $n^2 \geq 1$  for any natural  $n \geq 1$ ). Suppose that  $(b_n)$  is also bounded above. Then there exists  $M \in \mathbb{R}$  such that  $b_n \leq M$  for all  $n$ . This gives  $n^2 \leq M - 1$  or  $n \leq \sqrt{M - 1}$  for all  $n$ , a contradiction. Finally, for  $c_n$  one can verify that  $0 \leq c_n \leq 2$ , which we leave as an exercise (we recommend to plot the first terms of  $(c_n)$ , e.g., via Sage).

**5.B.14.** The sequence  $(a_n = \frac{1}{n} \sin(n))$  is bounded but not monotone. However, it is convergent. Indeed, we have  $-(1/n) \leq a_n \leq (1/n)$ , for all  $n \in \mathbb{Z}_+$ , so using the squeeze theorem we obtain  $a_n \rightarrow 0$ . We can verify this in Sage and also plot some terms of  $a_n$ , as follows:

```
a(n)=sin(n)/n; show(lim(a(n), n=oo))
points([n, a(n)] for n in range(1,200)], color="black")
```

Check yourself Sage’s output. Clearly, the sequence  $b_n$  diverges to  $+\infty$ , so it is not convergent. Also, it is easy to see that the sequence  $c_n = ((-1)^n + n)/n$  behaves as  $(a_n)$ . This means that  $(c_n)$  is bounded, and also convergent, though not monotone. We present the verification only via Sage, together with a syntax giving the plot of its first thirty terms. However, once more we leave for practice the execution of this block.

```
c(n) = ((-1)^n + n)/n; show(limit(c(n), n=oo))
list_plot([c(n) for n in range(1, 30)], color="black")
```

Next, one can prove that  $f_n = \frac{1}{\sqrt{n}} = n^{-1/2}$  is decreasing: Since  $\sqrt{n} \leq \sqrt{n+1}$  we have  $\frac{1}{\sqrt{n+1}} \leq \frac{1}{\sqrt{n}}$ , for all  $n \in \mathbb{Z}_+$ . It is also bounded: For any  $n \in \mathbb{Z}_+$  we have  $n \geq 1$ , so  $\sqrt{n} \geq 1$  and thus  $1/\sqrt{n} \leq 1$ . Therefore, by the monotone sequence theorem  $f_n$  should be convergent, and in particular we see that

$$\lim_{n \rightarrow +\infty} f_n = \frac{0}{+\infty} = 0 = \sup \left\{ \frac{1}{\sqrt{n}} : n \in \mathbb{Z}_+ \right\}.$$

Similarly for the sequence  $g_n = \frac{n!}{n^n}$ , which is decreasing and bounded. Thus, the monotone sequence theorem ensures its convergence, and in particular we deduce that

$$\lim_{n \rightarrow +\infty} g_n = 0 = \sup \left\{ \frac{n!}{n^n} : n \in \mathbb{Z}_+ \right\}.$$

This also follows by squeeze theorem, since we have  $0 < g_n \leq 1/n$  for all positive naturals  $n$ . This is because  $n! = n \cdot (n-1) \cdots 2 \cdot 1 < n \cdot n \cdots n \cdot 1 = n^{n-1}$  (so dividing by  $1/n^n$  we obtain the formula).

**5.B.18.** By the binomial theorem we have

$$e_n = 1 + \binom{n}{1} \frac{1}{n} + \cdots + \binom{n}{k} \frac{1}{n^k} + \cdots + \binom{n}{n} \frac{1}{n^n} = 2 + \binom{n}{2} \frac{1}{n^2} + \cdots + \binom{n}{k} \frac{1}{n^k} + \cdots + \binom{n}{n} \frac{1}{n^n}.$$

Since  $\binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{n \cdot (n-1) \cdots (n-k+1)}{k!}$ , for the general term we see that

$$\binom{n}{k} \frac{1}{n^k} = \frac{1}{k!} \cdot \frac{n \cdot (n-1) \cdots (n-k+1)}{n^k} = \frac{1}{k!} \cdot \frac{n}{n} \cdot \frac{n-1}{n} \cdots \frac{n-k+1}{n} = \frac{1}{k!} \cdot \left(1 - \frac{1}{n}\right) \cdots \left(1 - \frac{k-1}{n}\right).$$

Therefore

$$e_n = 2 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \cdots + \frac{1}{k!} \left(1 - \frac{1}{n}\right) \cdots \left(1 - \frac{k-1}{n}\right) + \cdots + \frac{1}{n^n}.$$

As  $n$  increases, the quantities  $\frac{1}{n}, \frac{2}{n}, \dots, \frac{k-1}{n}$  decrease and so the expressions  $(1 - \frac{1}{n}), (1 - \frac{2}{n}), \dots, (1 - \frac{k-1}{n})$  increase. So the general term of  $(e_n)$  increases, i.e.,  $(e_n)$  is increasing. Another way to obtain the monotonicity of  $(e_n)$  is based on the geometric mean inequality and in particular in Bernoulli’s inequality which we presented in Chapter 1. Also, since  $k! = 1 \cdot 2 \cdots k \geq 1 \cdot 2 \cdots 2 = 2^{k-1}$  we see that

$$2 < e_n < 1 + \sum_{k=1}^n \frac{1}{k!} < 1 + \sum_{k=1}^n \frac{1}{2^{k-1}} = 1 + \frac{1 - (1/2)^n}{1 - (1/2)} < 3,$$

since  $1 + \frac{1 - (1/2)^n}{1 - (1/2)} < 1 + \frac{1}{1 - (1/2)}$ . Thus  $(e_n)$  is also bounded,  $2 < e_n < 3$ , for any positive natural  $n$ , and by 5.B.11 it is convergent.

**5.B.24.** Yes: The range of  $f(x) = x^2$  is the set  $[0, +\infty)$ , which according to the remark in 5.B.23 is a closed subset of  $\mathbb{R}$ .

**5.B.29.** This is because the sine function  $f(x) = \sin(x)$  is continuous at any  $x \in \mathbb{R}$ . Verify this claim yourself, presenting a “delta-epsilon” proof.<sup>21</sup> Thus  $\lim_{x \rightarrow \pi/3} \sin(x) = \sin(\pi/3) = \sqrt{3}/2$ .

Let us now use Sage and combine the `limit` command with the `bool` function, to verify that the left/right limits coincide with the value of sine function at the limit point  $x_0$ . This idea is encoded by the following cell:

```
bool(sin(pi/3)==limit(sin(x), x=pi/3, dir="left"))
bool(sin(pi/3)==limit(sin(x), x=pi/3, dir="right"))
```

For both these commands Sage’s output is `True`, as it was expected.

<sup>21</sup>Hint: Use the identity  $\sin(x) - \sin(x_0) = 2 \cos(\frac{x+x_0}{2}) \sin(\frac{x-x_0}{2})$  and some classical inequalities related to the sine and cosine function.

**5.B.32.** (a) We may multiply the expression inside the given limit by  $\frac{1+\cos(x)}{1+\cos(x)}$ , so that we can form the difference of two squares in the numerator, that is,

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{1 - \cos(x)}{x} &= \lim_{x \rightarrow 0} \frac{1 - \cos(x)}{x} \cdot \frac{1 + \cos(x)}{1 + \cos(x)} = \lim_{x \rightarrow 0} \frac{1 - \cos^2(x)}{x(1 + \cos(x))} = \lim_{x \rightarrow 0} \frac{\sin^2(x)}{x(1 + \cos(x))} \\ &= \lim_{x \rightarrow 0} \frac{\sin(x)}{x} \cdot \lim_{x \rightarrow 0} \frac{\sin(x)}{1 + \cos(x)} = 1 \cdot \frac{0}{2} = 0. \end{aligned}$$

(b) Here we will use the so called trigonometric “half-angle” identity of the sine function, that is,  $2 \sin^2\left(\frac{x}{2}\right) = 1 - \cos(x)$ . We have

$$\lim_{x \rightarrow 0} \frac{1 - \cos x}{x^2 \sin(x^2)} = \lim_{x \rightarrow 0} \frac{2 \sin^2\left(\frac{x}{2}\right)}{x^2 \sin(x^2)} = \lim_{x \rightarrow 0} \frac{\frac{1}{2} \sin^2\left(\frac{x}{2}\right)}{\left(\frac{x}{2}\right)^2 \sin(x^2)} = \frac{1}{2} \left( \lim_{x \rightarrow 0} \frac{\sin\left(\frac{x}{2}\right)}{\frac{x}{2}} \right)^2 \cdot \lim_{x \rightarrow 0} \frac{1}{\sin^2(x^2)} = \frac{1}{2} \cdot \infty = \infty.$$

Note that this calculation must be considered “from the back”. Indeed, since the limits on the right-hand side exist (no matter whether finite or infinite) and the expression  $\frac{1}{2} \cdot \infty$  is meaningful (see the note after theorem 5.2.13), the original limit exists as well. On the other hand, observe that if we split the original limit into the product

$$\lim_{x \rightarrow 0} (1 - \cos x) \cdot \lim_{x \rightarrow 0} \frac{1}{x^2 \sin(x^2)},$$

then we will get the  $0 \cdot \infty$  type, which is an indeterminate form and tells us nothing about existence of the original limit. Finally, you may like to confirm your computation by Sage, which can be easily done by the cell

```
f(x)=(1-cos(x))/(x^2*sin(x^2)); limit(f(x), x=0)
```

**5.B.33.** (a) One can decompose the polynomial in the denominator, and simplify the given expression, i.e.,

$$\lim_{x \rightarrow 2} \frac{x - 2}{\sqrt{x^2 - 4}} = \lim_{x \rightarrow 2} \frac{x - 2}{\sqrt{(x - 2)(x + 2)}} = \lim_{x \rightarrow 2} \frac{\sqrt{x - 2}}{\sqrt{x + 2}} = \frac{0}{4} = 0.$$

(b) Here one can exploit the rule for limits of compositions of functions (see 5.2.20). Thus

$$\lim_{x \rightarrow 0} \frac{\sin(\sin(x))}{x} = \lim_{y \rightarrow 0} \frac{\sin(y)}{y} \cdot \lim_{x \rightarrow 0} \frac{\sin(x)}{x} = 1.$$

(c) We see that  $\lim_{x \rightarrow 0} \frac{\sin^2(x)}{x} = \lim_{x \rightarrow 0} \sin(x) \cdot \lim_{x \rightarrow 0} \frac{\sin(x)}{x} = 0 \cdot 1 = 0$ . Notice the original limit exists because both the right-hand side limits exist and their product is well-defined.

**5.B.34.** For instance, in the first case we have  $\lim_{x \rightarrow 0^-} f(x) = 1$  but  $\lim_{x \rightarrow 0^+} f(x) = +\infty$ . Hence  $\lim_{x \rightarrow 0} f(x)$  does not exist. Let us also explain the situation for  $k$  and similarly are treated the function  $g$  and  $h$ . For the sign function  $\text{sign} : \mathbb{R} \rightarrow \mathbb{R}$  we have

$$k(x) = \text{sign}(x) = \begin{cases} 1, & \text{if } x > 0, \\ 0, & \text{if } x = 0, \\ -1, & \text{if } x < 0. \end{cases}$$

Taking the sequence  $(x_n = 1/n)$  we see that  $\text{sign}(1/n) \rightarrow 1$  for  $n \rightarrow +\infty$ , while for the sequence  $(y_n = -1/n)$  we obtain  $\text{sign}(-1/n) \rightarrow -1$ , as  $n \rightarrow +\infty$ . Since we found two real sequences  $(x_n), (y_n)$  with  $\lim_{n \rightarrow +\infty} x_n = c = \lim_{n \rightarrow +\infty} y_n$  (where  $c = 0$ ), and  $\lim_{n \rightarrow +\infty} k(x_n) \neq \lim_{n \rightarrow +\infty} k(y_n)$  we deduce that the limit  $\lim_{x \rightarrow c} k(x)$  does not exist (notice that  $c = 0 \in \mathbb{R}$  is a limit point, see also Proposition 5.2.15). In Sage recall that we can treat limits of functions really quickly. For instance, for the functions  $h, k$  to verify the statement type

```
k(x)=sign(x); h(x)=abs(sin(x))/sin(x); limit(k(x), x=0); limit(h(x), x=0)
```

As a side remark notice that the sign function is very similar to the function  $g : \mathbb{R} \setminus \{0\} \rightarrow \{-1, 1\} \cong \mathbb{Z}_2$ , defined by  $g(x) = |x|/x$  which is everywhere continuous except at  $x = 0$ . In particular,  $g(0)$  is not defined and we see that

$$g(x) = \begin{cases} 1, & \text{if } x > 0, \\ -1, & \text{if } x < 0. \end{cases}$$

If you like to sketch the graph of  $g$ , say for  $-2 \leq x \leq 2$ , type

```
f(x)=abs(x)/x; plot(f, x, -2, 2, exclude=[0])
```

Notice here in our input we added the option `exclude`, to exclude the point that  $g$  is not defined. This syntax produces the known figure, i.e.,

**5.B.36.** Let us multiply both the numerator and denominator by  $1/\alpha^2$ , which yields

$$g(x) = \lim_{\alpha \rightarrow +\infty} \left( \frac{2x - 3 + 4x \frac{1}{\alpha} + \frac{2}{\alpha^2} \cdot \frac{\sin \frac{1}{\alpha}}{\frac{1}{\alpha}}}{1 + \frac{x}{\alpha}} \right) = \lim_{\alpha \rightarrow +\infty} \frac{2x - 3 + 4x \frac{1}{\alpha} + \frac{2}{\alpha^2}}{1 + \frac{x}{\alpha}} \cdot \lim_{\frac{1}{\alpha} \rightarrow 0} \frac{\sin \frac{1}{\alpha}}{\frac{1}{\alpha}} = 2x - 3.$$

This proves that  $g(x) = 2x - 3$ , i.e.,  $g(x)$  represents a line. It remains to prove the second claim. Observe that  $y = 2x - 3$  pass through  $A$ . Let  $M = [x_M, y_M]$  be the middle point of the segment  $BC$ . This has coordinates  $x_M = (6 + (-2))/2 = 2$  and  $y_M = (2 + 0)/2 = 1$ . These coordinates also lie on the line  $y = 2x - 3$ , and hence  $y = g(x)$  is a median of  $ABC$ .

**5.B.37.** (a) We see that

$$\lim_{x \rightarrow +\infty} \frac{3^{x+1} + x^5 - 4x}{3^x + 2^x + x^2} = \lim_{x \rightarrow +\infty} \frac{3 \cdot 3^x}{3^x} = 3.$$

(b) Here one computes

$$\lim_{x \rightarrow +\infty} \frac{4^x - 8x^6 - 2^x - 167}{3^x - 45x - \sqrt{11}\pi^{x+12}} = \lim_{x \rightarrow +\infty} \frac{4^x}{-\sqrt{11}\pi^{12} \cdot \pi^x} = -\infty.$$

(c) In view of the formula  $(a - b)(a + b) = a^2 - b^2$ , we have

$$\lim_{x \rightarrow 0} \frac{\sqrt{1+x} - \sqrt{1-x}}{x} = \lim_{x \rightarrow 0} \frac{(1+x) - (1-x)}{x(\sqrt{1+x} + \sqrt{1-x})} = \lim_{x \rightarrow 0} \frac{2}{\sqrt{1+x} + \sqrt{1-x}} = \frac{2}{\sqrt{1} + \sqrt{1}} = 1.$$

(d) Similarly we see that

$$\begin{aligned} \lim_{x \rightarrow \pi/4} \frac{\cos x - \sin x}{\cos(2x)} &= \lim_{x \rightarrow \pi/4} \frac{(\cos x + \sin x)(\cos x - \sin x)}{(\cos x + \sin x) \cos(2x)} = \lim_{x \rightarrow \pi/4} \frac{\cos^2 x - \sin^2 x}{(\cos x + \sin x) \cos(2x)} \\ &= \lim_{x \rightarrow \pi/4} \frac{1}{\cos x + \sin x} = \frac{1}{\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}} = \frac{\sqrt{2}}{2}. \end{aligned}$$

Notice the reduction above was made thanks to the identity  $\cos(2x) = \cos^2(x) - \sin^2(x)$ , where  $x \in \mathbb{R}$ .

**5.B.42.** For the function  $f$  we have  $f(x) = x^x = e^{\ln(x^x)} = e^{x \ln(x)}$ . Thus  $f$  is continuous as the composition of the continuous functions  $y_1 = e^x$  and  $y_2 = x \ln(x)$ . Similarly,  $g(x) = x^{\cos(x)} = e^{\cos(x) \ln(x)}$  and  $g$  is continuous as the composition of two continuous functions, namely  $y_1 = e^x$  and  $y_3 = \cos(x) \ln(x)$ .

**5.B.43.** Since  $f, g$  are continuous the given relation means that  $4 \cdot f(2) - g(2) = 2$ , and so  $g(2) = 22$ .

**5.B.44.** We have already seen such an example in 5.B.34. We mean the sign function  $f(x) = \text{sign}(x)$ , which has a ‘‘bump discontinuity’’ at  $x = 0$ . As we have explained in 5.B.34, essentially this is because  $\lim_{x \rightarrow 0^+} f(x) = 1 \neq \lim_{x \rightarrow 0^-} f(x) = -1$ . Sketch the graph of  $f$  to illustrate the situation.

**5.B.46.** The function  $1/x$  is continuous for all  $x \in \mathbb{R} \setminus \{0\}$ , and the function  $\sin(x)$  is continuous for all  $x \in \mathbb{R}$ . Thus the function  $f$  is continuous on the set  $(-\infty, 0) \cup (0, +\infty)$ , i.e., everywhere on  $\mathbb{R}$  except at  $x_0 = 0$ . In particular, at  $x_0 = 0$  it is easy to see that the limit of  $f$  does not exist. The function  $g$  is similar to  $f$ , except of that the oscillations are absorbed by the factor  $x$ . We see that  $-|x| \leq x \sin(\frac{1}{x}) \leq |x|$  and thus by the squeeze theorem we get  $\lim_{x \rightarrow 0} g(x) = 0$ . In particular,  $g$  is continuous everywhere on  $\mathbb{R}$ .

**5.B.49.** The family has the form

$$f_{\alpha,\beta}(x) = \begin{cases} \frac{\sqrt{2x^2 - x + 6} - \alpha x}{x + 2}, & \text{for } x < -2, \\ x^3 + \beta x + 4, & \text{for } x \geq -2, \end{cases}$$

and we see that for all  $x < -2$  the expression  $2x^2 - x + 6$  is positive (and hence  $f_{\alpha,\beta}$  is well-defined). We require the continuity of  $f_{\alpha,\beta}$  at any  $x \in \mathbb{R}$  and hence also at  $x_0 = -2$ , which is equivalent to the condition  $\lim_{x \rightarrow -2^-} f_{\alpha,\beta}(x) = f_{\alpha,\beta}(-2) = \lim_{x \rightarrow -2^+} f_{\alpha,\beta}(x)$ . Then we see that

$$\ell := \lim_{x \rightarrow -2^-} (f_{\alpha,\beta}(x) \cdot (x + 2)) = f_{\alpha,\beta}(-2) \cdot 0 = 0.$$

On the other hand, from the definition of  $f$  and  $\ell$ , we get

$$\ell = \lim_{x \rightarrow -2^-} (\sqrt{2x^2 - x + 6} - \alpha x) = \sqrt{\lim_{x \rightarrow -2^-} (2x^2 - x + 6)} - \lim_{x \rightarrow -2^-} (\alpha x) = 4 + 2\alpha.$$

Thus,  $4 + 2\alpha = 0$ , i.e.,  $\alpha = -2$ . Using this value, we compute

$$\begin{aligned} \lim_{x \rightarrow -2^-} f_{-2,\beta}(x) &= \lim_{x \rightarrow -2^-} \frac{\sqrt{2x^2 - x + 6} + 2x}{x + 2} = \lim_{x \rightarrow -2^-} \frac{2x^2 - x + 6 - 4x^2}{(x + 2)(\sqrt{2x^2 - x + 6} - 2x)} \\ &= \lim_{x \rightarrow -2^-} \frac{-2x^2 - x + 6}{(x + 2)(\sqrt{2x^2 - x + 6} - 2x)} = \lim_{x \rightarrow -2^-} \frac{(x + 2)(-2x + 3)}{(x + 2)(\sqrt{2x^2 - x + 6} - 2x)} \\ &= \lim_{x \rightarrow -2^-} \frac{(-2x + 3)}{(\sqrt{2x^2 - x + 6} - 2x)} = \frac{7}{8}. \end{aligned}$$

On the other hand,  $f_{\alpha,\beta}(-2) = -2(b + 2)$  and we arrive to the equation  $\frac{7}{8} = -2(b + 2)$ , that is,  $b = -\frac{39}{16}$ . Thus only the member  $f_{-2,-\frac{39}{16}}$  is continuous.

Using Sage we can define piecewise functions with many different ways. For instance one can combine the `def` command with `if` and `else`, as follows:

```
def f(x) :
    if x<-2 :
        return((sqrt(2*x^2-x+6)+2*x)/(x+2))
    else :
        return(x^3-(39/16)*x+4)
```

Now, to view  $f$  combine any of the `print` or `show` rules, with the `assume` command. Thus, for example, adding the syntax `assume(x < -2); show(f(x))` will give the first component of  $f$ , and similarly for the second, where instead one should type `assume(x >= -2)`. To evaluate  $f$  at different points  $x \in \mathbb{R}$  just type `f(-4)`, `f(-2)`, `f(0)`, etc. As for the continuity you can add the commands

```
show(bool(limit(f(x), x=-2, dir="+")==f(-2)))
show(bool(limit(f(x), x=-2, dir="-")==f(-2)))
```

or simply type

```
show(bool(limit(f(x), x=-2)==f(-2)))
```

Finally, to sketch the graph of  $f$  add the cell

```
plot(f, x, -10, 10, ymax=8, color="black")
```

The produced figure is here:

Another way to determine  $f$  and sketch its graph relies on the piecewise function in Sage, which we analyze in 5.C.5. Note that this method currently has some limitations (e.g., in computing limits) and Sage requires a significant amount of time to return an answer (see however in 5.C.5 and 6.D.43 for further details).

**5.B.51.** The given polynomial has at least two roots in  $(-1, 1)$ , This is because  $P(-1) > 0$ ,  $P(0) < 0$ ,  $P(1) > 0$  and thus there must be at least one root in each of these two subintervals, see also 5.2.19.

**5.B.52.** The solution is based on applying Bolzano's theorem via Sage, which goes as follows:

```
f(x) = x^3 - cos(x)*e^x + x*sin(x)
show(f(0)); show(f(pi/2))
```

Sage gives  $f(0) = -1 < 0$  and  $f(1) = \frac{\pi^3}{8} + \frac{\pi}{2} > 0$ , and hence by Bolzano's theorem  $f$  has at least a root in  $(0, \pi/2)$ . As for the implementation of the `find_root` function, just add the syntax `find_root(f, 0, pi/2)`. Sage's answer is 0.9221778114841418.

**5.C.1.** For  $f(x)$ , using the binomial theorem one computes

$$\begin{aligned} (x^n)' &= \lim_{h \rightarrow 0} \frac{(x+h)^n - x^n}{h} = \lim_{h \rightarrow 0} \frac{\binom{n}{1}x^{n-1}h + \binom{n}{2}x^{n-2}h^2 + \cdots + h^n}{h} = \\ &= nx^{n-1} + \lim_{h \rightarrow 0} \left( \binom{n}{2}x^{n-2}h + \cdots + h^{n-1} \right) = nx^{n-1}. \end{aligned}$$

For the derivative of  $g(x)$  we rely on identities from trigonometry, as those for  $\sin(x+h)$  and the results from 5.B.31 and 5.B.32, that is,  $\lim_{h \rightarrow 0} \frac{\sin h}{h} = 1$  and  $\lim_{h \rightarrow 0} \frac{\cos h - 1}{h} = 0$ , respectively. We have

$$\begin{aligned} (\sin(x))' &= \lim_{h \rightarrow 0} \frac{\sin(x+h) - \sin(x)}{h} = \lim_{h \rightarrow 0} \frac{\sin(x)\cos(h) + \cos(x)\sin(h) - \sin(x)}{h} = \\ &= \cos(x) \lim_{h \rightarrow 0} \frac{\sin(h)}{h} + \sin(x) \lim_{h \rightarrow 0} \frac{(\cos(h) - 1)}{h} = \cos(x) \cdot 1 + \sin(x) \cdot 0 = \cos(x). \end{aligned}$$

Similarly is treated the square root function  $h(x) = \sqrt{x} = x^{1/2}$ , which is left as an exercise. Here one can show that  $h'(x) = \frac{1}{2\sqrt{x}}$  for all  $x \neq 0$ , but  $f$  is not differentiable at  $x = 0$  (verify this claim by computing the left and right derivatives).

Note that the derivative of the first given function generalizes as  $(x^a)' = ax^{a-1}$ , for all  $x \in \mathbb{R}$  and all  $a > 0$ . When  $a$  is negative, we can use the relation  $(x^a)' = ax^{a-1}$  only for  $x \neq 0$ . These rules provide a way to compute  $h'(x)$  for  $x \neq 0$ :

$$(\sqrt{x})' = (x^{1/2})' = \frac{1}{2}x^{1-1/2} = \frac{1}{2}x^{-1/2} = \frac{1}{2x^{1/2}} = \frac{1}{2\sqrt{x}}.$$

**5.C.2.** The claim is based on the properties of  $f$  and occurs by the definition of the derivative of  $f$ , as follows:

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{f(x)f(h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{f(x)(f(h) - 1)}{h} = f(x) \cdot \lim_{h \rightarrow 0} \frac{f(h) - 1}{h} \\ &= f(x) \cdot \lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = f(x) \cdot f'(0) = f(x) \cdot 1 = f(x). \end{aligned}$$

**5.C.3.** Recall that

$$f(x) = \begin{cases} x, & \text{if } x \geq 0, \\ -x, & \text{if } x < 0. \end{cases}$$

Thus,  $f'(x) = 1$  for  $x > 0$  and  $f'(x) = -1$  for  $x < 0$ . For instance, for  $x > 0$  we can choose  $h$  small enough such that  $x + h > 0$ , and then

$$f'(x) = \lim_{h \rightarrow 0} \frac{|x+h| - |x|}{h} = \lim_{h \rightarrow 0} \frac{x+h-x}{h} = 1.$$

Similarly for  $x < 0$ . At  $x_0 = 0$  the function  $f$  cannot be differentiable, since the left-side derivative does not agree with the right-side derivative:

$$\lim_{x \rightarrow 0^+} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^+} \frac{x - 0}{x} = 1, \quad \lim_{x \rightarrow 0^-} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^-} \frac{-x - 0}{x} = -1.$$

Hence  $f'(0)$  does not exist (and this is what we should expect since the graph of  $f$  forms a corner at 0).

**5.C.4.** If  $f$  is differentiable at  $x_0$ , then the limit  $\lim_{x \rightarrow x_0} \frac{f(x) - f(x_0)}{x - x_0}$  exists and equals to  $f'(x_0)$ . Thus we also have

$$(x - x_0) \cdot f'(x_0) = (x - x_0) \cdot \lim_{x \rightarrow x_0} \frac{f(x) - f(x_0)}{x - x_0}.$$

Consider now the limits in both sides as  $x$  tends to  $x_0$ . In the l.h.s we obtain a zero, since  $\lim_{x \rightarrow x_0} ((x - x_0) \cdot f'(x_0)) = f'(x_0) \cdot \lim_{x \rightarrow x_0} (x - x_0) = f'(x_0) \cdot 0 = 0$ . For the limit in the r.h.s we write altogether

$$0 = \lim_{x \rightarrow x_0} (x - x_0) \cdot \lim_{x \rightarrow x_0} \frac{f(x) - f(x_0)}{x - x_0} = \lim_{x \rightarrow x_0} \left( (x - x_0) \cdot \frac{f(x) - f(x_0)}{x - x_0} \right) = \lim_{x \rightarrow x_0} (f(x) - f(x_0)),$$

which implies that  $\lim_{x \rightarrow x_0} f(x) = f(x_0)$ . Therefore,  $f$  is continuous at  $x_0$ .

**5.C.6.** In order to use the derivative  $\sin'(x) = \cos(x)$  and the chain rule, we first need to use the identity  $\cos(x) = \sin(x + \frac{\pi}{2})$ . This allows us to view  $\cos(x)$  as the composition  $\cos(x) = f(g(x))$ , with  $f(x) = \sin(x)$  and  $g(x) = x + \frac{\pi}{2}$ , respectively. Then, by the chain rule we get

$$(\cos(x))' = g'(x) \cdot f'(g(x)) = 1 \cdot \cos(x + \frac{\pi}{2}) = \cos(x) \cos(\pi/2) - \sin(x) \sin(\pi/2) = 0 - \sin(x) = -\sin(x).$$

**5.C.10.** We have  $f(1) = \alpha$  and since  $f'(x) = 2\alpha x - 4 \ln(x) - 4$ , it follows that  $f'(1) = 2\alpha - 4$ . Thus the tangent of  $f$  at the point  $P = [1, \alpha]$  is given by

$$y - \alpha = (2\alpha - 4)(x - 1) \iff y = (2\alpha - 4)x - \alpha + 4.$$

We finally see that this line passes through  $[0, 0]$  if and only if  $0 = (2\alpha - 4) \cdot 0 - \alpha + 4$ , that is,  $\alpha = 4$ .

**5.C.13.** The answer is  $y = 2 - x$ ;  $y = x$ .

**5.C.16.** It is useful to recall that the tangent function  $\tan(x) = \sin(x)/\cos(x)$  is not defined at any  $x = \frac{\pi}{2} + \kappa\pi$ , with  $\kappa \in \mathbb{Z}$ . Let us first plot  $\tan(x)$  (in fact, let us present the graph of a periodic extension of the tangent function on  $(-3\pi/2, 3\pi/2)$ ).

To obtain this we used Sage via the following block:

```
p=plot(tan(x), x, -pi/2, pi/2, ymax=5, ymin=-5, color="black")
p+=plot(tan(x-pi), x, -3*pi/2, -pi/2, ymax=5, ymin=-5, color="black",
detect_poles="False")
p+=plot(tan(x+pi), x, pi/2, 3*pi/2, ymax=5, ymin=-5, color="black",
detect_poles="False")
p.show(ticks=pi/2, tick_formatter=pi, aspect_ratio="1")
```

In this block ensure to include the options  $y_{\max}=5$ ,  $y_{\min}=-5$  for plotting correctly the tangent function. From the figure, it is evident that  $\tan(x)$  is strictly increasing for all  $x \in (-\pi/2, \pi/2)$ . Let us substantiate this claim rigorously with a mathematical proof.

Let  $x_1, x_2$  be real numbers such that  $-\frac{\pi}{2} < x_1 < x_2 < \frac{\pi}{2}$ . Based on the identity  $\sin(\alpha - \beta) = \sin(\alpha)\cos(\beta) - \sin(\beta)\cos(\alpha)$  we see that

$$\tan(x_2) - \tan(x_1) = \frac{\sin(x_2)}{\cos(x_2)} - \frac{\sin(x_1)}{\cos(x_1)} = \frac{\sin(x_2)\cos(x_1) - \sin(x_1)\cos(x_2)}{\cos(x_1)\cos(x_2)} = \frac{\sin(x_2 - x_1)}{\cos(x_1)\cos(x_2)} > 0,$$

since  $0 < x_2 - x_1 < \pi$ . Thus, for  $x_1 < x_2$  we have

$$\tan(x_2) - \tan(x_1) > 0 \iff \tan(x_1) < \tan(x_2) \iff f(x_1) < f(x_2),$$

which shows that the tangent function is increasing on  $(-\pi/2, \pi/2)$ . Alternatively, we can compute the first derivative of  $f$ , given by  $f'(x) = \tan'(x) = \frac{1}{\cos^2(x)}$  (see 5.E.76). Thus for any  $x \in (-\pi/2, \pi/2)$  we get  $f'(x) > 0$  and our claim follows.

**5.C.19.** The answer is given by  $\frac{\pi}{6} - \frac{2}{\sqrt{3}} 0.003$ .

**5.C.20.** The answers are  $\frac{1}{2} - \frac{\sqrt{3}\pi}{360}$  and  $\frac{\sqrt{2}}{2} + \frac{\sqrt{2}\pi}{360}$ , respectively.

**5.C.24.** The function  $f$  is continuous on its domain  $[-2, 2]$ . We have  $f'(x) = \frac{2}{3}x^{-\frac{1}{3}} = \frac{2}{3x^{1/3}}$ . Thus  $f'$  is not defined at  $x_0 = 0$ . Since  $x_0 \in (-2, 2)$ , this means that we cannot apply the mean value theorem. In the opposite, for the functions  $g, h$  the mean value theorem applies. Indeed,  $g$  is continuous on  $[1, 4]$  with  $g'(x) = \frac{1}{(x+1)^2}$ . Thus  $g$  is also differentiable on the open interval  $(1, 4)$  and according to the Theorem 5.3.9 there exists  $c \in (1, 4)$  satisfying  $g'(c) = \frac{g(4)-g(1)}{4-1} = \frac{4/5-1/2}{3} = \frac{1}{10}$ . From this we get  $(1+c)^2 = 10$ , that is,  $c = \pm\sqrt{10}-1$  and since  $c \in (1, 4)$  we can accept only the value  $c = \sqrt{10}-1 \approx 2.163$ . Similarly is treated the case for  $h$ .

**5.C.26.** It is sufficient to apply Cauchy's mean value theorem for the functions  $f(x) = x^{n+1}$  and  $g(x) = x^n$ , which are both continuous on  $[a, b]$ , and differentiable on  $(a, b)$ . Also, by assumption  $0 \notin (a, b)$  and hence  $g'(x) = nx^{n-1} \neq 0$  for all  $x \in (a, b)$ . Thus  $f, g$  satisfy the requirements of the Cauchy's mean value theorem. This gives that  $g(b) \neq g(a)$  and moreover there exists  $c \in (a, b)$  such that

$$\frac{f(b) - f(a)}{g(b) - g(a)} = \frac{f'(c)}{g'(c)} \iff \frac{b^{n+1} - a^{n+1}}{b^n - a^n} = \frac{(n+1)c^n}{nc^{n-1}} \iff \frac{n}{n+1} \left( \frac{b^{n+1} - a^{n+1}}{b^n - a^n} \right) = c,$$

for any  $n \in \mathbb{N} \setminus \{0\}$ . Since  $c \in (a, b)$  we are done.

**5.C.31.** (a)  $v(0) = 6$  m/s; (b)  $t = 3$  s,  $s(3) = 16$  m; (c)  $v(4) = -2$  m/s,  $a(4) = -2$  m/s<sup>2</sup>.

**5.C.34.** Such an example occurs by considering the limit  $\lim_{x \rightarrow 0} \frac{\sin(x)}{x+1}$ , which obviously equals to 0 and is not of some indeterminate form. Another example is the limit  $\lim_{x \rightarrow 0} \frac{\sin(x)}{e^x}$ .

**5.D.2.** Often, we may use Sage to evaluate convergent infinite series, or verify summation identities. Recall from Chapter 1 that this can be done via the command `sum`, whose general form is `sum(f(n), n, a, b)` (formally, this corresponds to the sum  $\sum_{n=a}^b f(n)$ ). Of course, one can replace `b` by `Infinity` or its alias `oo`, and this corresponds to infinite sums. This method can be applied for example when one tries to evaluate the zeta function  $\zeta(p)$ , for certain  $p$ , as in our example. In particular, an explicit implementation of our task goes as follows:

```
var("n")
show(sum(1/n^2, n, 1, oo))
show(sum(1/n^3, n, 1, oo))
show(sum(1/n^4, n, 1, oo))
show(sum(1/n^5, n, 1, oo))
show(sum(1/n^6, n, 1, oo))
show(sum(1/n^7, n, 1, oo))
show(sum(1/n^8, n, 1, oo))
show(sum(1/n^9, n, 1, oo))
```

Let us put Sage's output in a table:

$p$	$\zeta(p)$	$p$	$\zeta(p)$
2	$\pi^2/6$	3	$\zeta(3)$
4	$\pi^4/90$	5	$\zeta(5)$
6	$\pi^6/945$	7	$\zeta(7)$
8	$\pi^8/9450$	9	$\zeta(9)$

Hence Sage is able to evaluate explicitly  $\zeta(p)$  for  $p = 2, 4, 6, 8$ . However, as we expected, Sage is unable to compute the cases  $p = 3, 5, 7, 9$ . In these instances, Sage indicates that the sum we are trying to evaluate corresponds to the zeta function.

We will encounter further related applications in the sequel (see for example 5.D.8).

**5.D.7.** The series  $S_1$  converges absolutely. For instance, we see that

$$\sum_{n=1}^{\infty} \left| \frac{\sin(n)}{n^2} \right| \leq \sum_{n=1}^{\infty} \frac{1}{n^2} < \sum_{n=0}^{\infty} \frac{1}{2^n} = 2.$$

Passing to  $S_2$ , one observes that this is an alternating series (since  $\cos(\pi n) = (-1)^n$ ,  $n \in \mathbb{N}$ ). Moreover, we see that the sequence of the absolute values of its terms is decreasing, and  $\lim_{n \rightarrow \infty} \frac{1}{\sqrt[3]{n^2}} = 0$ . It follows that the series  $S_2$  is convergent. In addition, we see that

$$\sum_{n=1}^{\infty} \left| \frac{\cos(\pi n)}{\sqrt[3]{n^2}} \right| = \sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n^2}} \geq \sum_{n=1}^{\infty} \frac{1}{n} = +\infty,$$

which implies that  $S_2$  converges also conditionally.

**5.D.9.** We see that

$$1 \leq 1, \quad \frac{1}{2^2} + \frac{1}{3^2} < 2 \cdot \frac{1}{2^2} = \frac{1}{2}, \quad \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{6^2} + \frac{1}{7^2} < 4 \cdot \frac{1}{4^2} = \frac{1}{4}, \quad \dots,$$

and more general

$$\frac{1}{(2^n)^2} + \dots + \frac{1}{(2^{n+1} - 1)^2} < 2^n \cdot \frac{1}{(2^n)^2} = \frac{1}{2^n}, \quad n = 1, 2, \dots$$

Hence, by comparing the terms of both of the series, we get the required inequality. By the way, notice that from this inequality it follows that the series  $\sum_{n=1}^{\infty} \frac{1}{n^2}$  converges absolutely. Eventually, let us specify that

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6} < 2 = \sum_{n=0}^{\infty} \frac{1}{2^n}.$$

**5.D.15.** The radius of convergence equals to  $r = +\infty$ .

**5.D.16.** The radius of convergence equals to 1.

**5.D.17.** The domain of convergence is the closed interval  $[-1, 1]$ .

**5.D.18.** The answer is  $x \in [2 - \frac{1}{3}, 2 + \frac{1}{3}]$ .

**5.D.19.** The series converges for all  $x \in [-\sqrt[3]{2}, \sqrt[3]{2}]$ .

**5.D.20.** The series converges for all  $x \in [-1, 1]$

**5.E.3.** The obvious answer is  $x^2$ .

**5.E.4.** The natural cubic spline interpolating the given data is given by  $S_1(x) \equiv x$ ;  $S_2(x) \equiv x$ .

**5.E.5.** The complete cubic interpolation spline in question is given by  $S_i(x) = x + 3$ ,  $x \in [-3 + i - 1, -3 + i]$ ;  $i \in \{1, 2\}$ .

**5.E.6.** The mentioned values are given by  $\cos^2(\frac{\pi}{4}) = 1/2$ ,  $\cos^2(\frac{\pi}{3}) = 1/4$ ,  $\cos^2(\frac{\pi}{2}) = 0$ . Since the third value is zero, we need to compute only the values of the first two elementary Lagrange polynomials at the given points. Based on the definition of such polynomials and the given data, it follows that

$$\ell_0(1) = \frac{(1 - \frac{\pi}{3})(1 - \frac{\pi}{2})}{(\frac{\pi}{4} - \frac{\pi}{3})(\frac{\pi}{4} - \frac{\pi}{2})} = 8 \frac{(\pi - 3)(\pi - 2)}{\pi^2}, \quad \ell_1(1) = \frac{(1 - \frac{\pi}{4})(1 - \frac{\pi}{2})}{(\frac{\pi}{3} - \frac{\pi}{4})(\frac{\pi}{3} - \frac{\pi}{2})} = -9 \frac{(\pi - 4)(\pi - 2)}{\pi^2}.$$

Thus, we deduce that

$$P(1) = \frac{1}{2} \cdot 8 \frac{(\pi - 3)(\pi - 2)}{\pi^2} - \frac{1}{4} \cdot 9 \frac{(\pi - 4)(\pi - 2)}{\pi^2} + 0 = \frac{(7\pi - 12)(\pi - 2)}{4\pi^2} \approx 0.288913.$$

Note that the actual value is approximately  $\cos^2 1 \approx 0.291927$ .

**5.E.8.** Such a polynomial is given by  $x^4 + 2x^3 - x^2 + x - 2$ .

**5.E.15.** Consider any singleton (one-element set)  $X \subset \mathbb{R}$ .

**5.E.16.** The set  $C$  must be a singleton. Thus, let us choose  $C = \{0\}$ , for example. Now as  $A, B$  we can take the open subsets  $A = (-1, 0)$ , and  $B = (0, 1)$ , respectively.

**5.E.19.** Using the properties of powers one can express the general term of the given sequence as

$$a_n = \left(\sqrt{2} \cdot \sqrt[4]{2} \cdot \sqrt[8]{2} \cdots \sqrt[2^n]{2}\right) = 2^{\frac{1}{2}} \cdot 2^{\frac{1}{4}} \cdot 2^{\frac{1}{8}} \cdots 2^{\frac{1}{2^n}} = 2^{\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \cdots + \frac{1}{2^n}}.$$

Thus, in combination with the continuity of the exponential function (a property discussed in the paragraph 5.2.22), we get

$$\lim_{n \rightarrow \infty} a_n = 2^{\lim_{n \rightarrow \infty} \left(\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \cdots + \frac{1}{2^n}\right)} = 2^{\left(\sum_{n=1}^{\infty} \frac{1}{2^n}\right)}.$$

Next we use a known formula for the sum of geometric series:  $\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n = \frac{1}{2} \cdot \frac{1}{1 - \frac{1}{2}} = 1$ . Thus finally  $\lim_{n \rightarrow \infty} a_n = 2$ .

Notice in Sage we can simply type

```
n=var("n"); b=2**(sum(1/2**n, n, 1, oo)); b
```

which answers 2, and the claim follows.

**5.E.20.** Notice that every natural number  $k \geq 2$  satisfies the relation  $\frac{1}{(k-1)k} = \frac{1}{k-1} - \frac{1}{k}$ . (this identity is a special case of the so called partial fraction decomposition). Therefore, we compute

$$\begin{aligned} \lim_{n \rightarrow \infty} \left(\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{(n-1) \cdot n}\right) &= \lim_{n \rightarrow \infty} \left(\frac{1}{1} - \frac{1}{2} + \frac{1}{2} - \frac{1}{3} + \frac{1}{3} - \frac{1}{4} + \cdots + \frac{1}{n-1} - \frac{1}{n}\right) \\ &= \lim_{n \rightarrow \infty} \left(1 - \frac{1}{n}\right) = 1. \end{aligned}$$

Let us mention that this limit determines the sum of one of the so-called “telescoping series” (used by J. Bernoulli already about 300 years ago). In Sage we can verify the result as usual, i.e., by the cell

```
var("i, n"); limit(sum(1/(i*(i+1)), i, 1, n), n=oo)
```

**5.E.21.** We see that

$$\lim_{n \rightarrow \infty} \left(\frac{1}{n^2} + \frac{2}{n^2} + \cdots + \frac{n-2}{n^2} + \frac{n-1}{n^2}\right) = \lim_{n \rightarrow \infty} \left(\frac{1+n-1}{n^2} \cdot \frac{n-1}{2}\right) = \frac{1}{2}.$$

In Sage we can type `limit(sum(i/n**2, i, 1, n-1), n=oo)`, which provides a quick confirmation of our computation.

**5.E.23.** For these tasks one relies on the relation  $\lim_{n \rightarrow \infty} \left(1 + \frac{a}{n}\right)^n = e^a$ , where  $a \in \mathbb{R}$ , see 5.B.18. This means that

$$e^{-1} = \frac{1}{e} = \lim_{n \rightarrow \infty} \left(1 - \frac{1}{n}\right)^n = \lim_{n \rightarrow \infty} \left(\frac{n-1}{n}\right)^n.$$

Thus, the substitution  $m = n - 1$  gives

$$\lim_{n \rightarrow \infty} \left(\frac{n-1}{n}\right)^n = \lim_{m \rightarrow \infty} \left(\frac{m}{m+1}\right)^{m+1} = \lim_{m \rightarrow \infty} \left(\frac{m}{m+1}\right)^m \cdot \lim_{m \rightarrow \infty} \frac{m}{m+1}.$$

Clearly, the second limit is equal to 1 and replacing  $n$  with  $m$  we get the result

$$\frac{1}{e} = \lim_{n \rightarrow \infty} \left(\frac{n}{n+1}\right)^n.$$

In Sage we can easily verify this by typing `n = var("n"); f(n) = (n/(n+1))n; lim(f(n), n=oo)`. For the second limit we see that

$$\lim_{n \rightarrow \infty} \left(1 + \frac{1}{n^2}\right)^n = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n^2}\right)^{\frac{n^2}{n}} = \lim_{n \rightarrow \infty} \left(\left(1 + \frac{1}{n^2}\right)^{n^2}\right)^{\frac{1}{n}} = e^0 = 1.$$

For the third limit we will apply only Sage and leave to the reader the formal details. Hence type

```
n=var("n"); g(n)=(1-1/n)**(n^2); lim(g(n), n=oo)
```

This returns the value 0.

**5.E.27.** (a) We have  $a > 0$ , thus we also get  $0 < na < na + 1$  and  $0 < \frac{1}{na+1} < \frac{1}{na}$ , for all positive  $n$ . This gives

$$\left|\frac{1}{1+na} - 0\right| = \left|\frac{1}{1+na}\right| = \frac{1}{1+na} < \frac{1}{na} = \frac{1}{a} \cdot \frac{1}{n}, \quad \text{for all } n = 1, 2, \dots$$

As the sequence  $(1/n)$  tends to 0 and  $1/a > 0$ , the inequality obtained above allows us to invoke the result from 5.E.25, with  $n \geq N = 1$ . Thus  $\lim_{n \rightarrow \infty} \left(\frac{1}{1+na}\right) = 0$ .

(b) Obviously, the sequence  $(a_n)$  with general term  $a_n = \frac{x^n}{n!}$  satisfies  $a_n \neq 0$  for all  $n$ . Moreover,

$$\ell = \lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n \rightarrow \infty} \left| \frac{x^{n+1}}{(n+1)!} \cdot \frac{n!}{x^n} \right| = \lim_{n \rightarrow \infty} \left| \frac{x}{n+1} \right| = 0 < 1.$$

Thus, by the second result in 5.E.26 we get  $\lim_{n \rightarrow \infty} \frac{x^n}{n!} = 0$ , for all  $x \in \mathbb{R}$ .

**5.E.31.** By definition,  $x_1 = 1 > 0$ . Assuming that  $x_n > 0$  for some  $n$ , we get  $x_{n+1} = 1/(4 + x_n) > 0$ . Thus, by induction we see that  $(x_n)$  is a positive sequence, that is,  $x_n > 0$  for all  $n$ . Using this, for all  $n \geq 2$  one computes

$$|x_{n+1} - x_n| = \left| \frac{1}{4 + x_n} - \frac{1}{4 + x_{n-1}} \right| = \left| \frac{x_{n-1} - x_n}{(4 + x_n)(4 + x_{n-1})} \right| = \frac{|x_{n-1} - x_n|}{(4 + x_n)(4 + x_{n-1})} < \frac{1}{16} |x_n - x_{n-1}|,$$

Thus  $(x_n)$  is a contractive sequence and by 5.E.30 it is Cauchy, and hence convergent.

**5.E.32.** Obviously,  $\{a_k : k \geq n + 1\} \subseteq \{a_k : k \leq n\}$  and hence  $m_{n+1} = \sup\{a_k : k \geq n + 1\} \leq \sup\{a_k : k \geq n\} = m_n$ . This shows that the sequence  $(s_n)$  is decreasing. Similarly, the sequence  $(\ell_n)$  is increasing, since  $\ell_n \leq \inf\{a_k : k \geq n + 1\} = \ell_{n+1}$ , see also the discussion in 5.4.6. By assumption,  $(a_n)$  is bounded hence  $(s_n)$  and  $(\ell_n)$  are also bounded, and the result follows by 5.B.11.

**5.E.36.** The naturals  $\mathbb{N}$  form a closed subset of  $\mathbb{R}$  (recall by 5.B.20 that there are no limit points). Another explanation occurs from the fact that any  $b \notin \mathbb{N}$  has got a small neighbourhood disjoint with  $\mathbb{N}$ . On the other hand, the subset  $\mathbb{Q} \subset \mathbb{R}$  is neither closed nor open. Indeed, in 5.B.20 we saw that the set of all limit points of  $\mathbb{Q}$  is the real line  $\mathbb{R}$ , so  $\mathbb{Q}$  cannot be closed. Moreover, we saw that there are no interior points, so  $\mathbb{Q}$  cannot be open.

**5.E.37.** (a) The open subsets are  $\mathbb{R}^*$  and  $\mathbb{R} \setminus \mathbb{Z}$ .

(b) Only the set  $[1, 2] \cup \{5\}$  is closed.

**5.E.47.** We will show that the sequence is strictly increasing and bounded, so from the monotonicity theorem (5.B.11), it should be convergent. Obviously,  $a_1 = \sqrt{2} \leq a_2 = \sqrt{2 + \sqrt{2}}$ . Assume that  $a_k < a_{k+1}$  for some  $k$ . Using the induction hypothesis we see that  $2 + a_k < 2 + a_{k+1}$ , or  $\sqrt{2 + a_k} < \sqrt{2 + a_{k+1}}$ , that is  $a_{k+1} < a_{k+2}$ . Hence,  $a_n < a_{n+1}$  for all  $n \in \mathbb{N}$ , which means that  $(a_n)_{n \in \mathbb{N}}$  is strictly increasing. Notice now that  $a_1 = \sqrt{2} < 2$ . If it is also  $a_{n-1} < 2$ , then we get  $2 + a_{n-1} < 4$ , that is,  $\sqrt{2 + a_{n-1}} < 2$ , or equivalently  $a_n < 2$ . Thus  $(a_n)$  is bounded and by the monotonicity theorem (5.B.11) it is convergent,  $\lim_{n \rightarrow +\infty} a_n = \sup\{a_n : n \in \mathbb{N}\} = 2$ . To verify this final conclusion, let  $x = \lim_{n \rightarrow +\infty} a_n$ . Then taking the limits in both sides of the relation  $a_n = \sqrt{2 + a_{n-1}}$  we see that  $\sqrt{x + 2} = x$ , which has two solutions ( $x = -1, x = 2$ ), and the acceptable is the positive one.

**5.E.49.** We have  $\lim_{x \rightarrow 0} \frac{\sin^2(x)}{x} = \lim_{x \rightarrow 0} \sin(x) \cdot \lim_{x \rightarrow 0} \frac{\sin(x)}{x} = 0 \cdot 1 = 0$ . Apparently,  $\lim_{x \rightarrow 0} \frac{x}{\sin(x)} = 1^{-1} = 1$  and the limit  $\lim_{x \rightarrow 0} \frac{1}{\sin(x)}$  does not exist. Similarly, using the rule for the limit of a product we see that the limit  $\lim_{x \rightarrow 0} \frac{x}{\sin^2(x)}$  does not exist.

For the calculation of the limit  $\lim_{x \rightarrow 0} \frac{\arcsin(x)}{x}$  use the identity  $x = \sin(\arcsin(x))$ , which makes sense for any  $x \in (-1, 1)$ .

This gives  $\lim_{x \rightarrow 0} \frac{\arcsin(x)}{x} = \lim_{x \rightarrow 0} \frac{\arcsin(x)}{\sin(\arcsin(x))} = \lim_{y \rightarrow 0} \frac{y}{\sin y} = 1$ , where we substitute  $y = \arcsin(x)$ . Observe that  $y \rightarrow 0$  follows from substituting  $x = 0$  into  $y = \arcsin(x)$  and from continuity of this function at 0 (this also guarantees that such a substitution can be made).

Next, see that

$$\lim_{x \rightarrow 0} \frac{3 \tan^2(x)}{5x^2} = \lim_{x \rightarrow 0} \left( \frac{3}{5} \cdot \frac{\sin(x)}{x} \cdot \frac{\sin(x)}{x} \cdot \frac{1}{\cos^2(x)} \right) = \frac{3}{5} \cdot \lim_{x \rightarrow 0} \frac{\sin(x)}{x} \cdot \lim_{x \rightarrow 0} \frac{\sin(x)}{x} \cdot \lim_{x \rightarrow 0} \frac{1}{\cos^2(x)} = \frac{3}{5} \cdot 1 \cdot 1 \cdot 1 = \frac{3}{5}.$$

For the next case it is useful to sketch the graph of the function  $\sin(3x)/\sin(5x)$ , via Sage. This is given by

This graph occurs via the following cell in Sage:

```
a=plot(sin(3*x)/sin(5*x), x, -2*pi, 2*pi, detect_poles="show", ymin=-10,ymax=10,
color="black")
b=point((0, 3/5), size = 70, color="black")
c=text("3/5", (0.4, 0.3), color="black", fontsize="10"); show(a+b+c)
```

As we see, the limit under question must be equal to  $3/5$ . Let us verify this in a formal way:

$$\lim_{x \rightarrow 0} \frac{\sin(3x)}{\sin(5x)} = \lim_{x \rightarrow 0} \left( \frac{\sin(3x)}{3x} \cdot \frac{5x}{\sin(5x)} \cdot \frac{3}{5} \right) = \lim_{x \rightarrow 0} \frac{\sin(3x)}{3x} \cdot \lim_{x \rightarrow 0} \frac{5x}{\sin(5x)} \cdot \frac{3}{5} = \lim_{y \rightarrow 0} \frac{\sin y}{y} \cdot \lim_{z \rightarrow 0} \frac{z}{\sin z} \cdot \frac{3}{5} = \frac{3}{5}.$$

For a confirmation via Sage, type `lim(sin(3*x)/sin(5*x), x = 0)`. We leave to the reader to show that the final limit equals to  $3/5$ , as well.

**5.E.50.** Based on the fact that  $\lim_{x \rightarrow 0} \frac{e^x - 1}{x} = 1$ , for the first limit we obtain

$$\lim_{x \rightarrow 0} \frac{e^{5x} - e^{2x}}{x} = \lim_{x \rightarrow 0} \left( e^{2x} \frac{e^{(5-2)x} - 1}{(5-2)x} (5-2) \right) = \lim_{x \rightarrow 0} e^{2x} \cdot \lim_{x \rightarrow 0} \frac{e^{3x} - 1}{3x} \cdot 3 = e^0 \cdot \lim_{y \rightarrow 0} \frac{e^y - 1}{y} \cdot 3 = 1 \cdot 1 \cdot 3 = 3.$$

In a similar way one computes the second limit, and we leave the details for practice. We present the solution in Sage and include in a figure both plots.

```
G(x) = (e**(5*x) - e**(2*x)) / x; E(x) = (e**(5*x) - e**(-x)) / sin(2*x); show(lim(E(x), x=0))
a=plot(E(x), x, -pi, pi, detect_poles="show", ymin=-2, ymax=4, color="black")
b=plot(G(x), x, -pi, pi, detect_poles="show", ymin=-2, ymax=4, color="grey")
show(a+b)
```

Executing this block we get the confirmation for the limit and desired illustration of the graphs, see here:

**5.E.52.** Obviously,  $\lim_{x \rightarrow +\infty} (2 + \frac{1}{x}) = 2$ ,  $\lim_{x \rightarrow +\infty} \frac{1}{x} = 0$  and  $\lim_{x \rightarrow +\infty} x = +\infty$ . Thus,  $\lim_{x \rightarrow +\infty} (2 + \frac{1}{x})^{\frac{1}{x}} = 2^0 = 1$  and  $\lim_{x \rightarrow +\infty} x^{-x} = \lim_{x \rightarrow +\infty} (\frac{1}{x})^x = 0$ . Equally well, we could first compute the limit  $\lim_{x \rightarrow +\infty} (\frac{1}{x} \cdot \ln(2 + \frac{1}{x})) = 0 \cdot \ln 2 = 0$ , and then, as a generalization of the formula

$$\lim_{x \rightarrow x_0} f(x)^{g(x)} = e^{\lim_{x \rightarrow x_0} (g(x) \ln(f(x)))},$$

we obtain  $\lim_{x \rightarrow +\infty} (2 + \frac{1}{x})^{\frac{1}{x}} = e^{\lim_{x \rightarrow +\infty} (\frac{1}{x} \cdot \ln(2 + \frac{1}{x}))} = e^0 = 1$ . Similarly, we see that  $\lim_{x \rightarrow +\infty} (-x \ln(x)) = -\infty$ , and hence

$$\lim_{x \rightarrow +\infty} x^{-x} = e^{\lim_{x \rightarrow +\infty} (-x \ln(x))} = e^{-\infty} = 0.$$

Finally one must be cautious when calculating the final limit. Both one-sided limits exist, but are different, which implies that this limit does not exist:  $\lim_{x \rightarrow 0^+} e^{\frac{1}{x}} = e^{\lim_{x \rightarrow 0^+} \frac{1}{x}} = e^\infty = \infty$  and  $\lim_{x \rightarrow 0^-} e^{\frac{1}{x}} = e^{\lim_{x \rightarrow 0^-} \frac{1}{x}} = e^{-\infty} = 0$ . In Sage one can directly solve the task by the cell

```
f(x)=(2+(1/x))**(1/x); g(x)=x**(-x); j(x)=e**(1/x)
show([lim(f(x),x=+oo), lim(g(x),x=+oo), lim(j(x),x=0)])
```

**5.E.53.** The first limit equals to  $+\infty$ . For the second one, after multiplying by the fraction  $\frac{\sqrt{x^2+x+x}}{\sqrt{x^2+x+x}}$  it follows that  $\lim_{x \rightarrow +\infty} (\sqrt{x^2+x} - x) = 1/2$ . For the third case we see that  $\lim_{x \rightarrow +\infty} (x \sqrt{1+x^2} - x^2) = 1/2$ . Finally,  $\lim_{x \rightarrow 0^-} \frac{\sqrt{1+\tan(x)} - \sqrt{1-\tan(x)}}{\sin(x)} = 1$ .

**5.E.54.** In Sage we can directly type

```
x, n=var("x, n"); f(x)=((1+2*n*x)**n-(1+n*x)**(2*n))/(x**2); lim(f(x), x=0)
```

and this returns the answer  $-n^3$ . To verify this in a formal way, we will use the binomial theorem. This gives

$$(1 + 2nx)^n = 1 + \binom{n}{1} 2nx + \binom{n}{2} (2nx)^2 + P(x) x^3, \quad (1 + nx)^{2n} = 1 + \binom{2n}{1} nx + \binom{2n}{2} (nx)^2 + Q(x) x^3,$$

for some polynomials  $P, Q$ . Let us emphasize on the fact that this really holds for all  $n \in \mathbb{N}^*$  (if  $n = 1$ , the polynomials  $P, Q$  as zero constants). So, for all  $x \in \mathbb{R}$  we obtain the relations

$$(1 + 2nx)^n = 1 + 2n^2x + 2n^3(n-1)x^2 + P(x)x^3, \quad (1 + nx)^{2n} = 1 + 2n^2x + n^3(2n-1)x^2 + Q(x)x^3.$$

Based on these formulas we are now able to present the result, as follows:

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{(1 + 2nx)^n - (1 + nx)^{2n}}{x^2} &= \lim_{x \rightarrow 0} \frac{(2n^3(n-1) - n^3(2n-1))x^2 + (P(x) - Q(x))x^3}{x^2} \\ &= \lim_{x \rightarrow 0} (-n^3 + (P(x) - Q(x))x) = -n^3 + 0 = -n^3. \end{aligned}$$

**5.E.55.** By the definition of  $(a_n)$  and based on the trigonometric inequality  $|\cos(x)| \leq 1$ , ( $x \in \mathbb{R}$ ), we see that

$$|a_{n+1} - a_n| = \left| \frac{\cos(n+1)}{2^{n+1}} \right| \leq \frac{1}{2^{n+1}} < \frac{1}{2^n}.$$

Thus  $|a_{n+1} - a_n| < \frac{1}{2^n}$  and it follows that  $(a_n)$  is a Cauchy sequence. Thus it converges (in fact one can show that a sequence  $(a_n)$  satisfying  $|a_{n+1} - a_n| < c^n$ , for some  $c$  with  $0 < c < 1$  and for all  $n \in \mathbb{Z}_+$ , is a Cauchy sequence).

**5.E.58.** First, let us calculate the one-sided limits at the point  $x_0 = 0$ :

$$\lim_{x \rightarrow 0^-} (x-1)^{-\operatorname{sgn}(x)} = \lim_{x \rightarrow 0^-} (x-1) = -1, \quad \lim_{x \rightarrow 0^+} (x-1)^{-\operatorname{sgn}(x)} = \lim_{x \rightarrow 0^+} \frac{1}{x-1} = -1,$$

whence  $\lim_{x \rightarrow 0} (x-1)^{-\operatorname{sgn}(x)} = -1$ . However, the function will be continuous at  $0 = 0$ , if and only if  $f(0) = -1$ . Recall by the solution given in 5.B.34 that for the sign function we have adopted the convention  $\operatorname{sgn}(0) = 0$ . Thus  $f(0) = (-1)^0 = 1$ , and the function at hand is not continuous at  $x_0 = 0$ . Similarly, for  $x = 1$  we obtain

$$\lim_{x \rightarrow 1^-} (x-1)^{-\operatorname{sgn}(x)} = \lim_{x \rightarrow 1^-} \frac{1}{x-1} = -\infty, \quad \lim_{x \rightarrow 1^+} (x-1)^{-\operatorname{sgn}(x)} = \lim_{x \rightarrow 1^+} \frac{1}{x-1} = \infty.$$

Hence both one-sided limits at the point 1 exist, yet they differ. Thus the limit  $\lim_{x \rightarrow 1} f(x)$  does not exist, and the function is not continuous at  $x_1 = 1$ , as well.

**5.E.59.** The function is continuous at the points  $-\pi, 0, \pi$ , only right-continuous at the point 2, only left-continuous at the point 3, and discontinuous at 1.

**5.E.60.** The function is continuous if and only if  $p = 2$ .

**5.E.61.** The answer is  $a = 4$ .

**5.E.62.** The given function is continuous at every point of its domain  $\mathbb{R} \setminus \{\pm 1\}$ . Thus, the extended function will be continuous if and only if

$$f(-1) = \lim_{x \rightarrow -1} \left( (x^2 - 1) \sin \frac{2x - 1}{x^2 - 1} \right), \quad f(1) = \lim_{x \rightarrow 1} \left( (x^2 - 1) \sin \frac{2x - 1}{x^2 - 1} \right),$$

such that the limits in the right hand side exist and are finite (if either of these limits did not exist, or are infinite, then  $f$  cannot be extended to a continuous function). Indeed, since any  $x \in \mathbb{R}$ ,  $x \neq \pm 1$  satisfies  $\left| \sin \left( \frac{2x-1}{x^2-1} \right) \right| \leq 1$ , it follows that

$$-|x^2 - 1| \leq f(x) \leq |x^2 - 1|, \quad \forall x \in \mathbb{R}, x \neq \pm 1.$$

Clearly  $\lim_{x \rightarrow \pm 1} |x^2 - 1| = 0$ , and by the squeeze theorem we get  $f(\pm 1) = 0$ .

**5.E.70.** If  $f : [a, b] \rightarrow \mathbb{R}$  is injective then we have  $f(a) \neq f(b)$ , and we may assume that  $f(a) < f(b)$  (otherwise consider  $-f$ ). We will show that  $f$  is strictly increasing. First we will show that for any  $x \in (a, b)$  we have  $f(a) < f(x) < f(b)$ . Assume in the contrary that  $f(x) \leq f(a)$  or  $f(x) \geq f(b)$ . Because  $f$  is injective we essentially assume that  $f(x) < f(a)$  or  $f(x) > f(b)$ .

*Case  $f(x) < f(a)$ :* This means that  $f(x) < f(a) < f(b)$  and by applying (the general version of) the intermediate value theorem for the restriction  $f|_{[x, b]}$  we find some  $x_0 \in (x, b)$  with  $f(x_0) = f(a)$ , a contradiction since  $f$  is injective.

*Case  $f(x) > f(b)$ :* This means that  $f(a) < f(b) < f(x)$  and by applying (the general version of) the intermediate value theorem for the restriction  $f|_{[a, x]}$  we find some  $x_0 \in (a, x)$  with  $f(x_0) = f(b)$ , which is again a contradiction by injectivity.

Based now on our claim and taking  $x_1, x_2 \in \mathbb{R}$  with  $a < x_1 < x_2 < b$  it is easy to see that  $f(x_1) < f(x_2)$ , that is,  $f$  is strictly increasing.

**5.E.77.** We will solve this problem using logarithmic differentiation. In particular, let  $f$  be a positive function for which  $f'(x)$  exists. Then recall that

$$(\ln f(x))' = \frac{f'(x)}{f(x)}, \quad \text{that is,} \quad f'(x) = f(x) \cdot (\ln f(x))'.$$

Now, the given function is differentiable as a product of differentiable functions. Thus, by combining the previous rule with basic properties of the natural logarithm, we obtain

$$\begin{aligned} \left( \frac{\sqrt[4]{x-1} \cdot (x+2)^3}{e^x(x+132)^2} \right)' &= \frac{\sqrt[4]{x-1} \cdot (x+2)^3}{e^x(x+132)^2} \cdot \left[ \ln \frac{\sqrt[4]{x-1} \cdot (x+2)^3}{e^x(x+132)^2} \right]' \\ &= \frac{\sqrt[4]{x-1} \cdot (x+2)^3}{e^x(x+132)^2} \cdot \left[ 3 \ln(x+2) + \frac{1}{4} \ln(x-1) - x \ln(e) - 2 \ln(x+132) \right]' \\ &= \frac{\sqrt[4]{x-1} \cdot (x+2)^3}{e^x(x+132)^2} \left[ \frac{3}{x+2} + \frac{1}{4(x-1)} - 1 - \frac{2}{x+132} \right]. \end{aligned}$$

In Sage to verify this complicated computation use the cell

```
f(x) = ((x-1)**(1/4)) * (x+2)^3 / (exp(x) * (x+132)^2)
show(diff(f(x), x).simplify())
```

**5.E.78.** (1)  $a'(x) = x^2 \sin(x)$ ; (2)  $b'(x) = \cos(\sin(x)) \cos(x)$ ; (3)  $c'(x) = \frac{3x^2+2}{x^3+2x} \cos(\ln(x^3+2x))$ ; (4)  $d'(x) = \frac{2(1-2x)}{(1-x+x^2)^2}$ ; (5)  $\varepsilon'(x) = \frac{7}{8} x^{-\frac{1}{8}}$ ; (6)  $f'(x) = \cos(x) \cos(\sin(x)) \cos(\sin(\sin(x)))$ ; (7)  $g'(x) = \frac{\cos x}{3\sqrt[3]{\sin^2 x}}$ ; (8)  $h'(x) = \frac{2x^2}{1-x^6} \sqrt[3]{\frac{1+x^3}{1-x^3}}$ .

**5.E.79.** (a) Such a function is the floor function  $f(x) = \lfloor x \rfloor$  introduced in 5.B.48. For instance, we have  $\lfloor -2.2 \rfloor = -3$  and  $\lfloor 2.2 \rfloor = 2$ , thus  $f(-x) \neq f(x)$  and  $f$  cannot be even. Moreover,  $\lfloor -2.2 \rfloor = -3 \neq -2 = -\lfloor 2.2 \rfloor$ , and hence the floor function is neither odd.

(b) Suppose that  $f$  is even, that is,  $f(-x) = f(x)$  for all  $x$  in the domain of  $f$ . Taking the derivatives in both sides of this equation and based on the chain rule, we get  $f'(x) = (f(-x))' = (-x)' f'(-x) = -f'(-x)$ . This means that  $f'(-x) = -f'(x)$  and hence  $f'$  is odd. Similarly the case with  $f$  odd.

**5.E.80.** The derivative  $f'(x)$  of a polynomial  $f$  provides the slope of the tangent line to its graph at the point  $[x, f(x)] \in \mathbb{R}^2$ . In degree zero,  $f$  is a non-zero constant  $a \cdot x^0 = a \cdot 1 = a$  and its derivative vanishes everywhere. This confirms the fact that the graph in this case is the line  $y = a$ , parallel to the  $x$ -axis. In degree one,  $f(x) = ax + b$  for some  $a, b \in \mathbb{R}$  with  $a \neq 0$ , thus its derivative is the constant  $a$ . Consequently, the slope of the tangent is  $a$  everywhere, which is the property

characterizing a line. In degree two,  $f(x) = ax^2 + bx + c$  with  $a, b, c \in \mathbb{R}$  and  $a \neq 0$ . Obviously,  $f'(x) = 2ax + b$  and  $x = -\frac{b}{2a}$  is the only point where the slope is zero, i.e., the maximum or the minimum of the quadratic function, as pointed out in 5.A.2. In degree three  $f(x) = ax^3 + bx^2 + cx + d$  with  $a, b, c, d \in \mathbb{R}$  and  $a \neq 0$ . The derivative is the second degree polynomial  $f'(x) = 3ax^2 + 2bx + c$ . Clearly, there are points with tangent slope zero if and only if the latter quadratic expressions allows zero values. This happens if and only if its discriminant  $4(b^2 - 3ac)$  is non-negative. In particular, there will be two bumps on the graph if and only if  $b^2 > 3ac$ . The slope of the graph gets to zero only in one point if  $b^2 = 3ac$ , and then the graph curve looks similarly as the graph of  $f(x) = x^3$  at  $x = 0$ .

**5.E.82.** Observe first that  $(\sinh(x))' > 0$  for all  $x \in \mathbb{R}$ , hence  $f$  is strictly increasing on  $\mathbb{R}$  (as we see also in the graph of  $f$  above). Thus it has an inverse function, called the “inverse hyperbolic sine function” and denoted by  $\sinh^{-1}(x)$ . The domain and the range of  $f$  are both  $(-\infty, \infty)$ , hence the same applies for  $\sinh^{-1}$ . To compute its explicit form, let  $y = \sinh^{-1}(x)$ . Then  $x = \sinh(y) = \frac{e^y - e^{-y}}{2}$ , that is,  $e^y - e^{-y} - 2x = 0$ . Multiplying both sides of this equation by  $e^y$  we arrive to the equation  $e^{2y} - 2xe^y - 1 = 0$ , which is obviously a quadratic equation in the variable  $t = e^y$ . Its solutions have the form  $t_{\pm} = x \pm \sqrt{x^2 + 1}$ . However,  $t = e^y > 0$ , but  $x - \sqrt{x^2 + 1} < 0$ , from where we deduce that  $e^y = x + \sqrt{x^2 + 1}$ , or equivalently  $y = \ln(x + \sqrt{x^2 + 1})$ , i.e.,  $\sinh^{-1}(x) = \ln(x + \sqrt{x^2 + 1})$  for all  $x \in \mathbb{R}$ . You may like to confirm this expression in Sage, based on the command `arcsinh` which corresponds to the function  $\sinh^{-1}$ . This, for example, can be done via the cell

```
bool(arcsinh(x)==ln(x+sqrt(x^2+1)))
```

Recall now that  $\ln(f(x))' = f'(x)/f(x)$  and  $(\sqrt{g(x)})' = g'(x)/2\sqrt{g(x)}$ , where  $f, g$  are both positive on their domain. Thus,

$$(\sinh^{-1}(x))' = \left(\ln(x + \sqrt{x^2 + 1})\right)' = \frac{1 + \frac{x}{\sqrt{x^2 + 1}}}{x + \sqrt{x^2 + 1}} = \frac{1}{\sqrt{x^2 + 1}}, \quad x \in \mathbb{R}.$$

As a confirmation via Sage, just type

```
show(diff(ln(x+sqrt(x^2+1)), x).factor())
```

**5.E.86.** (1) It does not because the one-sided derivatives differ. On particular, we get  $\pi/2$  from the right and  $-\pi/2$  from the left.

(2) It does not.

(3) To provide an answer one should recall the derivative of absolute value function. In particular, the function  $f(x) := |x - 5| + |x - 9|$  has the desired properties.

(4) Suppose that  $f(x) = g(x) = 1$  at the rational numbers and  $f(x) = g(x) = -1$  at the irrational numbers.

(5) It is not hard to see that  $f'(x) < 0$ , for all  $x > e$ .

**5.E.87.** We see that  $f'(x) = 5 - 4\sin(x) > 0$ . This means that  $f$  is increasing and hence a bijection. Thus  $f^{-1}$  exists and since  $f(0) = 4$  we have  $f^{-1}(4) = 0$ . Moreover,  $f'(f^{-1}(4)) = f'(0) = 5 \neq 4$ , hence we may apply 5.3.6 which gives

$$(f^{-1})'(4) = \frac{1}{f'(f^{-1}(4))} = \frac{1}{f'(0)} = \frac{1}{5}.$$

**5.E.89.** From the conditions  $P(0) = 1$  and  $P'(0) = 1$  it follows that  $P(x) = bx^3 + cx^2 + x + 1$ , for some  $b, c \in \mathbb{R}$ . The two remaining conditions determine two equations for the variables  $b$  and  $c$ :  $b+c+2 = 2a+2$ ,  $3b+2c+1 = 5a+1$  with the unique solution  $b = c = a$ . Therefore, a polynomial satisfying the desired conditions should has the form  $P(x) = ax^3 + ax^2 + x + 1$ , with  $a \in \mathbb{R}$ . The derivative of  $P$  is a parabola given by  $P'(x) = 3ax^2 + 2ax + 1$  and we require  $P'(x) > 0$  or  $P'(x) < 0$ , which is equivalent saying that the discriminant  $\Delta = 4a^2 - 12a$  of  $P'$  is negative,  $\Delta < 0$ . This gives  $4a(a - 3) < 0$ , which is true for all  $a \in (0, 3)$ .

**5.E.91.** Let  $x_0 \in \mathbb{R}$  some arbitrary point. By means of the definition of the first derivative of a function on  $\mathbb{R}$ , and in combination with the relation  $f(x + y) = \frac{f(x)+f(y)}{1-f(x)f(y)}$  we see that

$$\begin{aligned} f'(x_0) &= \lim_{h \rightarrow 0} \frac{f(x_0 + h) - f(x_0)}{h} = \lim_{h \rightarrow 0} \frac{\frac{f(x_0)+f(h)}{1-f(x_0)f(h)} - f(x_0)}{h} = \lim_{h \rightarrow 0} \frac{f(x_0) + f(h) - f(x_0) + f^2(x_0)f(h)}{h(1 - f(x_0)f(h))} \\ &= \lim_{h \rightarrow 0} \frac{1 + f^2(x_0)}{1 - f(x_0)f(h)} \cdot \lim_{h \rightarrow 0} \frac{f(h)}{h} = \frac{1 + f^2(x_0)}{1 - f(x_0)f(0)} \cdot f'(0) = f'(0) \cdot (1 + f^2(x_0)). \end{aligned}$$

Here we have used that  $f(0) = 0$ , which we get from the relation  $f(x+y) = \frac{f(x)+f(y)}{1-f(x)f(y)}$  by setting  $y = 0$  and moreover that  $f$  is differentiable at 0, and hence  $\lim_{h \rightarrow 0} \frac{f(h)}{h} = \lim_{h \rightarrow 0} \frac{f(h+0)-f(0)}{h-0} = f'(0)$ . Thus  $f'(x) = f'(0)(1+f^2(x))$  for all  $x \in \mathbb{R}$  and  $f$  is differentiable on  $\mathbb{R}$ .

**5.E.95.** (a) The function has a local maximum at the point  $x_1 = e^{-2}$ . It has a local minimum at the point  $x_2 = 1$ .

(b) The answer is  $\frac{1}{\sqrt[3]{e}}$ .

(c) The answer is  $4 = p(-1) = p(2)$ ,  $-16 = p(-3)$ .

(d) No. For instance, if  $\alpha = \sqrt{2}/2$ , there is only a local extremum at the point.

**5.E.96.** The given function  $f$  has domain the whole real line and we have  $f'(x) = -e^{-x} = -\frac{1}{e^x} < 0$  for any  $x \in \mathbb{R}$ . Thus  $f$  is strictly decreasing on  $\mathbb{R}$ .

**5.E.97.** Obviously, a solution is given by  $x = 1$ . We will show that it is unique by using the function  $f(x) = x^{2025} + 2024x + \ln x - 2025$ . It is sufficient to show that  $f$  is strictly growing throughout its domain  $A = (0, +\infty)$ . Obviously,  $f$  is differentiable over  $A$  and its derivative is given by  $f'(x) = 2024x^{2024} + 2024 + \frac{1}{x}$ . But  $f'(x) > 0$  for all  $x \in A$ , so we are done.

**5.E.103.** Consider the function  $g(x) = x - \ln(x+1)$ , with  $g(0) = 0$ . The first derivative of  $g$  is given by

$$g'(x) = 1 - \frac{1}{x+1} = \frac{x}{x+1}.$$

Thus  $g'(x) = 0$  if and only if  $x = 0$ . For  $x > 0$  we have obviously  $g'(x) > 0$ , so  $g$  is strictly increasing on the open interval  $(0, +\infty)$ . Hence, for all  $x > 0$  we have  $g(x) > g(0) = 0$ , that is,  $x > \ln(x+1)$ . Since for  $x = 0$  this holds as an equality we have finally proved  $x \geq \ln(x+1)$  for all  $x \geq 0$ .

**5.E.104.** Consider the function  $f(x) = \alpha x^\beta - \beta x^\alpha - \alpha + \beta$ . We have  $f'(x) = \alpha\beta(x^{\beta-1} - x^{\alpha-1}) > 0$  for all  $x > 1$ , that is,  $f(x)$  is strictly increasing for all  $x \in (1, +\infty)$ . The point  $x = 1$  induces a critical point for  $f$ , i.e.,  $f'(1) = 0$  and we see that there  $f$  attains its minimum value  $f(1) = 0$ . Thus for all  $x > 1$  we have  $f(x) > 0$ , i.e.,  $\alpha x^\beta - \beta x^\alpha > \alpha - \beta$ .

**5.E.108.** (a) Obviously, this limit has the indeterminate form  $\frac{\infty}{\infty}$ .

(b) The l'Hospital's rule gives rise to the following limit

$$\lim_{x \rightarrow +\infty} \frac{x + \sin(x)}{x} = \lim_{x \rightarrow +\infty} \frac{1 + \cos(x)}{1} = \lim_{x \rightarrow +\infty} (1 + \cos(x)),$$

which does *not* exist (e.g., use Sage and type the syntax `limit(1 + cos(x), x = oo)`). However, the limit at hand exists. This is because

$$\frac{x-1}{x} \leq \frac{x + \sin x}{x} \leq \frac{x+1}{x},$$

which implies that  $\lim_{x \rightarrow +\infty} f(x) = 1$ .

**5.E.111.** The answers are  $a = 2/\pi$ ,  $b = 1$ ,  $c = 1/2$  and  $d = e^{-2}$ .

**5.E.116.** The perimeter is  $2\sqrt{5}r$ .

**5.E.117.** The answer here is the square with sides of length  $c$ .

**5.E.118.** We get  $h = \frac{4}{3}R$  and  $r = \frac{2\sqrt{2}}{3}R$ .

**5.E.119.** This triangle is the equilateral triangle, with area  $\sqrt{3}p^2/36$ .

**5.E.120.** The desired points have coordinates  $P = [2, -1/2]$ , and  $Q = [-2, -1/2]$ , respectively. Try to illustrate the situation via Sage.

**5.E.122.** To confirm the answer presented for  $x_0$  in [5.E.121](#) we may instead try to locate the global minimum of the function

$$g(x) = \frac{1}{f(x)} = \frac{x^2 + (b-h)(a-h)}{x(b-a)} = \frac{x}{b-a} + \frac{(b-h)(a-h)}{x(b-a)}, \quad x \in (0, +\infty).$$

This can be done with the help of the AM-GM inequality that we met in Chapter 1, that is,

$$\frac{y_1 + y_2}{2} \geq \sqrt{y_1 y_2}, \quad y_1, y_2 \geq 0,$$

where the equality occurs if and only if  $y_1 = y_2$ . The choice

$$y_1(x) = \frac{x}{b-a}, \quad y_2(x) = \frac{(b-h)(a-h)}{x(b-a)}$$

then gives

$$g(x) = y_1(x) + y_2(x) \geq 2 \sqrt{y_1(x) y_2(x)} = \frac{2}{b-a} \sqrt{(b-h)(a-h)}.$$

Therefore, if there is a number  $x > 0$  for which  $y_1(x) = y_2(x)$ , then the function  $g$  has the global minimum at  $x$ . In particular, the equation

$$y_1(x) = y_2(x), \quad \text{i. e.} \quad \frac{x}{b-a} = \frac{(b-h)(a-h)}{x(b-a)}$$

has a unique positive solution given by  $x_0 = \sqrt{(b-h)(a-h)}$ .

**5.E.126.** The inscribed rectangle has sides of lengths  $x$ ,  $\sqrt{3}/2(a-x)$ , thus its area is  $\sqrt{3}/2(a-x)x$ . The maximum occurs for  $x = a/2$ , hence the greatest possible area is  $(\sqrt{3}/8)a^2$ .

**5.E.127.** The dimensions of the pool are  $4 \text{ m} \times 4 \text{ m} \times 2 \text{ m}$ .

**5.E.128.** The answer is  $28 = 24 + 4$ .

**5.E.129.** The answer is  $a = 1$ .

**5.E.131.** (a) The first claim is obviously true. We do not need any absolute convergence to handle linear combinations. This is a direct consequence of the properties of limits.

(b) This statement is clearly false, in general. Consider the harmonic series  $\sum_{n=1}^{\infty} \frac{1}{n}$ . We saw in 5.D.9 that the series  $\sum_{n=1}^{\infty} \frac{1}{n^2}$  converges, while the harmonic series does not.

(c) Let us divide the series into a sum of two. The first one will collect the terms with  $|a_n| > n|a_n|^2$ , while the other sum the remaining terms. In the first case,  $|a_n| < \frac{1}{n}$ , and thus  $|\frac{a_n}{n}| < \frac{1}{n^2}$ . Consequently, this part of the series converges absolutely. The remaining part must converge, as well, as a consequence of the comparison with the converging series:  $|\frac{a_n}{n}| \leq |a_n|^2$ . As a sum of two absolutely convergent series, the initial series is absolutely convergent, too. Thus the claim is true.

**5.E.135.** (a) The ratio test gives

$$\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n \rightarrow \infty} \frac{2^{(n+1)^2} \cdot n!}{(n+1)! \cdot 2^{n^2}} = \lim_{n \rightarrow \infty} \frac{2^{2n+1}}{n+1} = \lim_{n \rightarrow \infty} \frac{2 \cdot 4^n}{n+1} = +\infty.$$

Thus the series does not converge.

(b) The sequence  $\left(\frac{2}{\sqrt{3n}}\right)_{n \in \mathbb{Z}_+}$  is decreasing, while recall that and the function  $f(x) = \arctan(x)$  is increasing on the whole real axis. So, the sequence  $\left(\arctan\left(\frac{2}{\sqrt{3n}}\right)\right)_{n \in \mathbb{Z}_+}$  is decreasing. Thus, it is an alternating series such that the sequence of the absolute values of its terms is decreasing. According to the Leibniz criterion, such an alternating series converges if and only if the sequence of its terms converges to zero, and this is satisfied:  $\lim_{n \rightarrow \infty} \arctan\left(\frac{2}{\sqrt{3n}}\right) = \arctan(0) = 0$  and hence

$$\lim_{n \rightarrow \infty} \left( (-1)^{n+1} \arctan\left(\frac{2}{\sqrt{3n}}\right) \right) = 0.$$

So the series  $T$  is convergent.

**5.E.137.** The required value is  $3/2$ .

**5.E.138.** The first series sums to 3 and the second sums to  $9/4$ .

**5.E.139.** We get  $\alpha > 0$ ,  $\beta \in \{-2, -1, 0, 1, 2\}$ , and  $\gamma \in (-\infty, -1) \cup (1, +\infty)$ .

**5.E.140.** This series is absolutely convergent.

**5.E.141.** The answer is  $\alpha \in [0, 1)$ .

**5.E.144.** We see that  $A(x) = \frac{1}{2} \ln \frac{1+x}{1-x}$  and  $B(x) = \frac{1+x}{(1-x)^3}$ , respectively.

**5.E.145.** For example:  $a_n = n/3$ ,  $b_n = n/2$ , with  $n \in \mathbb{N}$ .

**5.E.146.** The former series converges absolutely; the latter converges conditionally.

**5.E.147.** Yes, it does.

**5.E.148.** The answer is  $p \in \mathbb{R}$ .

**5.E.149.** This series is convergent.

**5.E.150.** The answer is  $S = 2/9$ .

## Differential and integral calculus

*we already have the menagerie, but what shall we do with it?  
– we'll learn to control it...*

### A. Derivatives of higher orders

*In the previous chapter we briefly explained the use of second order derivatives in the study of local extremes (see 5.C.28 for example). In this chapter we will study higher order derivatives in many details and derive such applications in a more systematic way. Notice that a higher order derivative refers to the repeated process of taking derivatives of derivatives, a procedure also known as “successive differentiation”.*

*As in Chapter 5, we will denote the second derivative of a function  $f$  by  $f'' = (f')'$ , and for derivatives of third or higher order we will write  $f^{(3)} = (f'')'$ ,  $f^{(4)} = (f^{(3)})'$ , etc. The bracket in the notation  $f^{(n)} = (f^{(n-1)})'$  is necessary to distinguish it from the  $n$ th power  $f^n$  of  $f$ . When for a function  $f$  we can consider arbitrarily many continuous derivatives, then the function is said to be smooth, see also the theoretical column for the notion of smooth functions (e.g., 6.1.9).*

*At this point it is also important to recall that in Sage the  $n$ th order derivative of a given function  $f$  can be computed via the command `diff(f, x, n)`. For the examples described below we advise the reader to use Sage and verify the computations, especially for the problems where a Sage implementation is not included.*

In the previous chapter, we were working either with an extremely large class of functions (for example, all continuous, all differentiable), or with only particular functions, (for example exponential, trigonometric, polynomial). However we had very few tools. We indicated how to discuss the local behaviour of functions near a given point by linear approximation. We learned how to measure instantaneous changes by differentiation.

Now we derive several results that will allow us to work with functions more easily when modeling real problems. We also deal with the task of summing infinitely many “infinitely small” changes, in particular, how to “integrate”. In the last part of the chapter we come back to series of functions. We also add useful techniques, how to deal with extra parameters in the functions, and we introduce some further integration concepts briefly.

### 1. Differentiation

**6.1.1. Higher order derivatives.** If the first derivative  $f'(x)$  of a function of one real variable has a derivative  $(f')'(x_0)$  at the point  $x_0$ , we say that the *second derivative* of function  $f$  (or second order derivative) exists. Then we write  $f''(x_0) = (f')'(x_0)$  or  $f^{(2)}(x_0)$ . A function  $f$  is *two times differentiable* on some interval, if it has a second derivative at each of its points. Derivatives of higher orders are defined inductively:

#### $k$ TIMES DIFFERENTIABLE FUNCTIONS

A function  $f$  of one real variable is *differentiable  $k$  times* at the point  $x_0$  for some natural number  $k > 1$ , if it is differentiable  $(k - 1)$  times on some neighbourhood of the point  $x_0$  and its  $(k - 1)$ -st derivative has a derivative at the point  $x_0$ . We write  $f^{(k)}(x)$  for the  $k$ -th derivative of the function  $f(x)$ .

If derivatives of all orders exist on an interval  $A$ , we say the function  $f$  is *smooth* or *infinitely differentiable* on  $A$ .

We use the notation *class of functions*  $C^k(A)$  for functions with continuous  $k$ -th derivative on the interval  $A$ , where  $k$  can attain values  $0, 1, \dots, \infty$ . Often we write only  $C^k$ , if the domain is known from the context. When  $k = 0$ ,  $C^0$  means *continuous functions*.

**6.A.1.** Determine the derivatives given below.

- |   |   |
|---|---|
| (1) $(x^2 \sin(x))''$ , $x \in \mathbb{R}$  | (5) $(x^x)''$ , $x > 0$                             |
| (2) $\left(\frac{2x}{4x+3}\right)''$ , $x \in \mathbb{R} \setminus \{-\frac{3}{4}\}$                  | (6) $(x^n)^{(n)}$ , $x \in \mathbb{R}$              |
| (3) $\left(\ln \sqrt{\frac{x^2+1}{x^2-1}}\right)''$ , with<br>$x \in (-\infty, -1) \cup (1, +\infty)$ | (7) $\left(\frac{x}{\ln(x)}\right)^{(3)}$ , $x > 0$ |
| (4) $(\tan(x))''$ , with<br>$x \in \mathbb{R} \setminus \{\frac{\pi}{2} + n\pi : n \in \mathbb{N}\}$  | (8) $(1/\sqrt{x(x-2)})''$ , with<br>$0 < x < 2$ .   |

**Solution.** (1) This is based on the product rule  $(fg)' = f'g + fg'$ . Applying this rule successively we obtain

$$(x^2 \sin(x))'' = \left((x^2 \sin(x))'\right)' = (2x \sin(x) + x^2 \cos(x))' = 2 \sin(x) + 4x \cos(x) - x^2 \sin(x).$$

(2) In this case we will apply twice the quotient rule  $\left(\frac{f}{g}\right)' = \frac{gf' - fg'}{g^2}$ . We get  $\left(\frac{2x}{4x+3}\right)' = \frac{2(4x+3) - 8x}{(4x+3)^2} = \frac{6}{(4x+3)^2}$ , hence

$$\begin{aligned} \left(\frac{2x}{4x+3}\right)'' &= \left(\frac{6}{(4x+3)^2}\right)' = \frac{6}{(4x+3)^3} \\ &= -\frac{48(4x+3)}{(4x+3)^4} = -\frac{48}{(4x+3)^3}. \end{aligned}$$

(3) For any  $x \in (-\infty, -1) \cup (1, +\infty)$  we can write

$$\begin{aligned} \ln \sqrt{\frac{x^2+1}{x^2-1}} &= \ln \left(\frac{x^2+1}{x^2-1}\right)^{\frac{1}{2}} = \frac{1}{2} \ln \left(\frac{x^2+1}{x^2-1}\right) \\ &= \frac{1}{2} [\ln(x^2+1) - \ln(x^2-1)]. \quad (*) \end{aligned}$$

This relation has many advantages. For instance, one can easily deduce that the given function is differentiable (as the difference of two differentiable functions). On the other hand, recall that a positive differentiable function  $f$  satisfies  $(\ln(f(x)))' = f'(x)/f(x)$  for all  $x$  in its domain. Hence, a combination of this rule with (\*) gives

$$\left(\ln \sqrt{\frac{x^2+1}{x^2-1}}\right)' = \frac{1}{2} \left[\frac{2x}{x^2+1} - \frac{2x}{x^2-1}\right] = -\frac{2x}{x^4-1}.$$

Now we can easily compute also the second derivative:

$$\left(\ln \sqrt{\frac{x^2+1}{x^2-1}}\right)'' = \left(-\frac{2x}{x^4-1}\right)' = \frac{2(1+3x^4)}{(x^4-1)^2}.$$

(4) For this you should apply the quotient rule twice. In particular, recall by 5.E.76 that  $(\tan(x))' = \frac{1}{\cos^2(x)}$ . Therefore,

$$\begin{aligned} \tan''(x) &\equiv (\tan(x))'' \equiv \frac{d^2}{dx^2} \tan(x) = \left(\frac{1}{\cos^2(x)}\right)' \\ &= 2 \frac{\sin(x)}{\cos^3(x)} = 2 \frac{\tan(x)}{\cos^2(x)}. \end{aligned}$$

We illustrate the concept of higher order derivatives with polynomials. Because the derivative of a polynomial is a polynomial with the degree one less than the original one, after a finite number of differentiations we obtain the zero polynomial. If  $k$  is the degree of the polynomial, then exactly  $k + 1$  differentiations yields zero. Then derivatives of all orders exist, hence  $f \in C^\infty(\mathbb{R})$ .

In the spline construction, see 5.1.9, we took care that the resulting functions belong to the class  $C^2(\mathbb{R})$ . Their third derivatives are piece-wise constant functions. That is why the splines do not belong to  $C^3(\mathbb{R})$ , even though all their higher order derivatives are zero in all of the inner points of all single intervals in the interpolation. Think this example through in detail!

The next assertion is a combinatorial corollary of Leibniz's rule for differentiation of a product of two functions:

**Lemma.** If two functions  $f$  and  $g$  have derivatives of order  $k$  at the point  $x_0$ , then their product also has the derivative of order  $k$  and the following equality holds:

$$(f \cdot g)^{(k)}(x_0) = \sum_{i=0}^k \binom{k}{i} f^{(i)}(x_0) g^{(k-i)}(x_0).$$

**PROOF.** For  $k = 0$ , the statement is trivial. For  $k = 1$  it is Leibniz's product rule. Suppose equality holds for some  $k$ . Differentiate the right hand side and use Leibniz's rule to obtain the expression

$$\sum_{i=0}^k \binom{k}{i} \left( f^{(i+1)}(x_0) g^{(k-i)}(x_0) + f^{(i)}(x_0) g^{(k-i+1)}(x_0) \right).$$

In this new sum, the sum of orders of the derivatives of products in all summands is  $k + 1$  and the coefficients of  $f^{(j)}(x_0) g^{(k+1-j)}(x_0)$  are the sums of binomial coefficients  $\binom{k}{j-1} + \binom{k}{j} = \binom{k+1}{j}$ .  $\square$

**6.1.2. The meaning of second derivative.** We have already

seen that the first derivative of a function is its linear approximation in the neighbourhood of a given point. The sign of a nonzero derivative determines whether the function is increasing or decreasing at the point  $x_0$ . The points where the first derivative is zero are called the *critical points* or *stationary points* of the given function.

If  $x_0$  is a critical point of function  $f$ , there are several possibilities for the behaviour of the function  $f$  in the neighbourhood of  $x_0$ . Consider the behaviour of the function  $f(x) = x^n$  in the neighbourhood of zero for different

(5) In 5.C.7 (d) we proved that  $(x^x)' = (\ln(x) + 1)x^x$ . Thus, for the second derivative we obtain

$$\begin{aligned} (x^x)'' &= \left( (x^x)' \right)' = \left( (\ln(x) + 1) e^{x \ln(x)} \right)' \\ &= \left( \ln(x) e^{x \ln(x)} \right)' + \left( e^{x \ln(x)} \right)' \\ &= \frac{1}{x} e^{x \ln(x)} + \ln(x) (\ln(x) + 1) e^{x \ln(x)} \\ &\quad + (\ln(x) + 1) e^{x \ln(x)} \\ &= \frac{x^x}{x} + x^x (\ln^2(x) + 2 \ln(x) + 1) \\ &= x^{x-1} + x^x (\ln(x) + 1)^2. \end{aligned}$$

(6) In this case we simply state the result and leave a formal computation for practice:  $\left(\frac{x}{\ln x}\right)^{(3)} = \frac{1}{x^2(\ln x)^2} - \frac{6}{x^2(\ln x)^4}$ .

(7) We see that

$$(x^n)^{(n)} = [(x^n)']^{(n-1)} = (nx^{n-1})^{(n-1)} = \dots = n!.$$

The last step of a formal proof includes an induction over  $n$ , which we leave as an exercise.

(8) For this case we just present the result, and leave the proof for practice:

$$\begin{aligned} \left(1/\sqrt{x(x-2)}\right)'' &= \frac{(2x^2 - 4x + 3)\sqrt{x^2 - 2x}}{x^6 - 6x^5 + 12x^4 - 8x^3} \\ &= \frac{2x^2 - 4x + 3}{\sqrt{(x-2)x(x-2)^2x^2}}. \end{aligned}$$

□

**6.A.2.** Use Sage to verify your answers in 6.A.1.

**Solution.** For most of the cases the answer is based on the command `diff(f, x, m)`, mentioned above. For instance, type

```
show(diff(x^2*sin(x), x, 2).full_simplify())
show(diff((2*x)/(4*x+3), x, 2).full_simplify())
f(x)=ln(sqrt((x^2+1)/(x^2-1)))
show(diff(f(x), x, 2).full_simplify())
show(diff(tan(x), x, 2))
show(diff(x^x, x, 2))
show(diff(x/ln(x), x, 3))
g(x)=1/sqrt(x*(x-2))
show(diff(g(x), x, 2).factor())
```

Notice the function `full_simplify()` (or `factor()`) was used to simplify the given expressions and make direct the verification, whenever necessary.

Finally observe also that the cell

```
[diff(x^n, x, n) for n in range(1, 100)]
```

gives a verification of the relation  $(x^n)^{(n)} = n!$ , presented in (7), for many values of  $n$ . However, a more precise program that offers a more practical demonstration of the theoretical result is as follows:"

```
# Define the variable x
x = var('x')
# Define a specific integer value for n
n = 4 # Change this to test different cases
```

$n$ . For odd  $n > 0$ ,  $f(x)$  will be increasing on all  $\mathbb{R}$ , while for even  $n$  it will be decreasing for  $x < 0$  and increasing for  $x > 0$ . In the latter case, the function will attain its minimal value among points in the (sufficiently small) neighbourhood of  $x_0 = 0$ .

The same argument applies to the function  $f'$ . If the second derivative is nonzero, its sign determines the behaviour of the first derivative. At the critical point  $x_0$  the derivative  $f'(x)$  is increasing if the second derivative is positive and decreasing if the second derivative is negative. If increasing, it is necessarily negative to the left of the critical point and positive to the right of it. In that case,  $f$  is decreasing to the left of the critical point and increasing to the right of it. So  $f$  attains its minimal value among all points from a (sufficiently small) neighbourhood of  $x_0$  at  $x_0$ .

On the other hand, if the second derivative is negative at  $x_0$ , the first derivative is decreasing. Thus the first derivative is negative to the left of  $x_0$  and positive to the right of it.  $f$  then attains its maximal value at  $x_0$  among all values in a neighbourhood of  $x_0$ .

A function which is differentiable on  $(a, b)$  and continuous on  $[a, b]$  has an absolute maximum and minimum on this interval. Both can be attained only at the boundary of the interval or at a point where the derivative is zero. Thus critical points may be sufficient for finding extremes. Second derivatives help to determine the type of extreme, if nonzero.

For a more precise discussion of the latter phenomena we consider higher order polynomial approximations of the functions. We then return to the qualitative study of the behaviour of functions with new tools.

**6.1.3. Taylor expansion.** As a surprisingly easy use of Rolle's theorem we derive an extremely important result. It is called the *Taylor expansion with remainder*<sup>1</sup>.

Consider the power series centered at  $a$ ,

$$S(x) = \sum_{n=0}^{\infty} a_n(x-a)^n.$$

Recall, power series can be differentiated term by term, cf. 5.4.10.

Differentiate the series  $S(x)$  repeatedly, to get the power series

$$S^{(k)}(x) = \sum_{n=k}^{\infty} n(n-1)\dots(n-k+1)a_n(x-a)^{n-k}.$$

Put  $x = a$ . Then  $S^{(k)}(a) = k! a_k$ . We can read the last statement as an equation for  $a_k$  and rewrite the original series as

$$S(x) = \sum_{n=0}^{\infty} \frac{1}{k!} S^{(k)}(a)(x-a)^n.$$

<sup>1</sup>Brook Taylor was an English mathematician (1685-1731) best known for his formalization of the polynomial approximations of functions, recognized by Lagrange as the "main foundation of differential calculus"

```
# Define the function f(x) = x^n
f = x^n
# Compute the n-th derivative
n_th_derivative = f.diff(x, n)
# Simplify the result
n_th_derivative_s = n_th_derivative.simplify()
# Print the result
print(f"The {n}-th derivative of x^{n} is:",
      n_th_derivative_s)
# Verify that the result matches n!
expected_result = factorial(n)
print(f"Expected result ({n}!):",
      expected_result)
# Check if the computed result matches n!
if n_th_derivative_s == expected_result:
    print("The result matches n!")
else:
    print("The result does not match n!.")
```

□

**6.A.3.** Use the generalized Leibniz rule (see lemma in 6.1.1) to compute the fourth-order derivative of the functions:

- (a)  $h(x) = x \cos(x)$ , (c)  $\ell(x) = x^3 \ln(x)$ ,
- (b)  $k(x) = e^{4x} x^4$ , (d)  $m(x) = e^x \arctan(x)$ .

Next describe a solution in Sage.

**Solution.** The generalized Leibniz’s rule for the 4th-order derivative of a product  $fg$  gives

$$\begin{aligned} (f(x)g(x))^{(4)} &= \binom{4}{0} f^{(0)}(x)g^{(4)}(x) + \binom{4}{1} f'(x)g^{(3)}(x) \\ &+ \binom{4}{2} f''(x)g''(x) + \binom{4}{3} f^{(3)}(x)g'(x) + \binom{4}{4} f^{(4)}(x)g(x) \\ &= f(x)g^{(4)}(x) + 4f'(x)g^{(3)}(x) + 6f''(x)g''(x) \\ &+ 4f^{(3)}(x)g'(x) + f^{(4)}(x)g(x). \quad (\#) \end{aligned}$$

Now, for case (a) we have  $h(x) = f(x)g(x)$  with  $f(x) = x$  and  $g(x) = \cos(x)$ , respectively. Moreover,  $g'(x) = -\sin(x)$ ,  $g''(x) = -\cos(x)$ ,  $g'''(x) = \sin(x)$ ,  $g^{(4)}(x) = \cos(x)$ ,  $f'(x) = 1$ , and  $f^{(k)}(x) = 0$  for all  $k \geq 2$ . Thus, an application of (#) gives  $h^{(4)}(x) = x \cos(x) + 4 \sin(x)$ .

A solution in Sage is based on the cell

```
h(x)=x*cos(x); show(diff(h,x,4))
```

Or, you may use the alternative

```
((diff(h(x),x,i) for i in [1..4]))
```

which gives us all the derivatives  $h'(x)$ ,  $h''(x)$ ,  $h^{(3)}(x)$  and  $h^{(4)}(x)$ . Similarly are treated the rest cases. □

**6.A.4. Generalized Leibniz rule and Sage.** For two symbolic functions  $f, g$  in Sage write a short program to implement the identity (#) presented in 6.A.3. Then verify the results for the functions  $h, k, \ell, m$ , by using this program, and hence independently of the command `diff(f * g, x, 4)`.

**Solution.** Recall from 5.C.8 that in Sage we can easily introduce symbolic functions by typing

Suppose  $f$  is a smooth function instead of a power series. We search for a good approximation by polynomials in the neighbourhood of a given point  $a$ .

TAYLOR POLYNOMIAL OF FUNCTION  $f$

For a  $k$  times differentiable (real or complex valued) function  $f$  of one real variable, define its *Taylor polynomial of  $k$ -th degree* centered at  $a$  by the formula

$$\begin{aligned} T_a^k f(x) &= f(a) + f'(a)(x - a) + \frac{1}{2} f''(a)(x - a)^2 \\ &+ \frac{1}{6} f^{(3)}(a)(x - a)^3 + \dots + \frac{1}{k!} f^{(k)}(a)(x - a)^k. \end{aligned}$$

The mean value theorem is used to show how good this approximation of  $f$  is.

TAYLOR EXPANSION WITH A REMAINDER

**Theorem.** Let  $f(x)$  be a function that is  $k$  times differentiable on the interval  $(a, b)$  and continuous on  $[a, b]$ . Then for all  $x \in (a, b)$  there exists a number  $c \in (a, x)$  such that

$$\begin{aligned} f(x) &= T_a^{k-1} f(x) + \frac{1}{k!} f^{(k)}(c)(x - a)^k \\ &= f(a) + f'(a)(x - a) + \dots \\ &+ \frac{1}{(k-1)!} f^{(k-1)}(a)(x - a)^{k-1} + \frac{1}{k!} f^{(k)}(c)(x - a)^k. \end{aligned}$$

**PROOF.** For fixed  $x$  define the remainder  $R$ , by

$$f(x) = T_a^{k-1} f(x) + R.$$

Then  $R = \frac{1}{k!} r(x - a)^k$  for a suitable number  $r$  (dependent on  $x$ ). Consider the function  $F(\xi)$  defined by

$$F(\xi) = \sum_{j=0}^{k-1} \frac{1}{j!} f^{(j)}(\xi)(x - \xi)^j + \frac{1}{k!} r(x - \xi)^k.$$

By the Leibniz rule, its derivative (here  $x$  is considered as a constant parameter) is

$$\begin{aligned} F'(\xi) &= f'(\xi) + \sum_{j=1}^{k-1} \left( \frac{1}{j!} f^{(j+1)}(\xi)(x - \xi)^j - \frac{1}{(j-1)!} f^{(j)}(\xi)(x - \xi)^{j-1} \right) \\ &\quad - \frac{1}{(k-1)!} r(x - \xi)^{k-1} \\ &= \frac{1}{(k-1)!} f^{(k)}(\xi)(x - \xi)^{k-1} - \frac{1}{(k-1)!} r(x - \xi)^{k-1} \\ &= \frac{1}{(k-1)!} (x - \xi)^{k-1} (f^{(k)}(\xi) - r), \end{aligned}$$

because the expressions in the sum cancel each other out sequentially. Now it suffices to notice that  $F(a) = F(x) = f(x)$  (recall that  $x$  is an arbitrarily chosen but fixed number from the interval  $(a, b)$ ). According to Rolle’s theorem there exists a number  $c$ ,  $a < c < x$  such that  $F'(c) = 0$ . That is the desired relation. □

```
var("x"); f=function("f")(x)
```

This, in combination with the `substitute_function`, gives rise to an alternative approach to obtain the first derivative of a given function. For instance, for  $f(x) = e^x$  we just need to add the code

```
f1=f.diff(x)
show(f1.substitute_function(f==exp(x)))
```

Check yourself that this block returns the first derivative of  $f(x) = e^x$ .

We are now ready to verify (‡), which can be done for example by the cell

```
f=function("f")(x)
g=function("g")(x)
f1=diff(f, x); f2=diff(f, x, 2)
f3=diff(f, x, 3); f4=diff(f, x, 4)
g1=diff(g, x); g2=diff(g, x, 2)
g3=diff(g, x, 3); g4=diff(g, x, 4)
h4x=f*g4+4*f1*g3+6*f2*g2+4*f3*g1+f4*g
show(h4x)
```

This block includes all the derivatives that one needs to encode (‡) inside the program, which we did here by the syntax named “h4x”. To confirm the expression of  $h^{(4)}(x)$  given in 6.A.3, it now suffices to add the code

```
show(h4x.substitute_function(f==x, g==cos(x)))
```

The rest cases can be confirmed similarly and left for practice. □

**6.A.5.** Let  $n \in \mathbb{N}$  be arbitrary. Find the  $n$ th derivative of function  $f(x) = \ln\left(\frac{1+x}{1-x}\right)$ , where  $x \in (-1, 1)$ . ○

**6.A.6.** Compute the 12th derivative of the function  $f(x) = e^{2x} + \cos(x) + x^{10} - 5x^7 + 6x^3 - 7x + 3$ , with  $x \in \mathbb{R}$ . ○

**6.A.7.** Compute the 26th derivative of the function  $f(x) = \sin(x) + x^{23} - x^{18} + 5x^{11} - 3x^8 + e^{2x}$ , with  $x \in \mathbb{R}$ . ○

 *Taylor polynomials extend the idea of linearization that we briefly discussed in Chapter 5. They provide high-order approximations of a function  $f$  by polynomials in the neighbourhood of a point (and thus locally). This is because such expansions are based on higher order derivatives of  $f$  at that point. We remark that as the terms of such polynomials increase (and hence their order), the induced approximations are improved.*

*Taylor expansions have many natural applications in mathematics, but also in other sciences (e.g., in physics). In the sequel, first are described exercises related to the computation of Taylor polynomials, and more interesting applications will be discussed hereafter. For our description we adopt the notation from the theoretical section 6.1.3, hence for example we will denote by  $T_a^k f(x)$  the  $k$ th-order Taylor expansion of  $f(x)$  around a point  $a$ .*

A special case of the last theorem is the mean value theorem, as an approximation by the Taylor polynomial of degree zero. See 5.3.9(1).

**6.1.4. Estimates for Taylor expansions.** A simple case of a Taylor expansion is when  $f$  is a polynomial:

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0, \quad a_n \neq 0.$$

Because the  $(n + 1)$ -th derivative  $f$  is identically zero, the Taylor polynomial of degree  $n$  has zero remainder, therefore for each  $x_0 \in \mathbb{R}$

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + \dots + \frac{1}{n!} f^{(n)}(x_0)(x - x_0)^n.$$

We can compute all the derivatives easily (for example the last term is always of the form  $a_n(x - x_0)^n$ ).

This result is a very special case of error estimation in Taylor expansion with the remainder. We know in advance that the remainder can be estimated by the size of the derivative, and for polynomials this is identically zero for some order onwards.

More generally, the estimation of the size of the  $k$ -th derivative on some interval can be used to estimate the error on the same interval.

Good examples of an expansion of an arbitrary degree are provided by the trigonometric functions  $\sin$  and  $\cos$ . By iterating the differentiation of the function  $\sin x$  we always have either sine or cosine with some signs. The absolute values do not exceed one. Thus we obtain a direct estimation of the speed of convergence of the power series

$$|\sin x - (T_0^k \sin)(x)| \leq \frac{|x|^{k+1}}{(k+1)!}.$$

This shows that for  $x$  much smaller than  $k$  the error is small, but for  $x$  comparable with  $k$  or bigger it may be large. In the figure, compare the approximation of the function  $\cos x$  by a Taylor polynomial of degree 68 in paragraph 5.4.12 on the page 429.

As mentioned in the introduction of the discussion of Taylor expansion of functions, if we start with a power series  $f(x)$  centered at  $a$ , then its partial sums coincide with Taylor polynomials  $T_a^k f(x)$ . The next statement is one of the simple formulations of the converse implication. This is when the given function  $f(x)$  is actually a power series on some neighbourhood of the given point  $a$ .

#### TAYLOR'S THEOREM

**Theorem.** Assume that the function  $f(x)$  is smooth on the interval  $(a - b, a + b)$  and all of its derivatives are bounded uniformly by a constant  $M > 0$ . So

$$|f^{(k)}(x)| \leq M, \quad k = 0, 1, \dots, x \in (a - b, a + b).$$

Then the power series  $S(x) = \sum_{n=0}^{\infty} \frac{1}{k!} f^{(k)}(a)(x - a)^n$  converges on the interval  $(a - b, a + b)$  to  $f(x)$ .

**6.A.8.** For the elementary functions  $\sin(x)$ ,  $\cos(x)$ ,  $e^x$  and  $\ln(x + 1)$  compute the third order Taylor expansion based on  $a = 0$ . ○

**6.A.9.** Determine the Taylor expansion  $T_1^3 f(x)$  for the functions  $f(x) = \frac{e^x}{x}$  and  $f(x) = \arctan(x)$ , with  $x \in \mathbb{R} \setminus \{0\}$  and  $x \in \mathbb{R}$ , respectively. Then verify your answers in Sage and moreover check the accuracy of the approximation near the point  $a$ .

**Solution.** The third-order Taylor expansion around the point  $a = 1$  is given by

$$T_1^3 f(x) = f(1) + f'(1)(x-1) + \frac{f''(1)}{2}(x-1)^2 + \frac{f'''(1)}{6}(x-1)^3.$$

For the first case we have  $f(1) = e$ , and

$$\begin{aligned} f'(1) &= \left. \frac{e^x}{x} - \frac{e^x}{x^2} \right|_{x=1} = 0, \\ f^{(2)}(1) &= \left. \frac{e^x}{x} - 2\frac{e^x}{x^2} + 2\frac{e^x}{x^3} \right|_{x=1} = e, \\ f^{(3)}(1) &= \left. \frac{e^x}{x} - 3\frac{e^x}{x^2} + 6\frac{e^x}{x^3} - 6\frac{e^x}{x^4} \right|_{x=1} = -2e. \end{aligned}$$

Thus it follows that  $T_1^3 \frac{e^x}{x} = e + \frac{e}{2}(x-1)^2 - \frac{e}{3}(x-1)^3$ .

In Sage in order to compute the Taylor expansion  $T_a^k f(x)$  of a given function  $f(x)$  around a point  $a$ , you can either apply the command `taylor(f(x), x, a, k)`, or type `f.taylor(x, a, k)`. Thus, a verification of the derivatives and the Taylor expansion presented above is obtained by the cell

```
f(x)=e^x/x
a=diff(f, x, 2); show(a); show(a(1))
b=diff(f, x, 3); show(b); show(b(1))
show(taylor(f(x), x, 1, 3))
```

In order to check the accuracy of the approximation near the point  $a = 1$ , we can check the values of  $f$  and  $T_1^3 f$  at a point close to  $a = 1$ , say at  $x = 1.1$ . The block

```
f(x)=exp(x)/x; T(x)=taylor(f(x), x, 1, 3)
show("Value of the function at x=1.1:",
     round(f(x=1.1), 10))
show("3rd degree Taylor pol. at x=1.1:",
     round(T(x=1.1), 10))
```

returns the desired answer, namely:

- Original value of the function at  $x = 1.1$ : 2.7310600218,
- 3rd degree Taylor polynomial at  $x = 1.1$ : 2.7309671437.

The function  $\arctan(x)$  can be treated in the same way. For instance, the syntax `show(taylor(arctan(x), x, 1, 3))` gives us the following expression.

$$T_1^3 \arctan(x) = \frac{\pi}{4} + \frac{1}{2}(x-1) - \frac{1}{4}(x-1)^2 + \frac{1}{12}(x-1)^3.$$

**PROOF.** The proof is identical with the special case of function  $\sin x$  above. Except that the universal bound by 1 is replaced by  $M$ , and thus the estimate of the remainders are

$$|f(x) - (T_a^k f)(x)| \leq \frac{M}{(k+1)!} |x|^{k+1}. \quad \square$$

**6.1.5. Local behaviour of functions.** With the Taylor expansions at hand, let us return to the local or global behaviour of real functions of one real variable. We have seen that the sign of the first derivative of a differentiable function determines whether it is increasing or decreasing on some neighbourhood of the given point. If the derivative is zero, it is one of the so called critical points, but we do not know about the function much without looking at higher derivatives.

We encountered the importance of the second derivative when analysing the critical points, see 6.1.2. Now we generalize the discussion of critical points for all orders. First we deal with the local extremes of functions.

In the following we consider real functions with a sufficiently high number of continuous derivatives, without specifically stating this assumption.

The point  $a$  in domain of  $f$  is a *critical point of order  $k$*  if and only if

$$f'(a) = \dots = f^{(k)}(a) = 0, \quad f^{(k+1)}(a) \neq 0.$$

Suppose  $f^{(k+1)}(a) > 0$  and  $f \in C^{k+1}$ . Then this continuous derivative is positive on a certain neighbourhood  $\mathcal{O}(a)$  of the point  $a$  as well. In that case, the Taylor expansion with the remainder gives

$$f(x) = f(a) + \frac{1}{(k+1)!} f^{(k+1)}(a)(x-a)^{k+1}$$

for all  $x$  in  $\mathcal{O}(a)$ . Because of that, the change of values of  $f(x)$  in a neighbourhood of  $a$  is given by the behaviour of  $(x-a)^{k+1}$ . Moreover, if  $k+1$  is an even number, then the values of  $f(x)$  in such a neighbourhood are necessarily larger than the value  $f(a)$ . So  $a$  is a local minimum. But if  $k$  is even then the values on the left are smaller, while those on right are larger than  $f(a)$ . So an extreme does not occur even locally. On the other hand, the graph of the function  $f(x)$  intersects its tangent  $y = f(a)$  at the point  $[a, f(a)]$  in the latter case, as discussed in more detail below.

Similarly, if  $f^{(k+1)}(a) < 0$ , then it is a local maximum for odd  $k$ , and there is no extreme for even  $k$ .

**6.1.6. Convex and concave functions.** The differentiable function  $f$  is *concave* at  $a$ , if its graph lies completely below the tangent at the point  $[a, f(a)]$  in a neighbourhood of  $a$ . That is,

$$f(x) \leq f(a) + f'(a)(x-a).$$

Similarly  $f$  is *convex* at  $a$ , if its graph is above the tangent at the point  $a$ . That is,

$$f(x) \geq f(a) + f'(a)(x-a).$$

To check the accuracy, one can apply the same method as for  $f(x) = \frac{e^x}{x}$ .  $\square$

**6.A.10.** Determine the Taylor expansion  $T_1^4 f(x)$  where  $f(x) = \ln(x^2)$ , with  $x \in (0, 2)$ . Next use Sage to plot together  $f(x)$  and  $T_1^4 f(x)$ , for  $x$  in the domain of  $f$ .  $\circ$

**6.A.11.** Consider the function  $f(x) = \cos(x)$  with  $x \in \mathbb{R}$ . Use Sage to sketch in one diagram the graph of  $f$  together with the graphs of Taylor polynomials  $T_a^k f(x)$  for  $k = 2, 3, 5, 7, 9$  and  $a = \pi/2$ , for certain intervals of  $\mathbb{R}$ .

**Solution.** Sage allows us to use different colours to present the required graphs, and this makes easier their recognition. Based on this remark, one can present the following figure.

To produce this figure we use the `taylor` function to introduce the required Taylor polynomials. We then sketch their graphs via the `plot` command, which we use with some more advanced options (for example, any polynomial comes with a label, that we did via the `legend_label` option). Let us present the full syntax in a block:

```
f(x)=cos(x)
p=plot(f(x), x, -2*pi, 2*pi,color="green",
legend_label=r"$f(x)=\cos(x)$")
T2(x)=taylor(f(x), x, pi/2, 2)
T3(x)=taylor(f(x), x, pi/2, 3)
T5(x)=taylor(f(x), x, pi/2, 5)
T7(x)=taylor(f(x), x, pi/2, 7)
T9(x)=taylor(f(x), x, pi/2, 9)
p2=plot(T2(x), x, -2*pi, 2*pi,
legend_label=r"$T^2_{\frac{\pi}{2}}(x)$")
p3=plot(T3(x), x, -pi, 2*pi, color="red",
legend_label=r"$T^3_{\frac{\pi}{2}}(x)$")
p5=plot(T5(x), x, -pi, 2*pi, color="orange",
legend_label=r"$T^5_{\frac{\pi}{2}}(x)$")
p7=plot(T7(x), -pi, 2*pi, color="black",
legend_label=r"$T^7_{\frac{\pi}{2}}(x)$")
p9=plot(T9(x), -pi, 2*pi, color="brown",
legend_label=r"$T^9_{\frac{\pi}{2}}(x)$")
show(p+p2+p3+p5+p7+p9)
```

For further practice with Taylor polynomials, check [6.B.40](#) and see also in [Section D](#) for a series of additional tasks (e.g., [6.D.5](#)).  $\square$

A function is convex or concave on an interval, if it has this property at all its points.

Suppose  $f$  has continuous second derivatives in a neighbourhood of  $a$ . The Taylor expansion of second order with the remainder implies

$$f(x) = f(a) + f'(a)(x - a) + \frac{1}{2}f''(c)(x - a)^2.$$

Then the function is convex, whenever  $f''(a) > 0$ , and concave whenever  $f''(a) < 0$ .

If the second derivative is zero, we can use derivatives of higher orders. But we can only make the same conclusion if the first other nonzero derivative after the first derivative is of even order. If the first nonzero derivative is of odd order, the points of the graph of the function on opposite sides of some small neighbourhood of the studied point will lie on opposite sides of the tangent at this point.

**6.1.7. Inflection points.** A point  $a$  is called an *inflection point* of a differentiable function  $f$ , if the graph of  $f$  crosses from one side of the tangent in the point  $a$  to the other. The latter discussion on concave and convex functions shows that the inflections can appear only at points with vanishing second derivative.

Suppose  $f$  has continuous third derivatives and write the Taylor expansion of third order with the remainder:

$$f(x) = f(a) + f'(a)(x - a) + \frac{1}{2}f''(a)(x - a)^2 + \frac{1}{6}f'''(c)(x - a)^3.$$

If  $a$  is a zero point of the second derivative such that  $f'''(a) \neq 0$ , then the third derivative is nonzero on some neighbourhood. Then  $a$  is an inflection point since the second derivative changes the sign at  $a$  and thus the tangent crosses the graph. In that case, the sign of the third derivative determines whether the graph of the function crosses the tangent from the top to the bottom or vice versa.

Moreover, if  $a$  is an isolated zero point of the second derivative and simultaneously an inflection point, then on some small neighbourhood of  $a$  the function is concave on one side and convex on the other. Thus the inflection points are points of the change between concave and convex behaviour of the graph of the function.

So far we have learned how to use Taylor polynomials to approximate smooth functions. Whenever we use an approximation technique, it is important to have a sense for how accurate our approximations are, as for example the Lagrange interpolation error presented in 5.E.9. For Taylor expansions the situation is encoded by the so called Remainder Theorem, which is described in theoretical section 6.1.3. Let us illustrate this by examples.

**6.A.12.** Determine the Taylor polynomial  $T_0^6 f(x)$ , where  $f(x) = \sin(x)$ , and next estimate the error of the approximation at the point  $x = \pi/4$ , according to the Theorem 6.1.3.

**Solution.** It is easy to prove that

$$T_0^6 \sin(x) = x - \frac{1}{6}x^3 + \frac{1}{120}x^5.$$

According to the statement in 6.1.3, the estimate of the remainder  $R$  at  $a = 0$  is thus given by (the absolute value of) the expression  $\frac{f^{(k+1)}(c)}{(k+1)!}x^{k+1}$ , for some  $c \in (0, \frac{\pi}{4})$  and  $k = 6$ . We compute  $f^{(7)}(x) = -\cos(x)$ , for all  $x \in \mathbb{R}$ , and so at  $x = \pi/4$  we obtain

$$R(\pi/4) = \left| \frac{-\cos(c)\pi^7}{7!4^7} \right| < \frac{1}{7!} \approx 0,0002.$$

□

**6.A.13.** Show that  $e^x \geq 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!}$ . ○

**6.A.14.** Find the estimation of the error of the approximation

$$\ln(1+x) \approx x - \frac{x^2}{2}$$

for  $x \in (-1, 0)$ . ○

**6.A.15.** Consider the sine function  $f(x) = \sin(x)$ , with  $x \in \mathbb{R}$ . Compute the Taylor polynomial  $T_0^4 f(x)$  and use Sage to plot together the graphs of  $T_0^4 f(x)$  and of  $f(x)$ . Finally, based on your answer estimate  $\sin(1^\circ)$ . ○

**6.A.16.** Compute an approximation of  $\cos \frac{\pi}{10}$  with an error less than  $10^{-5}$ . ○

Taylor series are power series having as partial sums the Taylor polynomials of a given function. Taylor series need not be convergent, and even if the Taylor series of a function  $f$  does converge, its limit may not be equal to  $f(x)$ .

Functions  $f$  whose Taylor series  $\sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!}(x-a)^n$  converges to  $f(x)$  for all  $x$  in some open neighbourhood of  $a$ , are said to be “analytic at  $a$ ”. When  $f$  is analytic at any point in an interval  $I \subset \mathbb{R}$ , then  $f$  is said to be “analytic on  $I$ ”, see also in 6.1.9. As we will explain below, for analytic functions the power series representation allows us to solve problems as if the function were a polynomial.

In general not all the functions are analytic, and in particular functions with discontinuities cannot be even expressed as Taylor series. However, most of the functions that

**6.1.8. Asymptotes of graphs of functions.** We introduce one more useful utility for understanding or sketching the graph of a function. We consider the *asymptotes*. These are lines in  $\mathbb{R}^2$  whose distance from the graph of  $f(x)$  converges to zero for  $x \rightarrow x_0$ .

Thus, an asymptote at the improper point  $\infty$  is a line  $y = ax + b$ , which satisfies

$$\lim_{x \rightarrow \infty} (f(x) - ax - b) = 0.$$

An *asymptote with a slope*. If such an asymptote exists, it satisfies

$$\lim_{x \rightarrow \infty} (f(x) - ax) = b$$

Consequently the limit

$$\lim_{x \rightarrow \infty} \frac{f(x)}{x} = a$$

also exists.

Conversely, if the last two limits exist, the limit from the definition of the asymptote exists as well, thus these are sufficient conditions, too.

The asymptote at the improper point  $-\infty$  is defined similarly.

In this way we find all the lines satisfying the properties of asymptotes with slope. It remains to consider lines perpendicular to the  $x$  axis:

The asymptotes at points  $a \in \mathbb{R}$  are lines  $x = a$  such that the function  $f$  has at least one of the one-sided limits at  $a$  has infinite value. They are called *asymptotes without slope*.

The real rational functions have asymptotes at all zero points of the denominator which are not zero points of the numerator as well.

We consider a simple illustrative example: Let

$$f(x) = x + \frac{1}{x}.$$

$f$  has two asymptotes  $y = x$  and  $x = 0$ . Indeed, the one-sided limits from the right and left at zero are clearly  $\pm\infty$ , while the limit  $f(x)/x = 1 + 1/x^2$  is of course 1 at the improper points. Finally the limit of  $f(x) - x = 1/x$  is zero at the improper points.

By differentiating,

$$f'(x) = 1 - x^{-2}, \quad f''(x) = 2x^{-3}.$$

The function  $f'(x)$  has two zero points  $\pm 1$ . At  $x = 1$ ,  $f$  has a local minimum. At  $x = -1$ ,  $f$  has a local maximum. The second derivative has no zero points in all its domain  $(-\infty, 0) \cup (0, \infty)$ , so  $f$  has no inflection points.

arise in applications are usually analytic. In the end of Chapter 5 we met for example the analytic functions

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots = \sum_{k=0}^{\infty} \frac{x^k}{k!},$$

$$\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} x^{2k+1},$$

$$\cos(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} x^{2k}.$$

In fact it is not hard to prove that the Taylor series of  $\cos(x)$  occurs from the Taylor series of  $\sin(x)$  around the origin, after differentiation.

Another example is induced by the equality

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \dots = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k} x^k.$$

This will be proved later in Section C, where you will have the chance to learn more details on the convergence of Taylor series (see 6.D.47).

Finally, a remarkable common property of all the examples mentioned above, is that the Taylor series in the r.h.s. are centered at  $a = 0$ . Such Taylor series are referred to as “Maclaurin series”. As we will see, from the Maclaurin series we can build many other examples through substitution and series multiplication.

**6.A.17.** Consider the functions

$$f(x) = \ln\left(\frac{1+x}{1-x}\right), \quad g(x) = e^{x^2} + x^2 e^{-2x}$$

with  $x \in (-1, 1)$  and  $x \in \mathbb{R}$ , respectively. Expand them into a Taylor series centered at the origin, that is, into a Maclaurin series, and then present a verification in Sage.

**Solution.** We first analyze the case for  $f(x)$ . We know that  $\ln(1+x) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} x^n$ , which implies that

$$\ln(1-x) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (-x)^n = -\sum_{n=1}^{\infty} \frac{1}{n} x^n.$$

Thus, for all  $x \in (-1, 1)$  we have the relation

$$\ln\left(\frac{1+x}{1-x}\right) = \ln(1+x) - \ln(1-x) = 2 \sum_{n=1}^{\infty} \frac{x^{2n-1}}{2n-1}.$$

In order to verify this computation in Sage we could type

```
var("n"); assume(x>0)
sum((2/(2*n-1))*x^(2*n-1), n, 1, oo)
```

and this prints out the desired result, i.e.,  $\ln(-(x+1)/(x-1))$ . On the other side, we could use Sage to derive the Taylor series directly, as follows:

```
f(x)=ln((1+x)/(1-x))
tf=taylor(f, x, 0, 10)
T=tf.power_series(QQ)
show(T)
```

**6.1.9. Analytic and smooth functions.** If  $f$  is smooth at  $a$ , the formal power series can be written

$$S(x) = \sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(a)(x-a)^n.$$

If this power series has a nonzero radius of convergence and simultaneously  $S(x) = f(x)$  on the respective interval, we say that  $f$  is an analytic function at  $a$ . A function is analytic on an interval, if it is analytic at its every point.

One of the most important functions in Mathematics and Physics is the following

GAUSSIAN FUNCTION

The analytic function

$$g(x) = e^{-x^2}.$$

is called the Gaussian function.

Indeed, the Gaussian is analytic – we simply replace  $x$  with  $-x^2$  in the power series for the exponential  $e^x$  and it is an analytic function on the entire  $\mathbb{R}$ . Its derivatives are easily computed, too. In particular  $g'(0) = 0$  is the only singular point and  $g''(0) = -2$ . Since the limits at  $\pm\infty$  are zero, the number  $g(0) = 1$  is the global maximum of the Gaussian function (see ?? for more detailed comments).

We shall see why the function is so important in Chapter 10 when dealing with probability and statistics.

The Gaussian  $g(x)$  and the function  $f(x) = g(1/x)$  are depicted on the figure,  $f(x)$  is the solid line, while the Gaussian function is dashed.

Notice how firmly the function  $f$  touches the  $x$  axis. We are going to explain this.

This returns the Taylor series corresponding to  $f(x)$ , in the following form

$$2x + \frac{2}{3}x^3 + \frac{2}{5}x^5 + \frac{2}{7}x^7 + \frac{2}{9}x^9 + O(x^{10}).$$

Here, Sage uses the “big O” notation to encode terms of higher order (in our case of order  $\geq 10$ , since we “asked” the Taylor expansion to be of order 10).

For the second function by the identity  $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$  we obtain

$$e^{x^2} = \sum_{n=0}^{\infty} \frac{x^{2n}}{n!}, \text{ for all } x \in \mathbb{R}. \text{ Moreover, } x^2 e^{-2x} =$$

$$x^2 \sum_{n=0}^{\infty} \frac{1}{n!} (-2x)^n = \sum_{n=0}^{\infty} \frac{(-2)^n}{n!} x^{n+2}, \text{ and hence}$$

$$e^{x^2} + x^2 e^{-2x} = \sum_{n=0}^{\infty} \frac{x^{2n} + (-2)^n x^{n+2}}{n!}.$$

The verification in Sage for this case is left for practice.  $\square$

**6.A.18.** Determine the Taylor series centered at the origin for the functions  $f(x) = \frac{1}{(1+x)^2}$ , with  $x \in (-1, 1)$ . Next confirm your result by Sage.  $\circ$

*Maclaurin series are also useful when compute limits, and here is a task for you to perform yourself, see also 6.D.6.*

**6.A.19.** Use the appropriate Maclaurin series to compute the limits  $\lim_{x \rightarrow 0} \frac{x \sin(x) - x^2}{x^4}$ , and  $\lim_{x \rightarrow 0} x^2 \left( e^{-\frac{1}{x^2}} - 1 \right)$ .  $\circ$

Let us now stress the use of derivatives when studying the “local behaviour” of functions, and hence revise the discussion initiated in Chapter 5 (cf. 5.C.15, 5.C.17). This is based on many new notions introduced in ??, and essentially includes the description of the following features of  $f$ :

- the domain and the range;
- parity and periodicity;
- discontinuities and their kind;
- points of intersections with the axes;
- the limits  $\lim_{x \rightarrow \pm\infty} f(x)$ ;
- the first and the second derivatives;
- the critical points (also called stationary points);
- the intervals of monotonicity;
- local and absolute extremes;
- the intervals where  $f$  is convex/concave;
- the points of inflection;
- the horizontal and inclined asymptotes;
- the graph.

In order to become familiar with these notions, we present many illustrative examples.

Not all smooth functions are analytic. It can be proven that for every sequence of numbers  $a_n$  there is a smooth function, whose derivatives of order  $k$  at a given point  $x_0$  are these numbers  $a_k$ .<sup>2</sup> Now, look more closely at our function

$$f(x) = e^{-1/x^2}.$$

It is a well defined smooth function at all points  $x \neq 0$ . Its limit at  $x = 0$  exists, and  $\lim_{x \rightarrow 0} f(x) = 0$ . By defining  $f(0) = 0$ ,  $f$  is a continuous function for all real  $x$ .

By a direct computation based on L’Hospital’s rule we compute the derivatives of  $f$  (the first three ones are at the picture, guess which line is which!). It suffices to consider only the right derivative, since the function is even.

$$\begin{aligned} f'(0) &= \lim_{x \rightarrow 0^+} \frac{e^{-1/x^2} - 0}{x} = \lim_{x \rightarrow 0^+} \frac{x^{-1}}{e^{1/x^2}} \\ &= \frac{1}{2} \lim_{x \rightarrow 0^+} \frac{x}{e^{1/x^2}} = 0. \end{aligned}$$

By differentiating  $f(x)$  at an arbitrary point  $x \neq 0$ ,  $f'(x) = e^{-1/x^2} \cdot 2x^{-3}$ . By repeated differentiation of the results, there is always a sum of finitely many terms of the form

$$C \cdot e^{-1/x^2} \cdot x^{-j},$$

where  $C$  is an integer and  $j$  is a natural number.

Next, assume it is already proven that the derivative of order  $k$  of  $f(x)$  exists and vanishes at zero. Compute the limit of the expression  $f^{(k)}(x)/x$  for  $x \rightarrow 0^+$ . This is a finite sum of limits of the expressions  $Cx^{-j} e^{-1/x^2} = x^{-j} / e^{1/x^2}$ . All these expressions are of type  $\infty/\infty$ , so L’Hôpital’s rule can be used repeatedly on them. After several differentiations of both the numerator and denominator (and a similar adjustment as above) there remains the same expression in the denominator, while in the numerator the power is non-negative. Thus the expression necessarily has a zero limit at zero, just as in the case of the first derivative above. The same holds for a finite sum of such expressions. So each derivative  $f^{(k)}(x)$  at zero exists with value zero.

<sup>2</sup>This is a special case of the Whitney extension theorem, which says that there is a smooth function on a Euclidean space with prescribed derivatives in all points of a closed set  $A$  if and only if the Taylor theorem estimates are true for the prescription. In the case of one single point  $A$ , the condition is empty. This is relevant for the Taylor theorem for functions of more than one real variable, as in Chapter 8. Hasler Whitney (1907-1989) was a very influential American mathematician.

- 6.A.20.** (a) Find the critical points and the local extremes of the function  $f(x) = \sqrt[3]{x^2} = x^{\frac{2}{3}}$ , with  $x \in \mathbb{R}$ .  
 (b) Provide an example of a function  $g$  satisfying  $g'(0) = 0$  but  $g$  does not attain a local extreme at  $x_0 = 0$ .  
 (c) Provide an example of a function having no local minima or maxima.

**Solution.** (a) The given function  $f$  is continuous in  $\mathbb{R}$  and for any  $x > 0$  we have (see also 5.C.24)

$$f'(x) = (x^{\frac{2}{3}})' = \frac{2}{3}x^{\frac{2}{3}-1} = \frac{2}{3}x^{-\frac{1}{3}} = \frac{2}{3\sqrt[3]{x}}.$$

Comparing the left and right derivatives, one can check that at  $x = 0$  the function  $f$  is *not* differentiable. This can be done quickly via Sage, by the syntax

```
f(x)=x^(2/3)
show(lim((f(x)-f(0))/x, x=0, dir="right"))
show(lim((f(x)-f(0))/x, x=0, dir="left"))
```

which prints out  $+\infty$ , and  $-\infty$ , respectively. Moreover, we see that  $f'(x) = 0$  has no solutions, hence  $f$  has no critical points (in terms of 6.1.5). We already know from Chapter 5 how to obtain a confirmation of the critical points via Sage: just add the cell

```
show(solve(diff(f, x).factor()==0, x))
```

On the other hand, we see that  $f'(x) > 0$  for  $x > 0$  and  $f'(x) < 0$  for  $x < 0$ . Hence  $f'$  changes from negative to positive at  $x_0 = 0$ , and since  $f$  is continuous at  $x_0 = 0$  this implies that  $f$  attains a local minimum at this point. Thus local extremes of a function may occur at places where the first derivative does *not* exist.

(b) An example is given by the function  $g(x) = x^3$ , which obviously satisfies  $g'(0) = 0$ , but the origin is neither a local minimum nor a local maximum of  $g$  (recall the graph of  $g$ , or see below). This shows that stationary points are not necessary local extremes.

(c) An example is given by the (equilateral) hyperbola  $y = h(x) = 1/x$  with  $x \in A := \mathbb{R} \setminus \{0\} = (-\infty, 0) \cup (0, +\infty)$ . Indeed, for  $x_1, x_2 \in (0, +\infty)$  with  $x_1 < x_2$  we have  $\frac{1}{x_1} > \frac{1}{x_2}$ , i.e.,  $h(x_1) > h(x_2)$ , and thus  $y = h(x)$  is strictly decreasing on  $(0, +\infty)$ . Since  $h$  is an odd function,  $h(-x) = -h(x)$  for all  $x \in A$ , we immediately deduce that  $h$  is strictly decreasing on  $(-\infty, 0)$ , as well, and hence on its whole domain  $A$ . This also follows by the first derivative test:  $h'(x) = -1/x^2 < 0$  for all  $x \in A$ . Hence there are no extreme points, a conclusion that one can illustrate by sketching the graph of  $h$  ( $h$  is an odd function, hence its graph is symmetric with respect to the origin, see also the figure below). Moreover, we have  $\lim_{x \rightarrow 0^+} h(x) = +\infty$  and hence the  $y$ -axis ( $x = 0$ ) is a vertical asymptote of  $h$ . In addition, the  $x$ -axis ( $y = 0$ ) is a horizontal asymptote, since  $\lim_{x \rightarrow +\infty} h(x) = 0$ .

In summary,  $f(x)$  is smooth on the whole of  $\mathbb{R}$ . It is strictly positive everywhere except for  $x = 0$ . All its derivatives at this point are zero.

It cannot be analytic at  $x_0 = 0$ . The limit of the function at the improper points  $\pm\infty$  is 1, while all its derivatives converge quickly to zero.

**6.1.10. Smooth jump functions.** The smooth functions are very “elastic” — from a local behaviour around one point we cannot deduce anything at all about the global behavior of such functions. On the other hand, analytic functions are completely determined just by derivatives at one point. In particular they are completely determined by their behaviour on an arbitrarily small neighbourhood of a single point from their domain. In this sense, analytic functions are very “rigid”.

In particular, the smooth functions allow for joining different constant values on disjoint open intervals in a differentiable way.

Let us look at such functions more closely now. We can modify  $f(x)$  from the previous paragraph in this way:

$$g(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ e^{-1/x^2} & \text{if } x > 0. \end{cases}$$

Again it is a smooth function on all of  $\mathbb{R}$ . By another modification there is another function  $h$ , which is nonzero at all inner points of the interval  $[-a, a]$ ,  $a > 0$  and zero elsewhere.

$$h(x) = \begin{cases} 0 & \text{if } |x| \geq a \\ e^{\frac{1}{x^2-a^2} + \frac{1}{a^2}} & \text{if } |x| < a. \end{cases}$$

This function is again smooth on all of  $\mathbb{R}$ . The last two functions are in the two figures. On the right, the parameter  $a = 1/2$  is used.

Finally we show how to get smooth analogies of the Heaviside functions. For two fixed real numbers  $a < b$ , define the function  $f(x)$  exploiting the above function  $g$  as follows:

$$f(x) = \frac{g(x-a)}{g(x-a) + g(b-x)}.$$

For all  $x \in \mathbb{R}$  the denominator of the fraction is positive (because  $g$  is non-negative). For each of the three intervals determined by numbers  $a$  and  $b$  at least one of the summands of the denominator is nonzero). Thus the definition yields a smooth function  $f(x)$  on all of  $\mathbb{R}$ . For  $x \leq a$  the numerator of the fraction is zero according to the definition of  $g$ . For  $x \geq b$

Our figure also contains the graph of the function  $k(x) = -1/x$ , which is symmetric to the graph of  $h(x) = 1/x$  with respect to the  $x$ -axis. Notice that  $k$  has the same domain as  $h$  and is strictly increasing on  $A$ , since  $k'(x) = \frac{1}{x^2} > 0$  for all  $x \in A$ . Hence it provides another example of a function having no local minima or maxima. A generalization occurs by the hyperbolas  $y = a/x$ , with  $a > 0$  and  $a < 0$ , respectively.

For convenience, let us finally include the code used in Sage to construct these graphs:

```
h(x)=1/x; k(x)=-1/x
p=plot(h(x), x, -5, 5, ymin=-5, ymax=5,
  rgbcolor=(0.2,0.2,0.5), thickness=1.2)
p+=text(r"$y=\frac{1}{x}$", \ x>0$, (3, 2),
  fontsize=16, rgbcolor=(0.2,0.2,0.5))
p+=text(r"$y=\frac{1}{x}$", \ x<0$, (-3, -2),
  fontsize=16, rgbcolor=(0.2,0.2,0.5))
p+=plot(k(x), x, -5, 5, ymin=-5, ymax=5,
  rgbcolor=(0.2,0.5,0.2), thickness=1.2)
p+=text(r"$y=-\frac{1}{x}$", \ x<0$, (-3, 2),
  fontsize=16, rgbcolor=(0.2,0.5,0.2))
p+=text(r"$y=-\frac{1}{x}$", \ x>0$, (3, -2),
  fontsize=16, rgbcolor=(0.2,0.5,0.2)); show(p)
```

□

**6.A.21. An annoying technicality.** Generally speaking, Sage is still a work “in progress” and hence its users may face some technicalities. For instance, try to produce the graph of  $f(x) = x^{\frac{2}{3}}$  with  $x \in \mathbb{R}$  (or of  $x \mapsto x^{\frac{1}{3}} = \sqrt[3]{x}$ ), in a traditional way. In this case Sage will sketch only the portion corresponding to the positive reals. This problem occurs since Sage returns complex numbers for odd roots of negative numbers, when the latter are numerically approximated. This is the situation when, for example, one tries to sketch the graph of  $f$ . In order to realize this fact, in your editor type the syntax

```
c1 = (-1)^(2/3); print(c1)
print(float(c1))
c2 = (-1.)^(2/3); print(c2); float(c2)
```

For  $c1$  and by the third command, Sage returns the error “unable to simplify to float approximation”, while for  $c2$  the error

the numerator and denominator are equal. In the next two figures there are functions  $f(x)$  with parameters  $a = 1 - \alpha$ ,  $b = 1 + \alpha$ . On the left  $\alpha = 0.8$ , and on the right  $\alpha = 0.4$ .

Finally, we can create a smooth analogue of the characteristic function of any interval  $[c, d]$ .

Write  $f_\varepsilon(x)$  for the latter function  $f(x)$  with parameters  $a = -\varepsilon$ ,  $b = +\varepsilon$ . For the interval  $(c, d)$  with the length  $d - c > 2\varepsilon$  define the function  $h_\varepsilon(x) = f_\varepsilon(x - c) \cdot f_\varepsilon(d - x)$ . This function is identically zero on the intervals  $(-\infty, c - \varepsilon)$  and  $(d + \varepsilon, \infty)$ . It is identically one on the interval  $(c + \varepsilon, d - \varepsilon)$ . Moreover, it is smooth everywhere. Locally it is either constant or monotonic (you should verify the last claim yourself). The smaller the  $\varepsilon > 0$ , the faster  $h_\varepsilon(x)$  jumps from zero to one around the beginning of the interval or back at the end of it.

The diagram shows the choices  $[c, d] = [1, 2]$  and  $\varepsilon = 0.6$ ,  $\varepsilon = 0.3$ .

**6.1.11. Differential of a function.**

In practical use of differential calculus, we often work with dependencies between several variables, say  $y$  and  $x$ . The choice of dependent and independent variable is not fixed. The explicit relation  $y = f(x)$  with some function  $f$  is then only one of possible options. Differentiation then expresses that the immediate change of  $y = f(x)$  is proportional to the immediate change of  $x$  with the proportion of  $f'(x) = \frac{df}{dx}(x)$ .

This relation is often written as  $dy = f'(x)dx$ , or

$$df(x) = f'(x)dx,$$

where we interpret  $df(x)$  as a linear map  $\mathbb{R} \rightarrow \mathbb{R}$  defined on increments of  $x$  at the given point,  $df(x)(v) = f'(x) \cdot v$ , while the identity map yields  $dx(x)(v) = v$ .

We talk about the *differential of function*  $f$ , which is the best linear approximation of the function  $f$  around the point

from the command `float(c2)` is about the difficulty of converting a complex number to float (notice the difference in the definition of `c1`, `c2`). In this case Sage advises us to use some of the options `abs()` or `real_part()`. Motivated by this, to cure our problem for the given  $f$  we may instead plot the graph of  $|x|^{\frac{2}{3}}$ , see the figure below.

**6.A.22.** Recall that if  $x_0$  is a critical point of a differentiable function and  $f''(x_0) > 0$ , then  $f'$  is strictly increasing near  $x_0$ . Therefore, the conditions  $f'(x_0) = 0$  and  $f''(x_0) > 0$  imply that  $x_0$  is a local minimum. Similarly, the conditions  $f'(x_0) = 0$  and  $f''(x_0) < 0$  imply that  $x_0$  is a local maximum. Show with a counterexample that the converse of these conclusions are not true in general.  $\circ$

**6.A.23.** Suppose that a function  $f : \mathbb{R} \rightarrow \mathbb{R}$  admits the line  $y = 3x + 1$  as an asymptote with slope, as  $x \rightarrow +\infty$ . Compute the limit

$$\lim_{x \rightarrow +\infty} \frac{xf(x) + 7x^2 + 2}{x^2f(x) + 3x^3 + 5x^2 + 2}.$$

**Solution.** By the definition of an asymptote with slope, we have

$$\lim_{x \rightarrow +\infty} \frac{f(x)}{x} = 3, \text{ and } \lim_{x \rightarrow +\infty} (f(x) - 3x) = 1.$$

Thus, if we denote by  $A$  the given limit, by dividing both the numerator and denominator by  $x^2$  we get

$$\begin{aligned} A &= \lim_{x \rightarrow +\infty} \frac{\frac{f(x)}{x} + 7 + \frac{2}{x^2}}{f(x) - 3x + 5 + \frac{2}{x^2}} \\ &= \frac{\lim_{x \rightarrow +\infty} \left(\frac{f(x)}{x}\right) + \lim_{x \rightarrow +\infty} \left(7 + \frac{2}{x^2}\right)}{\lim_{x \rightarrow +\infty} (f(x) - 3x) + \lim_{x \rightarrow +\infty} \left(5 + \frac{2}{x^2}\right)} = \frac{3 + 7}{1 + 5} = 5/3. \end{aligned}$$

$\square$

*Let us describe a problem which requires a bit of integration, but in a very elementary level and hence already treatable. Further similar problems we will analyze in Section B and also in the final section of this chapter.*

**6.A.24.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a twice differentiable function on  $\mathbb{R}$  satisfying for all  $x \in \mathbb{R}$  the relation

$$(\sqrt{2}x^2 + 1)f''(x) + 4\sqrt{2}xf'(x) + 2\sqrt{2}f(x) = 0. \quad (*)$$

(a) Find those differentiable functions  $g : \mathbb{R} \rightarrow \mathbb{R}$  satisfying  $g(x) = 2\sqrt{2}xf(x) + (\sqrt{2}x^2 + 1)f'(x)$ ;

(b) Based on your answer in (a), determine the function  $f$ , if in addition it is known that the graph  $C_f$  of  $f$  passes through

$x$ , i.e. the following approximation property is true:

$$(1) \quad \lim_{v \rightarrow 0} \frac{f(x+v) - f(x) - df(x)(v)}{v} = 0.$$

Since we are working in dimension 1, the definition is equivalent to the existence of the derivative  $f'(x)$  (all linear maps are just multiplications by a constant) and then the differential is  $df(x)(v) = f'(x)v$ . Later, we shall see that the situation is quite different for functions of more variables.

If the quantity  $x$  is expressed by another quantity  $t$ , e.g.  $x = g(t)$  and, moreover,  $g$  is differentiable, the chain rule for differentiating the composite functions says that  $f \circ g$  has the differential too and

$$df(t) = d(f \circ g)(t) = \frac{df}{dx}(x) \frac{dx}{dt}(t) dt.$$

We may also write  $dy = f'(x)dx = f'(g(t))g'(t)dt$ . Therefore  $dy$  can be seen as a linear approximation of the given quantity independently of the choice of the dependent variable.

**6.1.12. The numerical derivatives.** We shall conclude this

section with two straightforward applications of differentials. First we provide a brief introduction to the numerical procedures for differentiation. Then we discuss curves in the plane and space, starting with the graphs of functions. This will also provide first glimpses into the so called vector calculus (working with vector valued functions).

In the beginning of this textbook we discussed how to describe the values in a sequence if its immediate differences are known, (c.f. paragraphs 1.1.5, 1.2.1). Before proceeding the same way with the derivatives we clarify the connections between derivatives and differences. The key to this is the Taylor expansion with remainder.

Suppose that for some (sufficiently) differentiable function  $f(x)$  defined on the interval  $[a, b]$ , the values  $f_i = f(x_i)$  at the points  $x_0 = a, x_1, x_2, \dots, x_n = b$ , are given while  $x_i - x_{i-1} = h$  for some constant  $h > 0$  and all indices  $i = 1, \dots, n$ . Write the Taylor expansion of function  $f$  in the form

$$f(x_i \pm h) = f_i \pm hf'(x_i) + \frac{h^2}{2}f''(x_i) \pm \frac{h^3}{3!}f^{(3)}(x_i) + \dots$$

Suppose the expansion is terminated at the term containing  $h^k$  which is of order  $k$  in  $h$ . Then the actual error is bounded by

$$\frac{h^{k+1}}{(k+1)!} |f^{(k+1)}(x)|$$

on the interval  $[x_i - h, x_i + h]$ . If the  $(k+1)^{th}$  derivative  $f$  is continuous, it can be bounded by a constant. Then for small  $h$ , the error of the approximation by the Taylor polynomial of order  $k$  acts like  $h^{k+1}$  except for a constant multiple. Such an estimation is called an *asymptotic estimation*.

the origin and the tangent line of  $C_f$  at the origin is perpendicular to the line determined by the equation  $x + \sqrt{2}y - 1 = 0$ ;

(c) Use Sage to confirm that your answer in (b) satisfies indeed the initial condition (\*). Moreover, sketch the graph of  $f$  for  $-10 \leq x \leq 10$ . Where did we meet such a similar function earlier?

(d) Use Sage to specify the local extremes of  $f$  and characterize their type.

**Solution.** (a) By differentiating the relation  $g(x) = 2\sqrt{2}x f(x) + (\sqrt{2}x^2 + 1)f'(x)$ , with respect to  $x$ , we obtain

$$g'(x) = 2\sqrt{2}f(x) + 2\sqrt{2}x f'(x) + 2\sqrt{2}x f'(x) + (\sqrt{2}x^2 + 1)f''(x) = 0, \quad x \in \mathbb{R},$$

where the final equality follows by (\*). This implies that  $g(x) = c$  for all  $x \in \mathbb{R}$  for some constant  $c \in \mathbb{R}$ , i.e.,  $g$  is constant.

(b) One observes that

$$g(x) = 2\sqrt{2}x f(x) + (\sqrt{2}x^2 + 1)f'(x) = ((\sqrt{2}x^2 + 1)f(x))', \quad x \in \mathbb{R}.$$

In (a) we proved that  $g(x) = c$  for all  $x \in \mathbb{R}$ , hence a combination with the previous relation gives  $((\sqrt{2}x^2 + 1)f(x))' = c$ . Hence it is easy to guess that  $(\sqrt{2}x^2 + 1)f(x) = cx + \alpha$ , for some constant  $\alpha \in \mathbb{R}$ . As we will see in the forthcoming section, this follows by integrating both parts of the relation including the derivative, i.e.,

$$\int ((\sqrt{2}x^2 + 1)f(x))' dx = \int c dx \implies (\sqrt{2}x^2 + 1)f(x) = cx + \alpha, \quad \alpha \in \mathbb{R}.$$

The polynomial  $\sqrt{2}x^2 + 1$  has only complex roots, hence we can divide which yields the expression

$$f(x) = \frac{cx + \alpha}{\sqrt{2}x^2 + 1}, \quad \forall x \in \mathbb{R}. \quad (**)$$

To determine the constants  $c$  and  $\alpha$  we rely on the information specified by the scenario in (b). First,  $f$  passes through the origin, hence we need  $\alpha = 0$ . Next, the line  $x + \sqrt{2}y - 1 = 0$  is written as  $y = -\frac{1}{\sqrt{2}}x + 1 = -\frac{\sqrt{2}}{2}x + 1$ , which means that its slope equals to  $-\frac{\sqrt{2}}{2}$ . Since the tangent line of  $f$  at the origin should be perpendicular to this line, we need  $f'(0) = \frac{2}{\sqrt{2}} = \sqrt{2}$ , such that  $-\frac{\sqrt{2}}{2} \cdot \sqrt{2} = -1$ . Therefore, to determine  $c$  we need to solve the equation  $f'(0) = \sqrt{2}$ . So, let us use (\*\*) (for  $\alpha = 0$ ) to compute  $f'(x)$ :

$$f'(x) = \frac{c(-\sqrt{2}x^2 + 1)}{(\sqrt{2}x^2 + 1)^2}, \quad x \in \mathbb{R}.$$

Thus  $f'(0) = \sqrt{2}$  if and only if  $c = \sqrt{2}$ , which means that  $f(x) = \frac{\sqrt{2}x}{\sqrt{2}x^2 + 1}$ , for all  $x \in \mathbb{R}$ .

(c) A confirmation in Sage relies on the command `bool`, as follows (we also include the syntax for sketching  $C_f$ )

ASYMPTOTIC ESTIMATES

**Definition.** The expression  $G(h)$  is *asymptotically equal* to  $F(h)$  for  $h \rightarrow 0$ , write  $G(h) = O(F(h))$ , if the finite limit

$$\lim_{h \rightarrow 0} \frac{G(h)}{F(h)} = a \in \mathbb{R}$$

exists.

Similarly, compare the expressions for  $h \rightarrow \infty$  and use the same notation.

If the limit is zero, then we write  $G(h) = o(F(h))$ .

This way of denoting the asymptotic behaviour is often called the *big O* and *small o* notation. For instance, the differentiability of a function  $f$  means that the error of the approximation of  $f$  by its differential is  $o(|h|)$  for increments  $h$  of the argument.

Determine the values of the derivatives of  $f(x)$  at the points  $x_i$  as  $f_i^{(j)}$ . Write the Taylor expansion as:

$$f_{i \pm 1} = f_i \pm f'_i h + \frac{f''_i}{2} h^2 \pm \frac{f'''_i}{6} h^3 + \dots$$

Considering combinations of the two expansions and  $f_i$  itself, we can express the derivative  $f'_i$  as follows

$$\begin{aligned} \frac{f_{i+1} - f_{i-1}}{2h} &= f'_i + \frac{h^2}{3!} f_i^{(3)} + \dots \\ \frac{f_{i+1} - f_i}{h} &= f'_i + \frac{h}{2!} f''_i + \dots \\ \frac{f_i - f_{i-1}}{h} &= f'_i - \frac{h}{2!} f''_i + \dots \end{aligned}$$

This suggests a basic numerical approximation for derivatives:

CENTRAL, FORWARD, AND BACKWARD DIFFERENCES

The *central difference* is defined as

$$f'_i = \frac{f_{i+1} - f_{i-1}}{2h},$$

the *forward difference* is

$$f'_i = \frac{f_{i+1} - f_i}{h},$$

and the *backward difference* is

$$f'_i = \frac{f_i - f_{i-1}}{h}.$$

**Theorem.** The asymptotic estimate of the error of the central difference is  $O(h^2)$ . The errors of the backward and forward differences are  $O(h)$ .

**PROOF.** If we use the Taylor expansions with remainder of the appropriate order, we obtain an expression of the error of the approximation by the central difference in the form

$$\frac{1}{3!} h^2 (f^{(3)}(x_i + \xi h) - f^{(3)}(x_i - \eta h)).$$

```
f(x)=(sqrt(2)*x)/(sqrt(2)*x^2+1)
print(bool((sqrt(2)*x^2+1)*diff(f, x, 2) +
4*sqrt(2)*x*diff(f, x)+2*sqrt(2)*f(x)==0))
show(plot(f(x), x, -10, 10,
```

Here,  $0 \leq \xi, \eta \leq 1$  are the values from the remainder expression of  $f_{i+1}$  and  $f_{i-1}$ , respectively. The error of the second derivative in the other two cases is obtained similarly.  $\square$

Surprisingly, the central difference is one order better than the other two. But of course, the constants in the asymptotic estimates are important, too. In the case of the central difference, the bound on the third derivative appears, while in the two other cases second derivatives show up instead.

We proceed the same way when approximating the second derivative. To compute  $f''(x_i)$  from a suitable combination of the Taylor polynomials, we cancel both the first derivative and the value at  $x_i$ . The simplest combination cancels all the odd derivatives as well:

$$\frac{f_{i+1} - 2f_i + f_{i-1}}{h^2} = f_i^{(2)} + \frac{h^2}{12}f^{(4)}(x_i) + \dots$$

This is called the *second order difference*. Just as in the central first order difference, the asymptotic estimate of the error is

$$f_i^{(2)} = \frac{f_{i+1} - 2f_i + f_{i-1}}{h^2} + O(h^2).$$

Notice that the actual bound depends on the fourth derivative of  $f$ .

**6.1.13. The curvature of the graph of a function.** Imagine the graph of a function as a movement in the plane parametrized by the independent variable  $x$ . The vector  $(1, f'(x)) \in \mathbb{R}^2$  represents the velocity at  $x$  of such a movement. The tangent line through  $[x, f(x)]$  parametrized by this directional vector then represents a linear approximation of the curve. The goal is to discuss how “curved” is the graph at  $x$ . This is a straightforward exercise working with differentials in the setup of elementary plane geometry. It might need some effort to keep the attention.

If  $f''(x) = 0$  and simultaneously  $f'''(x) \neq 0$ , the graph of the function  $f$  intersects its tangent line. In such a case, the tangent line is the best approximation of the curve at the point  $x$  up to the second order as well. We describe this by saying that the graph of  $f$  has *zero curvature* at the point  $x$ .

```
ymin=-0.8, ymax=0.8, color="black"))
```

This block verifies our answer and produces the figure presented here:

(d) As shown in the graph above,  $f$  has two local extrema: one maximum and one minimum. Recall that critical points are found by solving the equation  $f'(x) = 0$ . Sage performs this calculation quickly for us:

```
f(x)=(sqrt(2)*x)/(sqrt(2)*x^2+1)
d1=diff(f, x).factor();
print(solve(d1==0, x))
```

This prints out two solutions, namely  $x_{\pm} = \pm \frac{1}{2}2^{3/4} = \pm \frac{\sqrt[4]{8}}{2} \approx \pm 0.84$ . An alternative to obtain these solutions is based on the command `roots` and can be implemented as follows:

```
f(x)=(sqrt(2)*x)/(sqrt(2)*x^2+1)
d1=diff(f, x).factor();
roots =d1.roots()
sols = []
for i in range(len(roots)):
    sols.append(roots[i][0])
print(sols)
```

Executing this block one gets the two solutions (without their multiplicities), i.e.,  $[-(1/2) * 2^{3/4}, (1/2) * 2^{3/4}]$ .

To verify that  $x_+$  (respectively,  $x_-$ ) is a point where  $f$  attains its local maximum (respectively, minimum) we will use the criterium of the second derivative. Hence it suffices to add the syntax

```
bool(diff(f, x, 2)(x=1/2*2^(3/4))<0)
bool(diff(f, x, 2)(x=-1/2*2^(3/4))>0)
```

which for both cases returns True. Or we can program Sage to check itself the critical points and print the corresponding result. For this it is sufficient to add in the initial block the following:

```
d2 = f.diff(2)
for a in sols:
    if d2(a)>0:
        print("{} is a local minimum"
              .format(a))
    if d2(a)<0:
        print("{} is a local maximum"
              .format(a))
```

The nonzero values of the first derivative describe the speed of the growth. Intuitively we expect the second derivative to describe the acceleration, including how “curved” the graph is. As a matter of convention, we want the curvature to be positive if the graph of the function is above its tangent.

The tangent at a fixed point  $P = [x, f(x)]$  is the limit of the secants. The lines passing through the points  $P$  and  $Q = [x + \Delta x, f(x + \Delta x)]$ . To approximate the second derivative, interpolate the points  $P$  and  $Q \neq P$  by the circle  $C_Q$ , whose center is at the intersection of the perpendicular lines to the tangents at  $P$  and  $Q$ .

It can be seen from the figure that if the angle between the tangent at the fixed point  $P$  and the  $x$  axis is  $\alpha$  and the angle between the tangent at the chosen point  $Q$  and the  $x$  axis is  $\alpha + \Delta\alpha$ , then the angle of the latter perpendicular lines is  $\Delta\alpha$  as well.

improve a bit the picture - should only  $\rho\Delta\alpha$  a perhaps make the measured arc thicker.

Denote the radius of the circle by  $\rho$ . Then the length of the arc between points  $P$  and  $Q$  is  $\rho\Delta\alpha$ . As  $Q$  approaches the fixed point  $P$ , the length  $\rho\Delta\alpha$  of the arc approaches the length  $\Delta s$  of the curve between  $P$  and  $Q$ , that is, the graph of the function  $f(x)$ . At the same time the circle approaches some limit circle  $C_P$ . This limit circle  $C_P$  is called the *osculating circle*.

Thus we arrive at the basic relation for the expected radius  $\rho$  of the circle  $C_P$  in terms of the linear approximations of the quantities:

$$\rho = \lim_{\Delta\alpha \rightarrow 0} \frac{\Delta s}{\Delta\alpha} = \frac{ds}{d\alpha}.$$

Notice that the quantity on the right hand side is well defined (independently of its rather intuitive justification).

Define the *curvature* of the graph of the function  $f$  at the point  $P$  as the number  $1/\rho$ . Zero curvature then corresponds to an infinite radius  $\rho$ .

For computing the radius  $\rho$  in terms of  $f$  we need to express the length of the arc  $s$  by the change of the angle  $\alpha$  and express the derivative of this function in terms of the derivative of  $f$ .

Notice that for an increasing angle  $\alpha$  the length of the arc can either increase or decrease, depending on whether the circle  $C_Q$  has its center above or below the graph of the function  $f$ . The sign of  $\rho$  then reflects whether the function is concave or convex. There is also the special case when the center “runs off” to infinity in the limit. Instead of a circle there is the tangent line.

There is no direct tool to compute the derivative  $\frac{ds}{d\alpha}$ . However,  $\text{tg } \alpha = \frac{df}{dx}$ . By differentiating this equality with respect to  $x$  we obtain (using the chain rule for differentials)

$$\frac{1}{(\cos \alpha)^2} \frac{d\alpha}{dx} = f''.$$

On the left hand side we can substitute

$$\frac{1}{(\cos \alpha)^2} = 1 + (\text{tg } \alpha)^2 = 1 + (f')^2$$

In this case the output looks like as follows:

```
-1/2*2^(3/4) is a local minimum
1/2*2^(3/4) is a local maximum
```

Finally, Sage can be used to compute the values of  $f$  at  $x_{\pm}$ , which allows us to summarize as follows: The point  $P_+ = [\frac{\sqrt[4]{8}}{2}, \frac{\sqrt[4]{2}}{2}]$  is a local maxima of  $f$ , while the point  $P_- = [-\frac{\sqrt[4]{8}}{2}, -\frac{\sqrt[4]{2}}{2}]$  is a local minima of  $f$ . Notice  $\pm \frac{\sqrt[4]{2}}{2} \approx \pm 0.59$ .  $\square$

**6.A.25. Local extrema numerically via Sage.** We should remark that Sage provides an in-built method which numerically finds the local extremes of a given function on an interval  $[a, b]$ , along with the points that these extremes values are attained. This technique relies on the commands `find_local_maximum(f, a, b)` and `find_local_minimum(f, a, b)`, respectively. Hence, for example, for the function  $f$  presented in 6.A.24 one could alternatively type

```
f(x)=(sqrt(2)*x)/(sqrt(2)*x^2+1);
show(find_local_maximum(f, -10, 10))
show(find_local_minimum(f, -10, 10))
```

This, indeed, returns the desired answers in the form  $(f(x_{\pm}), x_{\pm})$ , see here:

```
(0.5946035575013604, 0.8408963982254773),
(-0.5946035575013604, -0.8408963982254773).
```

**6.A.26.** Use Sage to sketch the real functions  $f, g, h, k$  for  $x \in [-2, 2]$ , and find numerically their local extrema, if any, where:

- (a)  $f(x) = \frac{1}{8}x^8 - \frac{3}{5}x^5 - 3x + 9$ ,
- (b)  $g(x) = x^2 - \frac{1}{6}x^3$ ,
- (c)  $h(x) = x\sqrt{x^2 + 4}$ ,
- (d)  $k(x) = \ln(x^3 + 8)$ .  $\circ$

**6.A.27.** Find all intervals on which the function  $f(x) = e^{-x^2}$ , with  $x \in \mathbb{R}$ , is concave.

**Solution.** We compute  $f'(x) = -2xe^{-x^2}$  and  $f''(x) = 2(2x^2 - 1)e^{-x^2}$  for all  $x \in \mathbb{R}$ . The sign of  $f''$  is given in the following table

$x$	$-\infty$	$-\sqrt{2}/2$	$\sqrt{2}/2$	$+\infty$
$f''(x)$	+	0	-	0
				+

Thus for any  $x \in (-\sqrt{2}/2, \sqrt{2}/2)$  we get  $f''(x) < 0$ , and the desired answer is given by the open interval  $(-\sqrt{2}/2, \sqrt{2}/2) \subset \mathbb{R}$ .  $\square$

**6.A.28. Remark.** Using Sage we might consider using the `bool` command, to verify the inequality  $f''(x) < 0$ , for all  $x \in (-\sqrt{2}/2, \sqrt{2}/2)$ , from the previous problem. Hence, for example, one could type

```
f(x)=exp(-x**2)
df2=diff(f, x, 2)
s=RealSet(-sqrt(2)/2, sqrt(2)/2)
bool(df2(x)<0 for x in s)
```

which implies (see the rule for differentiating inverse functions)

$$\frac{dx}{d\alpha} = \frac{1 + (\operatorname{tg} \alpha)^2}{f''} = \frac{1 + (f')^2}{f''}.$$

Now, we are almost finished, because the increment of the length of arc  $s$  dependent on  $x$  is given by the formula

$$\frac{ds}{dx} = (1 + (f')^2)^{1/2}.$$

Thus, by the chain rule,

$$\rho = \frac{ds}{d\alpha} = \frac{ds}{dx} \frac{dx}{d\alpha} = \frac{(1 + (f')^2)^{3/2}}{f''}.$$

Taking the reciprocal value, we have computed:

CURVATURE OF THE GRAPH

If  $f$  is in  $C^2$ , then the curvature of its graph is given by the formula

$$\rho^{-1}(x) = \frac{f''(x)}{(1 + (f'(x))^2)^{3/2}}$$

The result explains the relation between the curvature and the second derivative. The denominator of the fraction is always positive. It equals the third power of the length of the tangent vector of the given graph curve. The sign of the curvature is therefore given only by the sign of the second derivative, which confirms the ideas about concave and convex points of functions. In particular, in singular points, the curvature is just the second derivative.

If the second derivative is zero, the curvature  $1/\rho$  is also zero. If  $f''$  is large, then the radius  $\rho$  is small, thus the curvature is large as well.

Compute the curvature of simple functions yourself and use osculating circles while sketching their graphs. The computation at the critical points of the function  $f$  is easiest. The radius of the osculating circle is the reciprocal value of the second derivative with the corresponding sign.

**6.1.14. Vector differential calculus.** As mentioned already in the introduction to chapter five, most considerations related to differentiation are based on the fact that the functions are defined on real numbers and that their values can be added and multiplied by real numbers. That is why functions  $f : \mathbb{R} \rightarrow V$  need to have values in a vector space  $V$ . We call them *vector functions of one real variable* or more briefly *vector functions*.

Now, we digress to consider functions with values in the plane or in space. Thus,  $f : \mathbb{R} \rightarrow \mathbb{R}^2$  and  $f : \mathbb{R} \rightarrow \mathbb{R}^3$ . We consider (parametrized) curves in plane and space. We could work with values in  $\mathbb{R}^n$  for any finite dimension  $n$ .

For simplification, we work with the fixed standard bases  $e_i$  in  $\mathbb{R}^2$  and  $\mathbb{R}^3$ . So curves are given by pairs or triples of real functions of one real variable, respectively. The vector function  $r$  in plane or space, respectively, is given by

$$r(t) = x(t)e_1 + y(t)e_2, \quad r(t) = x(t)e_1 + y(t)e_2 + z(t)e_3.$$

In this block we used the `RealSet` command to define the interval of interest. Although Sage returns `True`, this result can be misleading and we cannot trust this method. This is because if we replace the last line by `bool(df2(x) > 0 for x in s)`, Sage will still return `True`. In fact, the `bool(df2(x) < 0 for x in s)` command checks if the condition is true for some sampled points within the interval, but does not guarantee that the inequality holds for all points in the interval. This is because it only evaluates the condition at specific points and does not perform a rigorous check over the entire range. Therefore, one should exercise caution when interpreting results from computer algebra systems.

**6.A.29.** Show that the function  $f(x) = x^a$  with  $0 < a < 1$  is concave for all  $x > 0$ . ○

**6.A.30.** Use Sage to determine the asymptotes of the function  $f(x) = x/(x^2 - 1)$ , with  $x \in \mathbb{R} \setminus \{\pm 1\}$ , and then sketch these asymptotes along with the graph of  $f$ . ○

**6.A.31.** Consider the function  $f(x) = \frac{e^x - 1}{e^x + 1}$  with  $x \in \mathbb{R}$ .  
 (a) Prove that  $f$  is increasing on  $\mathbb{R}$ , find its asymptotes and determine its range. Then use Sage to sketch the asymptotes along with the graph of  $f$ .  
 (b) Determine the extremes points, inflection points and intervals of convexity of  $f$ , if any. ○

**6.A.32.** Study the local behaviour of the function  $f(x) = x/(x + 1)^2$ , with  $x \in A := \mathbb{R} \setminus \{-1\}$ .

**Solution.** Let us begin with the asymptotes of  $f$ . Obviously,  $f$  is continuous on its domain  $A$ . Thus, the only place we may have a vertical asymptote is at the endpoint  $-1$ . Indeed, we see that the line  $x = -1$  is a vertical asymptote since  $\lim_{x \rightarrow -1^+} f(x) = \lim_{x \rightarrow -1^-} f(x) = -\infty$ . We also have  $\lim_{x \rightarrow -\infty} f(x) = \lim_{x \rightarrow \infty} f(x) = 0$ , thus the line  $y = 0$  is a horizontal asymptote. In Sage a computation of these limits can be done as usual, i.e.,

```
f(x)=x/(x+1)^2
show(lim(f(x), x=-1, dir="left"))
show(lim(f(x), x=-1, dir="right"))
show(lim(f(x), x=-oo)); lim(f(x), x=oo)
```

Next, by adding the command `show(diff(f,x).factor())` we obtain the first derivative of  $f$ ,

$$f'(x) = -\frac{(x-1)}{(x+1)^3}, \quad x \in A. \quad (b)$$

Try to verify these results by hand. By (b) we deduce that the equation  $f'(x) = 0$  has a unique solution, given by  $x = 1$ , hence  $f$  has a unique critical point. There it appears a relative maximum of  $f$ , with value  $f(1) = 1/4$  (see below for an explanation).

To determine the critical points of  $f$  via Sage, add in the previous block the syntax

```
solve(diff(f, x)==0, x)
```

(the command `diff(f,x).roots()` also works, as we explained in 6.A.24). Now, by (b) we also deduce that

The derivative of such a vector function is a vector, which approximates the map  $r$  by a linear map of the real line to the plane or to the space.

In the plane it is

$$\frac{dr}{dt}(t) = r'(t) = x'(t)e_1 + y'(t)e_2$$

and similarly in space.

The differential of a vector function in this context is:

$$dr = \left( \frac{dx}{dt}e_1 + \frac{dy}{dt}e_2 + \frac{dz}{dt}e_3 \right) dt$$

where the expression on the right hand side is understood as “selecting” an increment of the scalar independent variable  $t$  and mapping it linearly by multiplying the vector of the three derivative components. Thus the corresponding increment of the vector quantity  $r$  is obtained (of course, only two components in the plane).

The notation  $r(t)$  is a convenient way to describe curves in space. For example  $r(t) = (a \cos t, a \sin t, bt)$  or  $r(t) = a \cos t e_1 + a \sin t e_2 + b e_3$  for fixed constants  $a, b$  describes a circular helix. Here the parameter  $t$  is related to a suitable angle measured around the  $z$ -axis. The derivative of  $r(t)$  at  $t = t_0$ , determines the direction of the tangent line at  $r(t_0)$ . In Newtonian mechanics, the parameter  $t$  can stand for time, measured in suitable units. In this case the derivative of  $r(t)$  at time  $t = t_0$ , gives the velocity vector at the same time. The second derivative then represents the acceleration vector at the same time.

**6.1.15. Differentiating composite maps.** In linear algebra and geometry there are very useful special maps called forms. They have one or more vectors as their arguments and they are linear in each of their arguments. In this way we defined the length of the vectors (the dot product is a symmetric bilinear form) or the volume of a parallelepiped (this is an  $n$ -linear antisymmetric form, where  $n$  is the dimension of the space), see for example the paragraphs 2.3.23 a 4.1.19.

Of course, we insert vectors  $r(t)$  dependent on a parameter as the arguments of these operations. By a straightforward usage of the Leibniz rule for differentiation of a product of functions, the following is verified:

**Theorem.** (1) If  $r(t) : \mathbb{R} \rightarrow \mathbb{R}^n$  is a differentiable vector function and  $\Psi : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is a linear map, then the derivative of the map  $\Psi \circ r$  satisfies

$$\frac{d(\Psi \circ r)}{dt} = \Psi \circ \frac{dr}{dt}.$$

(2) Consider differentiable vectors  $r_1, \dots, r_k : \mathbb{R} \rightarrow \mathbb{R}^n$  and a  $k$ -linear form  $\Phi : \mathbb{R}^n \times \dots \times \mathbb{R}^n \rightarrow \mathbb{R}$  on the space  $\mathbb{R}^n$ . Then the derivative of the composed map

$$\varphi(t) = \Phi(r_1(t), \dots, r_k(t))$$

satisfies the (generalized) Leibniz's rule

$$\frac{d\varphi}{dt} = \Phi\left(\frac{dr_1}{dt}, r_2, \dots, r_k\right) + \dots + \Phi\left(r_1, \dots, r_{k-1}, \frac{dr_k}{dt}\right).$$

- $f'(x) < 0$  for all  $x \in (-\infty, -1) \cup (1, +\infty)$ ;
- $f'(x) > 0$  for all  $x \in (-1, 1)$ .

Thus  $f$  decreases for all  $x \in (-\infty, -1) \cup (1, +\infty)$  and increases for  $x \in (-1, 1)$ .

Let us now proceed with the second derivative. By adding the command `diff(f, x, 2)` we obtain the second derivative of  $f$ , given by  $f''(x) = \frac{2(x-2)}{(x+1)^4}$  for all  $x \in A$ . Hence  $x = 2$  is the unique solution of  $f''(x) = 0$  and we see that

- $f''(x) < 0$  for all  $x \in (-\infty, -1) \cup (-1, 2)$ ;
- $f''(x) > 0$  for all  $x \in (2, +\infty)$ .

Thus,  $f$  is convex for all  $x \in (2, +\infty)$  and concave for  $x \in (-\infty, -1) \cup (-1, 2)$ . It also follows that the unique inflection point of  $f$  appears at  $x = 2$ , with value  $f(2) = 2/9$ . Notice in order to verify that at the critical point located above, a relative maximum appears, we may use the criterion based on the second derivative (see below) and show that  $f''(1) < 0$ .

Let us finally focus on the graph of  $f$ . The origin is the unique intersection of the graph of  $f$  with the axes, while  $f$  is neither even nor odd (so its graph has no particular symmetries). To sketch the graph of  $f$  for certain  $x \in A$ , together with its vertical asymptote  $x = -1$ , we use the cell

```
f(x)=x/(x+1)^2
pf=plot(f, x, -5, 5, ymin=-5, ymax=1, color="black")
pm = point((1, 1/4), size=30, color="red")
pt = circle((-1, 0), 0.05, color="black")
pnf = point((2, 2/9), size=30, color="blue")
sy = line([(-1, -5), (-1, 5)], linestyle="--", thickness=0.8)
(pf+sy+pm+pt+pnf).show(ticks=1, tick_formatter=1)
```

Execute this block in your editor, to revise its “small” particularities (as red and blue colours for the presentation of the maximum and the inflection point of  $f$ , respectively). □

We will now focus on derivatives of functions defined “implicitly” by equations of the form  $F(x, y) = 0$ . In such cases it can be often impossible to solve the equation with respect to  $y$  (as an explicit function of  $x$ ). However, as we will see below it is still possible to find the derivative  $dy/dx$ , compute extrema and/or decide for the convexity features of  $y$ , etc. For instance, to compute  $dy/dx$  the trick is just to differentiate both sides of the given equation, and then solve for the derivative we are seeking for. This is the so called implicit differentiation, which has many useful applications.

**6.A.33. Implicit differentiation.** Find the extreme points of the real function  $y = f(x)$  given in the implicit form  $xy^2 - x^2y = 54$ .

**Solution.** Since  $y$  is a function of  $x$  we can differentiate the given relation with respect to  $x$ . We get

$$y^2 + 2xyy' - 2xy - x^2y' = 0,$$

and thus solving with respect to  $y'$  one deduces that

$$y' = \frac{2xy - y^2}{2xy - x^2}. \quad (\#)$$

(3) The previous statement remains valid even if  $\Phi$  also has values in the vector space, and is linear in all its  $k$  arguments.

**PROOF.** (1) The linear maps are given by a constant matrix of scalars  $A = (a_{ij})$  so that

$$\Psi \circ r(t) = \left( \sum_{i=1}^n a_{1i}r_i(t), \dots, \sum_{i=1}^n a_{mi}r_i(t) \right).$$

Carry out the differentiation separately for individual coordinates of the result. However, the derivative acts linearly with respect to scalar linear combinations, see Theorem 5.3.4. That is why the derivative is obtained simply by evaluating the original linear map  $\Psi$  on the derivative  $r'(t)$ .

(2) The second statement is obtained analogously. Write out the evaluation of the  $k$ -linear form on the vectors  $r_1, \dots, r_k$  in the coordinates in this way:

$$\Phi(r_1(t), \dots, r_k(t)) = \sum_{i_1, \dots, i_k=1}^n B_{i_1 \dots i_k} \cdot (r_1)_{i_1}(t) \dots (r_k)_{i_k}(t),$$

where the scalars  $B_{i_1 \dots i_k} = \Phi(e_{i_1}, \dots, e_{i_k})$  are given as the values of the given form on the chosen  $k$ -tuple of base vectors for every choice of indices. The rule for differentiating a product of scalar functions then yields the statement.

(3) If  $\Phi$  has vector values, it is given by finitely many components and the previous result can be used for each of them. □

In the Euclidean space  $\mathbb{R}^3$ , the scalar product assigns a scalar to two vectors, There is also the vector product, which assigns the vector  $u \times v \in \mathbb{R}^3$  to vectors  $u$  and  $v$ , see 4.1.21. This vector  $u \times v$  is orthogonal to both vectors  $u$  and  $v$ , its length equals the area of the parallelogram determined by  $u$  and  $v$  (in this order) and the orientation is such that the triple  $u, v, u \times v$  is a positively oriented basis.

The previous ideas immediately imply:

**Corollary.** Consider the vectors  $u(t)$  and  $v(t)$  in the space  $\mathbb{R}^3$ . The derivatives of their scalar product  $\langle u(t), v(t) \rangle$  and their vector product  $u(t) \times v(t)$  satisfy

- (1)  $\frac{d}{dt} \langle u(t), v(t) \rangle = \langle u'(t), v(t) \rangle + \langle u(t), v'(t) \rangle$
- (2)  $\frac{d}{dt} (u(t) \times v(t)) = u'(t) \times v(t) + u(t) \times v'(t)$

**6.1.16. The curvature of curves.** We develop far more powerful tools for studying curves in a more systematic way than when we discussed the curvature of the graphs of functions. We proceed in dimension three. Plane curves are a special case in which the third component is the constant zero.

Let  $r(s)$  be a curve in the Euclidean space  $\mathbb{R}^3$ . For our purposes, it is convenient to choose arc length  $s$  as for the parameter. It follows that  $\|\frac{dr}{ds}\| = 1$ , so that the tangent vector has unit length. When  $s$  is the parameter, the notation  $'$  is used for differentiation.

One can obtain this formula also in Sage by the cell

```
var("x"); y = function("y")(x)
eq = x*y**2 - y*x**2 == 54
dy = diff(y, x) #declare the derivative
sol = solve(diff(eq), dy) #solve the implicit
show(dy.subs(sol)) #substitute the solution
```

Thus Sage can be quickly programmed to implement an implicit differentiation for us, see also below.

Let us now return back to our task. Based on (#), we see that the equation  $y' = 0$  is equivalent to  $y(2x - y) = 0$ , which gives  $y = 0$ , or  $y = 2x$ . The first solution is not acceptable and hence we have  $y' = 0$  if and only if  $y = 2x$ . For  $y = 2x$  the given equation reduces to  $x^3 - 3^3 = 0$ , that is,  $(x - 3)(x^2 + 3x + 9) = 0$ . The real  $x = 3$  is the unique real solution of this equation, hence we get a stationary point of  $y$  with value  $y(3) = 6$ .

Next we need to characterize this critical point, and hence we need the second derivative. A differentiation of both sides in (#) gives the relation  $y'' = A(x)/B(x)$ , where  $A(x) = 2[(y + xy' - yy')(2xy - x^2) - (2xy - y^2)(y + xy' - x)]$  and  $B(x) = (2xy - x^2)^2$ , respectively. By replacing the coordinates  $[x = 3, y = 6]$  and since  $y'$  vanishes at this point, we finally deduce that

$$y''(3) = 12/27 > 0.$$

Thus,  $x = 3$  is local minimum of  $y = f(x)$ , with value  $y_{\min} = 6$ .  $\square$

**6.A.34.** Suppose that  $f : \mathbb{R} \rightarrow \mathbb{R}$  is a function which is twice differentiable on  $\mathbb{R}$  and satisfies

$$f^2(x) - xf(x) + 2x^2 - 7 = 0, \quad x \in \mathbb{R}.$$

If  $a \in \mathbb{R}$  is a stationary (critical) point of  $f$ , prove that  $a = \pm \frac{\sqrt{2}}{2}$ . Does  $f$  admit some inflection point?  $\circ$

Recall by Chapter 5 that first order derivatives provide linear approximations, which can be used to estimate values of differentiable functions (cf. 5.C.18). This idea is revised in 6.1.11, in terms of the “differential” of a differentiable function  $y = f(x)$ , defined by  $df(x) = f'(x)dx$ , i.e.,  $dy = f'(x)dx$ . This is of course an equivalent way to interpret the differentiability of  $f$ , which is encoded by the relation  $f'(x) = \frac{dy}{dx}$ . Notice  $dx$  is an independent variable which we may assign any non-zero real number, while  $dy$  (or  $df(x)$ ) is necessarily a dependent variable.

The differential of  $f$  can be viewed as a linear form on  $\mathbb{R}$ , satisfying  $df(x)(h) = f'(x)h$ , for all  $h \in \mathbb{R}$ , and provides the best linear approximation of  $f$ , around  $x$ . Let us illustrate the most basic features of this concept via examples.

**6.A.35.** Compute the differentials of the functions  $f(x) = e^{x^2}$ ,  $g(x) = \ln(x^2 + 1)$  and  $k(x) = \arctan(e^x)$  with  $x \in \mathbb{R}$ . Next present an implementation of these differentials via Sage.  $\circ$

So  $\langle r'(s), r'(s) \rangle = 1$  for all  $s$ . The curve  $r(s)$  is parametrized by the length  $s$ . By another differentiation of this equality we arrive at (using the symmetry of the dot product)

$$0 = \frac{d}{ds} \langle r'(s), r'(s) \rangle = 2 \langle r''(s), r'(s) \rangle.$$

Thus the vector  $r''(s)$  is always orthogonal to the vector  $r'(s)$ .

This corresponds to the idea that after the choice of a parametrization with a derivative of constant length, the second derivative in the direction of the movement vanishes. The second derivative lies in the plane orthogonal to the tangent vector.

FRENET FRAME

If the second derivative is nonzero, the normed vector

$$n(s) = \frac{1}{\|r''(s)\|} r''(s)$$

is the (principal) normal of the curve  $r(s)$ . The scalar function  $\kappa(s)$  satisfying (at the points where  $r''(s) \neq 0$ )

$$r''(s) = \kappa(s)n(s)$$

is called the curvature of the curve  $r(s)$ . At the zero points of the second derivative  $\kappa(s)$  is defined as 0.

At the nonzero points of the curvature, the unit vector  $b(s) = r'(s) \times n(s)$  is well defined and is called the binormal of the curve  $r(s)$ . By direct computation

$$\begin{aligned} 0 &= \frac{d}{ds} \langle b(s), r'(s) \rangle = \langle b'(s), r'(s) \rangle + \langle b(s), r''(s) \rangle \\ &= \langle b'(s), r'(s) \rangle + \kappa(s) \langle b(s), n(s) \rangle = \langle b'(s), r'(s) \rangle, \end{aligned}$$

which shows that the derivative of the binormal is orthogonal to  $r'(s)$ . Further,  $b'(s)$  is also orthogonal to  $b(s)$  (for the same reason as with  $r'$  above). Therefore it is a multiple of the principal normal  $n(s)$ . We write

$$b'(s) = -\tau(s)n(s).$$

The scalar function  $\tau(s)$  is called the torsion of the curve  $r(s)$ .

In the case of plane curves, the definitions of binormal and torsion do not make sense.

**6.A.36. Differentials.** Construct in Sage a routine having as input a pair  $(f, x_0)$  consisting of a function and a point, and as output the differential of  $f$  at  $x_0$  (assuming that  $f$  is differentiable at  $x_0$ ). Next use your program to test some cases explicitly.

**Solution.** To solve this task we can use the `def` command to define a routine with the name `Dif`. Notice that `Dif` should have two inputs, a function `f` depending on one variable, and a real number `x_0`. Since  $df(x) = f'(x)dx$ , we should program Sage to view  $dx$  as a variable different than  $x$ , and it is sufficient to introduce  $dx$  as a symbolic variable, similarly with  $x$ . In total, one can program Sage via the block

```
var("x, dx")
def Dif(f, x_0) :
    f1=diff(f, x)(x=x_0)
    show("The differential of f(x)=", f, ", ", " ",
        "at x=", x_0, ", ", " ", "equals to", ":", " ", (dx)*f1)
    return
```

Notice in the second line of this block the syntax corresponds to the derivative  $f'(x_0)$ .

Let us now test the routine. For this goal, we chose the following pairs  $(f, x_0)$ :

```
Dif(ln(x), 2*pi)
Dif(exp(x), 0)
Dif(cos(2*x), 2*pi)
Dif(ln(x^2+1), 4*pi)
Dif(arctan(exp(x)-x^3+4*x), pi/2)
```

In the first case and for the pair  $(\ln(x), 2\pi)$ , Sage's output has the form:<sup>1</sup>

The differential of  $f(x)=\log(x)$ , at  $x=2\pi$ ,  
equals to:  $\frac{dx}{2\pi}$ ,

which is obviously true. Execute the rest commands in your editor and next verify Sage's solutions by hand.

As a side remark, observe that when our input is a non-differentiable function  $f$  at  $x_0$ , our routine will return an error (similarly with the error that Sage returns when the derivative of a function at a point does not exist).  $\square$

**6.A.37.** Consider a function  $y = f(x)$  differentiable at a point  $x_0$ . The change in the values of  $y$  in a small neighbourhood around  $x_0$ , is given by  $\Delta(y) = f(x_0 + dx) - f(x_0)$ . We can approximate linearly  $\Delta(y)$  using the differential of  $f$  at  $x_0$ , that is,  $\Delta(y) \approx f'(x_0)dx$ . Based on this formula compare  $\Delta(y)$  and  $dy$  for the cases:

- (a)  $y = x^4 - x^2 + 3x + 2$  and  $x$  changes from 2 to 2.05;
- (b)  $y = x^2 + \sin^2(x)\cos(x)$  and  $x$  changes from  $\frac{\pi}{2}$  to  $\frac{\pi}{2} + 0.04$ ;
- (c)  $y = \ln(x + 1) - e^{\sqrt{x}}$  and  $x$  changes from 1 to 1.03.

**Solution.** (a) We have  $x_0 = 2$  and  $x_0 + dx = 2 + 0.05 = 2.05$ . Thus  $\Delta(y) = f(x_0 + dx) - f(x_0) = f(2.05) - f(2) \approx$

<sup>1</sup>To avoid confusions, recall that in Sage the function `log(x)` corresponds to the natural logarithm  $\ln(x)$ .

We have not yet computed the rate of change of the principal normal, which can be written as  $n(s) = b(s) \times r'(s)$ :

$$\begin{aligned} n'(s) &= b'(s) \times r'(s) + \kappa(s)b(s) \times n(s) \\ &= -\tau(s)n(s) \times r'(s) + \kappa(s)(-r'(s)) \\ &= \tau(s)b(s) - \kappa(s)r'(s). \end{aligned}$$

Summarizing, for all points with nonzero second derivative of the curve  $r(s)$  parametrized by the arc length we constructed the nice orthonormal basis  $(r'(s), n(s), b(s))$ , called *the Frenet frame* in the classical literature. At the same time, this basis is used in order to express the derivatives of its components in the well known form

FRENET-SERRET FORMULAE

For the Frenet frame  $(r'(s), n(s), b(s))$ , the so called *Frenet-Serret formulae* hold true

$$\begin{aligned} \frac{dr'}{ds}(s) &= \kappa(s)n(s), & \frac{dn}{ds}(s) &= \tau(s)b(s) - \kappa(s)r'(s) \\ \frac{db}{ds}(s) &= -\tau(s)n(s). \end{aligned}$$

The following theorem tells how crucial the curvature and torsion are. Notice that if the curve  $r(s)$  lies in one plane, then the torsion is identically zero. In fact, the converse is true as well. We shall not provide the proofs here.

**Theorem.** Two curves in the space  $\mathbb{R}^3$  parametrized by the length of their arc can be mapped to each other by a Euclidean transformation (i.e. an affine map keeping the distances) if and only if their curvature functions and torsion functions coincide, except for a possible constant shift of the parameter. Moreover, for every choice of smooth functions  $\kappa$  and  $\tau$  there exists a smooth curve with these parameters.

By a straightforward computation we can check that the curvature of the graph of the function  $y = f(x)$  in plane and the curvature  $\kappa$  of this curve defined in this paragraph coincide. Indeed, comparing the differentials of the length of the arc for the graph of a function (as a curve with coordinates  $x(t), y(t) = f(x(t))$ ):

$$ds = (1 + (f_x)^2)^{1/2} dx, \quad dx = (1 + (f_x)^2)^{-1/2} ds$$

(we write  $f_x = \frac{df}{dx}$ ), we obtain the following equality for the unit tangent vector of the graph of a curve

$$r'(s) = ((1 + (f_x)^2)^{-1/2}, f_x(1 + (f_x)^2)^{-1/2}).$$

Now, we have to go through a bit messy computation for the second derivative. Let us write shortly  $r = (x, y)$ ,  $y' = f_x x'$ ,  $x' = (1 + f_x^2)^{-1/2}$  (remind  $'$  always means derivative with respect to the arc length parameter  $s$ ). Then

$$\begin{aligned} x'' &= -\frac{1}{2}(x')^3 2f_x f_{xx} x' = -(x')^4 f_x f_{xx} \\ y'' &= f_{xx}(x')^2 + f_x x'' = f_{xx}(x')^2 - f_{xx} f_x^2 (x')^4. \end{aligned}$$

1.6085. On the other hand,  $dy|_{x=x_0} = f'(x_0)dx$ , that is,

$$dy = (4x^3 - 2x + 3)|_{x=2} dx = 31 \cdot 0.05 = 1.55.$$

Thus  $|\Delta(y) - dy| = \Delta(y) - dy \approx 1.6085 - 1.55 \approx 0.0585$ .

(b) In this case we have  $x_0 = \pi/2$  and  $x_0 + dx = \frac{\pi}{2} + 0.04$ . Based on the following block in Sage,

```
f(x)=x^2+(sin(x))^2*cos(x)
D=f((pi/2)+0.04)-f(pi/2)
show(N(D))
```

we compute  $\Delta(y) = f(\frac{\pi}{2} + 0.04) - f(\frac{\pi}{2}) \approx 0.08733$ . Also, we compute that

$$f'(\frac{\pi}{2}) = (2x + 2\sin(x)\cos^2(x) - \sin^3(x))|_{x=\pi/2} = \pi - 1.$$

Hence for the differential we get  $dy|_{x=\pi/2} = (\pi - 1) \cdot 0.04 \approx 0.08566$ , and we deduce that  $|\Delta(y) - dy| = \Delta(y) - dy \approx 0.00167$ .

(c) Let us answer this task only with the aid of Sage, and leave the formal computation as an exercise. An appropriate syntax has the form

```
f(x)=ln(x+1)-e**(sqrt(x))
D=f(1.03)-f(1); show(N(f(1.03)-f(1)))
d=(diff(f(x),x)(x=1))*0.03; show(N(d))
show(N(abs(D-d)))
```

In this block the first `show` command implies that  $\Delta y \approx 0.025887$ , while the second gives  $dy \approx 0.025774$ . After introducing `f`, `D` and `d`, one could directly type the final command, which implies that  $|\Delta(y) - dy| \approx 0.00011$ .

At the end of the day, what we should keep from this task is that a formal computation of  $dy$  for all the three cases (a), (b) and (c), is easier than computing explicitly  $D(y)$ . In fact, for complicated functions the computation of  $D(y)$  can be extremely hard, but it is always easier to compute differentials. Finally, you may like to verify yourself that a receipt for improving the approximation is to choose smaller increments  $dx$ .  $\square$

**6.A.38.** Recall that the formula  $f(x) \approx f(x_0) + f'(x_0)(x - x_0)$  determines the linear (tangential) approximation of a differentiable function  $f$  at a point  $x_0$ .

(a) Show that this is equivalent to the approximation formula  $\Delta(y) \approx dy$ ;

(b) For the function  $f(x) = 1/x$  compare the linear approximation of the value  $f(1.1)$ , obtained in 5.C.18, with the value determined by the relation  $f(x_0 + dx) \approx f(x) + dy$ .

**Solution.** (a) We have  $f(x) \approx f(x_0) + f'(x_0)(x - x_0)$  and since  $x - x_0 = dx$ , this can be equivalently expressed as  $f(x) \approx f(x_0) + f'(x_0)dx$ . Using the definition of the differential of  $f$  at  $x_0$  (which we simply denote by  $dy$ ), we finally get the equivalent expression  $f(x) \approx f(x_0) + dy$ , that is,  $f(x_0 + dx) \approx f(x_0) + dy$ , where in the l.h.s the variable  $x$  was replaced by  $x_0 + dx$ . Hence, the tangential approximation is equivalent to the relation  $f(x_0 + dx) - f(x_0) \approx dy$ , i.e.,  $\Delta(y) \approx dy$ . This proves (a).

(b) Recall by 5.C.18 that the tangential approximation of  $1/x$  around  $x_0 = 1$  is the line  $L(x) = 2 - x$ , and hence

Hence

$$\begin{aligned} (x'')^2 + (y'')^2 &= f_{xx}^2 (x')^8 (f_x + (1 + f_x^2)^2 + f_x^4 \\ &\quad - 2f_x^2(1 + f_x^2)) \\ &= f_{xx}^2 (1 + f_x^2)^{-4} (f_x^2 + 1) \\ &= f_{xx}^2 (1 + f_x^2)^{-3}. \end{aligned}$$

We have arrived at the expected formula

$$\kappa^2 = \|r''\|^2 = \left(\frac{d^2f}{dx^2}\right)^2 (1 + (f_x)^2)^{-3}.$$

## 2. Integration

**6.2.1. Indefinite integral.** Now, we reverse the procedure of differentiation. We want to reconstruct the actual values of a function using its immediate changes. If we consider the given function  $f(x)$  as the (say continuous) derivative of an unknown function  $F(x)$ , then at the level of differentials we can write

$$dF = f(x) dx.$$

We call the function  $F$  the *primitive function* or the *indefinite integral* of the function  $f$  (we can also find the name *anti-derivative* in the literature). Traditionally we write

$$F(x) = \int f(x) dx.$$

**Lemma.** The primitive function  $F(x)$  to the function  $f(x)$  is determined uniquely on each interval  $[a, b]$  up to an additive constant.

**PROOF.** The statement follows immediately from Lagrange's mean value theorem, see 5.3.9. Indeed, if  $F'(x) = G'(x) = f(x)$  on the whole interval  $[a, b]$ , then the derivative of the function  $(F - G)(x)$  vanishes at all points  $c$  of the interval  $[a, b]$ . The mean value theorem implies that for all points  $x$  in this interval,

$$F(x) - G(x) = F(a) - G(a) + 0 \cdot (x - a).$$

Thus the difference of the values of the functions  $F$  and  $G$  is constant on the interval  $[a, b]$ .  $\square$

The previous lemma supports another notation for the indefinite integral:

$$F(x) = \int f(x) dx + C$$

with an unknown constant  $C$ .

The primitive functions are well defined for complex functions  $f$ , where the real and the imaginary part of the indefinite integrals are real primitive functions to the real and the imaginary parts of  $f$ . Thus, with no loss of generality, we work only with real functions in the sequel.

$L(1.1) = 0.9$ . Using the differential  $dy$  at  $x_0$ , by the claim in (a) we should get the same result. For, we have  $dy = -\frac{1}{x^2}dx$ . Moreover,  $1.1 = x_0 + dx = 1 + 0.1$ , i.e.,  $dx = 0.1$ , and hence we get  $dy|_{x_0=1} = -1 \cdot 0.1 = -0.1$ . Then the relation  $f(x_0 + dx) \approx f(x_0) + dy|_{x_0=1}$  gives

$$f(1.1) \approx f(1) + (-0.1) = 1 - 0.1 = 0.9,$$

as required. □

The relation  $df(x)(h) = f'(x)h$  and the replacement of the increment  $dx$  by some small positive number  $h$  close to zero, allows us to rephrase the approximation formula  $\Delta(y) \approx dy$  as  $f(x+h) - f(x) \approx f'(x)h$ , i.e.,  $\frac{f(x+h) - f(x)}{h} \approx f'(x)$ . Based then on the Taylor expansion of  $f$  around  $x$ , and using the  $O$ -notation (see 6.1.12) we can finally arrive to the equation

$$f'(x) = \frac{f(x+h) - f(x)}{h} + O(h).$$

Obviously, this establishes a first-order accurate approximation of  $f'(x)$ , since the dominate term in the truncation error is  $O(h)$ . The expression  $\frac{f(x+h) - f(x)}{h}$  is known as the “forward difference” formula for the first derivative. Similarly, one can consider the “backward difference” formula  $\frac{f(x) - f(x-h)}{h}$ , which gives another first-order accurate approximation of  $f'(x)$ , see 6.1.12.

**6.A.39. Remark on the role of  $h$ .**

The figure below illustrates the forward and backward difference formulas for the approximations of  $f'(0.5)$ , where  $f(x) = 3x^2 - x + 14$  with  $x \in I = [-1, 2]$  and  $h = 1$ . Check yourself that since  $h$  is big enough, this will not produce a “good” approximation of  $f'(0.5)$ . Hence, to improve the approximations in general small increments  $h$  closer to zero are more adaptable (see also below).

**6.A.40.** Consider the function  $f(x) = e^{x^2} - \frac{9}{10}$ . For the steps  $h = 0.1$  and  $h = 0.01$ , use Sage to find the forward and backward difference approximations of the derivative  $f'(0.2)$ .

**6.2.2. Newton integral.** We consider the value of a real function  $f(x)$  as an immediate increment of the region bounded by the graph of the function  $f$  and the  $x$  axis and try to find the area of this region between boundary values  $a$  and  $b$  of some interval. We relate this idea with the indefinite integral.

Suppose we are given a real function  $f$  and its indefinite integral  $F(x)$ , i.e.  $F'(x) = f(x)$  on the interval  $[a, b]$ .

Divide the interval  $[a, b]$  into  $n$  parts by choosing the points

$$a = x_0 < x_1 < \dots < x_n = b.$$

Approximate the values of the derivatives at the points  $x_i$  by the forward differences. That is, by the expressions

$$f(x_i) = F'(x_i) \simeq \frac{F(x_{i+1}) - F(x_i)}{x_{i+1} - x_i}.$$

Finally the sum over all the intervals of our partition yields the approximation of the area:

$$\begin{aligned} \sum_{i=0}^{n-1} f(x_i)(x_{i+1} - x_i) &\simeq \sum_{i=0}^{n-1} \frac{F(x_{i+1}) - F(x_i)}{x_{i+1} - x_i} (x_{i+1} - x_i) \\ &= \sum_{i=0}^{n-1} (F(x_{i+1}) - F(x_i)) = F(b) - F(a). \end{aligned}$$

Therefore we expect that for “nice enough” functions  $f(x)$ , the area of the region bounded by the graph of the function and the  $x$  axis (including the signs) can be calculated as a difference of the values of the primitive function at the boundary points of the interval. This procedure is called the *Newton integration*.<sup>3</sup>

<sup>3</sup>Isaac Newton (1642-1726) was a phenomenal English physicist and mathematician. The principles of integration and differentiation were formulated independently by him and Gottfried Leibniz in the late 17th century. It took nearly another two centuries before Bernhard Riemann introduced the completely rigorous modern version of the integration process.

Then, estimate the absolute value of the actual error. Which formula provides the better approximation and for which  $h$ ?

**Solution.** We have  $x = 0.2$ , hence the forward/backward difference formulas have the form

$$\frac{f(0.2 + h) - f(0.2)}{h}, \quad \frac{f(0.2) - f(0.2 - h)}{h}.$$

It is easy to estimate these expressions for the given  $h$  via Sage, and a recommendation is here:

```
f(x)=exp(x^(2))-0.9;
forw01=(f(0.2+0.1)-f(0.2))/0.1; show(forw01)
back01=(f(0.2)-f(0.2-0.1))/0.1; show(back01)
forw001=(f(0.2+0.01)-f(0.2))/0.01; show(forw001)
back001=(f(0.2)-f(0.2-0.01))/0.01; show(back001)
```

Based on Sage's output, for  $h = 0.1$ , we deduce that

$$f'(0.2) \stackrel{\text{forw. diff}}{\approx} \frac{f(0.3) - f(0.2)}{0.1} \approx 0.53364,$$

$$f'(0.2) \stackrel{\text{back. diff}}{\approx} \frac{f(0.2) - f(0.1)}{0.1} \approx 0.30761,$$

while for  $h = 0.01$  we get

$$f'(0.2) \stackrel{\text{forw. diff}}{\approx} \frac{f(0.21) - f(0.2)}{0.01} \approx 0.42761,$$

$$f'(0.2) \stackrel{\text{back. diff}}{\approx} \frac{f(0.2) - f(0.19)}{0.01} \approx 0.40513.$$

Of course, the second choice  $h = 0.01$  gives better approximations. For, the derivative of  $f$  is given by  $f'(x) = 2x e^{x^2}$ , thus  $f'(0.2) = 0.4163243$ . As for a confirmation via Sage, in the previous cell add the line

```
f1=diff(f(x), x)(x=0.2); show(f1)
```

Let us now estimate the errors, where it is reasonable to treat the case  $h = 0.01$  only, which provides smaller errors. So, to evaluate the differences  $|f'(0.2) - 0.42761|$ , and  $|f'(0.2) - 0.40513|$ , we may add in our block the lines

```
show(N(abs(f1-forw001)))
show(N(abs(f1-back001)))
```

We deduce that  $|f'(0.2) - 0.42761| \approx 0.0112841$  and  $|f'(0.2) - 0.40513| \approx 0.0111986$ . Thus, the backward difference with  $h = 0.01$  approximates  $f'(0.2)$  with the smallest actual error.  $\square$

**6.A.41.** For  $h = 0.1$ , and for the function  $f$  given in 6.A.40, use Sage to illustrate the forward and backward difference approximation of  $f'(0.2)$ , together with the tangent line of  $f$  at  $x = 0.2$ .  $\circ$

A combination of the forward and backward differences induces the "central difference" formula, given by

$$\frac{f(x + h) - f(x - h)}{2h}.$$

This provides another approximation of  $f'(x)$ , which has in fact truncation error being of order of  $O(h^2)$ , see 6.1.12.

**6.A.42.** For the function  $f$  introduced in 6.A.40, show that the central difference approximation of the derivative  $f'(0.2)$ ,

NEWTON INTEGRAL

If  $F$  is the primitive function to the function  $f$  on the interval  $[a, b]$ , then we write

$$\int_a^b f(x) dx = [F(x)]_a^b = F(b) - F(a)$$

and call it the *Newton (definite) integral* with the bounds  $a$  and  $b$ .

We prove later that for all continuous functions  $f \in C^0[a, b]$  the Newton integral exists and computes the area as expected. This is one of the fascinating theorems in elementary calculus. Before going into this, we discuss how to compute these integrals.

**6.2.3. Integration "by heart".** We show several procedures for computing the Newton integral. We exploit the knowledge of differentiation, and look for primitive functions.

The easiest case is the one where the given function is known as a derivative. To learn such cases, it suffices to read the tables for function derivatives in the menagerie the other way round. Hence:

INTEGRATION TABLE

For arbitrary nonzero  $a, b \in \mathbb{R}$  and  $n \in \mathbb{Z}, n \neq -1$ :

- $\int a dx = ax + C$
- $\int ax^n dx = \frac{a}{n+1} x^{n+1} + C$
- $\int e^{ax} dx = \frac{1}{a} e^{ax} + C$
- $\int \frac{a}{x} dx = a \ln x + C$
- $\int a \cos(bx) dx = \frac{a}{b} \sin(bx) + C$
- $\int a \sin(bx) dx = -\frac{a}{b} \cos(bx) + C$
- $\int a \cos(bx) \sin^n(bx) dx = \frac{a}{b(n+1)} \sin^{n+1}(bx) + C$
- $\int a \sin(bx) \cos^n(bx) dx = -\frac{a}{b(n+1)} \cos^{n+1}(bx) + C$
- $\int a \operatorname{tg}(bx) dx = -\frac{a}{b} \ln(\cos(bx)) + C$
- $\int \frac{a}{a^2 + x^2} dx = \operatorname{arctg}\left(\frac{x}{a}\right) + C$
- $\int \frac{-1}{\sqrt{a^2 - x^2}} dx = \arccos\left(\frac{x}{a}\right) + C$
- $\int \frac{1}{\sqrt{a^2 - x^2}} dx = \arcsin\left(\frac{x}{a}\right) + C.$

In all the above formulae, it is necessary to clarify the domain on which the indefinite integral is well defined. We leave this to the reader.

with step  $h = 0.01$ , is much better than the corresponding forward and backward difference approximations. In particular, show that this approximation coincides with  $f'(0.2)$ , up to the first four decimal digits. ○

*Calculus helps us understand various fundamental phenomena, such as the intrinsic geometry of curves and surfaces. We will start with a task that demonstrates the concept of the curvature of the graph of a function, as introduced in ???. To maintain continuity with our previous discussion (cf. 6.A.33), we recommend solving this task using implicit differentiation, though other methods are also available.*

**6.A.43.** Determine the curvature of the ellipse  $x^2 + 2y^2 = 2$  at its vertices. Also determine the equations of the circles of osculation at these vertices. ○

*Let us now explore how to work with parametrized curves in both plane and space within the context of calculus. These curves can be viewed as real-valued functions in  $\mathbb{R}^2$  and  $\mathbb{R}^3$ , respectively, though the concept easily generalizes to  $\mathbb{R}^n$  (see 6.1.14 for a brief introduction to such functions, which are examples of “vector functions”).*

*These curves have numerous applications in Newtonian mechanics, where velocity and acceleration are described by the first and second derivatives of such parametric functions with respect to the parameter  $t$ , representing time. We will start with a simple task involving the derivatives of plane curves, which is left as an easy challenge for you and can be solved using Sage, as well.*

**6.A.44.** (a) Use the chain rule to prove that any differentiable plane curve  $\alpha(t) = [x(t), y(t)]$  satisfies

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt},$$

assuming that  $x'(t) = dx/dt \neq 0$ .

(b) Compute using two alternative methods the derivative  $\frac{dy}{dx}$  for the parametric curves

$$\alpha(t) = [t + 1, 2t^3], \quad \beta(t) = [1/(1 + t^2), \ln(t + 1)],$$

where  $t \in [0, 2]$  for both cases. Next evaluate  $\frac{dy}{dx}$  at  $t = 0$  and  $t = 2$  (if it is defined there).

(c) Use Sage to confirm your computations in (b) and then plot the curves  $\alpha, \beta$  via the command `parametric_plot`. ○

**6.A.45. Cycloid.** Consider the plane curve  $\alpha$  given by the parametric equations

$$x(t) = t - \sin(t), \quad y(t) = 1 - \cos(t), \quad t \in [0, 2\pi].$$

This is part of the so-called “cycloid”, which is the curve traced by a point on a circle as it rolls along a straight line

Further rules can be added by observations of special structure of the given functions. For example,

$$\int \frac{f'(x)}{f(x)} dx = \ln |f(x)| + C$$

for all continuously differentiable functions  $f$  on intervals where they are nonzero.

Of course, the rules for differentiating a sum of differentiable functions and constant multiples of differentiable functions yield analogous rules for the indefinite integral. So the sum of two indefinite integrals is the indefinite integral of the sum of the integrated functions, up to the freedom in the chosen constant, etc.

**6.2.4. Integration by parts.** The Leibniz rule for derivatives,  $(F \cdot G)'(t) = F'(t)G(t) + F(t)G'(t)$ , can be interpreted in the realm of the primitive functions. This observation leads to the following very useful practical procedure. It also has theoretical consequences.

INTEGRATION BY PARTS

The formula for computing the integral on the left hand side

$$\int F(x)G'(x) dx = F(x)G(x) - \int F'(x)G(x) dx + C$$

is called *integration by parts*.

The above formula is useful if we can compute  $G$  and at the same time compute the integral on the right hand side.

The principle is best shown on an example. Compute

$$I = \int x \sin x dx.$$

In this case the choice  $F(x) = x, G'(x) = \sin x$  will help. Then  $G(x) = -\cos x$  and therefore

$$I = x(-\cos x) - \int -\cos x dx = -x \cos x + \sin x + C.$$

Some integrals can be dealt with by inserting the factor 1, so that  $G'(x) = 1$ :

$$\begin{aligned} \int \ln x dx &= \int 1 \cdot \ln x dx \\ &= x \ln x - \int \frac{1}{x} x dx = x \ln x - x + C. \end{aligned}$$

**6.2.5. Integration by substitution.** Another useful procedure is derived from the chain rule for differentiating composite functions. If

$$F'(y) = f(y), \quad y = \varphi(x),$$

where  $\varphi$  is a differentiable function with nonzero derivative, then

$$\frac{dF(\varphi(x))}{dx} = F'(y) \cdot \varphi'(x)$$

and thus  $F(y) + C = \int f(y) dy$  can be computed as

$$F(\varphi(x)) + C = \int f(\varphi(x))\varphi'(x) dx.$$

without slipping.<sup>2</sup> Use calculus to show that the angle  $\theta$  of the tangent lines of  $\alpha$  at the points  $P = [x(\frac{2\pi}{3}), y(\frac{2\pi}{3})] \in \alpha$  and  $Q = [x(\frac{4\pi}{3}), y(\frac{4\pi}{3})] \in \alpha$ , respectively, is such that  $\tan(\theta) = -\sqrt{3}$ .

**Solution.** Recall that  $\sin(2\pi/3) = \sqrt{3}/2 = -\sin(4\pi/3)$  and  $\cos(2\pi/3) = -1/2 = \cos(4\pi/3)$ . Thus we compute  $P = [x_P, y_P] = [\frac{2\pi}{3} - \frac{\sqrt{3}}{2}, \frac{3}{2}]$  and  $Q = [x_Q, y_Q] = [\frac{4\pi}{3} + \frac{\sqrt{3}}{2}, \frac{3}{2}]$ , respectively. The tangent line of  $\alpha$  passing through  $P$  is the line

$$\ell_P(x) = y_P + k_{\frac{2\pi}{3}} \cdot (x - x_P), \quad k_{\frac{2\pi}{3}} = \left. \frac{dy}{dx} \right|_{t=\frac{2\pi}{3}}.$$

Similarly, the tangent line of  $\alpha$  passing through  $Q$  is the line

$$\ell_Q(x) = y_Q + k_{\frac{4\pi}{3}} \cdot (x - x_Q), \quad k_{\frac{4\pi}{3}} = \left. \frac{dy}{dx} \right|_{t=\frac{4\pi}{3}}.$$

We compute

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{\sin(t)}{1 - \cos(t)} = \frac{1}{\tan(t/2)} = \cot(t/2),$$

and thus it follows that  $k_{\frac{2\pi}{3}} = \frac{\sqrt{3}}{3}$  and  $k_{\frac{4\pi}{3}} = -\frac{\sqrt{3}}{3}$ . Hence the angle  $\theta = \angle PRQ$ , where  $R$  is the intersection points of  $\ell_P, \ell_Q$ , is given by

$$\tan(\theta) = \frac{k_{\frac{4\pi}{3}} - k_{\frac{2\pi}{3}}}{1 + k_{\frac{2\pi}{3}} \cdot k_{\frac{4\pi}{3}}} = \frac{-\frac{\sqrt{3}}{3} - \frac{\sqrt{3}}{3}}{1 - \frac{1}{3}} = -\sqrt{3}.$$

An illustration is given here:

This figure and all the computations presented above can be done easily in Sage, and we leave this part as an exercise, see 6.A.46. For more details on the cycloid, see for example 6.D.17 in Section D.  $\square$

**6.A.46.** For the task in 6.A.45 illustrate the situation in Sage and confirm the related computations.  $\circ$

*In the end of the next section we will return back to parametric curves and learn how to compute their lengths and the areas of the regions bounded or enclosed by of their graphs. Hence soon we will also learn how to deal with integrals involving parametric equations.*

<sup>2</sup>When the circle has radius  $r$  the parametric equations of the cycloid are given by  $[r \cdot x(t), r \cdot y(t)]$ , and in our case we fixed  $r = 1$ . Be aware that the cycloid is *not* an ellipse.

By substituting  $x = \varphi^{-1}(y)$ , we obtain the originally desired primitive function. This is often written as follows:

#### INTEGRATION BY SUBSTITUTION

If  $\varphi(x)$  is differentiable with a nowhere vanishing derivative, then

$$F(y) = \int f(y) dy = \int f(\varphi(x))\varphi'(x) dx = F(\varphi(x)).$$

We talk about substituting the variable  $y$  by  $y = \varphi(x)$ .

On the level of differentials, the substitution can be easily understood in a way that (linearized) increments of the variable  $y$  and  $x$  are in mutual relation formally described by

$$dy = \varphi'(x) dx,$$

which corresponds the relation between the integrated quantities

$$f(y) dy = f(\varphi(x))\varphi'(x) dx.$$

As an illustration, we verify the last but one integral in the list in 6.2.3 using this method. To compute

$$I = \int \frac{1}{\sqrt{1-x^2}} dx.$$

Choose the substitution  $x = \sin t$ , for all  $t \in (-\frac{\pi}{2}, \frac{\pi}{2})$ . Then  $dx = \cos t dt$ . So

$$\begin{aligned} I &= \int \frac{1}{\sqrt{1-\sin^2 t}} \cos t dt = \int \frac{1}{\sqrt{\cos^2 t}} \cos t dt \\ &= \int dt = t + C. \end{aligned}$$

By substitution  $t = \arcsin x$  into the result,  $I = \arcsin x + C$ .

While substituting, the actual existence of the inverse function to  $y = \varphi(x)$  is required. To evaluate a definite Newton integral, it is needed to correctly recalculate the bounds of integration. Problems with the domains of the inverse functions can sometimes be avoided by dividing the integration into several intervals. We return to this point later.

**6.2.6. Integration by reduction to recurrences.** Often the use of substitutions and integrating by parts leads to recurrent relations, from which desired integrals can be evaluated. We illustrate by an example. Integrating by parts, to evaluate

$$\begin{aligned} I_m &= \int \cos^m x dx = \int \cos^{m-1} x \cos x dx \\ &= \cos^{m-1} x \sin x - (m-1) \int \cos^{m-2} x (-\sin x) \sin x dx \\ &= \cos^{m-1} x \sin x + (m-1) \int \cos^{m-2} x \sin^2 x dx. \end{aligned}$$

Using the formula  $\sin^2 x = 1 - \cos^2 x$ ,

$$mI_m = \cos^{m-1} x \sin x + (m-1)I_{m-2}.$$

The initial values are

$$I_0 = x, \quad I_1 = \sin x.$$

**B. Integration**

*In this section we will focus on tasks related to the notion of integration. As we pronounced before, the processes of differentiation and integration are inverse to each other, a result that we will confirm later in terms of the “fundamental theorem of calculus”. This theorem is in a sense the main link between the so called “differentiable calculus” and “integral calculus” and we will have the chances to analyze many examples a few below.*

*Let us begin with the notion of indefinite integrals, also called antiderivatives, which are introduced in 6.2.1 (see also 6.2.2).<sup>3</sup> We first present a few easy examples, based on basic rules from integration (see the “Integration Table” in 6.2.3).*

**6.B.1. Integration by heart.** Using integration “by heart” (see 6.2.3) evaluate the indefinite integrals given below. Next confirm your answers via Sage.

- (1)  $\int e^{-x} dx$ , with  $x \in \mathbb{R}$ ; (2)  $\int \frac{1}{\sqrt{4-x^2}} dx$ , with  $x \in (-2, 2)$ ; (3)  $\int \frac{1}{x^2+3} dx$ , with  $x \in \mathbb{R}$ ; (4)  $\int \frac{3x^2+1}{x^3+x+2} dx$ , with  $x \neq -1$ ; (5)  $\int |x| dx$ , with  $x \in \mathbb{R}$ .

**Solution.** (1) The primitive of  $f(x) = e^{-x}$  is the function  $F(x) = -e^{-x}$ , since  $(-e^{-x})' = e^{-x}$ . Thus, by the definition of the indefinite integral given in 6.2.1, we have  $\int f(x) dx = F(x) + C = -e^{-x} + C$ , for some constant  $C$ . (2) Use the formula  $\int \frac{dx}{\sqrt{1-x^2}} = \arcsin(x) + C$ , for some constant  $C \in \mathbb{R}$ . This gives

$$\int \frac{1}{\sqrt{4-x^2}} dx = \int \frac{\frac{1}{2}}{\sqrt{1-\left(\frac{x}{2}\right)^2}} dx = \arcsin\left(\frac{x}{2}\right) + C.$$

(3) Use the formula  $\int \frac{dx}{1+x^2} = \arctan(x) + C$ , for some constant  $C \in \mathbb{R}$ . We have

$$\begin{aligned} \int \frac{1}{x^2+3} dx &= \frac{1}{3} \int \frac{1}{\frac{x^2}{3}+1} dx = \frac{1}{\sqrt{3}} \int \frac{\frac{1}{\sqrt{3}}}{1+\left(\frac{x}{\sqrt{3}}\right)^2} dx \\ &= \frac{1}{\sqrt{3}} \arctan\left(\frac{x}{\sqrt{3}}\right) + C. \end{aligned}$$

(4) Use the formula  $\int \frac{f'(x)}{f(x)} dx = \ln|f(x)| + C$ , with  $C \in \mathbb{R}$ . Hence, we obtain

$$\int \frac{3x^2+3}{x^3+3x+2} dx = \ln|x^3+3x+2| + C.$$

(5) The function  $f(x) = |x|$  is continuous on  $\mathbb{R}$ , hence it has a primitive function on  $\mathbb{R}$ . This has the form  $\frac{x^2}{2} + c_1$ , for  $x \geq 0$ ,

<sup>3</sup>The notation for the indefinite integral was first introduced by Leibniz in 1675.

Integrals in which the integrated function depends on expressions of the form  $(x^2 + 1)$  can be reduced to these types of integrals using the substitution  $x = \operatorname{tg} t$ . For example, to compute

$$J_k = \int \frac{dx}{(x^2+1)^k}$$

the latter substitution yields (notice that  $dx = \cos^{-2} t dt$ )

$$J_k = \int \frac{dt}{\cos^2 t \left(\frac{\sin^2 t}{\cos^2 t} + 1\right)^k} = \int \cos^{2k-2} t dt.$$

For  $k = 2$ , the result is

$$J_2 = \frac{1}{2}(\cos t \sin t + t) = \frac{1}{2} \left( \frac{\operatorname{tg} t}{1 + \operatorname{tg}^2 t} + t \right).$$

After the reverse substitution  $t = \operatorname{arctg} x$

$$J_2 = \frac{1}{2} \left( \frac{x}{1+x^2} + \operatorname{arctg} x \right) + C.$$

When evaluating definite integrals, we can compute the whole recurrence after evaluating with the given bounds. For example while integrating over the interval  $[0, 2\pi]$ , the integrals have these values:

$$I_0 = \int_0^{2\pi} dx = [x]_0^{2\pi} = 2\pi$$

$$I_1 = \int_0^{2\pi} \cos x dx = [\sin x]_0^{2\pi} = 0$$

$$I_m = \int_0^{2\pi} \cos^m x dx = \begin{cases} 0 & \text{for odd } m \\ \frac{m-1}{m} I_{m-2} & \text{for even } m. \end{cases}$$

Thus for even  $m = 2n$ , the result is

$$\int_0^{2\pi} \cos^{2n} x dx = \frac{(2n-1)(2n-3)\dots 3 \cdot 1}{2n(2n-2)\dots 2} 2\pi.$$

For odd  $m$  it is zero (as could be guessed from the graph of the function  $\cos x$ ).

**6.2.7. Integration of rational functions.** The next goal is the integration of the quotients of two polynomials  $f(x)/g(x)$ . There are several simplifications to start with.

If the degree of the polynomial  $f$  in the numerator is greater or equal to the degree of the polynomial  $g$  in the denominator, carry out the division with remainder (see the paragraph 5.1.2). This reduces the integration to a sum of two integrals.

The division provides

$$f = q \cdot g + h, \quad \frac{f}{g} = q + \frac{h}{g}.$$

Thus,  $\int f(x)/g(x) dx = \int q dx + \int h(x)/g(x) dx$  where the first integral is easy and the second one is again an expression of the type  $h(x)/g(x)$ , but with degree of  $g(x)$  strictly larger than the degree of  $h(x)$  (such functions are called *proper rational functions*).

and  $-\frac{x^2}{2} + c_2$ , for  $x \leq 0$ , for some constants  $c_1, c_2 \in \mathbb{R}$ . It is easy to see that  $c_1 = c_2 = c \in \mathbb{R}$  and hence

$$\int |x| dx = \frac{1}{2}x|x| + c = \begin{cases} \frac{x^2}{2} + c, & \text{if } x \geq 0; \\ -\frac{x^2}{2} + c, & \text{if } x \leq 0; \end{cases}$$

A powerful capability of Sage, as most of the available computer algebra programs, is its ability to integrate symbolically. In Sage we will learn to integrate functions in many different ways and also numerically. For antiderivatives (indefinite integrals) one uses the `integral` function, via the syntax `integral(f(x), x)`, which can be rewritten as `f.integral(x)`. An alternative reads as `f.integrate(x)`. Later we will see that the situation of definite integrals does not differ much.

Recall that the indefinite integral (as an infinite set) can be represented by one specific function and its translations. Hence, one could expect that Sage will print out a function with a constant  $C$ , as in the relation  $F(x) = \int f(x) dx + C$ . However, Sage ignores  $C$  and hence you should always assume that this is implicitly part of the answer. Keeping in mind these details, we are now ready to solve our task. This can be done by the cell

```
show(integral(e^(-x), x))
show(integral(1/(sqrt(4-x^2)), x))
show(integral(1/(x^2+3), x))
show(integral((3*x^2+1)/(x^3+x+2), x))
show(integral(abs(x)))
```

Check yourself that this provides the desired answers.

Often, computing integrals via Sage we may need to add restrictions, via the command `assume`. For instance, type

```
m=var("m"); assume(m>1)
show(integral(1/x^m, x))
```

Notice without the command `assume(m > 1)`, Sage is not able to produce a result. We will meet further such examples in the sequel.  $\square$

**6.B.2.** Let  $f$  be a continuous function on  $\mathbb{R}$  with  $f(x) \neq 0$ , for all  $x \in \mathbb{R}$ . Suppose that the primitive function  $F$  of  $f$  satisfies  $4F(x) = f(x)$ , for all  $x \in \mathbb{R}$ , and moreover that  $f(4) = 4$ . Find the type of  $f$ .  $\circ$

**6.B.3.** (a) Write a routine in Sage which will print out a primitive of an integrable function  $f$ .

(b) Use your routine to find the primitive of some of the functions presented in the “Integration Table” in 6.2.3.

**Solution.** This is an easy task that one can implement as follows:

```
function("f")(x)
def Primitive_function(f) :
    F(x)=integral(f, x).factor()
    show("A primitive function of f(x)=", f,
        " is given by ", ":", F(x))
    return
```

Thus we can assume that the degree of  $g$  is strictly larger than the degree of  $f$ . We introduce the procedure to integrate proper rational functions by a simple example.

Observe that we can integrate  $(a+x)^{-n}$ ,  $n > 1$ , and

$$\int \frac{1}{a+x} dx = \ln|a+x| + C.$$

Summing such simple fractions yields more complicated ones:

$$\frac{-2}{x+1} + \frac{6}{x+2} = \frac{4x+2}{x^2+3x+2}$$

which can be integrated directly:

$$\int \frac{4x+2}{x^2+3x+2} dx = -2 \ln|x+1| + 6 \ln|x+2| + C.$$

This suggests looking for a procedure to express proper rational functions as a sum of simple ones. In the example, it is straightforward to compute the unknown coefficients  $A$  and  $B$ , once the roots of the denominator are known:

$$\frac{4x+2}{x^2+3x+2} = \frac{4x+2}{(x+1)(x+2)} = \frac{A}{x+1} + \frac{B}{x+2}.$$

Multiply both sides by the polynomial  $x^2+3x+2$  from the denominator and compare coefficients of the individual powers of  $x$  in the resulting polynomials:

$$4x+2 = A(x+2)+B(x+1) \implies 2A+B = 2, A+B = 4.$$

This procedure is called *decomposition into partial fractions*. It is a purely algebraic procedure based on properties of polynomials.

Without loss of generality, suppose that the denominator  $g(x)$  and the numerator  $f(x)$  do not share any real or complex roots and that  $g(x)$  has exactly  $n$  distinct real roots  $a_1, \dots, a_n$ . Then the points  $a_1, \dots, a_n$  are all the discontinuities of the function  $f(x)/g(x)$ .

Split the expression  $\frac{f(x)}{g(x)}$  according to the factors of the denominator. Thus, assume  $g(x)$  is the product

$$g(x) = p(x)q(x)$$

of two coprime polynomials. By the Bezout identity (see 12.3.8 on the page 1082), which is a corollary of the polynomial division with a remainder, there exist polynomials  $a(x)$  and  $b(x)$  of degrees strictly less than the degree of  $g$  such that

$$a(x)p(x) + b(x)q(x) = 1.$$

Multiplying this equality by the quotient  $f(x)/g(x)$ , gives

$$\frac{f(x)}{g(x)} = \frac{a(x)}{q(x)} + \frac{b(x)}{p(x)}.$$

Thus, we may restrict our attention to cases where the denominator  $g(x)$  cannot be decomposed further into two coprime polynomials.

Suppose that the polynomial  $g(x)$  has only real roots. Then there is a unique decomposition into factors  $(x - a_i)^{n_i}$ , where  $n_i$  are the multiplicities of the roots  $a_i$ ,  $i = 1, \dots, k$ . By a sequential use of the latter procedure with coprime

(b) To test the routine it is easy:

```
a,b=var("a, b")
Primitive_function(a*x^3)
Primitive_function(e^(a*x))
Primitive_function(a/x)
Primitive_function(a*sin(x*b))
Primitive_function(a/(a^2+x^2))
Primitive_function(1/sqrt(a^2+x^2))
Primitive_function(x*abs(x))
Primitive_function((3*x^2)*sqrt(1+(1/x^2)))
```

For instance, for the final case Sage’s output has the form:

A primitive function of  $f(x) = 3x^2\sqrt{1 + \frac{1}{x^2}}$  is  
 given by  $x^3 \left(\frac{x^2+1}{x^2}\right)^{\frac{3}{2}}$

Observe that when the input  $f$  is an integrable function, but there is no function, built up of addition, subtraction, multiplication, division, roots, exponents, logarithms, trigonometric functions, and inverse trigonometric functions which will have, as its derivative the function  $f$ , then Sage will *not* provide an answer. Such are the functions

$$e^{-x^3} \sin(x), e^{-x^3} \sin(x^2),$$

or the “Gaussian” (also called the “*error function*”) that we will meet later (this has a crucial role in statistics) However, one can still numerically compute such integrals, a situation that we will encounter later.  $\square$

*Trigonometric identities are often useful when integrating expression involving trigonometric functions. Test your skills on trigonometric identities by evaluating the following indefinite integral.*

**6.B.4.** Compute the integral  $A = \int \sin^2(x) \cos^2(x) dx$ .  $\circ$

Next we present a simple application of antiderivatives, where a given “initial condition” allows us to compute explicitly the constant of integration  $C$ . In particular, this provides an example of solving a first order differential equation with an initial condition (also referred to as an “initial value problem”). Further such problems we will meet in the end of this section (see 6.B.64, 6.B.65).

**6.B.5. An initial value problem.** Determine a curve  $y = f(x)$  passing from the point  $P = [1, 3]$  with slope  $\frac{2}{5}x$ . Then use the command `dsolve` in Sage to confirm your answer.

**Solution.** By assumption the slope of  $y = f(x)$  is  $\frac{2}{5}x$ , which means that  $f'(x) = \frac{df}{dx} = \frac{2}{5}x$ . By integration, we get

$$f(x) = \int f'(x) dx = \int \frac{2}{5}x dx = \frac{2}{5} \int x dx = \frac{x^2}{5} + C.$$

To specify the constant  $C \in \mathbb{R}$  use the equation  $f(1) = 3$ , i.e.,  $\frac{1}{5} + C = 3$ . This gives  $C = 14/5$  and hence  $y = f(x) = \frac{1}{5}(x^2 + 14)$ .

polynomials  $p(x)$  and  $q(x)$ , we obtain a representation of  $f(x)/g(x)$  as a sum of fractions of the form

$$\frac{f(x)}{g(x)} = \frac{r_1(x)}{(x - a_1)^{n_1}} + \dots + \frac{r_k(x)}{(x - a_k)^{n_k}},$$

where the degrees of the polynomials  $r_i(x)$  are strictly smaller than the degrees of the denominators. Finally, each of the summands can be represented as a sum

$$\frac{r(x)}{(x - a)^n} = \frac{A_1}{x - a} + \frac{A_2}{(x - a)^2} + \dots + \frac{A_n}{(x - a)^n}.$$

Indeed, we multiply the equation by  $(x - a)^n$  and start comparing the coefficients from the highest powers of the polynomial  $r(x)$  and compute sequentially  $A_1, A_2, \dots$  after expanding all the products. This can be done faster by suitable additions and subtractions, starting by the highest orders. For example,

$$\frac{5x - 16}{(x - 2)^2} = 5 \frac{x - 2}{(x - 2)^2} - 6 \frac{1}{(x - 2)^2} = \frac{5}{x - 2} + \frac{-6}{(x - 2)^2}.$$

Finally, we have to handle the case, where there are not enough real roots. There always exists a factorization of  $g(x)$  into linear factors with complex roots (see the fundamental theorem of Algebra in 1.A.6 on page 6). The non-real roots always appear in conjugated pairs, since  $\overline{g(z)} = g(\bar{z})$  for a polynomial with real coefficients.

Repeating the above procedure for ratios of complex polynomials gives the same result, but with complex coefficients. If we insist in having real expressions only, we may collect the conjugate pairs together and get quadratic factors expressed as sums of squares  $(x - a)^2 + b^2$  and their powers. The procedure works well and guarantees that it is possible to find summands in the form of

$$\frac{Bx + C}{((x - a)^2 + b^2)^n}.$$

As in the real roots case, there is always a corresponding decomposition into partial fractions of the form

$$\frac{A_1x + B_1}{(x - a)^2 + b^2} + \dots + \frac{A_nx + B_n}{((x - a)^2 + b^2)^n}$$

in the case of a power  $((x - a)^2 + b^2)^n$  of such quadratic (irreducible) factor as well.

The factorization of the polynomials and the further computations might be quite time consuming. The reader could prefer to experiment with computer algebra software instead. This works well in Maple by calling the procedure `convert(h, parfrac, x)` that decomposes the expression  $h$  rationally dependent on the variable  $x$  into partial fractions.

The important point is that we can already integrate all of the above partial fractions. The last mentioned ones lead to integrals discussed in example 6.2.6.

In summary, the rational functions  $f(x)/g(x)$  can be integrated easily, if the corresponding decomposition of the polynomial in the denominator  $g(x)$  is known. The reality is not that simple when computing (definite) Newton integrals. Although we find the primitive functions, the problematic points are the discontinuities of rational functions, in whose

To solve the system  $\{\frac{df}{dx} = \frac{2}{5}x, f(1) = 3\}$  with Sage we will use the command `desolve(F, y, [a, b])`, which involves the differential equation that we want to solve (this is denoted by  $F$  and it will necessarily include the first derivative `diff(y, x)` of  $y = f(x)$ ), the function  $y$ , which we should first introduce as a symbolic function in Sage, and the numbers  $a, b$  which are specified by the initial condition  $y(a) = b$ . For our case this technique takes the form

```
y = function("y")(x)
difeq = diff(y, x) - (2/5)*x == 0
h = desolve(difeq, y, [1, 3])
show(h)
```

Sage's output has the desired form, i.e.,  $\frac{1}{5}x^2 + \frac{14}{5}$ . □

A very elementary method of integration is the so called *integration by parts* (see 6.2.4). This method is appropriate for computing integrals of the following form:

$$\begin{aligned} & \int P(x) a^{bx} dx, & \int P(x) \sin(bx) dx, \\ & \int P(x) \cos(bx) dx, & \int P(x) \log_a^n x dx, \\ & \int x^b \log_a^n(kx) dx, & \int P(x) \arcsin(bx) dx, \\ & \int P(x) \arccos(bx) dx, & \int P(x) \arctan(bx) dx, \\ & \int P(x) \operatorname{arccot}(bx) dx, & \int a^{bx} \sin(cx) dx, \end{aligned}$$

and  $\int a^{bx} \cos(cx) dx$ , where  $P$  is an arbitrary polynomial,  $a \in (0, 1) \cup (1, +\infty)$ ,  $b, c \in \mathbb{R} \setminus \{0\}$ ,  $n \in \mathbb{N}$  and  $k > 0$ . Let us now illustrate this method by a series of examples.

**6.B.6. Integration by parts.** Using integration by parts, evaluate the integral  $L = \int (x^2 + 1) e^{-x} dx$ , with  $x \in \mathbb{R}$ .

**Solution.** Here we should apply integration by parts twice:

$$\begin{aligned} L &= \int (x^2 + 1) (-e^{-x})' dx = -(x^2 + 1) e^{-x} \\ &\quad - \int (x^2 + 1)' (-e^{-x}) = -(x^2 + 1) e^{-x} + 2\ell, \end{aligned}$$

where  $\ell = \int x e^{-x} dx$ . Next we have

$$\begin{aligned} \ell &= \int x(-e^{-x})' = -x e^{-x} - \int (x)'(-e^{-x}) \\ &= -x e^{-x} + \int e^{-x} = -x e^{-x} - e^{-x} + C, \end{aligned}$$

for some constant  $C \in \mathbb{R}$ . Thus, all together we obtain  $L = -e^{-x}(x^2 + 2x + 3) + C$ . □

**6.B.7.** Using integration by parts, compute the indefinite integrals given below:

(a)  $K = \int x \cos(x) dx$ , with  $x \in \mathbb{R}$ ;

neighbourhood these functions are unbounded. We return to this problem later (see paragraph 6.2.14 below).

**6.2.8. Riemann integral.** We return to the idea of defining the integral as a tool for computing the area of the region bounded by the graph of a function and the  $x$  axis. This is our next goal. We prove that for all continuous functions on a closed bounded interval, this definition yields the same result as the Newton integral.

Consider a real function  $f$  defined on the interval  $[a, b]$ . Choose a partition of this interval along with the choice of representatives  $\xi_i$  of the respective parts, i.e.  $a = x_0 < x_1 < \dots < x_n = b$  and  $\xi_i \in [x_{i-1}, x_i]$ ,  $i = 1, \dots, n$ . The number  $\delta = \min_i \{x_i - x_{i-1}\}$  is called the *norm of the partition*. Define the *Riemann sum* corresponding to the chosen partition along with the chosen representatives  $\Xi = (x_0, \dots, x_n; \xi_1, \dots, \xi_n)$  as

$$S_{\Xi} = \sum_{i=1}^n f(\xi_i) \cdot (x_i - x_{i-1}).$$

RIEMANN INTEGRAL<sup>4</sup>

**Definition.** The *Riemann integral* of the function  $f$  on the interval  $[a, b]$  exists, if for every sequence of partitions with representatives  $(\Xi_k)_{k=0}^{\infty}$  with norms of the partitions  $\delta_k$  approaching zero, the limit

$$\lim_{k \rightarrow \infty} S_{\Xi_k} = S$$

exists and its value does not depend on the choice of the sequence of partitions and their representatives. Then we write

$$S = \int_a^b f(x) dx.$$

This definition does not look very practical, but nonetheless it allows us to formulate and prove several simple properties of the Riemann integral:

<sup>4</sup>Bernhard Riemann (1826-1866) was an extremely influential German mathematician with many contributions to infinitesimal analysis, differential geometry, and in particular complex analysis and analytic number theory.

$$(b) M = \int (2x - 1) \ln(x) dx, \text{ with } x > 0;$$

$$(c) N = \int e^x \sin(\beta x) dx, \text{ with } x, \beta \in \mathbb{R}. \quad \circ$$

**6.B.8.** Determine the integrals given below and next use Sage to confirm your answers:

$$(a) \int \frac{x}{\cos^2(x)} dx, \text{ with } x \neq \frac{\pi}{2} + k\pi, k \in \mathbb{Z};$$

$$(b) \int x^2 e^{-3x} dx, \text{ with } x \in \mathbb{R};$$

$$(c) \int \cos^2(x) dx, \text{ with } x \in \mathbb{R}. \quad \circ$$

The substitution method, introduced in 6.2.5, is another very important technique to compute integrals. The next series of exercises is based on this method. Notice later you will meet a more systematic illustration of the substitution method, along the integration of rational and irrational functions, but also in many trigonometric integrals.

**6.B.9. Substitution method.** Using a suitable substitution, determine the integral  $\int f(x) dx$ , where  $f(x)$  is given below.

Moreover, use Sage to confirm your answer.

$$(1) f(x) = \sqrt{2x - 5}, \text{ with } x > \frac{5}{2};$$

$$(2) f(x) = (7 + \ln(x))^7 / x, \text{ with } x > 0;$$

$$(3) f(x) = \cos(x) / (1 + \sin(x))^2, \text{ with } x \neq \frac{(3+4k)\pi}{2}, k \in \mathbb{Z};$$

$$(4) f(x) = (1 - 2x)^{2025}, \text{ with } x < 1/2;$$

**Solution.** (1) Set  $t = 2x - 5$  such that  $dt = 2 dx$ , i.e.,  $dx = \frac{dt}{2}$ . Thus

$$\int \sqrt{2x - 5} dx = \frac{1}{2} \int \sqrt{t} dt = \frac{t^{\frac{3}{2}}}{\frac{3}{2}} + C = \frac{1}{3}(2x - 5)^{\frac{3}{2}} + C$$

for some constant  $C$ .

(2) Set  $t = 7 + \ln(x)$  such that  $dt = \frac{dx}{x}$ . Then we get

$$\int \frac{(7 + \ln(x))^7}{x} dx = \int t^7 dt = \frac{t^8}{8} + C = \frac{(7 + \ln(x))^8}{8} + C.$$

(3) Set  $t = 1 + \sin(x)$  such that  $dt = \cos(x) dx$ . Then

$$\int \frac{\cos(x)}{(1 + \sin(x))^2} dx = \int \frac{dt}{t^2} = -\frac{1}{t} + C = -\frac{1}{(1 + \sin(x))} + C.$$

(4) Set  $t = 1 - 2x$  such that  $dt = -2 dx$ , i.e.,  $dx = -\frac{dt}{2}$ . Then

$$\begin{aligned} \int (1 - 2x)^{2025} dx &= -\frac{1}{2} \int t^{2025} dt = -\frac{1}{2} \cdot \frac{t^{2026}}{2026} + C \\ &= -\frac{(1 - 2x)^{2026}}{4052} + C, \quad C \in \mathbb{R}. \end{aligned}$$

A verification via Sage occurs with the same method presented in 6.B.1. Hence one can type

```
show(integral(sqrt(2*x-5), x))
show(integral(((7+ln(x))^7)/x, x))
show(integral((cos(x)/(1+sin(x))^2), x))
```

**Theorem.** (1) Suppose  $f$  is a bounded real function defined on the interval  $[a, b]$ , and  $c \in [a, b]$  is an inner point of this interval. Then the integral  $\int_a^b f(x) dx$  exists if and only if both of the integrals  $\int_a^c f(x) dx$  and  $\int_c^b f(x) dx$  exist. In that case

$$\int_a^b f(x) dx = \int_a^c f(x) dx + \int_c^b f(x) dx.$$

(2) Suppose  $f$  and  $g$  are two real functions defined on the interval  $[a, b]$ , and that both of the integrals  $\int_a^b f(x) dx$  and  $\int_a^b g(x) dx$  exist. Then the integral of their sum also exists and

$$\int_a^b (f(x) + g(x)) dx = \int_a^b f(x) dx + \int_a^b g(x) dx.$$

(3) Suppose  $f$  is a real function defined on the interval  $[a, b]$ ,  $C \in \mathbb{R}$  is a constant, and the integral  $\int_a^b f(x) dx$  exists. Then the integral  $\int_a^b Cf(x) dx$  also exists and

$$\int_a^b Cf(x) dx = C \int_a^b f(x) dx.$$

**PROOF.** (1) First suppose that the integral over the whole interval exists. When computing it, we can limit ourselves to limits of the Riemann sums whose partitions have the point  $c$  among their partitioning points. Each such sum can be obtained as a sum of two partial Riemann sums. If these two partial sums would depend on the chosen partitions and representatives in the limit, then the total sums could not be independent on the choices in limit. (It suffices to keep the sequence of partitions of the subinterval the same, and change the other so that the limit would change).

Conversely, if both Riemann integrals on both subintervals exists, they can be approximated with arbitrary precision by the Riemann sums, and moreover independently on their choice. If a partitioning point  $c$  is added to any sequence of Riemann sums over the whole interval  $[a, b]$ , the value of the whole sum is changed. Also the values of the partial sums over the intervals belonging to  $[a, c]$  and  $[c, b]$  change at most by a multiple of the norm of the partition and possible differences of the bounded function  $f$  on all of  $[a, b]$ . This is a number arbitrarily close to zero for a decreasing norm of the partition. Necessarily the partial Riemann sums of the function over the two parts of the interval also converge to the limits, whose sum is the Riemann integral over  $[a, b]$ .

(2) In every Riemann sum, the sum of the functions manifests as the sum of the values in the chosen representatives. Because multiplication of real numbers is distributive, each Riemann sum becomes the sum of the two Riemann sums with the same representatives for the two functions. The statement follows from the elementary properties of limits.

(3) Each of the Riemann sum is multiplied by the constant  $C$ . So the claim follows from the elementary properties of limits.  $\square$

and similarly for final case. □

**6.B.10.** Using a suitable substitution determine  $\int e^{x^3+4} x^2$ , with  $x \in \mathbb{R}$ . Next use Sage to confirm the answer. ○

**6.B.11.** Compute  $\int \cos^5(x) \sin(x) dx$ , with  $x \in \mathbb{R}$ . ○

**6.B.12.** Compute  $\int \frac{\sin^4(x)}{\cos^4(x)} dx$ , with  $x \in (-\frac{\pi}{2}, \frac{\pi}{2})$ . ○

**6.B.13.** Use Sage to confirm the answers presented in **6.B.11** and **6.B.12**, respectively. ○

**6.B.14.** Evaluate  $\int \cos^5(x) \sin^2(x) dx$ . ○

*Combining integration by parts with the substitution method is a very common situation. Hence we will meet often examples which rely on combining both methods, as the task presented below.*

**6.B.15.** Evaluate the following integrals:

(a)  $\int x^3 e^{-x^2} dx$ , with  $x \in \mathbb{R}$ ;

(b)  $\int x \arcsin(x^2) dx$ , with  $x \in (-1, 1)$ ;

(c)  $\int e^{\sqrt{x}} dx$ , with  $x > 0$ . ○

**6.B.16. Integration by reduction to recurrences.** Let  $n$  be a non-negative integer.

(a) Set  $I_n = \int x^n e^x dx$ , with  $I_0 = e^x$ . Show that  $I_n = x^n e^x - nI_{n-1}$  and next compute  $I_1, I_2, I_3$ .

(b) Set  $J_n = \int (\ln(x))^n dx$ . Show that  $J_n = x(\ln(x))^n - nJ_{n-1}$  and next compute  $J_1, J_2, J_3$ .

**Solution.** (a) Integration by parts gives the result:

$$I_n = \int x^n (e^x)' dx = x^n e^x - n \int x^{n-1} e^x dx = x^n e^x - nI_{n-1}.$$

It is easy now to compute  $I_1, I_2, I_3$ :

$$I_1 = x e^x - e^x = e^x(x - 1),$$

$$I_2 = x^2 e^x - 2e^x(x - 1) = e^x(x^2 - 2x + 2),$$

$$I_3 = x^3 e^x - 3e^x(x^2 - 2x + 2) = e^x(x^3 - 3x^2 + 6x - 6).$$

You can also prove that  $I_n = e^x p_n(x)$  where the polynomial  $p_n$  is of order  $n$  and defined recursively by

$$p_n(x) = x^n - n p_{n-1}(x), \quad p_0(x) = 1.$$

(b) This can be solved similarly and left for practice. □

**6.B.17.** Let  $I_n = \int \sin^n(x) dx$  with  $n \in \mathbb{N}$ . Prove that

$$I_n = -\frac{1}{n} \sin^{n-1}(x) \cos(x) + \frac{n-1}{n} I_{n-2}.$$

Then use this relation to compute  $I_2$  and  $I_3$ . ○

**6.2.9. The fundamental theorem.** The following result is crucial for understanding the relation between the integral and the derivative. The complete proof of this theorem is somewhat longer, so it is broken into several subsections.

FUNDAMENTAL THEOREM OF INTEGRAL CALCULUS

**Theorem.** For every continuous function  $f$  on a finite interval  $[a, b]$  there exists its Riemann integral  $\int_a^b f(x) dx$ . Moreover, the function  $F(x)$  given on the interval  $[a, b]$  by the Riemann integral

$$F(x) = \int_a^x f(t) dt$$

is a primitive function to  $f$  on this interval.

**6.2.10. Upper and lower Riemann integral.** In the first step for proving the existence of the integral, we use an alternative definition, in which the choice of representatives and the corresponding value  $f(\xi_i)$  is replaced by the suprema  $M_i$  of the values  $f(x)$  in the corresponding subintervals  $[x_{i-1}, x_i]$ , or by the infima  $m_i$  of the function  $f(x)$  in the same subintervals, respectively. We speak of upper and lower Riemann sums, respectively (in literature, this process is also called the *Darboux integral*).

Because the function is continuous, it is bounded on a closed interval, hence all the above considered suprema and infima exist and are finite. Then the *upper Riemann sum* corresponding to the partition  $\Xi = (x_0, \dots, x_n)$  is given by the expression

$$S_{\Xi, \text{sup}} = \sum_{i=1}^n \left( \sup_{x_{i-1} \leq \xi \leq x_i} f(\xi) \right) (x_i - x_{i-1}) = \sum_{i=1}^n M_i (x_i - x_{i-1}).$$

The *lower Riemann sum* is

$$S_{\Xi, \text{inf}} = \sum_{i=1}^n \left( \inf_{x_{i-1} \leq \xi \leq x_i} f(\xi) \right) (x_i - x_{i-1}) = \sum_{i=1}^n m_i (x_i - x_{i-1}).$$

For each partition  $\Xi = (x_0, \dots, x_n; \xi_1, \dots, \xi_n)$  with representatives, there are the inequalities

$$(1) \quad S_{\Xi, \text{inf}} \leq S_{\Xi, \xi} \leq S_{\Xi, \text{sup}}$$

Moreover, the infima and suprema can be approximated with arbitrary precision by the actual values of terms in the sequences. Thus, we might suspect that the Riemann integral exists if and only if for all sequences of partitions with norms approaching zero, the limits of both the upper and lower sums will exist and they will be equal. This is indeed true for all bounded functions: ○

An important situation in integration occurs along the integration of rational functions, see 6.2.7. The key point here is the decomposition of a such a function as a sum of simple rational functions. Integrating the partial fractions corresponding to real roots of a denominator of a rational function is very easy. For instance,

$$\int \frac{A}{x-x_0} dx \stackrel{y=x-x_0}{\underset{dy=x}{=}} A \ln|y| + C = A \ln|x-x_0| + C_1,$$

$$\int \frac{A}{(x-x_0)^n} dx \stackrel{y=x-x_0}{\underset{dy=x}{=}} \int \frac{A}{y^n} dy = \frac{Ay^{-n+1}}{-n+1} + C_2$$

$$= \frac{A}{(1-n)(x-x_0)^{n-1}} + C_2,$$

for some constants  $C_1, C_2$ , and for all  $A, x_0 \in \mathbb{R}, n \in \mathbb{N}$  with  $n \geq 2$ . Rational functions  $f(x)/g(x)$  can be integrated easily, assuming that we know the corresponding factorization of the polynomial in the denominator  $g(x)$  in terms of its roots and their multiplicities. Next we will cover all the possible cases and to begin with, here are a few easy tasks for you.

**6.B.18.** Evaluate the integral  $\int R(x) dx$ , for  $R(x) = \frac{6}{x-2}$ , with  $x \neq 2$  and  $R(x) = \frac{6}{(x+4)^3}$ , with  $x \neq -4$ . ○

**6.B.19.** (a) Prove that

$$\int \frac{dx}{(ax+b)^n} = \frac{1}{a(1-n)(ax+b)^{n-1}} + C.$$

(b) Compute  $\int \frac{dx}{9x^2+6x+1}$  by applying the formula in (a). ○

**6.B.20.** Suppose that  $P(x) = ax^2 + bx + c$  ( $a \neq 0$ ) is a parabola with a double root, i.e.,  $\Delta = b^2 - 4ac = 0$ . Prove that

$$\int \frac{dx}{ax^2 + bx + c} = -\frac{2}{2ax + b} + C.$$

Use this formula to confirm your result in 6.B.19, (b). ○

**6.B.21.** Evaluate the integral  $\int \frac{1}{5x^2 + 5x + 2} dx$ . Next use Sage to confirm your result.

**Solution.** The given parabola  $P(x) = x^2 + 5x + 2$  has negative discriminant  $\Delta = -15$ , and hence two complex conjugate roots, given by  $-\frac{1}{2} \pm i\frac{\sqrt{15}}{10}$ . By completing the square we get

$$P(x) = 5\left(x^2 + x + \frac{2}{5}\right) = 5\left(\left(x + \frac{1}{4}\right) - \frac{1}{4} + \frac{2}{5}\right)$$

$$= 5\left(\left(x + \frac{1}{2}\right)^2 + \frac{3}{20}\right) = 5\left(\left(x + \frac{1}{2}\right)^2 + \left(\sqrt{3/20}\right)^2\right)$$

$$= 5\left(\left(x + \frac{1}{2}\right)^2 + \left(\sqrt{15/10}\right)^2\right).$$

**Theorem.** Let the function  $f$  be bounded on a closed interval  $[a, b]$ . Then

$$S_{\text{sup}} = \inf_{\Xi} S_{\Xi, \text{sup}}, \quad S_{\text{inf}} = \sup_{\Xi} S_{\Xi, \text{inf}}$$

are the limits of all sequences of upper and lower sums with norm approaching zero, respectively.

The Riemann integral of the function  $f$  exists if and only if  $S_{\text{sup}} = S_{\text{inf}}$ .

**PROOF.** First, notice that choosing two partitions  $\Xi_1, \Xi_2$ , there is the common refinement  $\Xi$  and we arrive at the inequalities  $S_{\Xi_1, \text{inf}} \leq S_{\Xi, \text{inf}} \leq S_{\Xi, \text{sup}} \leq S_{\Xi_2, \text{sup}}$ . Thus,  $S_{\text{sup}}$  is well defined since it is the infimum of a set of real values bounded from below by any of the  $S_{\Xi, \text{inf}}$ . Similarly for the value  $S_{\text{inf}}$ , which is bounded from above by any of  $S_{\Xi, \text{sup}}$ .

Refine a partition  $\Xi_1$  to  $\Xi_2$  by adding new points. Then

$$S_{\Xi_1, \text{sup}} \geq S_{\Xi_2, \text{sup}}, \quad S_{\Xi_1, \text{inf}} \leq S_{\Xi_2, \text{inf}}.$$

By the definition of the infimum, there are sequences of partitions  $\Xi_k$  for which  $S_{\text{sup}}$  is the limit of the sums  $S_{\Xi_k, \text{sup}}$ . Moreover, every two partitions have a common refinement. Thus it may be assumed that  $\Xi_k$  in the sequence is always a partition obtained by refining the previous one. Hence the sums  $S_{\Xi_k, \text{sup}}$  form a non-increasing sequence of real numbers converging to  $S_{\text{sup}}$ .

A similar argument applies to  $S_{\text{inf}}$ . Hence the values

$$S_{\text{sup}} = \inf_{\Xi} S_{\Xi, \text{sup}}, \quad S_{\text{inf}} = \sup_{\Xi} S_{\Xi, \text{inf}}$$

are good candidates for the limits of upper and lower sums.

Next, consider a fixed partition  $\Xi$  with  $n$  inner partitioning points of the interval  $[a, b]$ , and another partition  $\Xi_1$ , whose norm is a small number  $\delta$ . In the common refinement  $\Xi_2$ , there will be only  $n$  intervals contributing to the sum  $S_{\Xi_2, \text{sup}}$  by eventually smaller contribution than in the case of  $\Xi_1$ . Now,  $f$  is a bounded function on  $[a, b]$  and thus each of these contributions will be bounded by a universal constant multiplied by the norm  $\delta$  of the partition. Hence when choosing  $\delta$  sufficiently small, the distance of  $S_{\Xi_1, \text{sup}}$  from  $S_{\text{sup}}$  will not be larger than twice the distance of  $S_{\Xi, \text{sup}}$  from  $S_{\text{sup}}$ .

Finally, return to the sequence of partitions  $\Xi_k$  as chosen above, and choose an  $\varepsilon > 0$ . Then there is some  $m \in \mathbb{N}$  such that the distance of  $S_{\Xi_k, \text{sup}}$  from  $S_{\text{sup}}$  is less than  $\varepsilon$  for all  $k \geq m$ . Hence for arbitrary partition  $\Xi$  with appropriately small norm  $\delta > 0$  the distance of  $S_{\Xi, \text{sup}}$  from  $S_{\text{sup}}$  does not exceed  $2\varepsilon$ .

In summary, for arbitrary  $2\varepsilon > 0$ , there is  $\delta > 0$  such that for all partitions with norm at most  $\delta$  the inequality  $|S_{\Xi, \text{sup}} - S_{\text{sup}}| < 2\varepsilon$  holds. This is exactly the statement that the number  $S_{\text{sup}}$  is the limit of all sequences of upper sums with norms of the partition approaching zero.

The statement for lower sums is proved in exactly the same way.

It remains to deal with the existence of the Riemann integral  $\int_a^b f(x) dx$ . If  $S_{\text{sup}} = S_{\text{inf}}$ , then all Riemann sums of

Thus  $\int \frac{1}{P(x)} dx = \frac{1}{5} \int \frac{dx}{(x + \frac{1}{2})^2 + (\sqrt{15}/10)^2}$ . Next, set  $u = x + \frac{1}{2}$  with  $du = dx$ , and use the known formula (see 6.2.3)

$$\int \frac{dx}{x^2 + \delta^2} = \frac{1}{\delta} \arctan\left(\frac{u}{\delta}\right) + C. \quad (\#)$$

This gives

$$\begin{aligned} \frac{1}{5} \int \frac{dx}{(x + \frac{1}{2})^2 + (\sqrt{15}/10)^2} &= \frac{1}{5} \int \frac{du}{u^2 + (\sqrt{15}/10)^2} \\ &= \frac{1}{5} \cdot \frac{1}{\sqrt{15}/10} \arctan\left(\frac{u}{\sqrt{15}/10}\right) + C \\ &= \frac{2\sqrt{15}}{15} \arctan\left((\sqrt{15}/3)(2x + 1)\right) + C, \end{aligned}$$

for some constant  $C$ . For a confirmation give the cell show(integral(1/(5 \* x^2 + 5 \* x + 2), x)).  $\square$

*Integrals of a rational function  $Q$  of the form  $Q(x) = (a_1x + b_1)/(a_2x^2 + b_2x + c_2)$  can be solved by forming on the numerator the derivative of the dominator. Then we decompose the fraction into two rational functions and hence our integral decomposes into two integrals, that are easier to be computed. Let us describe such an example.*

**6.B.22.** Evaluate the integral  $A = \int \frac{3x + 7}{x^2 - 4x + 15} dx$ , with  $x \in \mathbb{R}$ .

**Solution.** The derivative of  $g(x) = x^2 - 4x + 15$  is the line  $2x - 4$ , with  $x \in \mathbb{R}$ . Let  $f(x) = 3x + 7$ , with  $x \in \mathbb{R}$ , as well. We see that  $f(x) = \frac{3}{2}(2x - 4) + 4 \cdot \frac{3}{2} + 7 = \frac{3}{2}(2x - 4) + 13$ . Thus

$$A = \int \frac{f(x)}{g(x)} dx = \frac{3}{2} \int \frac{2x - 4}{g(x)} dx + 13 \int \frac{dx}{g(x)} = \alpha + \beta.$$

For  $\alpha := \frac{3}{2} \int \frac{2x - 4}{g(x)} dx$ , by setting  $u = g(x) = x^2 - 4x + 15$  we get  $du = (2x - 4) dx$  and thus

$$\alpha = \frac{3}{2} \int \frac{du}{u} = \frac{3}{2} \ln(x^2 - 4x + 15) + C_1, \quad C_1 \in \mathbb{R}.$$

For the second integral  $\beta := 13 \int \frac{dx}{g(x)}$  by completing the square we get  $g(x) = (x - 2)^2 + 11$ . Thus an application of the relation (#) appearing in the proof of 6.B.21, gives

$$\beta = 13 \int \frac{dx}{(x - 2)^2 + (\sqrt{11})^2} = \frac{13}{\sqrt{11}} \arctan\left(\frac{x - 2}{\sqrt{11}}\right) + C_2$$

for some constant  $C_2$ . Hence all together we get that  $A = \frac{3}{2} \ln(x^2 - 4x + 15) + \frac{13}{\sqrt{11}} \arctan\left(\frac{x - 2}{\sqrt{11}}\right) + C$ .  $\square$

**6.B.23.** If  $K_n = K_n(x_0, a) = \int \frac{dx}{((x - x_0)^2 + a^2)^n}$ , where  $a, x_0 \in \mathbb{R}$  are fixed, prove that

$$K_n = \frac{1}{a^2} \left( \frac{2n - 3}{2n - 2} K_{n-1} + \frac{x - x_0}{(2n - 2)((x - x_0)^2 + a^2)^{n-1}} \right)$$

sequences of the partitions have the same limit because of the inequalities (1).

If the Riemann integral does not exist, then there exist two sequences of partitions  $\Xi_k$  and  $\bar{\Xi}_k$  and their representatives with different limits of Riemann sums. Suppose the first limit is larger then the other one. Then the upper Riemann sums can be selected for the first sequence and the lower Riemann sums for the second sequence. Their difference will then be at least as large. In particular, in view of the previous part of the proof, this implies  $S_{\text{sup}} > S_{\text{inf}}$ .  $\square$

**6.2.11. Uniform continuity.** Until now, we have only used the continuity of the function  $f$  to know that all such functions are bounded on a closed finite interval. It remains to show that for continuous functions  $S_{\text{sup}} = S_{\text{inf}}$ .

From the definition of continuity, for every point  $x \in [a, b]$  and every neighbourhood  $\mathcal{O}_\varepsilon(f(x))$  there exists a neighbourhood  $\mathcal{O}_\delta(x)$  such that  $f(\mathcal{O}_\delta(x)) \subset \mathcal{O}_\varepsilon(f(x))$ . This statement can be rewritten in this way: for  $y, z \in \mathcal{O}_\delta(x)$ , i.e.

$$|y - z| < 2\delta,$$

it is true that  $f(y), f(z) \in \mathcal{O}_\varepsilon(f(x))$ , i.e.

$$|f(y) - f(z)| < 2\varepsilon.$$

A global variant of such a property is needed; it is called the *uniform continuity* of a function  $f$ :

#### UNIFORM CONTINUITY

**Definition.** Let  $f$  be a function on a closed finite interval  $[a, b]$ .  $f$  is *uniformly continuous* on  $[a, b]$ , if for every  $\varepsilon > 0$  there exists  $\delta > 0$  such that for all  $z, y \in [a, b]$  satisfying  $|y - z| < \delta$ , the inequality  $|f(y) - f(z)| < \varepsilon$  holds.

#### UNIFORM CONTINUITY

**Theorem.** Each continuous function on a finite closed interval  $[a, b]$  is *uniformly continuous*.

**PROOF.** Fixing some  $\varepsilon > 0$ , the definition of continuity of  $f$  provides for each  $x \in [a, b]$  the values  $\delta(x)$ , such that  $f(y) \in \mathcal{O}_\varepsilon(f(x))$  for all  $y \in \mathcal{O}_{2\delta(x)}(x)$ . Since every finite closed interval is compact, it is covered by finitely many of such neighbourhoods  $\mathcal{O}_{\delta(x)}(x)$ , determined by points

for all  $n \neq 1$ , and that  $K_1(x_0, a) = \frac{1}{a} \arctan\left(\frac{x-x_0}{a}\right) + C$ .

**Solution.** We will apply integration by parts. In terms of 6.2.4 we have  $F(x) = 1/((x-x_0)^2 + a^2)^n$  and  $F'(x) = -2n(x-x_0)/((x-x_0)^2 + a^2)^{n+1}$ . If you are not sure for this differentiation, use Sage and the cell

```
var("a, n, x0"); F(x)=1/((x-x0)^2+a^2)**n
show(diff(F(x), x).factor())
```

Sage prints out the following expression which agrees with ours:  $-2(a^2 + x^2 - 2xx_0 + x_0^2)^{-n-1}n(x-x_0)$ . Moreover,  $G'(x) = 1$  and we may fix  $G(x) = (x-x_0)$ . Thus,

$$K_n(x_0, a) = \int F(x)G'(x) dx = \frac{x-x_0}{((x-x_0)^2 + a^2)^n} + 2n \int \left( \frac{(x-x_0)^2 + a^2}{((x-x_0)^2 + a^2)^{n+1}} - \frac{a^2}{((x-x_0)^2 + a^2)^{n+1}} \right) dx$$

$$= \frac{x-x_0}{((x-x_0)^2 + a^2)^n} + 2n(K_n(x_0, a) - a^2 K_{n+1}(x_0, a)),$$

or equivalently,

$$K_{n+1} = \frac{1}{a^2} \left( \frac{2n-1}{2n} K_n + \frac{1}{2n} \frac{x-x_0}{((x-x_0)^2 + a^2)^n} \right).$$

Replacing  $n$  by  $n-1$  in this formula, we get the result. On the other hand, the case  $n=1$  follows easily by the relation (#), used in the proof of 6.B.21.  $\square$

**6.B.24.** Using the result from 6.B.23, compute the integral given below and next verify your answer via Sage:

$$I = \int \frac{30x - 77}{(x^2 - 6x + 13)^2} dx, \quad x \in \mathbb{R}.$$

**Solution.** This provides an example of partial fractions for multiple complex roots in the form of

$$\frac{Ax+B}{[(x-x_0)^2 + a^2]^n}, \quad \text{with } A, B, x_0 \in \mathbb{R}, a > 0, n \in \mathbb{N} \setminus \{0, 1\},$$

which again can be solved by forming on the numerator the derivative of the expression  $(x-x_0)^2 + a^2$  appearing in the denominator, that is,  $\frac{A}{2} \cdot \frac{2(x-x_0)}{[(x-x_0)^2 + a^2]^n} + (B + Ax_0) \cdot \frac{1}{[(x-x_0)^2 + a^2]^n}$ . Hence one needs to compute the two induced integrals, which can be done by the methods applied above. For our problem we have

$$I = 15 \int \frac{2x-6}{(x^2-6x+13)^2} dx + 13 \int \frac{dx}{(x^2-6x+13)^2}.$$

To compute the first integral set  $u = x^2 - 6x + 13$  with  $du = (2x-6) dx$ . Then

$$15 \int \frac{2x-6}{(x^2-6x+13)^2} dx = 15 \int \frac{du}{u^2} = -\frac{15}{u} + C_1 = -\frac{15}{x^2-6x+13} + C_1,$$

for some constant  $C_1$ . For the second integral by completing the square one gets  $x^2 - 6x + 13 = (x-3)^2 + 2^2$ . Hence

$$13 \int \frac{1}{(x^2-6x+13)^2} dx = 13 \int \frac{dx}{((x-3)^2 + 2^2)^2}.$$

$x_1, \dots, x_k$ . Choose  $\delta$  as the minimum of all the (finitely many)  $\delta(x_i)$ .

Choose any two points  $y, z \in [a, b]$  with  $|y-z| < \delta$ , they both belong to one of  $\mathcal{O}_{2\delta(x_i)}(x_i)$ . Thus  $|f(y)-f(z)| \leq |f(y)-f(x_i)| + |f(x_i)-f(z)| < 2\varepsilon$  and  $f$  has the desired property.  $\square$

**6.2.12. Finishing the proof of Theorem 6.2.9.** Now we complete the proof of the existence of the Riemann integral. Choose  $\varepsilon$  and  $\delta$  as in the definition of the uniform continuity of  $f$ . Consider any partition  $\Xi$  with  $n$  intervals and norm at most  $\delta$ . Then, writing  $J_i = [x_{i-1}, x_i]$ ,

$$\left| \sum_{i=1}^n \sup_{\xi \in J_i} f(\xi)(x_i - x_{i-1}) - \sum_{i=1}^n \inf_{\xi \in J_i} f(\xi)(x_i - x_{i-1}) \right|$$

$$= \sum_{i=1}^n (\sup_{\xi \in J_i} f(\xi) - \inf_{\xi \in J_i} f(\xi))(x_i - x_{i-1})$$

$$\leq \varepsilon \cdot (b-a).$$

For decreasing norm of the partition, the upper and lower sums are arbitrarily close to each other. In particular the upper Riemann integral and the lower Riemann integral coincide.

To complete the proof of the fundamental theorem of integral calculus, it is still needed to verify the statement about the existence of a primitive function. For a continuous function  $f$  on interval  $[a, b]$  there exists the Riemann integral  $F(x) = \int_a^x f(t) dt$  for every  $x \in [a, b]$ . As in the statement about uniform continuity, there is  $\delta > 0$ , dependent on a fixed small  $\varepsilon > 0$ , such that

$$|f(x + \Delta x) - f(x)| < \varepsilon$$

for all  $0 \leq \Delta x < \delta$  on the interval  $[a, b]$ . The difference of the derivative of  $F(x)$  and the integrated function  $f(x)$  is expressed by the limit of the expressions

$$\alpha = \frac{1}{\Delta x} \left( \int_a^{x+\Delta x} f(t) dt - \int_a^x f(t) dt \right) - f(x)$$

$$= \frac{1}{\Delta x} \left( \int_x^{x+\Delta x} f(t) dt \right) - f(x)$$

for  $\Delta x$  approaching zero.

Now choose  $0 < \Delta x < \delta$  and replace the integrated function by the constant value  $f(x)$ . Then the values  $f(\xi)$  at any point  $\xi \in [x, x + \Delta x]$  are distant from  $f(x)$  by at most  $\varepsilon$ . Hence the Riemann integral in question cannot be different from  $f(x)\Delta x$  by more than  $\varepsilon\Delta x$ . Thus, we arrived at the following estimate:

$$|\alpha| = \left| \frac{1}{\Delta x} \left( \int_x^{x+\Delta x} f(t) dt \right) - f(x) \right| < \varepsilon.$$

But that means that at the point  $x$ , the one-sided right derivative of the function  $F(x)$  exists and equals  $f(x)$ . The result for the left derivative is proved in the same way, just working with the interval  $[x - \Delta x, x]$ . This finishes the proof of the theorem 6.2.9.

We can now apply 6.B.23 with  $x_0 = 3$ ,  $a = 2$  and  $n = 2$ . In particular we have

$$\begin{aligned} 13 \cdot K_2(3, 2) &= 13 \int \frac{dx}{((x-3)^2 + 2^2)^2} \\ &= \frac{13}{2^2} \left( \frac{1}{2} K_1(3, 2) + \frac{x-3}{2((x-3)^2 + 2^2)} \right) \\ &= \frac{13}{4} \left( \frac{1}{4} \arctan \left( \frac{x-3}{2} \right) + C_2 + \frac{x-3}{2((x-3)^2 + 2^2)} \right) \\ &= \frac{13}{16} \arctan \left( \frac{x-3}{2} \right) + \frac{13(x-3)}{8(x^2 - 6x + 13)} + C_2, \end{aligned}$$

for some constant  $C_2$ . In total we get

$$I = \frac{13}{16} \arctan \left( \frac{x-3}{2} \right) + \frac{13x-159}{8(x^2 - 6x + 13)} + C, \quad C \in \mathbb{R}.$$

A verification via Sage occurs as usual, i.e., type `show(integral((30 * x - 77)/(x^2 - 6 * x + 13)^2, x))`. □

**6.B.25.** Consider the rational function

$$R(x) = \frac{x^2 - x - 1}{x^3 + 3x^2 - 16x + 12}.$$

- (a) Find its domain and its discontinuities and sketch its graph.
- (b) Find the decomposition of  $R$  into partial fractions.
- (c) Evaluate the integral  $\int R(x) dx$ .

**Solution.** (a) Let us express  $R$  as  $R(x) = f(x)/g(x)$ . It is obvious that  $g(1) = 0$  and based on the Horner's scheme we get the factorization  $g(x) = (x-1)(x-2)(x+6)$ . Using Sage one can type `factor(x**3 + 3*x**2 - 16*x + 12)`. Hence, the domain of  $R$  is the set  $\mathbb{R} \setminus \{-6, 1, 2\}$ . Notice the dominator  $g$  has three distinct real roots and none of them is a root of the numerator  $f$ . Hence, all the discontinuities of  $R = f/g$  appear at the roots 1, 2 and  $-6$  of  $g$ , as we can see also from the graph of  $R$ :

(b) Let us assume that

$$R(x) = \frac{x^2 - x - 1}{(x-1)(x-2)(x+6)} = \frac{A_1}{x-1} + \frac{A_2}{x-2} + \frac{A_3}{x+6} \quad \int_a^b f(x) dx = F(b) - F(a) = F'(c)(b-a) = f(c)(b-a).$$

**6.2.13. Important remarks.** (1) Theorems 6.2.9 and 6.2.8 claim that the Riemann integral is a linear map

$$\int : C[a, b] \rightarrow \mathbb{R}$$

from the vector space of continuous functions on the interval  $[a, b]$  to real numbers. Hence it is a linear form on the vector space  $C[a, b]$ .

(2) We proved that every continuous function is a derivative of some function. Hence the concepts of the Newton and Riemann integrals coincide for continuous functions. Therefore the Riemann integral of continuous functions can be computed as the difference of values  $F(b) - F(a)$  of the primitive function  $F$ .

(3) In the first step of the proof of the theorem 6.2.9 we proved the important statement that for bounded functions  $f$  on finite intervals  $[a, b]$  the limits of the upper and lower sums always exist. They are called respectively *the upper Riemann integral* and *the lower Riemann integral* and they are also denoted by  $\overline{\int}_a^b f(x) dx$  and  $\underline{\int}_a^b f(x) dx$ .

In this way we can define the Riemann integral for continuous functions as in the above proof.

(4) We derived the important property of continuous functions called *the uniform continuity* on finite closed intervals  $[a, b]$ . Clearly every uniformly continuous function is continuous as well, but the converse is not true on open intervals. As an example, consider the function  $f(x) = \sin(1/x)$  on the interval  $(0, 1)$ .

(5) Consider a function  $f$  on an interval  $[a, b]$ , which is only *piece-wise continuous*. This means that  $f$  is continuous in all points  $c \in [a, b]$  except for finitely many *discontinuities*  $c_i$ ,  $a < c_i < b$ , in which it has finite one-sided limits. Because of the additivity of the integral with respect to the interval of integration, see 6.2.8(1), the last theorem implies that in this case the integral

$$F(x) = \int_a^x f(t) dt$$

exists for all  $x \in [a, b]$  and the derivative of the function  $F(x)$  exists at all points  $x$  where  $f$  is continuous. It can be verified that  $F(x)$  is continuous at the remaining points. So it is a continuous function on the whole interval  $[a, b]$ . When evaluating the integral by primitive functions, it is necessary to choose its individual parts so that they are connected continuously at the points  $c_i$ . Then the entire integral can be again computed as a difference of the function  $F(x)$  at its boundary values.

(6) Lagrange's mean value theorem for differentiable functions has an analogue which is called *the integral mean value theorem*. Suppose  $f(x)$  is continuous on an interval  $[a, b]$  and its primitive function is  $F(x)$ . The mean value theorem claims that there exists a point  $c$ ,  $a < c < b$  such that

for some reals  $A_1, A_2, A_3$  to be specified. This relation can be equivalently written as (by multiplying by the denominator)

$$f(x) = A_1(x-2)(x+6) + A_2(x-1)(x+6) + A_3(x-1)(x-2).$$

There are many approaches to compute  $A_1, A_2, A_3$ . For instance, we may gather together like powers of the variable and equate their coefficients. This gives a set of equations to solve for  $A_1, A_2, A_3$ . As an alternative we can plug  $x = 1$  into this equation, which gives  $A_1 = 1/7$ . Likewise, the substitution of  $x = 2$  gives  $A_2 = 1/8$  while those of  $x = -6$  yields  $A_3 = 41/56$ .

Thus, the decomposition of  $R$  into partial fractions is given by

$$R(x) = \frac{1}{7(x-1)} + \frac{1}{8(x-2)} + \frac{41}{56(x+6)}. \quad (*)$$

Sage provides a built-in method for computing the decomposition of a rational function into partial fractions, given by the command `partial_fraction`. For instance, for a Sage confirmation of (\*) one may use the cell

```
f(x)=(x^2-x-1); g(x)=(x-1)*(x-2)*(x+6)
R(x)=f(x)/g(x); show(R.partial_fraction())
```

(c) This is easy and relies on our previous conclusion (\*), i.e.,

$$\begin{aligned} \int R(x) dx &= \frac{1}{7} \int \frac{1}{x-1} dx + \frac{1}{8} \int \frac{1}{x-2} dx \\ &+ \frac{41}{56} \int \frac{1}{x+6} dx = \frac{1}{7} \ln|x-1| + \\ &+ \frac{1}{8} \ln|x-2| + \frac{41}{56} \ln|x+6| + C, \end{aligned}$$

for some constant  $C$ . Adding in the previous cell the command `show(integral(R,x))`, Sage confirms our answer.  $\square$

**6.B.26.** Evaluate the integral  $\int Q(x) dx$ , where

$$Q(x) = \frac{x}{(x-1)^2(x^2+2x+2)}, \quad x \neq 1.$$

**Solution.** According to the discussion in 6.2.7, we may assume that

$$Q(x) = \frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{Cx+D}{x^2+2x+2},$$

for  $A, B, C, D \in \mathbb{R}$ . This can be equivalently expressed as

$$x = A(x-1)(x^2+2x+2) + B(x^2+2x+2) + (Cx+D)(x-1)^2.$$

By setting  $x = 1$  we immediately get  $B = 1/5$ . By comparing the coefficients at the same powers of the polynomials we also get  $A = 1/25$ ,  $C = -1/25$ , and  $D = -8/25$ . Hence

$$Q(x) = \frac{1}{25(x-1)} + \frac{1}{5(x-1)^2} - \frac{x+8}{25(x^2+2x+2)}. \quad (*)$$

An easy way to verify this fractional decomposition is by Sage, via the function `partial_fraction` as in 6.B.25, i.e.,

This statement can be derived directly from the definition of the Riemann integral. It can be then used in the final step of the proof of the fundamental theorem of integral calculus.

**6.2.14. Improper integrals.** When discussing the integration of rational functions  $f$ , there is a need

to consider definite integrals over intervals, where  $f(x)$  has improper (one-sided) limits. Here  $f$  is neither continuous nor bounded. Thus earlier definitions and results may not apply. We speak of “improper” integrals.

A simple solution is to discuss the definite integral on a smaller sub-interval, and determine whether the limit value of such a definite integral exists when the boundary approaches the problematic point. If it does, the corresponding improper integral exists and equals this limit. We illustrate this procedure by an example:

$$I = \int_0^2 \frac{dx}{(2-x)^{1/4}}.$$

This is an improper integral, because the integrand  $f(x) = (2-x)^{-1/4} = \frac{1}{\sqrt[4]{2-x}}$  has its left-sided limit  $\infty$  at the point  $b = 2$ . The integrand is continuous at all other points. Thus, for  $0 < \delta < 2$ , consider the integrals (substituting  $y = 2-x$ )

$$\begin{aligned} I_\delta &= \int_0^{2-\delta} \frac{dx}{\sqrt[4]{2-x}} = \int_\delta^2 y^{-1/4} dy \\ &= \left[ \frac{4}{3} y^{3/4} \right]_\delta^2 = \frac{4}{3} [2^{3/4} - \delta^{3/4}]. \end{aligned}$$

Notice that  $dy = -dx$  and  $x = 2 - \delta$  corresponds to  $y = \delta$ . When  $x = 0$ , then  $y = 2$ .

The limit when  $\delta \rightarrow 0$  from the right clearly exists, so the improper integral is evaluated.

$$I = \int_0^2 \frac{dx}{\sqrt[4]{2-x}} = \frac{4}{3} 2^{3/4}.$$

We proceed in the same way to integrate over an unbounded interval. In this case, we speak of *improper Riemann integrals of the first kind*. The integrals of unbounded functions on finite intervals are *improper Riemann integrals of the second kind*.

More explicitly, we can define the integrals of both kinds as follows. For  $a \in \mathbb{R}$  and  $f$  defined on  $[a, b)$  and bounded on each  $[a, c] \subset [a, b)$ ,

$$I = \int_a^b f(x) dx = \lim_{c \rightarrow b} \int_a^c f(x) dx,$$

if the integrals and limit on the right hand side exist. Here  $b$  is either finite or  $b = \infty$ . Similarly we can have a finite fixed upper bound and  $-\infty \leq a < c < b$  and infinite lower bound. If both  $a$  and  $b$  are infinite, we can evaluate the integral as a sum of two integrals with a chosen fixed bound in the middle as in

$$\int_{-\infty}^{\infty} f(x) dx = \int_{-\infty}^a f(x) dx + \int_a^{\infty} f(x) dx.$$

```
Q(x)=x/((x-1)^2*(x^2+2*x+2))
show(R.partial_fraction())
```

Based now on (\*) we can write

$$\int Q(x) dx = \int \frac{dx}{25(x-1)} + \int \frac{dx}{5(x-1)^2} - \int \frac{x+8}{25(x^2+2x+2)} dx = \frac{1}{25} \ln|x-1| - \frac{1}{5(x-1)} - \frac{1}{50} \ln(x^2+2x+2) - \frac{7}{25} \arctan(x+1) + C,$$

for some constant  $C$ . Here, as in 6.B.22 we get

$$\int \frac{x+8}{x^2+2x+2} dx = \int \left( \frac{\frac{1}{2}(2x+2)}{x^2+2x+2} + \frac{7}{x^2+2x+2} \right) dx = \frac{1}{2} \int \frac{2x+2}{x^2+2x+2} dx + 7 \int \frac{1}{(x+1)^2+1} dx = \frac{1}{2} \ln(x^2+2x+2) + 7 \arctan(x+1) + C.$$

**6.B.27.** Evaluate the integral  $A = \int Q(x) dx$ , where

$$Q(x) = \frac{2x^4 + 2x^2 - 5x + 1}{x(x^2 - x + 1)^2}, \quad x \neq 0.$$

Next confirm your result in Sage. □ ○ ○

**6.B.28.** Evaluate  $\int \frac{1}{e^{3x} - 2e^{2x}} dx$ , with  $x \neq \ln(2)$ .

*Let us also integrate an improper rational function  $f(x)/g(x)$ , which means that the degree of the polynomial  $f$  in the numerator is greater or equal to the degree of the polynomial  $g$  in the denominator. In such a case we should first carry out the division with remainder.*

**6.B.29.** Evaluate  $\int \frac{x^3 + 2x^2 + x - 1}{x^2 - x + 1} dx$ , with  $x \in \mathbb{R}$ .

Can you confirm all the steps of your proof via Sage?

**Solution.** The degree of the numerator  $f(x) = x^3 + 2x^2 + x - 1$  is bigger from the degree of the dominator  $g(x) = x^2 - x + 1$ , hence we proceed by division of polynomials:

$$\begin{array}{r} x^3 + 2x^2 + x - 1 \\ x^2 - x + 1 \overline{) \phantom{x^3 + 2x^2 + x - 1}} \\ \underline{-x^3 + x^2 - x} \phantom{- 1} \\ 3x^2 - 1 \\ \underline{-3x^2 + 3x - 3} \\ 3x - 4 \end{array}$$

This means that  $f(x) = g(x)(x+3) + 3x-4$  and implies the following decomposition

$$\frac{f(x)}{g(x)} = (x+3) + \frac{3x-4}{x^2-x+1}. \quad (b)$$

The division of polynomials can be successfully performed in Sage, and a way goes as follows

Its existence and its value do not depend on the choice of such bound, because by changing it, we only change both summands by the same finite value, but with opposite sign.

At the same time a limit for which the upper and lower bound would approach  $\pm\infty$  at the same speed can lead to different results! For example

$$\int_{-a}^a x dx = \left[ \frac{1}{2}x^2 \right]_{-a}^a = 0,$$

even though the values of the integrals  $\int_a^b x dx$  with  $a$  fixed and  $b \rightarrow \infty$  diverge to infinity. (This is the typical behavior for all odd functions.)

Clearly, if  $f$  is continuous on  $[a, b)$ , then the Newton integral  $F(x) = \int_a^x f(y) dy$  exists for all  $x \in [a, b)$  and the improper Riemann integral exists if and only if  $\lim_{x \rightarrow b} F(x)$  exists, and its value is this limit. Thus, for continuous  $f(x)$  as in our simple example above, we compute the definite Newton integral and take its limit. This is what we did. □

The integrated functions may have more discontinuities with infinite one-sided limits and the interval of integration may be unbounded. Then the integration intervals must be split in such a way that the individual intervals of integration include only one of the above phenomena.

Hence when evaluating the improper integral of a rational function, divide the given interval according to the discontinuities of the integrated function. Then compute all the improper integrals separately. ○ ○

**6.2.15. Mean value of a function.** For a finite set of  $n$  numbers, the mean value, or arithmetic mean, is obtained by summing the numbers and dividing by  $n$ . For a Riemann integrable function  $f(x)$  on an interval (finite or infinite)  $[a, b]$ , the *mean value* is defined by

$$m(f) = \frac{1}{b-a} \int_a^b f(x) dx.$$

By definition,  $m(f)$  is the altitude of the rectangle over the interval  $[a, b]$ , which has the same area as that of the region between the  $x$  axis and the graph of the  $f(x)$  (counted with signs according to being above or below the  $x$ -axis). Hence the *integral mean value theorem* is true in general:

**Proposition.** If  $f(x)$  is a Riemann integrable function on an interval  $[a, b]$ , then there exists a number  $m(f)$  satisfying

$$\int_a^b f(x) dx = m(f)(b-a).$$

**6.2.16. Integral criterion for series.** Using the improper integral, we can also decide the question of convergence for a class of infinite series with summands expressed as values of a function in integers:

```
f(x)=x^3+2*x^2 + x - 1 ; g(x)=x^2-x+1
show(f.maxima_methods().divide(g))
```

Sage's output has the form  $[x + 3, 3x - 4]$ , where the first expression encodes the quotient and the second one the remainder. One may like to certify Sage's answer by adding the syntax `bool(g(x)*(x+3)+3*x-4==f(x))`, which returns True. Based now on (b) one has

$$\begin{aligned} \int \frac{f(x)}{g(x)} dx &= \int (x + 3) dx + \int \frac{3x - 4}{x^2 - x + 1} \\ &= \frac{x^2}{2} + 3x + \frac{3}{2} \ln(x^2 - x + 1) \\ &\quad - \frac{5}{\sqrt{3}} \arctan\left(\frac{2x - 1}{\sqrt{3}}\right) + C. \end{aligned}$$

Here, to compute the integral  $\ell = \int \frac{3x - 4}{x^2 - x + 1} dx$  you can apply the same method as 6.B.22 (since  $g(x)$  has only complex roots). In particular,

$$\begin{aligned} \ell &= \frac{3}{2} \int \frac{2x - 1}{x^2 - x + 1} dx - \frac{5}{2} \int \frac{dx}{(x - \frac{1}{2})^2 + (\frac{\sqrt{3}}{2})^2} \\ &= \frac{3}{2} \ln(x^2 - x + 1) - \frac{5}{\sqrt{3}} \arctan\left(\frac{2x - 1}{\sqrt{3}}\right) + c, \end{aligned}$$

for some constant  $c$ . This agrees with Sage's output for the command `integral((3*x-4)/(x^2-x+1),x)`.  $\square$

*Many integrals may initially appear complicated. In such cases, the power of the substitution method becomes evident. For instance, the substitution method often allows us to transform irrational functions into rational ones, which are easier to integrate.*

The tasks below focus on integrating irrational functions and serve as preparation for the material covered in the final section of this chapter, where more space is dedicated to this topic. But first, let us describe a few useful hints.

- Hint 1: This is about integrals of the form

$$\int f(x, \sqrt[p_1]{x}, \sqrt[p_2]{x}, \dots, \sqrt[p_k]{x}) dx$$

for certain numbers  $p_1, p_2, \dots, p_k \in \mathbb{N}$  and a rational function  $f$ . In this case we set  $\sqrt[n]{x} = t$ , i.e.,  $t^n = x$ , where  $n$  is the least common multiple of  $p_1, \dots, p_k$ . This substitution reduces the integrated function (integrand) to a rational function, which we can always integrate. When instead of the expressions  $\sqrt[p_j]{x}$  we have  $\sqrt[p_j]{ax + b}$  for all  $j = 1, \dots, k$ , where  $a, b \in \mathbb{R}$ , then set  $t^n = ax + b$ , where  $n$  occurs in the same vein as above.

- Hint 2: This is about integrals of the type

$$\int f\left(x, \sqrt[p_1]{\frac{ax+b}{cx+d}}, \sqrt[p_2]{\frac{ax+b}{cx+d}}, \dots, \sqrt[p_k]{\frac{ax+b}{cx+d}}\right) dx,$$

where the values  $a, b, c, d \in \mathbb{R}$  are such that  $ad - bc \neq 0$ . In this case we set  $t^n = \frac{ax+b}{cx+d}$ , where again  $n$  is the least

INTEGRAL CRITERION

**Theorem.** Let  $\sum_{n=1}^{\infty} f(n)$  be a series such that the function  $f : \mathbb{R} \rightarrow \mathbb{R}$  is positive and nonincreasing on the interval  $[1, \infty)$ . Then this series converges if and only if the integral

$$\int_1^{\infty} f(x) dx.$$

converges.

**PROOF.** If the integral is interpreted as the area of a region under the curve, the criterion is clear.

Indeed, notice that the given series diverges or converges if and only if the same is true for the same series without the first summand. Moreover, by the monotonicity of  $f(x)$ , there are the following estimates

$$\tilde{s}_k = \sum_{n=2}^k f(n) \leq \int_1^k f(x) dx \leq \sum_{n=1}^{\infty} f(n) = s_k,$$

because  $\tilde{s}_k$  is the lower sum of the Riemann integral while  $s_k$  is the upper sum. Thus, the integral converges if and only if the series does, as expected.  $\square$

**6.2.17. New acquisitions to the ZOO.** As a matter of fact,

primitive functions (Newton integrals) are very rarely described in terms of known elementary functions. Indeed, nearly all continuous functions lead to integrals which we cannot express in this way. Functions obtained by integration often appear in applications. Many of them have names and there are efficient methods how to approximate them numerically (we shall come to this point briefly in 6.2.23 below). Such functions either appear as the primitive functions or they are given by definite integrals dependent on further parameter(s). We present just a few (important) examples now.

In the methods of signal processing, a very important function is the so called *sinc function*:

$$(1) \quad \text{sinc}(x) = \frac{\sin(x)}{x}.$$

We shall meet the sinc function in our discussion of Fourier transform in 7.2.6. Check yourself that it is a smooth function with limit values

$$f(0) = 1, f''(0) = -\frac{1}{3}, \dots, f^{(2k)}(0) = (-1)^k \frac{1}{2k+1},$$

whilst all  $f^{(2k+1)}(0)$  vanish. This is easily seen from the Taylor expansion of the sine function (try to verify this by computing the derivatives directly - a good exercise on multiple use of L'Hospital even for very small orders). The even function sinc has its absolute maximum at the point  $x = 0$  and many local maxima and minima, with inflexions between them. It oscillates with a fast decreasing amplitude as  $x$  approaches infinity. The  $x$ -axis is the asymptot for both infinities.

common multiple of  $p_1, \dots, p_k$ . This converts the integrand to a rational function, as well.

**6.B.30.** Determine the integrals  $\int f(x) dx$ , where

(a)  $f(x) = \frac{1}{\sqrt{x^3 + \sqrt[5]{x^7}}}$ , with  $x > 0$ ;

(b)  $f(x) = \frac{x+1}{\sqrt[3]{3x+1}}$ , with  $x \neq -\frac{1}{3}$ ;

(c)  $f(x) = \frac{1}{x} \sqrt{\frac{x+1}{x-1}}$ , with  $x \in \mathbb{R} \setminus [-1, 1]$ .

**Solution.** (a) For all  $x > 0$  we have

$$f(x) = \frac{1}{\sqrt{x^3 + \sqrt[5]{x^7}}} = \frac{1}{\sqrt{x^2 \cdot x + \sqrt[5]{x^5 \cdot x^2}}} = \frac{1}{x(\sqrt{x + \sqrt[5]{x^2}})}.$$

The least common multiply of 2, 5 is 10. Hence, according to the first hint above to compute  $\int f(x) dx$  we set  $\sqrt[10]{x} = t$ , that is,  $t^{10} = x$  with  $10t^9 dt = dx$ . Then it is easy to see that  $\sqrt{x} = t^5$  and  $\sqrt[5]{x^2} = t^4$ , thus

$$\begin{aligned} \int f(x) dx &= \int \frac{dx}{x(\sqrt{x + \sqrt[5]{x^2}})} = \int \frac{10t^9}{t^{10}(t^5 + t^4)} dt \\ &= 10 \int \frac{dt}{t^6 + t^5}. \end{aligned}$$

Now we see that the function  $Q(t) = \frac{1}{t^6+t^5} = \frac{1}{t^5(1+t)}$  admits the following decomposition into simple fractions:

$$Q(t) = -\frac{1}{t+1} + \frac{1}{t} - \frac{1}{t^2} + \frac{1}{t^3} - \frac{1}{t^4} + \frac{1}{t^5}.$$

You can verify this expression by Sage and the command

```
var("t"); show((1/(t^6+t^5)).partial_fraction())
```

Thus

$$\begin{aligned} 10 \int Q(t) dt &= 10 \int \left( -\frac{1}{t+1} + \frac{1}{t} - \frac{1}{t^2} + \frac{1}{t^3} - \frac{1}{t^4} + \frac{1}{t^5} \right) dt \\ &= 10 \left( -\ln(t+1) + \ln(t) + \frac{1}{t} - \frac{1}{2t^2} + \frac{1}{3t^3} - \frac{1}{4t^4} \right) + C \\ &= \ln \frac{x}{(1 + \sqrt[10]{x})^{10}} + \frac{10}{\sqrt[10]{x}} - \frac{5}{\sqrt[5]{x}} + \frac{10}{3\sqrt[10]{x^3}} - \frac{5}{2\sqrt[5]{x^2}} + C \end{aligned}$$

for some constant  $C$ .

(b) Set  $t = \sqrt[3]{3x+1}$ , i.e.,  $t^3 = 3x+1$  and  $dx = t^2 dt$ . Then

$$\begin{aligned} \int \frac{x+1}{\sqrt[3]{3x+1}} dx &= \int \frac{\frac{t^3-1}{3} + 1}{t} t^2 dt = \int \frac{t^3-1+3}{3} t dt \\ &= \frac{1}{3} \int (t^4 + 2t) dt = \frac{1}{3} \left( \frac{t^5}{5} + t^2 \right) + C \\ &= \frac{1}{15} (3x+1)^{\frac{5}{3}} + \frac{1}{3} (3x+1)^{\frac{2}{3}} + C. \end{aligned}$$

Remember always to use Sage to verify your computations. For instance, one may find difficult to simplify the result of the back substitution  $t = \sqrt[3]{3x+1}$  in the expression  $\frac{1}{3} \left( \frac{t^5}{5} + t^2 \right)$ . There are many different ways to implement this, and here we present one based on the function subs.

GAMMA, SI, AND MORE

The sine integral function is defined by

(2) 
$$\text{Si}(x) = \int_0^x \text{sinc}(t) dt.$$

Other important functions are *Fresnel's sine and cosine integrals*

(3) 
$$\text{FresnelS}(x) = \int_0^x \sin\left(\frac{1}{2}\pi t^2\right) dt$$

(4) 
$$\text{FresnelC}(x) = \int_0^x \cos\left(\frac{1}{2}\pi t^2\right) dt.$$

One of the most important mathematical functions ever is the *Gamma function*. It is defined for all positive real numbers  $z$  by

(5) 
$$\Gamma(z) = \int_0^\infty e^{-t} t^{z-1} dt.$$

For all integers  $n \geq 0$ ,  $n! = \Gamma(n+1)$ .

The function  $\text{Si}(x)$  is shown in the left figure. Both Fresnel's functions are shown on the right.

The Gamma function is defined via an improper integral dependent on the parameter  $z$ . We shall provide some theory for such functions in the next part of this chapter. In particular, it can be proved that this function is analytic at all points  $0 < z \in \mathbb{R}$ .

For small  $z \in \mathbb{N}$ , we can evaluate:

$$\Gamma(1) = \int_0^\infty e^{-t} t^0 dt = [-e^{-t}]_0^\infty = 1$$

$$\Gamma(2) = \int_0^\infty e^{-t} t^1 dt = [-e^{-t} t]_0^\infty + \int_0^\infty e^{-t} dt = 1$$

$$\Gamma(3) = \int_0^\infty e^{-t} t^2 dt = 0 + 2 \int_0^\infty e^{-t} t dt = 0 + 2 = 2.$$

Integration by parts reveals immediately

$$\Gamma(z+1) = z\Gamma(z).$$

Hence for all positive integers  $n$  this function yields the value of the factorial:

$$\Gamma(n) = (n-1)!.$$

The following figure shows the behaviour of the functions  $f_1(x) = \ln(\Gamma(x+1))$ ,  $f_2(x) = \ln(\Gamma(x))$  together with the function  $x \ln x - x + 1$  (the dashed one, the dots are the actual values of  $\ln(n!)$ ).

```
var("t"); a(t)=(1/3)*((t^5/5) + t^2)
show(a.subs(t=(3*x+1)^(1/3)))
```

As for the given integral, just type

```
show(integral((x+1)/(3*x+1)^(1/3), x))
```

Observe that in our result there are still computations that can be done to arrive to a more solid expression, as  $\frac{1}{5}(3x+1)^{\frac{5}{3}}(x+2)$ . The same can be done in Sage, by adding in the last two show commands the function factor, that is, `show(a.subs(t=(3*x+1)^(1/3)).factor())` and `show(integral((x+1)/(3*x+1)^(1/3), x).factor())`, respectively. Check yourself Sage's outputs.

(c) In this case set  $t = \sqrt{\frac{x+1}{x-1}}$ , thus  $t^2 = \frac{x+1}{x-1}$  and  $x = \frac{t^2+1}{t^2-1}$ . Moreover, it is easy to see that  $dx = \frac{-4t}{(t^2-1)^2} dt$ . This substitution will convert the initial integrand to a rational functional, namely

$$\int \frac{1}{x} \sqrt{\frac{x+1}{x-1}} dx = \int \frac{t^2-1}{t^2+1} \frac{-4t^2}{(t^2-1)^2} dt = - \int \frac{4t^2}{(t^2+1)(t^2-1)} dt.$$

If  $Q(t) = -\frac{4t^2}{(t^2+1)(t^2-1)}$  then we see that

$$Q(t) = -2 \frac{2t^2}{(t^2+1)(t^2-1)} = -2 \left( \frac{(t^2+1) + (t^2-1)}{(t^2+1)(t^2-1)} \right) = -2 \left( \frac{1}{t^2+1} + \frac{1}{t^2-1} \right).$$

However,  $\frac{1}{t^2-1} = \frac{1}{2} \left( \frac{1}{t-1} - \frac{1}{t+1} \right)$ , and in total we get

$$Q(t) = -\frac{2}{t^2+1} - \frac{1}{t-1} + \frac{1}{t+1}.$$

One can recover this expression in Sage by the cell

```
var("t")
(-(4*t^2)/((t^2-1)*(t^2+1))).partial_fraction()
```

Thus now we can rewrite our integral as

$$\begin{aligned} \int \frac{1}{x} \sqrt{\frac{x+1}{x-1}} dx &= \int \left( \frac{1}{t+1} - \frac{1}{t-1} - \frac{2}{t^2+1} \right) dt \\ &= \ln|t+1| - \ln|t-1| - 2 \arctan(t) + C \\ &= \ln \left| \frac{t+1}{t-1} \right| - 2 \arctan(t) + C \\ &= \ln \left| \frac{\sqrt{\frac{x+1}{x-1}} + 1}{\sqrt{\frac{x+1}{x-1}} - 1} \right| - 2 \arctan \left( \sqrt{\frac{x+1}{x-1}} \right) + C. \end{aligned}$$

For a Sage confirmation type the usual

```
show(integral((1/x)*sqrt((x+1)/(x-1)), x))
```

The relatively good approximation should not be a surprise, because we may clearly write  $\ln(n!) = \sum_{k=1}^n \ln k$  and the latter expression can be approximated by the integral  $\int_1^n \ln x = n \ln n - n + 1$ . Hence we came close to a very important and famous formula approximating  $n!$  by  $n^n e^{1-n}$ .

STIRLING'S FORMULA

The asymptotic estimate for the factorial function is

$$\ln n! = n \ln n - n + 1 + O(\ln n)$$

There is the famous *Stirling's approximation* formula making this estimate much more precise

$$(6) \quad \sqrt{2\pi n} n^{n+\frac{1}{2}} e^{-n} \leq n! \leq e n^{n+\frac{1}{2}} e^{-n}.$$

The lower approximation is so good, that the function  $\sqrt{2\pi n} n^{n+\frac{1}{2}} e^{-n}$  would completely overlap with the black one on the picture above.

We shall not provide the proof of the Stirling formula here. In order to understand the qualitative behavior of such functions (e.g. their differentiability etc.) we need to understand the limit processes much better. Before diving into this in the next section, we introduce several direct applications of the Riemann integral.

6.2.18. Riemann measurable sets. The definition of the

Riemann integral is motivated by the concept of the area of rectangles in the plane with coordinates  $x$  and  $y$ . The definite integral  $\int_a^b$  is designed to correspond to the area of the region bounded by the  $x$  axis, the values of the function  $y = f(x)$  and boundary lines  $x = a, x = b$ . Moreover, the area of the region above the  $x$  axis is given with a positive sign, while values under the axis lead to a negative sign.

From geometry, the length of an interval on the real line, and the area of a parallelogram determined by two vectors in the plane are basic concepts. This extends to the area of a parallelepiped in Euclidean vector space  $\mathbb{R}^n$ . The areas/volumes of other subsets are yet to be defined. For some simple objects like triangles, polygons and polyhedrons, their area is given naturally by the generally expected properties of area

□

Recall from 6.2.2 that for an arbitrary function  $f$  that is continuous and bounded on a bounded interval  $(a, b)$ , it holds the so called Newton-Leibniz formula, given by

$$\int_a^b f(x) dx = [F(x)]_a^b := \lim_{x \rightarrow b^-} F(x) - \lim_{x \rightarrow a^+} F(x). \quad (\star)$$

Here, as usual  $F'(x) = f(x)$  is the primitive function of  $f$ , with  $x \in (a, b)$ . Under the given conditions, the function  $F$  always exists and so do both the proper limits appearing in  $(\star)$ . Therefore, to compute the definite integral one just needs to find the antiderivative and determine the respective one-sided limits. We also recall that the computation of definite integrals via Sage is simple, and relies on the command `integral(f, x, a, b)`, or `f.integral(x, a, b)`, see below for examples.

**6.B.31.** Compute  $\int_{\frac{\pi}{6}}^{\frac{\pi}{3}} \tan^2(x) dx$  and  $\int_0^{\frac{\pi}{4}} \frac{x}{\cos^2(x)} dx$ . ○

**6.B.32.** Compute the integrals given below by hand, and next present a confirmation by Sage.

(a)  $\int_0^1 \frac{x}{\sqrt{1-x^2}} dx$ , (b)  $\int_1^2 \frac{1}{\sqrt{x^2-1}} dx$ . ○

**6.B.33.** Compute the integral  $\int_{\pi/4}^{\pi} \sin(3x) \cos(x) dx$  in Sage. Next provide a formal computation. ○

**6.B.34.** Prove the following inequalities:

(a)  $\frac{\sqrt{2}}{20} \leq \int_0^1 \frac{x^9}{\sqrt{1+x}} dx \leq \frac{1}{10}$ ;

(b)  $1 < \int_0^{\pi/2} \frac{\sin(x)}{x} dx < \frac{\pi}{2}$ . ○

**6.B.35.** Let  $f : [-a, a] \rightarrow \mathbb{R}$  be a continuous function,  $a \in \mathbb{R}$ .

(a) If  $f$  is even show that  $\int_{-a}^a f(x) dx = 2 \int_0^a f(x) dx$ .

(b) If  $f$  is odd show that  $\int_{-a}^a f(x) dx = 0$ . ○

**6.B.36.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a continuous function which is periodic with period  $T > 0$ .

(1) Show that the integral  $\int_a^{a+T} f(x) dx$  has the same value for every real number  $a$ , in particular,

$$\int_a^{a+T} f(x) dx = \int_0^T f(x) dx.$$

(2) More in general, show that

$$\int_a^{a+nT} f(x) dx = n \int_0^T f(x) dx,$$

(invariance with respect to Euclidean motions and additivity with respect to finite union of disjoint objects). We shall come to conceptual definitions in the next two chapters, mainly via generalizing the Riemann integral. Now we can start with several answers based on the univariate calculus.

We start with the question how to measure the “volume” of one-dimensional subsets.

We say that the subset  $A \subset \mathbb{R}$  is (Riemann) measurable, if the function  $\chi : \mathbb{R} \rightarrow \mathbb{R}$

$$\chi_A(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A. \end{cases}$$

is Riemann integrable. That is, the (improper) integral

$$m(A) = \int_{-\infty}^{\infty} \chi_A(x) dx$$

exists (the finiteness of its value doesn’t matter). The function  $\chi_A$  is called the characteristic function of the set  $A$ , the value  $m(A)$  is called the Riemann measure of the set  $A$ . Notice that for an interval  $A = [a, b]$  this yields the value

$$\int_{-\infty}^{\infty} \chi_A(x) dx = \int_a^b dx = b - a,$$

just as expected.

The elementary properties of the Riemann integral imply that this definition of “size” has reasonable properties. The measure of a union of finitely many measurable pairwise disjoint subsets is the sum of their measures. In particular, every finite set  $A$  has zero measure.

If instead we choose a countable union, this property is no longer true. For example, consider the set  $\mathbb{Q}$  of all rational numbers as the union of one-element subsets. While every set containing only finitely many points has a zero measure by our definition, the characteristic function  $\chi_{\mathbb{Q}}$  is not Riemann integrable over any finite interval  $[a, b]$ . This is an essential flaw of the Riemann approach and we shall comment on how to improve it in the end of this chapter.

Notice, the upper Riemann integral of the characteristic set  $\chi_A$  corresponds to the infimum of the sums of lengths of finitely many intervals, by which we can cover the given set  $A$ . The lower integral is the supremum of the sums of lengths of finitely many disjoint intervals that can be embedded into the set  $A$ . We shall proceed in the same way in higher dimensions when defining the Jordan measure. For now, just remark that the area of a plane figure bounded by a graph of a function in the way described above is consistent with expectations and we are going to deduce some straightforward consequences for special higher dimensional concepts.

**6.2.19. Length of a curve.** The Riemann integral can be effectively used to compute the length of a curve in multidimensional Euclidean vector space  $\mathbb{R}^n$ . For the sake of simplicity, we deal with a curve in  $\mathbb{R}^2$  with coordinates  $x, y$ . Suppose a parametric description of a curve  $F : \mathbb{R} \rightarrow \mathbb{R}^2$ ,

$$F(t) = [f(t), g(t)]$$

for any  $a \in \mathbb{R}$  and  $n \in \mathbb{Z}$ .

**6.B.37.** Use 6.B.36, to compute the following integrals:

- (a)  $\int_{\pi/6}^{\pi/6+2\pi} |\sin(x)| dx$ ;  
 (b)  $\int_{2\pi}^{4\pi} |\sin(x)| dx$ ;

**Solution.** (a) The function  $f(x) = |\sin(x)|$  is periodic with period  $T = \pi > 0$ . To confirm this claim in Sage use the `bool` command, as usual, i.e.,

```
f(x)=abs(sin(x)); bool(f(x+pi)==f(x))
```

The first integral corresponds to the grey area in the following figure:

An application of the formula given in the second part of 6.B.36 gives

$$\begin{aligned} \int_{\pi/6}^{\pi/6+2\pi} |\sin(x)| dx &= \int_0^{2\pi} |\sin(x)| dx \\ &= 2 \int_0^{\pi} |\sin(x)| dx = 2 \int_0^{\pi} \sin(x) dx \\ &= 2[-\cos(x)]_0^{\pi} = 2 \cdot 2 = 4. \end{aligned}$$

To confirm this computation in Sage add in the previous cell the syntax `integral(f(x), x, pi/6, 2 * pi + pi/6)`.

(b) Since  $\int_0^{\pi} |\sin(x)| dx = 2$ , the second integral is also 4, see the figure given for this case:

Here is a formal computation:

$$\begin{aligned} \int_{2\pi}^{4\pi} |\sin(x)| dx &= \int_0^{4\pi} |\sin(x)| dx - \int_0^{2\pi} |\sin(x)| dx \\ &= 4 \int_0^{\pi} |\sin(x)| dx - 2 \int_0^{\pi} |\sin(x)| dx \\ &= (4 - 2) \int_0^{\pi} |\sin(x)| dx = 2 \cdot 2 = 4. \end{aligned}$$

Once more, to confirm the result via Sage just type `integral(abs(sin(x)), x, 2 * pi, 4 * pi)`.  $\square$

*According to the fundamental theorem of integral calculus, whenever  $f : A \subseteq \mathbb{R} \rightarrow \mathbb{R}$  is a continuous function and*

$\circ$  is given. Look at it as a trajectory of a movement. Assume that  $f(t)$  and  $g(t)$  have piece-wise continuous derivatives.

By differentiating the map  $F(t)$  we obtain vectors corresponding to the speed of the movement along this trajectory. Hence the total length of the curve (i.e. distance traveled over time between the values  $t = a, t = b$ ) is given by the integral over the interval  $[a, b]$ , with the integrated function  $h(t)$  being the length of the vectors  $F'(t)$ . Therefore the length  $s$  is given by the formula

$$s = \int_a^b h(t) dt = \int_a^b \sqrt{(f'(t))^2 + (g'(t))^2} dt.$$

The result can be seen intuitively as a corollary of Pythagoras' theorem: the linear increment  $\Delta s$  of the length of the curve corresponding to the increment  $\Delta t$  of variable  $t$  is given by the proportion in the orthogonal triangle and thus at the level of differentials

$$ds = \sqrt{(g'(t))^2 + (f'(t))^2} dt.$$

In the special case when the curve is the graph of a function  $y = f(x)$  between points  $a < b$ , we obtain

$$s = \int_a^b \sqrt{1 + (f'(x))^2} dx$$

and at the level of differentials,

$$ds = \sqrt{1 + (f'(x))^2} dx,$$

just as expected.

As an example, we calculate the circumference of the unit circle as twice the integral of the function  $y = \sqrt{1 - x^2}$  over  $[-1, 1]$ . We know that the result is  $2\pi$ , because  $\pi$  is defined in this way.

$$\begin{aligned} s &= 2 \int_{-1}^1 \sqrt{1 + (y')^2} dx = 2 \int_{-1}^1 \sqrt{1 + \frac{x^2}{1 - x^2}} dx \\ &= 2 \int_{-1}^1 \frac{1}{\sqrt{1 - x^2}} dx = 2[\arcsin x]_{-1}^1 = 2\pi. \end{aligned}$$

If we instead use

$$y = \sqrt{r^2 - x^2} = r\sqrt{1 - (x/r)^2}$$

and bounds  $[-r, r]$  in the previous calculation, by substituting  $x = rt$  we obtain the circumference of the circle with radius  $r$ :

$$\begin{aligned} s(r) &= 2 \int_{-r}^r \sqrt{1 + \frac{(x/r)^2}{1 - (x/r)^2}} dx = 2 \int_{-1}^1 \frac{r}{\sqrt{1 - t^2}} dt \\ &= 2r[\arcsin x]_{-1}^1 = 2\pi r. \end{aligned}$$

The result is of course well known from elementary geometry. Nevertheless, by using integral calculus, we derive the important fact that the length of a circle is linearly dependent on its diameter  $2r$ . The number  $\pi$  is exactly the ratio, appearing in this dependency.

$a \in A$ , the function

$$F(x) = \int_a^x f(t) dt, \quad x \in A,$$

satisfies  $F'(x) = f(x)$  for any  $x \in A$ . Therefore  $F$  is a primitive of  $f$  on  $A$ . This function plays a key role in integral calculus and in many cases can be used to simplify our computations. The next series of tasks are based on this scheme and will help us to master the fundamental theorem of calculus. Further similar exercises are presented in Section D.

**6.B.38.** (a) Find the derivative of the function  $F(x) = \int_0^x t^5 \ln(t+1) dt$ , with  $x \in (-1, 1)$ .

(b) If  $F(x) = \int_1^x (t^2 \sin(t) + 4 \cos(4t)) dt$ , with  $x > 0$ , show that  $\lim_{x \rightarrow \infty} g(x) = 1$ , where  $g(x) := \frac{F'(x)}{x^2+2}$ .  $\circ$

**6.B.39. Local extremes.** Find the local extremes of the function

$$F(x) = \int_0^x \frac{\sin(t)}{t} dt, \quad \text{with } x > 0.$$

**Solution.** For all  $x > 0$  we have  $F'(x) = \frac{\sin(x)}{x}$ . Thus, the critical points of  $F$ , i.e., the solutions of the equation  $F'(x) = 0$  have the form  $x = k\pi$  for  $k \in \mathbb{Z}_+$ , and they all provide local extremes of  $F$ . In particular, the second derivative of  $F$  has the form

$$F''(x) = \left( \frac{\sin(x)}{x} \right)' = \frac{x \cos(x) - \sin(x)}{x^2}, \quad x > 0,$$

and we see that  $F''(k\pi) = \frac{k\pi \cdot \cos(k\pi)}{(k\pi)^2} = \frac{(-1)^k}{k\pi}$ . Thus

- $F''(k\pi) < 0$  if  $k$  is odd  $\implies F$  attains a local maximum at  $(2m+1)\pi$ , with  $m \in \mathbb{N}$ .
- $F''(k\pi) > 0$  if  $k$  is even  $\implies F$  attains a local minimum at  $(2m)\pi$ , with  $m \in \mathbb{Z}_+$ .  $\square$

**6.B.40.** Find the third-order Taylor expansion of the function

$$f(x) = \int_0^x \frac{1}{1+t^2} dt, \quad x \in \mathbb{R},$$

around the point  $a = 0$ , both by hand and by Sage.

**Solution.** Recall by 6.A.8 that we want to determine the polynomial

$$T_0^3 f(x) = f(0) + f'(0)x + \frac{f''(0)}{2}x^2 + \frac{f^{(3)}(0)}{6}x^3. \quad (b)$$

Obviously,  $f(0) = 0$  and

$$f'(x) = \frac{1}{1+x^2}, \implies f'(0) = 1,$$

$$f''(x) = \left( \frac{1}{1+x^2} \right)' = \frac{-2x}{(1+x^2)^2}, \implies f''(0) = 0,$$

$$f^{(3)}(x) = \left( \frac{-2x}{(1+x^2)^2} \right)' = \frac{2(3x^2-1)}{(1+x^2)^3}, \implies f^{(3)}(0) = -2.$$

**6.2.20. Areas and volumes.** The Riemann integral can be used to compute areas or volumes of shapes defined by a graph of a function. As an example, calculate the area of a circle with radius  $r$ . The quarter-circle bounded by the function  $\sqrt{r^2-x^2}$  for  $0 \leq x \leq r$  determines one quarter of the area. Use the substitution  $x = r \sin t$ ,  $dx = r \cos t dt$  (cf. the corollary for  $I_2$  in the paragraph 6.2.6) to obtain by symmetry

$$\begin{aligned} a(r) &= 4 \int_0^r \sqrt{r^2-x^2} dx = 4r^2 \int_0^{\pi/2} \cos^2 t dt \\ &= 4r^2 \int_0^{\pi/2} \sin^2 t dt = \frac{1}{2} 4r^2 \int_0^{\pi/2} \cos^2 t + \sin^2 t dt \\ &= 2r^2 \int_0^{\pi/2} dt = \pi r^2. \end{aligned}$$

It is worth noticing that this well known formula is derived from the principles of integral calculus. The area of a circle is not only proportional to the square of the radius, but this proportion is again given by the constant  $\pi$ .

Notice the ratio of the area to the perimeter of a circle.

$$\frac{\pi r^2}{2\pi r} = \frac{1}{2}r.$$

The square with the same area has the side of length  $\sqrt{\pi r}$  and therefore its perimeter is  $4\sqrt{\pi r}$ . Hence the perimeter of a square with the area of the unit circle is  $4\sqrt{\pi}$ , compared to the perimeter  $2\pi$  of the unit circle, which is about 0.8 less. It can be shown that in fact the circle is the shape with the smallest perimeter among all with the same area. We derive such results in comments about the calculus of variations in chapter 9.

Another analogy of this approach is the computation of the volume or the surface area of a *solid of revolution*. Such a set in  $\mathbb{R}^3$  is defined by plotting the graph of a function  $y = f(x)$  (for  $x$  in an interval  $[a, b]$ ) in the plane  $xy$  and rotating this plane around the  $x$  axis. This is exactly what happens when producing pottery on a jigger – the hands shape the clay in the form of  $y = f(x)$ .

add appropriate picture here!

When computing the area of the surface, an increment  $\Delta x$  causes the area to increase by the multiple of the length  $\Delta s$  of the curve given by the graph of the function  $y = f(x)$  and the size of the circle with radius  $f(x)$ . Hence the surface area  $A(f)$  is computed by the formula

$$A(f) = 2\pi \int_a^b f(x) ds = 2\pi \int_a^b f(x) \sqrt{1+(f'(x))^2} dx,$$

where the differential  $ds$  is given by the increment on the length of curve  $y = f(x)$ , see above. If instead we determine the solid of revolution by its bound parametrized in the  $xy$  plain by a pair of functions  $[x(t), y(t)]$ , then the corresponding differential of the length  $s$  has the form  $ds = \sqrt{(x'(t))^2 + (y'(t))^2} dt$ . Thus we obtain

$$A = 2\pi \int_a^b y(t) \sqrt{(y'(t))^2 + (x'(t))^2} dt.$$

Thus, according to (b) we get  $T_0^3 f(x) = x - \frac{x^3}{3}, x \in \mathbb{R}$ .

In Sage, as in 6.A.9 one can use the command `taylor`, though now the variable  $t$  should be included as a symbolic variable and assume that  $x > 0$ :

```
var("x, t"); assume(x>0)
f(x)=integral(1/(1+t^2), t, 0, x)
T(x)=taylor(f(x), x, 0, 3); show(T(x))
```

Sage's output has the form  $-\frac{1}{3}x^3 + x$ . □

**6.B.41.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a differentiable function on  $\mathbb{R}$ , having continuous second derivative everywhere on  $\mathbb{R}$  and a local extremum at  $x_0 = 1$ . If for some constants  $\alpha, \beta \in \mathbb{R}$  with  $\alpha \neq 1$  we have the relation

$$\int_0^1 (x f''(x) + \alpha f'(x)) dx = \beta \quad (*)$$

and the graph  $C_f$  of  $f$  passes through the point  $P = [0, \beta] \in \mathbb{R}^2$ , compute  $f(1)$  in terms of  $\alpha$  and  $\beta$ .

**Solution.** By assumption,  $f$  is differentiable everywhere on  $\mathbb{R}$  and hence also at  $x_0 = 1$ , and moreover attains a local extremum at  $x_0$ , so we have  $f'(x_0) = f'(1) = 0$ . We also have  $f(0) = \beta$ , since  $P$  belongs to the graph of  $f$ . Thus, if  $A$  is the left-hand-side of  $(*)$ , by applying integration by parts we get

$$\begin{aligned} A &= \int_0^1 x f''(x) dx + \alpha \int_0^1 f'(x) dx = [x f'(x)]_0^1 \\ &\quad - \int_0^1 x' f'(x) + a [f(x)]_0^1 = f'(1) - [f(x)]_0^1 + a [f(x)]_0^1 \\ &= 0 - (f(1) - f(0)) + a(f(1) - f(0)) \\ &= (\alpha - 1)(f(1) - f(0)) = (\alpha - 1)(f(1) - \beta). \end{aligned}$$

Thus we should have  $(\alpha - 1)(f(1) - \beta) = \beta$  from where we get  $f(1) = \frac{\beta}{\alpha - 1} + \beta = \frac{\alpha\beta}{\alpha - 1}$ . □

**6.B.42.** Consider the function

$$F(x) = x \int_1^x f(t) dt + (1 - x) \int_0^x f(t) dt$$

with  $x \in [0, 1]$ , where  $f : [0, 1] \rightarrow \mathbb{R}$  is continuous function on  $\mathbb{R}$  with  $f(0)f(1) \neq 0$ . Show that there exists  $\xi \in (0, 1)$  with

$$f(\xi) = \int_0^1 f(t) dt. \quad (*)$$

**Solution.** The function  $F$  is differentiable on  $[0, 1]$  and it easy to see that it satisfies  $F(0) = 0 = F(1)$ . Therefore, by Rolle's theorem there exists  $\xi \in (0, 1)$  with  $F'(\xi) = 0$ . We will show that  $\xi$  satisfies  $(*)$ . In particular, a combination of the product rule with the fundamental theorem of calculus

When computing the volume of the same solid, then the increase of  $\Delta x$  causes the volume increase by a multiple of this increment and the area of the circle with radius  $f(x)$ . Hence it is given by the formula

$$V(f) = \pi \int_a^b (f(x))^2 dx.$$

As an example of using the formulas for surface and volume, we derive the well known formulas for the surface of the sphere and volume of the ball with diameter  $r$ .

$$\begin{aligned} A_r &= 2\pi \int_{-r}^r r \sqrt{1 - (x/r)^2} \frac{1}{\sqrt{1 - (x/r)^2}} dt \\ &= 2\pi r \int_{-r}^r dt = 4\pi r^2 \\ V_r &= \pi \int_{-r}^r (r^2 - x^2) dx \\ &= \pi \left[ r^2 x - \frac{1}{3} x^3 \right]_{-r}^r = \frac{4}{3} \pi r^3. \end{aligned}$$

Similarly to the circle, the ball is also the object which has the smallest surface among all with the given volume. That is the reason why small soap bubbles almost always assume this shape.

**6.2.21. Differential equations.** Theorem 6.2.9 can be understood in the following way. Given a continuous function  $f(x)$  on a bounded interval  $[a, b]$ , the set of all functions  $y$  of one variable  $x$  satisfying the equality

$$y' = f(x)$$

is given by the formula

$$y(x) = \int_a^x f(t) dt + C$$

with the constant  $C = y(a)$ . This is the simplest instance of *differential equations*. More generally, ordinary differential equations of first order are given as

$$y' = f(x, y),$$

where  $f(x, y)$  depends on two unknown variables  $x$  and  $y$ . A solution to this equation is a function  $y = y(x)$ , such that the equality is true upon substitution. Similarly, dependence on higher derivatives of  $y$  may be included.

We return to this concept in Chapter 8, see 8.3.2. For the present, we discuss one very special type of equations with *separated variables*

$$y' = f(x)g(y)$$

and add a few observations concerning analytic solutions. Rewrite the equation in terms of the differentials, cf. 6.1.11,

$$\frac{1}{g(y)} dy = f(x) dx.$$

Find the primitive functions on both sides to determine the unknown function  $y = y(x)$  implicitly.

(see 6.2.9), gives

$$\begin{aligned} F'(x) &= \left( x \int_1^x f(t) dt \right)' + \left( (1-x) \int_0^x \right)' \\ &= \int_1^x f(t) dt + x f(x) - \int_0^x f(t) dt + (1-x)f(x) \\ &= - \left( \int_0^x f(t) dt + \int_x^1 f(t) dt \right) + f(x) \\ &= - \int_0^1 f(t) dt + f(x). \end{aligned}$$

This expression combined with the equation  $F'(\xi) = 0$  yields the result.  $\square$

**6.B.43.** Let  $f : [0, 1] \rightarrow \mathbb{R}$  be a continuous function. Show that

$$\int_0^\pi x f(\sin(x)) dx = \frac{\pi}{2} \int_0^\pi f(\sin(x)) dx.$$

**Solution.** Set  $A = \int_0^\pi x f(\sin(x)) dx$ . The trick is the substitution  $u = \pi - x$  with  $du = -dx$ . For  $x = 0$  we have  $u = \pi$  and for  $x = \pi$  we have  $u = 0$ . Recall also that

$$\begin{aligned} \sin(\pi - u) &= \sin(\pi) \cos(u) - \sin(u) \cos(\pi) \\ &= 0 - (-1) \sin(u) = \sin(u), \end{aligned}$$

for all  $u \in \mathbb{R}$ . Thus

$$\begin{aligned} A &= - \int_\pi^0 (\pi - u) f(\sin(\pi - u)) du \\ &= \int_0^\pi (\pi - u) f(\sin(u)) du \\ &= \pi \int_0^\pi f(\sin(u)) du - \int_0^\pi u f(\sin(u)) du, \end{aligned}$$

and the result follows easily.  $\square$

*Along the proof of the fundamental theorem of integral calculus we used the notion of “uniformly continuous functions”, see 6.2.11. Uniform continuity is a stronger condition than continuity, since the real number  $\delta$  in the relative definition depends only on  $\varepsilon$ . Thus, every uniformly continuous function defined on a subset  $A \subseteq \mathbb{R}$  is also continuous, but the converse is not true (think for example of the hyperbola  $1/x$  on  $(0, 1)$ ). Let us present an alternative way to think about uniformly continuous functions and discuss some examples.*

**6.B.44.** Show that a function  $f : A \subseteq \mathbb{R} \rightarrow \mathbb{R}$  is uniformly continuous if and only if for any two sequences  $(x_n), (y_n)$  in  $A$  with  $x_n - y_n \rightarrow 0$ , we also have  $f(x_n) - f(y_n) \rightarrow 0$ , as  $n \rightarrow \infty$ .

**Solution.** Let us prove the one direction and leave the converse as an exercise. So, let  $f : A \subseteq \mathbb{R} \rightarrow \mathbb{R}$  be a uniformly continuous function. Then, for every  $\varepsilon > 0$  there exists  $\delta > 0$  such that for all  $x, y \in A$  satisfying  $|x - y| < \delta$  the inequality  $|f(x) - f(y)| < \varepsilon$  holds. Let  $(x_n), (y_n)$  be sequences on  $A$

Indeed, if  $G(y)$  and  $F(x)$  are the primitive functions with  $G'(y) = \frac{1}{g(y)}$  and  $F'(x) = f(x)$ , and  $y(x)$  satisfies  $G(y(x)) = F(x)$ , then differentiating both sides with respect to  $x$  yields

$$0 = G'(y(x))y'(x) - F'(x) = \frac{y'(x)}{g(y(x))} - f(x)$$

as expected. Of course, it is necessary to be careful with the values  $y$  for which  $g(y) = 0$ , which need to be discussed separately.

For example, the equation  $y' = y$  leads to the implicit definition

$$\ln |y| = x + C,$$

which for positive  $y$  provides  $y(x) = D e^x$  with positive constant  $D$ , the constant solution  $y = 0$  corresponds to  $D = 0$ . Negative values of  $y$  correspond to negative constants  $D$  in the same expression.

If  $y(0) = 1$ , we recover the exponential  $y(x) = e^x$ .

**6.2.22. Analytic solutions.** As we know, the power series are differentiated and integrated term by term, thus the solution  $y(x)$  to the equation  $y' = f(x)$  with a known analytic function  $f(x) = \sum_{n=0}^\infty a_n x^n$  must be

$$y(x) = \sum_{n=0}^\infty \frac{1}{n+1} a_n x^{n+1} + y(0),$$

where  $y(0)$  is the free integration constant. The solution is defined on the convergence domain of the power series (which has to be same as that of  $f$  by the lim sup formula). Of course we might use series centered in other points  $x_0$  if prescribing the initial value  $y(x_0)$ . (We shall prove much later, that actually there is always the unique solution with the given initial prescribed value  $y(0)$  in Chapter 8.)

The latter equation  $y' = y$  had the analytic solution  $e^x$ , too. Let us consider the general case of this type, i.e. equations of the form

$$(1) \quad y' = f(y)$$

with an analytic right-hand side  $f(y)$ . Given the initial condition  $y(x_0) = y_0$ , straightforward differentiation with the help of the chain rule and the equation (1) shows

$$\begin{aligned} y'(x_0) &= f(y_0) \\ y''(x_0) &= f'(y)y'|_{x=x_0} = f'(y)f(y)|_{x=x_0} = f'(y_0)f(y_0) \\ y'''(x_0) &= (f''(y)y'f(y) + f'(y)f'(y)y')|_{x=x_0} \\ &= f''(y_0)(f(y_0))^2 + (f'(y_0))^2 f(y_0) \\ &\vdots \end{aligned}$$

Two crucial observations are due here. First, giving the initial condition  $y(x_0) = y_0$ , all derivatives  $y^{(k)}(x_0)$  are given at this point by the equation. Thus, if an analytic solution exists, we know it explicitly. So we have to focus on the convergence of the known formal expression of the series  $y(x) = \sum_{n=0}^\infty \frac{1}{n!} y^{(n)}(x_0)(x - x_0)^n$  and we arrive at the theorem below.

with  $x_n - y_n \rightarrow 0$ , and let  $\varepsilon > 0$  be given. By the definition of a convergent sequence this means that there exists some natural  $n_0$  such that  $|x_n - y_n| < \varepsilon$  for all  $n \geq n_0$ . But then we also get  $|f(x_n) - f(y_n)| < \varepsilon$  for all  $n \geq n_0$ , which is equivalent to say that  $\lim_{n \rightarrow \infty} (f(x_n) - f(y_n)) = 0$ .  $\square$

**6.B.45.** Let  $f : A \rightarrow \mathbb{R}$  be a continuous function defined on subset  $A$  of  $\mathbb{R}$ . Provide examples verifying that:

- (a) If  $A$  is not closed, then  $f$  may not be uniformly continuous on  $A$ ;
- (b) If  $A$  is not bounded, then  $f$  may not be uniformly continuous on  $A$ .  $\circ$

**6.B.46.** Based on 6.B.44, show that the hyperbola  $f(x) = 1/x$  with  $x \in (0, 1)$  is not uniformly continuous.  $\circ$

**6.B.47.** Show that the sine function  $\sin(x)$  is uniformly continuous on  $\mathbb{R}$ .

**Solution.** First we will use the Lagrange’s mean value theorem (see 5.3.9) to show that  $|\sin(x) - \sin(y)| \leq |x - y|$ , for any  $x, y \in \mathbb{R}$ . If  $x = y$  we have nothing to prove, so assume that  $x \neq y$ . Without loss of generality we may also assume that  $x < y$ . The sine function  $\sin(x)$  satisfies the conditions of the Lagrange’s mean value theorem on the interval  $[x, y]$ . Thus, there exists some  $\xi \in (x, y)$  with

$$\frac{\sin(x) - \sin(y)}{x - y} = \sin'(\xi) = \cos(\xi).$$

Since  $|\cos(\xi)| \leq 1$  we get  $\left| \frac{\sin(x) - \sin(y)}{x - y} \right| \leq 1$ , which implies that  $|\sin(x) - \sin(y)| \leq |x - y|$ , for any  $x, y \in \mathbb{R}$ .

Let us now prove that  $\sin(x)$  is uniformly continuous on  $\mathbb{R}$ . Given some  $\varepsilon > 0$  take  $\delta = \varepsilon$ . If  $x, y \in \mathbb{R}$  satisfy  $|x - y| < \delta$ , by the previous inequality we will have  $|\sin(x) - \sin(y)| \leq |x - y| < \delta = \varepsilon$ , which proves the claim.  $\square$

**6.B.48.** Show that the cos function  $\cos(x)$  is uniformly continuous on  $\mathbb{R}$ .  $\circ$

**6.B.49.** Let  $f : A \rightarrow \mathbb{R}$  be a continuous function defined on a subset  $A \subseteq \mathbb{R}$ .

- (a) Show with an example that if  $(x_n)$  is a Cauchy sequence on  $A$ , then the sequence  $(f(x_n))$  may fail to be Cauchy.
- (b) If  $f$  is in addition uniformly continuous on  $A$ , show that the sequence  $(f(x_n))$  is Cauchy for any Cauchy sequence  $(x_n)$  on  $A$ .  $\circ$

**6.B.50.** Which of the following functions is uniformly continuous on the given domain?

$f(x) = x^2$  on  $A = [0, 1]$ ,  $g(x) = \tan(x)$  on  $B = [0, \pi/2)$ ,  $h(x) = x^2$  on  $\mathbb{R}$ , and  $k(x) = x^3$  on  $\mathbb{R}$ .  $\circ$

In many cases we should compute integrals over an infinite interval, or integrals of functions containing a discontinuity, see 6.2.14. In such cases one speaks for “improper integrals”, which are in general definite integrals that cover an unbounded area. For convenience we summarize the following rules:

In its proof, the second observation will be most helpful: the expressions for the derivatives  $y^{(n)}$  are universal polynomials  $P_n$

$$y^{(n)}(x) = P_n(f(x), f'(x), \dots, f^{(n-1)}(x))$$

in the derivatives of the function  $f$ , all with non-negative coefficients and independent of the particular equation.<sup>5</sup>

CAUCHY-KOVALEVSKAYA THEOREM IN DIMENSION ONE

**Theorem.** Assume  $f(y)$  is a real analytic function convergent on the interval  $(x_0 - a, x_0 + a) \subset \mathbb{R}$  and consider the differential equation (1) with the condition  $y(x_0) = y_0$ . Then the formal power series  $y(x) = \sum_{n=0}^{\infty} \frac{1}{n!} y^{(n)}(x_0)(x - x_0)^n$  converges on a neighborhood of  $x_0$  and provides the solution to (1) satisfying the initial condition.

**PROOF.** The second observation above suggests how to prove the convergence of the “candidate series” similarly as we proved the convergence of power series in general, i.e. by finding another converging series whose partial sums will bound our’s from above. This was the original Cauchy’s approach to this theorem and we talk about the *method of majorants*.

Without loss of generality we shall fix  $x_0 = 0$  and  $y(0) = 0$  (we may always use shifted quantities  $z = y - y_0$  and  $t = x - x_0$  to transform the general case). Assume we can find another analytic function  $g(x) = \sum_{n=0}^{\infty} \frac{1}{n!} b_n x^n$  with all  $b_n = g^{(n)} \geq 0$ , i.e.  $g$  has got all derivatives non-negative at the origin, such that  $g^{(n)}(0) \geq |f^{(n)}(0)|$  for all  $n$ .

Now, replace  $f$  in the equation (1) by  $g$  and write formal power series  $z(x) = \sum_{n=0}^{\infty} \frac{z^{(n)}}{n!} x^n$  for the potential solution of this equation as above. In particular, we deduce (recall the universal polynomials  $P_n$  have got non-negative coefficients)

$$\begin{aligned} z^{(n)}(0) &= P_n(g(z(0)), \dots, g^{(n-1)}(z(0))) \\ &\geq P_n(|f(y(0))|, \dots, |f^{(n-1)}(y(0))|) \geq |y^{(n)}(0)| \end{aligned}$$

and, consequently, convergence of  $z(x)$  will imply absolute convergence of  $y(x)$ , i.e. the claim of the Theorem. We try to find a majorant in the form of a geometric series.

Let us pick  $r > 0$ , smaller than the radius of convergence of  $f$ . Then obviously, there is a constant  $C > 0$  such that the derivatives  $a_n = f^{(n)}(0)$  satisfy  $|\frac{1}{n!} a_n r^n| \leq C$  for all  $n$ , i.e.  $|a_n| \leq C \frac{n!}{r^n}$  (the series would certainly not converge otherwise). We may recognize the derivatives of a geometric series and write

$$(2) \quad g(z) = C \sum_{n=0}^{\infty} \frac{z^n}{r^n} = C \frac{r}{r - z}$$

with derivatives  $g^{(n)}(0) = C \frac{n!}{r^n}$ .

Finally, we have to prove that the solution of the equation  $z' = g(z)$  is analytic. We can easily integrate this equation

<sup>5</sup>Although we shall not need the explicit formulae for these polynomials, they are well known under the name *Faà di Bruno’s formula*. In principle, they are direct generalization of the Leibniz rule to higher order derivatives.

(1)  $\int_a^{+\infty} f(x) dx = \lim_{c \rightarrow +\infty} \int_a^c f(x) dx$ ,  
 where  $f$  is assumed to be continuous on  $[a, +\infty)$ .

(2)  $\int_{-\infty}^b f(x) dx = \lim_{c \rightarrow -\infty} \int_c^b f(x) dx$ ,  
 where  $f$  is assumed to be continuous on  $(-\infty, b]$ .

(3)  $\int_{-\infty}^{+\infty} f(x) dx = \int_{-\infty}^0 f(x) dx + \int_0^{+\infty} f(x) dx$ ,  
 where  $f$  is assumed to be continuous on  $\mathbb{R}$ .

(4)  $\int_a^b f(x) dx = \lim_{t \rightarrow b^-} \int_a^t f(x) dx$ ,  
 where  $f$  is assumed to be continuous on  $[a, b)$ .

(5)  $\int_a^b f(x) dx = \lim_{t \rightarrow a^+} \int_t^b f(x) dx$ ,  
 where  $f$  is assumed to be continuous on  $(a, b]$ .

(6)  $\int_a^b f(x) dx = \int_a^c f(x) dx + \int_c^b f(x) dx$ ,  
 where  $f$  is assumed to be continuous on  $[a, c) \cup (c, b]$ .

**6.B.51.** Show that the integral  $L = \int_0^2 \frac{1}{(x-1)^2} dx$  is divergent, i.e.,  $L = +\infty$ .

**Solution.** Observe that  $x_0 = 1$  is an improper point of the function  $f(x) = 1/(x-1)^2$  and

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1} f(x) = +\infty.$$

Hence the line  $x = 1$  is a vertical asymptote of  $f$ . However the integrand  $f$  is continuous at all other points, see also its graph below.

Already from the graph we understand that the statement should be true. To prove it we will extend the method presented in 6.2.14 for computing the integral  $I$  appearing there, in particular this improper integral corresponds to case (6) of those listed above. Hence we have

$$\begin{aligned} L &= \int_0^2 f(x) dx = \int_0^1 f(x) dx + \int_1^2 f(x) dx \\ &= \lim_{\delta \rightarrow 1^-} \int_0^\delta f(x) dx + \lim_{\varepsilon \rightarrow 1^+} \int_\varepsilon^2 f(x) dx. \end{aligned}$$

with separated variables directly. Written with the help of differentials,  $(r-z) dz = Cr dx$ . Thus, the implicit equation reads  $\frac{1}{2}(r-z)^2 = -Cr x + D$ , where the constant  $D$  is determined by  $z(0) = 0$ . Consequently  $D = \frac{1}{2}r^2$  and a simple computation reveals the solution of the implicit equation

$$z(x) = r \left( 1 \pm \sqrt{1 - \frac{2Cx}{r}} \right).$$

The option with the minus sign satisfies our initial condition. This clearly is an analytic function,  $g$  provides the requested majorant, and the proof is finished.  $\square$

**6.2.23. Numerical approximation of integration.** Just

as in paragraph 6.1.12, we use the Taylor expansion to propose simple approximations of integration. We deal with an integral  $I = \int_a^b f(x) dx$  of an analytic function  $f(x)$  and a uniform partition of the interval  $[a, b]$  using points  $a = x_0, x_1, \dots, x_n = b$  with distances  $x_i - x_{i-1} = h > 0$ . Denote the points in the middle of the intervals in the partitions by  $x_{i+1/2}$  and the values of the function at the points of the partition by  $f(x_i) = f_i$ .

Compute the contribution of one segment of the partition to the integral by the Taylor expansion (knowing that the power series might be integrated term by term). Integrate symmetrically around the middle values so that the derivatives of odd orders cancel each other out while integrating:

$$\begin{aligned} \int_{-h/2}^{h/2} f(x_{i+1/2} + t) dt &= \int_{-h/2}^{h/2} \left( \sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(x_{i+1/2}) t^n \right) dt \\ &= \sum_{k=0}^{\infty} \left( \int_{-h/2}^{h/2} \frac{1}{k!} f^{(k)}(x_{i+1/2}) t^k dt \right) \\ &= \sum_{k=0}^{\infty} \frac{h^{2k+1}}{2^{2k}(2k+1)!} f^{(2k)}(x_{i+1/2}). \end{aligned}$$

A simple numerical approximation of integration on one segment of the partition is the *trapezoidal rule*. This uses the area of a trapezoid given by the points  $[x_i, 0], [x_i, f_i], [x_{i+1}, 0], [x_{i+1}, f_{i+1}]$  for approximation. This area is

$$P_i = \frac{1}{2}(f_i + f_{i+1})h.$$

In total, the integral  $I$  is approximated by

$$I_{\text{trap}} = \sum_{i=0}^{n-1} P_i = \frac{h}{2}(f_0 + 2f_1 + \dots + 2f_{n-1} + f_n).$$

Compare  $I_{\text{trap}}$  to the exact value of  $I$  computed by contributions over individually segments of the partition. Express the values  $f_i$  by the middle values  $f_{i+1/2}$  and the derivatives  $f_{i+1/2}^{(k)}$  in the following way:

$$\begin{aligned} f_{i+1/2 \pm 1/2} &= f_{i+1/2} \pm \frac{h}{2} f'_{i+1/2} + \frac{h^2}{2!2^2} f''_{i+1/2} \\ &\quad \pm \frac{h^3}{3!2^3} f^{(3)}_{i+1/2} + \dots \end{aligned}$$

Now, obviously  $F(x) = -1/(x - 1)$  satisfies  $F'(x) = f(x)$  and hence is a primitive of  $f$ . Applying the fundamental theorem of integral calculus we obtain

$$\int_0^\delta f(x) dx = F(\delta) - F(0) = -\frac{\delta}{\delta - 1},$$

$$\int_\varepsilon^2 f(x) dx = F(2) - F(1 + \varepsilon) = -\frac{\varepsilon - 2}{\varepsilon - 1},$$

and hence

$$L = \lim_{\delta \rightarrow 1^-} \frac{\delta}{1 - \delta} + \lim_{\varepsilon \rightarrow 1^+} \frac{\varepsilon - 2}{1 - \varepsilon} = (+\infty) + (+\infty) = +\infty.$$

These computations can be done quickly in Sage, e.g., by the block

```
F(x)=-1/(x-1); var("delta, eps")
show((F(delta)-F(0)).factor())
show(lim((F(delta)-F(0)), delta=1, dir="-"))
show((F(2)-F(eps)).factor())
show(lim((F(2)-F(eps)), eps=1, dir="+"))
```

Notice the command `integral(1/(x - 1)2, x, 0, 2)` gives an error which confirms itself the divergence of  $L$ , check yourself the very end of Sage's output for this command.  $\square$

**6.B.52.** Show that  $\int_1^{+\infty} \frac{\arctan(x)}{x\sqrt{x}} dx$  is a finite real number.

○

In 6.2.17 one meets several new acquisitions to the ZOO. One of them is the Gamma function, defined for all positive real numbers  $z$  by

$$\Gamma(z) = \int_0^\infty e^{-x} x^{z-1} dx.$$

The Gamma function is well defined and analytic for  $z > 0$  (and more generally for complex numbers  $z$  with positive real part). Moreover,  $\Gamma$  converges for all  $z > 0$  and the next task shows that the Gamma function can be seen as an extension of the factorial function to real positive numbers.<sup>4</sup>

**6.B.53. An interpretation of the factorial.** (a) Prove the recurrence formula  $\Gamma(n + 1) = n\Gamma(n)$ ,  $n \in \mathbb{Z}_+$ . (b) Using (a) show that  $\Gamma(n + 1) = n!$ , for all naturals  $n$ . (c) For some  $a > 0$  prove that

$$\int_0^\infty e^{-ax} x^{n-1} dx = \frac{1}{a^n} \Gamma(n).$$

(d) Using the “Gaussian integral”  $\int_0^\infty e^{-u^2} du = \frac{\sqrt{\pi}}{2}$ , show that  $\Gamma(1/2) = \sqrt{\pi}$ .

<sup>4</sup>The gamma function was introduced by the Leonhard Euler (1707-1783) at 1729, as a natural extension of the factorial operation  $n!$  (in the sense that  $n$  was replaced by a real or a complex number).

Thus, the contribution  $P_i$  to the approximation is

$$P_i = \frac{1}{2}(f_i + f_{i+1})h = h \left( f_{i+1/2} + \frac{h^2}{2!2^2} f''(i+1/2) \right) + O(h^5).$$

Estimate the error  $\Delta_i = I - I_{\text{trap}}$  over one segment of the partition:

$$\Delta_i = h \left( f_{i+1/2} + \frac{h^2}{24} f''_{i+1/2} - f_{i+1/2} - \frac{h^2}{8} f''_{i+1/2} + O(h^4) \right)$$

$$= -\frac{h^3}{12} f''_{i+1/2} + O(h^5).$$

The total error is thus estimated as

$$|I - I_{\text{trap}}| = \frac{1}{12} n h^3 |f''| + n O(h^5)$$

$$= \frac{1}{12} (b - a) h^2 |f''| + O(h^4)$$

where  $|f''|$  represents an upper estimate for  $|f''(x)|$  of  $f$  over the interval of integration.

If the linear approximation of the function over the individual segments does not suffice, we can try approximations by quadratic polynomials. To do so, three values are always needed, so work with segments of the partition in pairs. Suppose  $n = 2m$  and consider  $x_i$  with odd indices. We choose

$$f_{i+1} = f(x_i + h) = f_i + \alpha_i h + \beta_i h^2$$

$$f_{i-1} = f(x_i - h) = f_i - \alpha_i h + \beta_i h^2$$

which implies

$$\beta_i = \frac{1}{2h^2} (f_{i+1} + f_{i-1} - 2f_i).$$

The approximation of the integral over two segments of the partition between  $x_{i-1}$  and  $x_{i+1}$  is now estimated by the expression (notice we integrate the quadratic polynomial with the requested values  $f_{i-1}$ ,  $f_i$ ,  $f_{i+1}$  in the points  $x_{i-1}$ ,  $x_i$ ,  $x_{i+1}$ , respectively. It is not necessary to know the constant  $\alpha_i$ )

$$P_i = \int_{-h}^h f_i + \alpha_i t + \beta_i t^2 dt = 2h f_i + \frac{2}{3} \beta_i h^3$$

$$= 2h f_i + \frac{2h}{6} (f_{i+1} + f_{i-1} - 2f_i)$$

$$= \frac{h}{3} (f_{i+1} + f_{i-1} + 4f_i).$$

This procedure is called *Simpson's rule*<sup>6</sup>. The entire integral is now approximated by

$$I_{\text{Simp}} = \frac{1}{3} h (f_0 + 4 \sum_{m=0}^{n-1} f_{2m+1} + 2 \sum_{m=1}^{n-1} f_{2m} + f_{2n}).$$

As with the trapezoidal rule above, the total error is estimated by

$$|I - I_{\text{Simp}}| = \frac{1}{180} (b - a) h^4 |f^{(4)}| + O(h^5),$$

where  $|f^{(4)}|$  represents the upper bound for  $|f^{(4)}(x)|$  over the interval of integration.

<sup>6</sup>This way of approximating the integral is attributed to the English mathematician and inventor Thomas Simpson (1710-1761).

**Solution.** (a) Integration by parts gives the result, i.e.,

$$\begin{aligned} \Gamma(n+1) &= \int_0^\infty e^{-x} x^n dx \\ &= [-x^n e^{-x}]_0^\infty + n \int_0^\infty e^{-x} x^{n-1} dx \\ &= -\lim_{x \rightarrow \infty} \frac{x^n}{e^x} + n\Gamma(n) = 0 + n\Gamma(n) = n\Gamma(n). \end{aligned}$$

Above we used the fact  $\lim_{x \rightarrow \infty} \frac{x^n}{e^x} = 0$ . This limit has the intermediate form  $\frac{\infty}{\infty}$  and a way to compute it occurs by applying the l'Hopital's rule  $n$  times:

$$\lim_{x \rightarrow +\infty} \frac{x^n}{e^x} \stackrel{\infty}{=} \lim_{x \rightarrow +\infty} \frac{n x^{n-1}}{e^x} \stackrel{\infty}{=} \dots \stackrel{\infty}{=} \lim_{x \rightarrow \infty} \frac{n!}{e^x} = 0.$$

(b) Obviously,

$$\Gamma(1) = \int_0^\infty e^{-x} dx = [-e^{-x}]_0^\infty = 1.$$

Moreover, a direct computation shows that

$$\Gamma(2) = \int_0^\infty e^{-x} x dx = 1 = \Gamma(1).$$

Thus we can write  $\Gamma(2) = 1 \cdot \Gamma(1) = 1!$ , and similarly by integration by parts one can prove that  $\Gamma(3) = 2\Gamma(2) = 2!$ . Let us apply induction over  $n$  to prove the general formula. For the inductive step suppose  $\Gamma(n) = (n-1)!$  for some  $n$ . Then, by (a) we see that  $\Gamma(n+1) = n\Gamma(n) = n(n-1)! = n!$ , for all naturals  $n$ .

(c) For any positive integer we have  $\Gamma(n) = \int_0^\infty e^{-x} x^{n-1} dx$ . For  $a > 0$  set  $x = ay$  with  $dx = a dy$ . Then we see that

$$\Gamma(n) = \int_0^\infty e^{-ay} (ay)^{n-1} a dy = a^n \int_0^\infty e^{-ay} y^{n-1} dy,$$

i.e.,  $\int_0^\infty e^{-ay} y^{n-1} dy = \frac{\Gamma(n)}{a^n}$ . The result now follows.

(d) This is based on the substitution  $x = u^2$ :

$$\begin{aligned} \Gamma(1/2) &= \int_0^\infty e^{-x} x^{-\frac{1}{2}} dx = \int_0^\infty \frac{e^{-x}}{\sqrt{x}} dx \\ &\stackrel{x=u^2}{dx=2u du} 2 \int_0^\infty e^{-u^2} du = 2 \frac{\sqrt{\pi}}{2} = \sqrt{\pi}. \end{aligned}$$

□

*Recall that the mean value of a function over a given interval provides a single value that represents the average behavior of the function on that interval. This concept is fundamental in various areas of mathematics, since it allows the estimation of the overall effect of a function over an interval without being necessary to consider every individual point. This gives many applications in physics and engineering, where average values are often more useful than point values (such as in calculating average velocity, average temperature, or average concentration of a substance).*

### 3. Sequences, series and limit processes

While building a menagerie of functions, we encountered power series, which extended the collection of all polynomials in a natural way, see 5.4.10. We obtained the class of analytic functions in this way. We have also got the message that they are always smooth and may be integrated and differentiated term by term on the entire domain of convergence. We gave the link to a straightforward technical proof of these statements in 9.4.2 on page 873. Now we shall develop simple tools and show similar results for much more general series of function.

Moreover, functions often depend on further parameters which are dummy when differentiating or integrating, but we need to understand how the result behaves with respect to these parameters. For instance, what about the differentiability of the Gamma function introduced above? Or, when computing volume or area depending on a free parameter, how to minimize it?

Finally, in the end of this chapter we briefly introduce some more advanced concepts of integration.

#### 6.3.1. How well behaved is a sequence of functions? We

return to the discussion of the limits of sequences of functions and the sum of series of functions in view of the methods of differential and integral calculus. Consider a convergent series of functions

$$S(x) = \sum_{n=1}^{\infty} f_n(x)$$

on an interval  $[a, b]$ . Natural questions include:

- If all functions  $f_n(x)$  are continuous at some point  $x_0 \in [a, b]$ , is the function  $S(x)$  also continuous at the point  $x_0$ ?
- If all functions  $f_n(x)$  are differentiable at some point  $a \in [a, b]$ , is the function  $S(x)$  also differentiable there and does the equality  $S'(x) = \sum_{n=1}^{\infty} f'_n(x)$  hold?
- If all functions  $f_n(x)$  are Riemann integrable on an interval  $[a, b]$ , is the function  $S(x)$  also integrable there and does the equality  $\int_a^b S(x) dx = \sum_{n=1}^{\infty} \int_a^b f_n(x) dx$  hold?

Notice, it does not matter whether we discuss series or sequences, since the former ones are just limits of the sequences of the partial sums. First, we demonstrate by examples that the answers to all three questions above are "NO!". Then we find additional conditions on the convergence of the series (or sequences) which guarantees the validity of all three statements. Later we shall mention alternative concepts of integration which are more satisfactory than the Riemann integral for an even wider classes of functions.

#### 6.3.2. Examples of nasty sequences. (1) Consider the functions

$$f_n(x) = (\sin x)^n$$

on the interval  $[0, \pi]$ . The values of these functions are non-negative and smaller than one at all points  $0 \leq x \leq \pi$ , except

On the other hand, the integral mean value theorem provides a rigorous way to calculate the average value of a function over an interval. Next we will describe applications related to these theorems, see also see 6.2.15.

**6.B.54.** For the function  $f(\theta) = \cos(2\theta)e^{1+\sin(2\theta)}$ , determine its average value on  $[-\pi/4, \pi/4]$ .

**Solution.** The average value of  $f$  on  $[-\pi/4, \pi/4]$  is given by

$$m(f) = \frac{1}{\pi/4 - (-\pi/4)} \int_{-\pi/4}^{\pi/4} f(\theta) d\theta = \frac{2}{\pi} \int_{-\pi/4}^{\pi/4} f(\theta) d\theta.$$

To compute this integral one may set  $u = 1 + \sin(2\theta)$ , such that  $du = 2 \cos(2\theta)d\theta$ . We also have  $u = 2$  for  $\theta = \pi/4$ , and  $u = 0$  for  $\theta = -\pi/4$ , thus we get

$$m(f) = \frac{2}{\pi} \cdot \frac{1}{2} \int_0^2 e^u du = \frac{e^2 - 1}{\pi}.$$

Here is a confirmation in Sage:

```
var("th"); f(th)=cos(2*th)*e^(1+sin(2*th))
show((2/pi)*integral(f(th), th, -pi/4, pi/4))
```

□

**6.B.55.** Determine the average velocity  $m(v)$  of a solid in the time interval  $[1, 2]$ , if its velocity is given by

$$v(t) = \frac{t}{\sqrt{1+t^2}}, \quad t \in [1, 2].$$

You can omit the units.

**Solution.** To solve the problem, it suffices to realize that the sought average velocity is the mean value of function  $v$  on interval  $[1, 2]$ . Hence

$$m(v) = \frac{1}{2-1} \int_1^2 \frac{t}{\sqrt{1+t^2}} dt = \int_2^5 \frac{1}{2\sqrt{x}} dx = \sqrt{5} - \sqrt{2}$$

with  $1 + t^2 = x, t dt = dx/2$ . □

Further exercises on improper integrals and other applications related to definite integrals are presented in Section D. Next we describe a few tasks about lengths of curves, areas of regions, and volumes.

**6.B.56. Arc length.** Determine the length of the parametric curve defined by  $x(t) = e^t - t, y(t) = 4e^{t/2}$  with  $0 \leq t \leq 1$ . Then present the solution via Sage.

**Solution.** According to 6.2.18, the length of a curve  $\alpha(t) = [x(t), y(t)]$  on  $\mathbb{R}^2$  defined on the interval  $[a, b]$  is given by the integral

$$s_{\alpha(t)} \equiv s(\alpha(t)) = \int_a^b \sqrt{(x'(t))^2 + (y'(t))^2} dt.$$

for  $x = \frac{\pi}{2}$ , where the value is 1. Hence on the whole interval  $[0, \pi]$ , these functions converge to the function

$$f(x) = \lim_{n \rightarrow \infty} f_n(x) = \begin{cases} 0 & \text{for all } x \neq \frac{\pi}{2} \\ 1 & \text{for } x = \frac{\pi}{2}. \end{cases}$$

point by point. The limit of the sequence of functions  $f_n$  is a discontinuous function, even though all functions  $f_n(x)$  are continuous. The problematic point is an inner point of the interval.

The same phenomenon occurs for a series of functions, because the sum is the limit of partial sums. Hence in the previous example, it suffices to express  $f_n$  as the  $n$ -th partial sum. For example,  $f_1(x) = \sin x, f_2(x) = (\sin x)^2 - \sin x$ , etc. The figure plots the functions  $f_m(x)$  for  $m = n^3, n = 1, \dots, 10$ .

(2) We look at the second question, i.e. badly behaving derivatives. A natural idea based on the same principle as above is to construct a sequence of functions which has the same nonzero derivative at one point, but becomes smaller and smaller. So they converge pointwise to the identically zero function.

The next figure plots the functions

$$f_n(x) = x(1-x^2)^n$$

on the interval  $[-1, 1]$  for values  $n = m^2, m = 1, \dots, 10$ .

It is immediate that  $\lim_{n \rightarrow \infty} f_n(x) = 0$  and that all functions  $f_n(x)$  are smooth. Their derivative at  $x = 0$  is

$$f'_n(0) = ((1-x^2)^n - 2nx^2(1-x^2)^{n-1})|_{x=0} = 1$$

for all  $n$ . But the limit function for the sequence  $f_n$  has a zero derivative at every point.

(3) The counterexample to the third statement is in 6.2.18 already. The characteristic function  $\chi_{\mathbb{Q}}$  of rational numbers can be expressed as a sum of countably many functions, which are numbered exactly by rational numbers. They are zero everywhere except for the single point after which they

For the given curve we have  $x'(t) = e^t - 1$  and  $y'(t) = 2e^{t/2}$ , with  $(x'(t))^2 + (y'(t))^2 = (e^t + 1)^2$ . Thus

$$s = \int_0^1 \sqrt{(e^t + 1)^2} dt = \int_0^1 (e^t + 1) dt = [e^t]_0^1 + [t]_0^1 = e - 1 + 1 = e.$$

In Sage you can confirm all these computations by the following cell:

```
var('t'); x(t)=e^t-t; y(t)=4*e^(t/2)
X(t)=diff(x(t), t); show(X(t))
Y(t)=diff(y(t), t); show(Y(t))
l(t)=(X(t)*X(t)+Y(t)*Y(t)).factor(); show(l(t))
s=integral(sqrt(l(t)), t, 0, 1).simplify_full()
show(s)
```

Using the command `parametric_plot` you can plot the given curve, which can be done just by adding in the previous block the syntax

```
p=parametric_plot((x(t), y(t)), (t, 0, 1))
p.show(aspect_ratio=1/4)
```

□

*It is often useful to jump via Sage from classical integration to numerical integration. This for example can be useful for cases where we need an approximation, or in cases where a “closed form” of the integral does not exist, as for example the case of Gaussian  $f(x) = e^{-x^2}$  whose antiderivative is the so-called “error function”  $\operatorname{erf}$ . This is an interesting situation which, till the end of this chapter, we will implement in many different ways.*

*Notice in Sage an option to approximate a definite integral relies on the command `n(integral(f, x, a, b))`, or `numerical_approx(integral(f, x, a, b))`. For instance for the Gaussian  $f(x) = e^{-x^2}$  try the cell*

```
f(x)=e^(-x^2)
show(integral(f, x, 0, 1))
print(n(integral(f, x, 0, 1)))
```

Sage’s output has the form

$$\frac{1}{2} \sqrt{\pi} \operatorname{erf}(1)$$

and 0.746824132812427, respectively. Built-in methods that Sage provides for numerical integration will be discussed later. We begin with the following task about the arc length of parametric curves.

**6.B.57.** Given a curve  $c : [a, b] \rightarrow \mathbb{R}^2$  in the parametric form  $c(t) = [x(t), y(t)]$ , present a routine in Sage that will compute numerically the length of  $c$  on  $[a, b]$  and plot its graph. Then, test your routine for the following cases and next confirm routine’s result by a formal computation:

- (1)  $c(t) = [\cos^3(t), \sin^3(t)]$ ,  $t \in [0, \pi/2]$ ;
- (2)  $c(t) = [t, \ln(\cos(t))]$ ,  $t \in [0, \pi/4]$ ;

are named for, where the value is 1. Riemann integrals of all such functions are zero, but the sum is not a Riemann integrable function.

This example illustrates the fundamental flaw of the Riemann integral, to which we return later.

We present an example where the limit function  $f$  is integrable, all functions  $f_n$  are continuous, but the value of the integral is not the limit of the integrals of  $f_n$ . We modify the sequence of the functions  $x(1 - x^2)^n$  used above. They integrate to  $\int_0^1 x(1 - x^2)^n dx = \frac{1}{2(n+1)}$ . Thus, we consider the functions

$$f_n(x) = 2(n+1)x(1 - x^2)^n.$$

These functions with  $n = m^2$ ,  $m = 1, \dots, 10$  are on the next diagram.

It is quite easy to verify that the values of these functions converge to zero for every  $x \in [0, 1]$  (for example the reader can check  $\ln(f_n(x)) \rightarrow -\infty$ ). But for all  $n$

$$\int_0^1 f_n(x) dx = 1 \neq 0.$$

**6.3.3. Uniform convergence.** A reason of failure in all three previous examples is the fact that the speed of pointwise convergence of values  $f_n(x) \rightarrow f(x)$  varies dramatically point from point. Hence a natural idea is to confine the problem to cases where the convergence will have roughly the same speed over all the interval:

#### UNIFORM CONVERGENCE

**Definition.** We say that the sequence of functions  $f_n(x)$  converges uniformly on interval  $[a, b]$  to the limit  $f(x)$ , if for every positive number  $\varepsilon$ , there exists a natural number  $N \in \mathbb{N}$  such that for all  $n \geq N$  and all  $x \in [a, b]$  the inequality

$$|f_n(x) - f(x)| < \varepsilon$$

holds.

A series of functions converges uniformly on an interval, if the sequence of its partial sums converges uniformly.

Albeit the choice of the number  $N$  depends on the chosen  $\varepsilon$ , it is independent on the point  $x \in [a, b]$ . This is the difference from pointwise convergence, where  $N$  depends on both  $\varepsilon$  and  $x$ . We visualise the definition graphically in this way: if we consider a zone created by a translation of the limit function  $f(x)$  to  $f(x) \pm \varepsilon$  for arbitrarily small, but fixed positive

- (3)  $c(t) = [t \sin(t), t \cos(t)]$ ,  $t \in [0, 4\pi]$ ;  
 (4)  $c(t) = [\sin^2(t), \cos^2(t)]$ ,  $t \in [0, \frac{\pi}{2}]$ . ○

**6.B.58.** Compute the length  $s$  of a part of the so-called “trac-trix”, that is, the parametric curve  $\alpha(t) = [f(t), g(t)]$  defined by

$$f(t) = r \cos t + r \ln \left( \tan \left( \frac{t}{2} \right) \right), \quad g(t) = r \sin(t),$$

with  $t \in [\pi/2, a]$ , where  $r > 0$ , and  $a \in (\pi/2, \pi)$ . Next use Sage to plot  $\alpha$  for the values  $r = 1, 2, \dots, 5$  in one figure. ○

**6.B.59. Area of half ellipses.** Consider the curve  $\alpha(t) = [x(t), y(t)] = [4 \cos(t), 3 \sin(t)]$ , with  $0 \leq t \leq \pi$ .

(a) Show that  $\alpha(t)$  is the half of a horizontal ellipses centered at the origin, with major axes of length 8 and minor axes of length 6. Use Sage to plot  $\alpha$  and color the region bounded by the  $x$ -axis and the ellipsis.

(b) Compute the area of this region.

**Solution.** (a) Obviously,  $\alpha(t)$  is the half of a horizontal ellipses centered at the origin of  $\mathbb{R}^2$ , since it satisfies the equation  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$  with  $a = 4$  and  $b = 3$ . Thus the major axes has length  $2a = 8$  and the minor axes has length  $2b = 6$ , respectively. To plot  $\alpha$  we will use the command `parametric_plot` as above, that is,

```
x(t)=4*cos(t); y(t)=3*sin(t)
show(parametric_plot((x(t), y(t)), (t, 0, pi),
fill=True, fillcolor="lightgrey",
aspect_ratio=1, color="black", thickness=1.5))
```

which produces the following figure:

(b) To find the area under the given parametric curve we need first to compute the integral

$$\begin{aligned} \int_0^\pi y(t)x'(t) dt &= \int_0^\pi 3 \sin(t)(4 \cos(t))' dt \\ &= -12 \int_0^\pi \sin^2(t) dt = -\frac{12}{2} \int_0^\pi (1 - \cos(2t)) dt \\ &= -6 \left[ t - \frac{\sin(2t)}{2} \right]_0^\pi = -6\pi. \end{aligned}$$

Thus the required area equals to  $|\int_0^\pi y(t)x'(t) dt| = 6\pi$ . In Sage to confirm this result it is sufficient to add in the previous block the cell

```
F(t)=y(t)*diff(x(t), t)
show(abs(integral(F(t), t, 0, pi)))
```

$\varepsilon$ , all of the functions  $f_n(x)$  will fall into this zone, except for finitely many of them. The first and the last of the nasty examples above do not have this property; In the second example, the sequence of derivatives  $f'_n$  lacked it.

**6.3.4.** The three claims in the following theorem say that all three generally false properties discussed in 6.3.1 are true features for uniform convergence (but beware the subtleties when differentiating).

CONSEQUENCES OF UNIFORM CONVERGENCE

**Theorem.** (1) Let  $f_n(x)$  be a sequence of functions continuous on a closed interval  $[a, b]$  and converging uniformly to the function  $f(x)$  on this interval. Then  $f(x)$  is also continuous on the interval  $[a, b]$ .

(2) Let  $f_n(x)$  be a sequence of Riemann integrable functions on a finite closed interval  $[a, b]$  which converge uniformly to the function  $f(x)$  on this interval. Then  $f(x)$  is Riemann integrable, and

$$\int_a^b f(x) dx = \int_a^b \left( \lim_{n \rightarrow \infty} f_n(x) \right) dx = \lim_{n \rightarrow \infty} \int_a^b f_n(x) dx.$$

(3) Let  $f_n(x)$  be a sequence of functions differentiable on a closed interval  $[a, b]$  and assume  $f_n(x_0) \rightarrow f(x_0)$  at some point  $x_0 \in [a, b]$ . Moreover, assume all derivatives  $g_n(x) = f'_n(x)$  are continuous and converge uniformly to the function  $g(x)$  on the same interval. Then the function  $f(x) = f(x_0) + \int_{x_0}^x g(t) dt$  is differentiable on the interval  $[a, b]$ , the functions  $f_n(x)$  converge to  $f(x)$  and  $f'(x) = g(x)$ . In other words,

$$\frac{d}{dx} f(x) = \frac{d}{dx} \left( \lim_{n \rightarrow \infty} f_n(x) \right) = \lim_{n \rightarrow \infty} \left( \frac{d}{dx} f_n(x) \right)$$

**PROOF OF THE FIRST CLAIM.** Fix an arbitrary fixed point  $x_0 \in [a, b]$  and let  $\varepsilon > 0$  be given. It is required to show that

$$|f(x) - f(x_0)| < \varepsilon$$

for all  $x$  close enough to  $x_0$ . From the definition of uniform convergence,

$$|f_n(x) - f(x)| < \varepsilon$$

for all  $x \in [a, b]$  and all sufficiently large  $n$ . Choose some  $n$  with this property and consider  $\delta > 0$  such that

$$|f_n(x) - f_n(x_0)| < \varepsilon$$

for all  $x$  in  $\delta$ -neighbourhood of  $x_0$ . That is possible because  $f_n(x)$  are continuous for all  $n$ . Then

$$\begin{aligned} |f(x) - f(x_0)| &\leq |f(x) - f_n(x)| + |f_n(x) - f_n(x_0)| \\ &\quad + |f_n(x_0) - f(x_0)| < 3\varepsilon \end{aligned}$$

for all  $x$  in the  $\delta$ -neighbourhood of  $x_0$ . This is the desired inequality with the bound  $3\varepsilon$ . □

**6.B.60. Area.** Calculate the area  $E$  between the  $x$ -axis and the graph of  $f(x) = x^2 - 3x - 4$  for  $4 \leq x \leq 5$ . Next use Sage to illustrate the area in question.

**Solution.** An easy computation shows that  $E = \frac{17}{6}$ , and this corresponds to grey region in the figure given here:

To obtain the required illustration in Sage, we will use the polygon method, which is the core of our program presented below. Details on this method are postponed to Section D, see (b) in 6.D.43.

```
f(x)=x^2-3*x-4
p=plot(f(x), x, 3, 5, thickness=2,
color="black")
p+=line([(5, 0), (5, 6)],

**6.B.61.** Compute the volume of a solid created by rotation of a bounded surface, whose boundary is the curve  $x^4 - 9x^2 + y^4 = 0$ , around the  $x$ -axis. You may omit the units.

**Solution.** If  $[x, y]$  is a point on the  $x^4 - 9x^2 + y^4 = 0$ , clearly this curve also intersects points  $[-x, y]$ ,  $[x, -y]$ ,  $[-x, -y]$ . Thus is symmetric with respect to both axes  $x, y$ . For  $y = 0$ , we have  $x^2(x - 3)(x + 3) = 0$ , i.e. the  $x$  axis is intersected by the boundary curve at points  $[-3, 0]$ ,  $[0, 0]$ ,  $[3, 0]$ . In the first quadrant, it can then be expressed as a graph of the function

$$f(x) = \sqrt[4]{9x^2 - x^4}, \quad x \in [0, 3].$$

The sought volume is thus a double (here we consider  $x > 0$ ) of the integral

$$\int_0^3 \pi f^2(x) dx = \pi \int_0^3 \sqrt{9x^2 - x^4} dx.$$

**Remark.** In fact, the arguments in the proof show a more general claim. Indeed, if the functions  $f_n(x)$  converge uniformly to  $f(x)$  on  $[a, b]$ , and the individual functions  $f_n(x)$  have the limits (or one-sided limits)  $\lim_{x \rightarrow x_0} f_n(x) = a_n$ , then the limit  $\lim_{x \rightarrow x_0} f(x)$  exists if and only if the limit  $\lim_{n \rightarrow \infty} a_n = a$  exists. Then they are equal, that is,

$$a = \lim_{n \rightarrow \infty} \left( \lim_{x \rightarrow x_0} f_n(x) \right) = \lim_{x \rightarrow x_0} \left( \lim_{n \rightarrow \infty} f_n(x) \right).$$

The reader should be able to modify the above proof for this situation.

**6.3.5. Proof of the second claim.** The proof of this part of the theorem is based upon a generalization of the properties of Cauchy sequences of numbers to uniform convergence of functions. In this way we can work with the existence of the limit of a sequence of integrals without needing to know the limit.

UNIFORMLY CAUCHY SEQUENCES

**Definition.** The sequence of functions  $f_n(x)$  on interval  $[a, b]$  is *uniformly Cauchy*, if for every (small) positive number  $\varepsilon$ , there exists a (large) natural number  $N$  such that for all  $x \in [a, b]$  and all  $m, n \geq N$ ,

$$|f_n(x) - f_m(x)| < \varepsilon.$$

Every uniformly convergent sequence of functions on interval  $[a, b]$  is also uniformly Cauchy on the same interval. To see this, it suffices to notice the usual bound

$$|f_n(x) - f_m(x)| \leq |f_n(x) - f(x)| + |f(x) - f_m(x)|$$

based on the triangle inequality.

Before coming to the proof 6.3.4(2), we mention the following:

**Proposition.** Every uniformly Cauchy sequence of functions  $f_n(x)$  on the interval  $[a, b]$  uniformly converges to some function  $f$  on this interval. □

**PROOF.** Of course, the condition for a sequence of functions to be uniformly Cauchy implies that also for all  $x \in [a, b]$ , the sequence of values  $f_n(x)$  is a Cauchy sequence of real (or complex) numbers. Hence the sequence of functions  $f_n(x)$  converges pointwise to some function  $f(x)$ .

Choose  $N$  large enough so that

$$|f_n(x) - f_m(x)| < \varepsilon$$

for some small positive  $\varepsilon$  chosen beforehand and all  $m, n \geq N, x \in [a, b]$ . Now choose one such  $n$  and fix it, then

$$|f_n(x) - f(x)| = \lim_{m \rightarrow \infty} |f_n(x) - f_m(x)| \leq \varepsilon$$

for all  $x \in [a, b]$ . Hence the sequence  $f_n(x)$  converges to its limit uniformly. □

**PROOF OF THE SECOND CLAIM IN 6.3.4.** Recall that every uniformly convergent sequence of functions is also uniformly Cauchy and that the Riemann sums of all single terms  $f_n(x)$

Using the substitution  $t = \sqrt{9 - x^2}$  ( $x dx = -t dt$ ), we get

$$\int_0^3 \sqrt{9x^2 - x^4} dx = \int_0^3 x \cdot \sqrt{9 - x^2} dx = - \int_3^0 t^2 dt = 9.$$

Thus the final answer is  $18\pi$ . □

**6.B.62. Torricelli's trumpet (1641).** Let a part of a branch of the hyperbola  $xy = 1$  for  $x \geq a$ , where  $a > 0$ , rotate around the  $x$  axis. Show that the solid of revolution created in this manner has a finite volume  $V$  and simultaneously an infinite surface  $S$ .

**Solution.** We know that

$$\begin{aligned} V &= \pi \int_a^{+\infty} \left(\frac{1}{x}\right)^2 dx = \pi \int_a^{+\infty} \frac{1}{x^2} dx \\ &= \pi \left( \lim_{x \rightarrow +\infty} -\frac{1}{x} - \left(-\frac{1}{a}\right) \right) = \frac{\pi}{a} \end{aligned}$$

and

$$\begin{aligned} S &= 2\pi \int_a^{+\infty} \frac{1}{x} \cdot \sqrt{1 + \left(-\frac{1}{x^2}\right)^2} dx = 2\pi \int_a^{+\infty} \frac{\sqrt{x^4 + 1}}{x^3} dx \\ &\geq 2\pi \int_a^{+\infty} \frac{1}{x} dx = 2\pi \left( \lim_{x \rightarrow +\infty} \ln x - \ln a \right) = +\infty. \end{aligned}$$

The fact that the given solid (the so called Torricelli's trumpet) cannot be painted with a finite amount of colour, but can be filled with a finite amount of fluid, is called the "*Torricelli's paradox*". Realize however that a real color painting has a nonzero width, which the computation does not take into account. For example, if we would paint it from the inside, a single drop of color would undoubtedly "block" the trumpet of infinite length. □

*A differential equation is an equation involving derivatives. Many physical and engineering problems naturally lead to differential equations, making it essential to learn how to formulate and solve them. For instance, in Chapter 3 we encountered differential equations in the context of population growth.*

Differential equations fall into two main categories, "ordinary differential equations" (ODEs) and "partial differential equations" (PDEs). An ODE involves derivatives with respect to a single independent variable, and next we focus on ODEs of first order. Typically, such equations are written as  $y' = F(x, y)$ , where  $y = f(x)$ , see 6.2.21. If  $F$  is in the form  $y' = F(x, y) = f(x)g(y)$  for some functions  $f, g$ , the ODE is called separable. For  $g(y) \neq 0$  we can solve it by separating the variables:

$$\frac{dy}{g(y)} = f(x) dx \Rightarrow \int \frac{dy}{g(y)} = \int f(x) dx.$$

Let's explore some simple problems, with a more detailed discussion on differential equations postponed to Chapter 8.

of the sequence converge to  $\int_a^b f_n(x) dx$  independently of the choice of the partition and the representatives. Hence, if

$$|f_n(x) - f_m(x)| < \varepsilon$$

for all  $x \in [a, b]$ , then also

$$\left| \int_a^b f_n(x) dx - \int_a^b f_m(x) dx \right| \leq \varepsilon |b - a|.$$

Therefore the sequence of numbers  $\int_a^b f_n(x) dx$  is Cauchy, and hence convergent.

The Riemann sums of the limit function  $f(x)$  can be made arbitrarily close to those of  $f_n(x)$  for large  $n$ , by the same argument as above. So  $f(x)$  is integrable. Moreover,

$$\left| \int_a^b f_n(x) dx - \int_a^b f(x) dx \right| \leq \varepsilon |b - a|,$$

so the limit value is as expected. □

**6.3.6. Proof of the third claim.** For the corresponding result about derivatives, extra care is needed regarding the assumptions: If the differentiable functions  $\tilde{f}_n(x) = f_n(x) - f_n(x_0)$  are considered instead of  $f_n(x)$ , the derivatives do not change. Hence without loss of generality it can be assumed that all functions satisfy  $f_n(x_0) = 0$ .

Then the first assumption of the theorem is satisfied automatically. For all  $x \in [a, b]$ , we can write

$$f_n(x) = \int_{x_0}^x g_n(t) dt.$$

Because the functions  $g_n$  converge uniformly to  $g$  on all of  $[a, b]$ , the functions  $f_n(x)$  converge to

$$f(x) = \int_{x_0}^x g(t) dt.$$

$g$  is a uniform limit of continuous functions, thus  $g$  is again continuous. By 6.2.8, for the relations between the Riemann integral and the primitive function, the proof is finished.

**6.3.7. Uniform convergence of series.** For infinite series, we apply the previous three results to the sequences of partial sums. Thus the following corollary is an immediate consequence:

**6.B.63. Differential equations.** Compute the limit  $\lim_{x \rightarrow +\infty} f(x)$  if it is known that the function  $f(x)$  satisfies the differential equation

$$f'(x) + \alpha \cdot e^x (f(x))^2 = 0,$$

with initial condition  $f(0) = 1/\alpha$ , where  $\alpha > 0$  is some constant. Next use Sage to solve the given differential equation for  $\alpha = 3$ .

**Solution.** Let us write  $y = f(x)$ . Then, the given differential equation takes the form as  $y' = -\alpha \cdot e^x y^2$ , or equivalently

$$\frac{dy}{dx} = -\alpha \cdot e^x y^2 \iff -\frac{dy}{y^2} = \alpha \cdot e^x dx.$$

Hence, by integrating we obtain

$$-\int \frac{dy}{y^2} = \alpha \int e^x dx,$$

which is equivalent to

$$-\int y^{-2} dy = \alpha e^x + C$$

that is,  $y^{-1} = \alpha e^x + C$ . Thus  $y = f(x) = \frac{1}{\alpha e^x + C}$  and to find  $C$  one relies on the initial condition  $f(0) = 1/\alpha$ , which gives  $C = 0$ . Thus  $f(x) = \frac{1}{\alpha e^x}$  and we see that  $\lim_{x \rightarrow +\infty} f(x) = 0$ .

Recall by 6.B.5 that a method to solve (1st order) ODEs relies on the command `desolve`. Since  $a = 3$  in this case one can type

```
var("x"); y = function("y")(x)
a=3; show(desolve(diff(y, x) + a*e^x*y^2, y))
```

and Sage's output has the form  $\frac{1}{3y(x)} = C + e^x$ , which is of course equivalent to our answer for  $a = 3$ .  $\square$

**6.B.64.** Solve the ODE  $\frac{dy}{dx} = e^{\sin(x)} \cos(x) y^{1/2}$  with initial condition  $y(0) = 16$ .  $\circ$

**6.B.65.** Solve the task in 6.B.64 using Sage. Moreover, plot the solution together with the "slope field" of the corresponding differential equation.

**Solution.** Recall by 6.B.5 that in order to solve an initial value problem in Sage we use the `desolve` command and include the option `ics = [x0, y0]` (or simply `[x0, y0]`), where  $y_0 = y(x_0)$  represents the initial condition. Thus, in our case one can type

```
var("x")
y = function("y")(x)
h=desolve(diff(y, x) - e^(sin(x))*cos(x)*sqrt(y),
y, ics=[0, 16])
show(h)
```

which prints out the expression  $2\sqrt{y(x)} = e^{\sin(x)} + 7$ , hence confirms our result in 6.B.64.

Having a differential equation of the form  $y' = F(x, y)$ , plotting the slope field means that we plot a line at  $(x, y)$  with slope  $F(x, y)$ . Such details will be analyzed more carefully in Chapter 8. However, we may already discuss the built-in method that Sage provides for this procedure.

CONSEQUENCES FOR UNIFORM CONVERGENCE OF SERIES

**Theorem.** Consider a sequence of functions  $f_n(x)$  on interval  $[a, b]$ .

(1) If all the functions  $f_n(x)$  are continuous on  $[a, b]$  and the series

$$S(x) = \sum_{n=1}^{\infty} f_n(x)$$

converges uniformly to the function  $S(x)$ , then  $S(x)$  is continuous on  $[a, b]$ .

(2) If all the functions  $f_n(x)$  are Riemann integrable on  $[a, b]$  and the series

$$S(x) = \sum_{n=1}^{\infty} f_n(x)$$

uniformly converges to  $S(x)$  on  $[a, b]$ , then  $S(x)$  is integrable on  $[a, b]$  and

$$\int_a^b \left( \sum_{n=1}^{\infty} f_n(x) \right) dx = \sum_{n=1}^{\infty} \int_a^b f_n(x) dx.$$

(3) If all the functions  $f_n(x)$  are continuously differentiable on the interval  $[a, b]$ , if the series  $S(x) = \sum_{n=1}^{\infty} f_n(x)$  converges for some  $x_0 \in [a, b]$ , and if the series  $T(x) = \sum_{n=1}^{\infty} f'_n(x)$  converges uniformly on  $[a, b]$ , then the series  $S(x)$  converges.  $S(x)$  is continuously differentiable on  $[a, b]$  and  $S'(x) = T(x)$ . That is:

$$\frac{d}{dx} \left( \sum_{n=1}^{\infty} f_n(x) \right) = \sum_{n=1}^{\infty} \frac{d}{dx} f_n(x).$$

**6.3.8. Test of uniform convergence.** A simple way to test that a series of functions converges uniformly is to use a comparison with the absolute convergence of a suitable series of numbers. This is often called the *Weierstrass test*.

Suppose a sequence of functions  $f_n(x)$  is given on an interval  $I = [a, b]$  satisfying

$$|f_n(x)| \leq a_n \in \mathbb{R}$$

for suitable real constants  $a_n$  and for all  $x \in [a, b]$ . Let

$$s_k(x) = \sum_{n=1}^k f_n(x)$$

for distinct indices  $k$ . For  $k > m$ ,

$$\begin{aligned} |s_k(x) - s_m(x)| &= \left| \sum_{n=m+1}^k f_n(x) \right| \\ &\leq \sum_{n=m+1}^k |f_n(x)| \leq \sum_{n=m+1}^k a_n. \end{aligned}$$

The latter is based on the syntax `plot_slope_field`, but first we need to introduce the function  $F$  representing the differential equation. One can also plot the solution curves (“integral curves”), as slope fields, via the command `streamline_plot(F(x, y), (x, a, b), (y, a, b))`. For our task, we have  $\frac{dy}{dx} = e^{\sin(x)} \cos(x)y^{1/2}$ , thus we need to consider the function  $F(x, y) = e^{\sin(x)} \cos(x)y^{1/2}$ , and the implementation takes the form

```
var("x, y")
c1=implicit_plot(2*sqrt(y)==e^(sin(x))+7,
(x, 0, 25), (y, 0, 25))
F(x, y)=e^(sin(x))*cos(x)*sqrt(y)
p1=plot_slope_field(F(x, y), (x, 0, 25), (y, 0, 25))
p2=streamline_plot(F(x, y), (x, 0, 25), (y, 0, 25))
show(p1+c1, figsize=6); show(p2, figsize=6)
```

This produces the following figures

Here, at the left hand side with blue appears the solution of our initial value problem, while the slope field has grey colour and appears in the background. At the right hand side we see the integral curves, as slope fields. □

*Numerical integration is a fundamental technique in computational mathematics, used to approximate the area under a curve, especially when an exact analytical solution is challenging or impossible to obtain. It complements the numerical differentiation that we met earlier in 6.1.12 and is invaluable for analyzing functions where direct solutions are impractical. Below, we will explore examples using the trapezoid rule and Simpson's rule, see 6.2.23.*

**6.B.66. Trapezoid rule.** Compute the error of estimating the integral

$$I = \int_0^\pi \sin(x) dx$$

by the trapezoid rule with  $n = 4$  intervals. Demonstrate this by the following two ways:

- i) Compute the actual error given by the difference  $|I - I_{\text{trap}}|$ .
- ii) Apply the formula  $\frac{(b-a)h^2}{12} |f''|$ , where  $|f''|$  represents an upper estimate of  $|f''(x)|$  over the integral of integration  $[a, b]$ , where  $f(x) = \sin(x)$ .

**Solution.** The trapezoid rule with  $n = 4$  intervals has the form

$$I_{\text{trap}} = \frac{h}{2} [f(x_0) + 2f(x_1) + 2f(x_2) + 2f(x_3) + f(x_4)],$$

If the series of the (nonnegative) constants  $\sum_{n=1}^\infty a_n$  is convergent, then the sequence of its partial sums is a Cauchy sequence. But then the sequence of partial sums  $s_n(x)$  is uniformly Cauchy.

By 6.3.5 the following is verified:

THE WEIERSTRASS TEST

**Theorem.** Let  $f_n(x)$  be a sequence of functions defined on interval  $[a, b]$  with  $|f_n(x)| \leq a_n \in \mathbb{R}$ .

If the series of numbers  $\sum_{n=1}^\infty a_n$  is convergent, then the series  $S(x) = \sum_{n=1}^\infty f_n(x)$  converges uniformly.

**6.3.9. Consequences for power series.** The Weierstrass test allows us to derive the properties of power series in a very straightforward way. Consider a series

$$S(x) = \sum_{n=0}^\infty a_n(x - x_0)^n$$

centered at a point  $x_0$ .

We saw earlier in 5.4.9, that each power series converges on an entire interval  $(x_0 - \delta, x_0 + \delta)$ . The radius of convergence  $\delta \geq 0$  can be zero or  $\infty$ , see 5.4.13. Moreover, the series obtained by integrating or differentiating a power series term by term must have the same radius of convergence (by the very formula based on  $\limsup$ ).

In the proof of theorem 5.4.9, a comparison with a suitable geometric series is used to verify the convergence of power series. By the Weierstrass test, every power series  $S(x)$  converges uniformly on every compact (i.e. bounded closed) interval  $[a, b]$  contained in the interval  $(x_0 - \delta, x_0 + \delta)$ . Thus the crucial result follows again:

DIFFERENTIATION AND INTEGRATION OF POWER SERIES

**Theorem.** Every power series  $S(x)$  is continuous and is continuously differentiable at all points inside its interval of convergence. The function  $S(x)$  is Riemann integrable and can be differentiated or integrated done term by term.

*Abel's theorem* states that power series are continuous even at the boundary points of their domain when they converge there (including eventual infinite limits). We do not prove it here.

The pleasant properties of power series also reveal limitations on the use in practical modelling. In particular, it is not possible to approximate piece-wise continuous or non-differentiable functions very well by using power series. Of course, it should be possible to find better sets of functions  $f_n(x)$  than just the values  $f_n(x) = x^n$ , up to constants. The best known examples are Fourier series and wavelets discussed in the next chapter.

where the step size  $h$  satisfies  $h = \frac{b-a}{n}$ , see 6.2.23. For our case we have  $f(x) = \sin(x)$ ,  $a = 0$ ,  $b = \pi$  and  $h$  equals  $\pi/4$ . Thus,  $x_0 = 0$ ,  $x_1 = \pi/4$ ,  $x_2 = \pi/2$ ,  $x_3 = 3\pi/4$ , and  $x_4 = \pi$ , with  $f(x_0) = 0 = f(x_4)$ ,  $f(x_1) = \frac{\sqrt{2}}{2} = f(x_3)$  and  $f(x_2) = 1$ . This gives

$$I_{\text{trap}} = \frac{\pi}{8} [2(1 + \sqrt{2})] \approx 1.896,$$

where we used Sage to compute this expression by the command

```
N((pi/8)*2*(1+sqrt(2)))
```

An illustration of the trapezoid rule is given here

Let us now derive the actual error of the estimation as suggested in (i). You can easily compute  $I = 2$ , thus

$$|I - I_{\text{trap}}| \approx \left| \int_0^\pi \sin(x) dx - 1.896 \right| \approx 0.104.$$

This error should not differ dramatically from the result in (ii). Indeed, we see that  $f''(x) = -\sin(x)$  and over the interval  $[0, \pi]$  the maximum value of  $|f''(x)| = |\sin(x)|$  equals 1. This gives us

$$\frac{(b-a)^3}{12n^2} \max_{x \in [0, \pi]} |f''(x)| \stackrel{n=4}{=} \frac{\pi^3}{192} \approx 0.162.$$

Therefore, the actual error 0.104 is less than the theoretical upper bound 0.162, which is consistent with the idea that the theoretical error estimate often provides an upper bound on the actual error.

We also conclude that the trapezoid rule underestimates the actual integral value. This occurs because  $f(x) = \sin(x)$  is concave (down) on the interval of integration, i.e.,  $f''(x) < 0$  for all  $x \in [0, \pi]$ . This characteristic is typical of the trapezoid rule's behaviour with concave functions, as illustrated in the figure above. □

**6.B.67.** Create a routine in Sage to demonstrate the computation of the trapezoid rule with  $n$  intervals. Apply your program to estimate the integral

$$L = \int_{\pi/2}^{3\pi/2} \cos(x) dx,$$

with  $n = 4$ . Additionally, provide a formal proof, and calculate both the actual and theoretical errors of the estimation, as discussed in 6.B.66. ○

**6.B.68.** Apply the Simpson's rule to approximate the integral

$$I = \int_0^1 \frac{1}{1+x} dx \text{ with } h = 1/4 \text{ and } h = 1/2 \text{ respectively.}$$

**6.3.10. Laurent series.** We return to the smooth function  $f(x) = e^{-1/x^2}$  from paragraph 6.1.9 in the context of Taylor series expansions. It is not analytic at the origin, because all its derivatives are zero there and the function is strictly positive at all other points. At all points  $x_0 \neq 0$  this function is given by its convergent Taylor series with radius of convergence  $r = |x_0|$ . At the origin the Taylor series converges only at the one point 0.

Replace  $x$  with the expression  $-1/x^2$  into the power series for  $e^x$ . The result is the series of functions

$$S(x) = \sum_{n=0}^{\infty} \frac{1}{n!} (-1)^n x^{-2n} = \sum_{n=-\infty}^0 \frac{(-1)^{|n|}}{|n|!} x^{2n}.$$

The series converges at all points  $x \neq 0$ . It gives a good idea about the behaviour near the exceptional point  $x = 0$ .

Thus we consider the following series similar to power series but more general:

### LAURENT<sup>7</sup> SERIES

A series of functions of the form

$$S(x) = \sum_{n=-\infty}^{\infty} a_n (x - x_0)^n$$

is called a *Laurent series centered at  $x_0$* . The series is convergent if both its parts with positive and negative exponents converge separately.

The importance of Laurent series can be seen with rational functions. Consider such a function  $S(x) = f(x)/g(x)$  with coprime polynomials  $f$  and  $g$  and consider a root  $x_0$  of polynomial  $g(x)$ . If the multiplicity of this root is  $s$ , then after multiplication we obtain the function  $\tilde{S}(x) = S(x)(x - x_0)^s$ , which is analytic on some neighbourhood of  $x_0$ . Therefore we can write

$$\begin{aligned} S(x) &= \frac{a_{-s}}{(x-x_0)^s} + \dots + \frac{a_{-1}}{x-x_0} + a_0 + a_1(x-x_0) + \dots \\ &= \sum_{n=-s}^{\infty} a_n (x-x_0)^n. \end{aligned}$$

Consider the two parts of the Laurent series separately:

$$S(x) = S_- + S_+ = \sum_{n=-\infty}^{-1} a_n (x-x_0)^n + \sum_{n=0}^{\infty} a_n (x-x_0)^n.$$

For the series  $S_+$ , Theorem 5.4.9 implies that its radius of convergence  $R$  is given by  $R^{-1} = \limsup_{n \rightarrow \infty} \sqrt[n]{|a_n|}$ . Apply the same idea to the series  $S_-$  with  $1/x$  substituted for  $x$ . It is then apparent that the series  $S_-(x)$  converges for  $|x-x_0| > r$ , where  $r = \limsup_{n \rightarrow \infty} \sqrt[n]{|a_{-n}|}$ .

<sup>7</sup>Pierre Alphonse Laurent (1813-1854) was a French engineer and military officer. He submitted his generalization of the Taylor series into the Grand Prix competition of the French Académie des Sciences. For formal reasons it was not considered. It was published much later, after the author's death.

Then, compare the accuracy of these results with those obtained using the trapezoidal rule. Which method provides a better approximation? ○

**6.B.69.** Create a routine in Sage to demonstrate the computation of the Simpson’s rule with  $n$  intervals, where  $n$  is an even integer. Next use your program to verify the result presented in 6.B.68 for  $h = 1/4$ , and illustrate the Simpson’s approximation. ○

**6.B.70.** Calculate the theoretical error  $\frac{(b-a)^5}{180 n^4} |f^{(4)}|$  of Simpson’s approximation with  $h = 1/4$  for the integral  $I$  given in 6.B.68, where  $|f^{(4)}|$  represents the upper bound of  $|f^{(4)}(x)|$  with  $x \in [0, 1]$ . Then, compare this theoretical error with the actual error computed earlier. ○

**C. Sequences, series and limit processes**

*We are already familiar with sequences of real numbers, power series and the concept of convergence. Our aim now is to readdress the discussion on series of functions in light of the methods of differential and integral calculus.*

*First we will consider sequences whose terms are functions rather than real or complex numbers. Sequences of functions naturally arise in real analysis and are crucial in approximation theory. We will illustrate the consequences of the uniform convergence of sequences and series of functions through numerous examples. Additionally, we will discuss tasks related to the differentiation and integration of power series, along with other applications. Let us begin, however, with numerical series. Thanks to the integral criterion of convergence (see 6.2.15), one can address the question of convergence for a broader class of series. The next few tasks will highlight this fact.*

**6.C.1. Applications of the integral criterion of convergence.** Decide whether the following sums converge or diverge and confirm your computations in Sage:

$$T_1 = \sum_{n=1}^{\infty} \frac{1}{n \ln n}, \quad T_2 = \sum_{n=1}^{\infty} \frac{1}{n^2}.$$

**Solution.** Observe that we cannot decide the convergence of none of these series by using the ratio or root test. This is because

$$\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n \rightarrow \infty} \sqrt[n]{a_n} = 1.$$

However, using the integral criterion for convergence of series one obtains:

$$\int_1^{\infty} \frac{1}{x \ln(x)} dx = \int_0^{\infty} \frac{1}{t} dt = \lim_{\delta \rightarrow \infty} [\ln(t)]_0^{\delta} = \infty,$$

hence the series  $S_1$  diverges. On the other hand,

$$\int_1^{\infty} \frac{1}{x^2} dx = \lim_{\delta \rightarrow \infty} \left[ -\frac{1}{x} \right]_1^{\delta} = 1,$$

hence the series  $S_2$  converges. □

Notice that the conclusions about convergence remain true even for complex values of  $x$  substituted into the expression. Laurent series can be considered as functions defined on a domain in the complex plain. We return to this in chapter 9. The following theorem is proved already.

CONVERGENCE OF THE LAURENT SERIES ON THE ANNULUS

**Theorem.** *The Laurent series  $S(x)$  centered at  $x_0$  converges for all  $x \in \mathbb{C}$  satisfying  $r < |x - x_0| < R$  and diverges for all  $x$  satisfying  $|x - x_0| < r$  or  $|x - x_0| > R$ , where*

$$r = \limsup_{n \rightarrow \infty} \sqrt[n]{|a_{-n}|}, \quad R^{-1} = \limsup_{n \rightarrow \infty} \sqrt[n]{|a_n|}.$$

The Laurent series need not converge at any point, because possibly  $R < r$ . If we look for an example of the above case of rational functions expanded to Laurent series at some of the roots of the denominator, then clearly  $r = 0$  and therefore, as expected, it converges in the punctured neighbourhood of this point  $x_0$ .  $R$  is given by the distance to the closest root of the denominator. In the case of the first example, the function  $e^{-1/x^2}$ ,  $r = 0$  and  $R = \infty$ .

**6.3.11. Integrals dependent on parameters.**

When integrating a function  $f(x, y_1, \dots, y_n)$  of 1 real variable  $x$  depending on further real parameters  $y_1, \dots, y_n$  with respect to the single variable  $x$ , the result is a function  $F(y_1, \dots, y_n)$  depending on all the parameters. Such a function  $F$  often occurs in practice. For instance, we can look for the volume or area of a body which depends on parameters, and determine the minimal and maximal values (with additional constrains as well). Often it is desirable to interchange the operations of differentiation and integration. That this can be done is proved below. We begin with an examination of continuous dependency on the parameters.

For sake of simplicity, we shall deal with functions  $f(x, y)$  depending on two variables,  $x \in [a, b]$ ,  $y \in [c, d]$ . We say  $f$  is *continuous* on  $I = [a, b] \times [c, d] \subset \mathbb{R}^2 = \mathbb{C}$  if for each  $z = (x, y)$  from the domain of  $f$  and  $\varepsilon > 0$  there is some  $\delta > 0$  such  $|f(w) - f(z)| < \varepsilon$  if  $w \in \mathcal{O}_{\delta}(z)$ . (Notice the definition is the same as with the univariate functions, just we use the distance in the plane.)

The function  $f(x, y)$  is called *uniformly continuous* if for each  $\varepsilon > 0$ , there is  $\delta > 0$  such that for any two points  $z, w$  in  $I \subset \mathbb{R}^2 = \mathbb{C}$ ,  $|z - w| < \delta$  implies  $|f(z) - f(w)| < \varepsilon$ . Exactly the same argument as with univariate functions, based on the fact that every open cover of a compact set in the complex plane contains a finite subcover, cf. Theorem 5.2.8(5), provides the following lemma (cf. the proof of Theorem 6.2.11).

**Lemma.** *Each continuous function  $f(x, y)$  on  $I = [a, b] \times [c, d]$  is uniformly continuous.*

Now we are ready for the following important claim:

**6.C.2.** Using the integral criterion, decide on the convergence of the series

$$\sum_{n=1}^{\infty} \frac{1}{(n+1)\ln^2(n+1)}.$$

**Solution.** The function

$$f(x) = \frac{1}{(x+1)\ln^2(x+1)}, \quad x \in [1, +\infty)$$

is clearly positive and nonincreasing on its whole domain, thus the given series converges if and only if the integral

$$\int_1^{+\infty} f(x) dx$$

converges. By using the substitution  $y = \ln(x+1)$  (where  $dy = dx/(x+1)$ ), we can compute

$$\int_1^{+\infty} \frac{1}{(x+1)\ln^2(x+1)} dx = \int_{\ln 2}^{+\infty} \frac{1}{y^2} dy = \frac{1}{\ln 2}.$$

Hence the series converges.  $\square$

Next we will explore examples related to the concept of “uniform convergence”, which is a stronger notion than pointwise convergence.

Recall that given a sequence of functions  $(f_n)$  defined on an interval  $I = [a, b]$ , we say that  $(f_n)$  converges uniformly to a function  $f$  on  $[a, b]$ , if for every  $\varepsilon > 0$  there exists  $N \in \mathbb{N}$  such that for all  $n \geq N$  and  $x \in [a, b]$  we have  $|f_n(x) - f(x)| < \varepsilon$ . In other words, we have  $f(x) - \varepsilon < f_n(x) < f(x) + \varepsilon$  for all  $n \geq N$  and  $x \in [a, b]$ , thus uniform convergence means that all of the functions  $f_n(x)$  are close to  $f(x)$  for all points  $x \in [a, b]$ , except for finitely many of them, see the figure given below and see also 6.3.3.

Notice that we can equivalent interpret the condition of uniform convergence as (see 6.D.46)

$$\lim_{n \rightarrow \infty} \sup_{x \in [a, b]} |f_n(x) - f(x)| = 0.$$

It is also important to note that uniform convergence implies pointwise convergence (and the uniform limit function is the same as the pointwise limit function), but the converse is not true. Before discussing tasks on uniform convergence, we will first emphasize some natural tasks related to the pointwise

**Theorem.** Assume  $f(x, y)$  is a function defined for all  $x$  lying in a bounded interval  $[a, b]$  and all  $y$  in a bounded interval  $[c, d]$ , continuous on  $I = [a, b] \times [c, d]$ . Consider the (Riemann) integral

$$F(y) = \int_a^b f(x, y) dx.$$

Then the function  $F(y)$  is continuous on  $[c, d]$ .

**PROOF.** Fix a point  $y \in [c, d]$ , small  $\varepsilon > 0$ , and choose a neighbourhood  $W$  of  $y$  such that for all  $\bar{y} \in W \subset [c, d]$  and all  $x \in [a, b]$  (remember  $f$  is uniformly continuous)

$$|f(x, \bar{y}) - f(x, y)| < \varepsilon.$$

The Riemann integral of continuous functions is evaluated by approximations of finite sums (equivalently: upper, lower, or Riemann sums with arbitrary representatives  $\xi_i$ , see paragraph 6.2.9).

The goal is to establish that the Riemann sums for the integrals with parameters  $y$  and  $\bar{y}$  cannot differ much. In the following estimate for any partition with  $k$  intervals and representatives  $\xi_i$ , first use the standard properties of the absolute value and then exploit the choice of  $W$ :

$$\begin{aligned} & \left| \sum_{i=0}^{k-1} f(\xi_i, \bar{y})(x_{i+1} - x_i) - \sum_{i=0}^{k-1} f(\xi_i, y)(x_{i+1} - x_i) \right| \\ & \leq \sum_{i=0}^{k-1} |f(\xi_i, \bar{y}) - f(\xi_i, y)|(x_{i+1} - x_i) \\ & < \varepsilon(b - a). \end{aligned}$$

It follows that the limit values for any sequences of the partitions and representatives  $F(y)$  and  $F(\bar{y})$  cannot differ by more than  $\varepsilon(b-a)$  either, so the function  $F$  is continuous.  $\square$

**6.3.12. Integrating twice.** The fact that the integral  $F(y) = \int_a^b f(x, y) dx$  of a continuous function  $f : [a, b] \times [c, d] \rightarrow \mathbb{R}$  in the plane is again a continuous function  $F : [c, d] \rightarrow \mathbb{R}$  allows us to repeat the integration and write

$$(1) \quad I = \int_c^d \int_a^b f(x, y) dx dy = \int_c^d \left( \int_a^b f(x, y) dx \right) dy.$$

The next theorem is the simplest version of the claim known as *Fubini theorem*.

FUBINI THEOREM

**Theorem.** Consider a continuous function  $f : [a, b] \times [c, d] \rightarrow \mathbb{R}$  in the plane  $\mathbb{R}^2$ . The multiple integration (1) is well defined and does not depend on the order of integration, i.e.,

$$I = \int_c^d \left( \int_a^b f(x, y) dx \right) dy = \int_a^b \left( \int_c^d f(x, y) dy \right) dx.$$

convergence of sequences of functions. See also the discussion in 6.3.1, where similar problems are addressed.

**6.C.3.** Provide an example for each of the following scenarios:

- (a) A sequence of continuous functions  $(f_n)$  that converges pointwise to a function  $f$  which is discontinuous;
- (b) A sequence of differentiable functions  $(f_n)$  that converges pointwise to a function  $f$  which is non-differentiable;
- (c) A sequences of integrable functions  $(f_n)$  that converges pointwise to a function  $f$  which is non-integrable.  $\circ$

**6.C.4.** Inspect which of the sequences  $(f_n)_{n \in \mathbb{Z}_+}$  given below, converge uniformly on the given domain:

- (1)  $f_n(x) = \sin(nx)/n$ , with  $x \in \mathbb{R}$ ;
- (2)  $f_n(x) = nx/(n+x)$ , with  $x \in [0, 1]$ ;
- (3)  $f_n(x) = e^{\frac{x^4}{4n^2}}$ , with  $x \in \mathbb{R}$ ;
- (4)  $f_n(x) = e^{\frac{x}{n}}$ , with  $x \in [0, 1]$ ;
- (5)  $f_n(x) = x^n$ , with  $x \in [0, 1]$ .

**Solution.** (1) In the first case it is easy to see that  $f_n \rightarrow 0$  pointwise on  $\mathbb{R}$ , that is, the limit function is the zero one,  $f(x) = 0$ . The sequence  $(f_n)$  also converges uniformly on  $\mathbb{R}$ . This is essentially derived from the inequality

$$|f_n(x)| = \left| \frac{\sin(nx)}{n} \right| = \frac{|\sin(nx)|}{n} \leq \frac{1}{n}.$$

Thus, given some  $\varepsilon > 0$ , we will have  $|f_n(x) - 0| < \varepsilon$  for all  $x \in \mathbb{R}$  if  $n > \frac{1}{\varepsilon}$ . Since  $\frac{1}{\varepsilon}$  does not depend on  $x$  we conclude.

(2) We may express  $f_n$  as

$$f_n(x) = \frac{x}{1 + \frac{x}{n}}, \quad x \in [0, 1],$$

and it is obvious that  $(f_n)$  is pointwise convergent on  $[0, 1]$  with  $\lim_{n \rightarrow \infty} f_n(x) = f(x) = x$ , for all  $x \in [0, 1]$ . Next we see that

$$|f_n(x) - f(x)| = \frac{x^2}{n+x} \leq \frac{1}{n}, \quad x \in [0, 1]$$

and using this we deduce that  $\sup_{x \in [0,1]} |f_n(x) - f(x)| \leq \frac{1}{n}$ . Thus  $\lim_{n \rightarrow \infty} \sup_{x \in [0,1]} |f_n(x) - f(x)| = 0$  and  $(f_n)$  is uniformly convergent in the interval  $[0, 1]$ .

(3) The sequence  $(f_n)_{n \in \mathbb{Z}_+}$  converges pointwise to the constant function  $f(x) = 1$  on  $\mathbb{R}$ , since

$$\lim_{n \rightarrow \infty} e^{\frac{x^4}{4n^2}} = e^0 = 1, \quad x \in \mathbb{R}.$$

However, we see that  $f_n(\sqrt{2n}) = e > 2$ , for all  $n \in \mathbb{Z}_+$ , which does not allow uniform convergence over  $\mathbb{R}$  (be aware that in the definition of uniform convergence, it suffices to consider  $\varepsilon \in (0, 1)$ ).

(4) Obviously,  $\lim_{n \rightarrow \infty} e^{\frac{x}{n}} = 1$ , i.e., the pointwise limit function is the constant function  $f(x) = 1$ . Next we see that

$$\sup_{x \in [0,1]} |f_n(x) - f(x)| = \sup_{x \in [0,1]} (e^{\frac{x}{n}} - 1) = e^{\frac{1}{n}} - 1,$$

**PROOF.** We know  $f$  is uniformly continuous on the product of intervals  $[a, b] \times [c, d]$  in the plane. Thus, for each  $\varepsilon > 0$  there is  $\delta > 0$  such that  $|f(x_1, y_1) - f(x_2, y_2)| < \varepsilon$  whenever  $|x_1 - x_2| < \delta$  and  $|y_1 - y_2| < \delta$ .

We know both Riemann integrals in (1) exist, thus we may fix a sequence  $\Xi_k$  of partitions of the interval  $[a, b]$  into  $k$  subinterval  $[x_{i-1}, x_i]$  of equal size  $1/k$  and with representatives  $\xi_{i,k}$ ,  $i = 1, \dots, k$ , and similarly for the interval  $[c, d]$  with the subintervals  $[y_{j-1}, y_j]$  and representatives  $\eta_{j,k}$ ,  $j = 1, \dots, k$ . Then we may write

$$I = \int_c^d \lim_{k \rightarrow \infty} S_k(y) dy, \quad S_k(y) = \left( \sum_{i=1}^k f(\xi_{i,k}, y) \frac{1}{k} (b-a) \right)$$

If  $\frac{1}{k} < \delta$ , then

$$\begin{aligned} & \left| \int_a^b f(x, y) dx - \sum_{i=1}^k f(\xi_{i,k}, y) \frac{1}{k} (b-a) \right| \\ & \leq \sum_{i=1}^k \left| \int_{x_{i-1}}^{x_i} f(x, y) dx - f(\xi_{i,k}, y) \frac{1}{k} (b-a) \right| \\ & \leq \sum_{i=1}^k \int_{x_{i-1}}^{x_i} |f(x, y) - f(\xi_{i,k}, y)| dx \\ & \leq \varepsilon (b-a). \end{aligned}$$

Thus, the convergence of

$$\lim_{k \rightarrow \infty} S_k(y) = F(y) = \int_a^b f(x, y) dx$$

is uniform on  $[c, d]$ . In particular, we may swap the integral and the limit to obtain

$$\begin{aligned} I &= \lim_{k \rightarrow \infty} \int_c^d \left( \sum_{i=1}^k f(\xi_{i,k}, y) \frac{1}{k} (b-a) \right) dy \\ &= \lim_{k \rightarrow \infty} \sum_{i=1}^k \left( \int_c^d f(\xi_{i,k}, y) dy \right) \frac{1}{k} (b-a) \\ &= \lim_{k \rightarrow \infty} \left( \lim_{\ell \rightarrow \infty} \sum_{i=1}^k \sum_{j=1}^{\ell} f(\xi_{i,k}, \eta_{j,\ell}) \frac{1}{k} \frac{1}{\ell} (b-a)(d-c) \right). \end{aligned}$$

This double limit can be clearly rewritten as

$$\lim_{k \rightarrow \infty} \left( \sum_{i=1}^k \sum_{j=1}^{\ell_k} f(\xi_{i,k}, \eta_{j,\ell_k}) \frac{1}{k} \frac{1}{\ell_k} (b-a)(d-c) \right)$$

for a suitable sequence of indices  $\ell_k \rightarrow \infty$ .

Finally, take any sequence of indices  $k_n \rightarrow \infty$  and  $\ell_n \rightarrow \infty$ , divide intervals  $(a, b)$  and  $(c, d)$  to  $k_n$  and  $\ell_n$  equal parts, and choose some representatives  $(x_{i,k_n}, y_{j,\ell_n})$  in all the corresponding small rectangles. Then the absolute value of the difference

$$\sum_{i=1}^{k_n} \sum_{j=1}^{\ell_n} f(\xi_{i,k_n}, \eta_{j,\ell_n}) - \sum_{i=1}^{k_n} \sum_{j=1}^{\ell_n} f(x_{i,k_n}, y_{j,\ell_n})$$

and hence

$$\lim_{n \rightarrow \infty} \sup_{x \in [0,1]} |f_n(x) - f(x)| = \lim_{n \rightarrow \infty} (e^{\frac{1}{n}} - 1) = 1 - 1 = 0.$$

Thus  $(f_n)$  is uniformly convergent over  $[0, 1]$ .

(5) Let us first use Sage to sketch some members of  $(f_n)$ . We use the following cell:

```
q=plot(x^5, x, 0, 1, color="steelblue")
q+= text (r"$f_5(x)=x^5$", (0.84, 0.25),
color="steelblue", fontsize="14")
#q+=plot(x^5, x, 0, pi, color="black")
q+=plot(x^4, x, 0, 1, color="darkgreen")
q+= text (r"$x^4$", (0.8, 0.47),
color="darkgreen", fontsize="14")
q+=plot(x^3, x, 0, 1, color="magenta")
q+= text (r"$x^3$", (0.8, 0.57),
color="magenta", fontsize="14")
q+=plot(x^2, x, 0, 1, color="orange")
q+= text (r"$x^2$", (0.8, 0.7),
color="orange", fontsize="14")
q+=plot(x, x, 0, 1, color="darkred")
q+= text (r"$f_1(x)=x$", (0.74, 0.85),
color="darkred", fontsize="14")
q+=line([(1, 0), (1, 1^5)], linestyle="--")
q.show(ymax=1)
```

Executing this block we obtain the graph of the first 5 members of the sequence  $(f_n)$ , which we present here:

An alternative but less informative way to plot some terms of  $(f_n)$  goes as follows:

```
var("n"); f(n, x)=x^n
p=plot([f(n, x) for n in [1, 2..5]], (x, 0, 1))
show(p)
```

As we have already seen in Chapter 5 (see 5.B.3), the limit function of  $(f_n(x) = x^n)$  on  $[0, 1]$  is given by

$$\lim_{n \rightarrow \infty} (x^n) = f(x) = \begin{cases} 0, & \text{if } x \in [0, 1), \\ 1, & \text{if } x = 1. \end{cases}$$

Thus

$$|f_n(x) - f(x)| = \begin{cases} 0, & \text{for } x = 1, \\ |x^n|, & \text{for } x \in [0, 1), \end{cases}$$

is at most  $\varepsilon(b-a)(c-d)$  whenever  $\frac{1}{k_n} < \delta$  and  $\frac{1}{\ell_n} < \delta$ . Thus, we see that the value of the iterated integral can be expressed as the limit of double sums, where the representatives of the individual rectangles are chosen arbitrarily.<sup>8</sup> This expression does not depend on the order of our integration and thus the two possibilities for the iterated integrals must coincide.  $\square$

**6.3.13. Differentiation in the integrals.** We are ready to discuss the differentiation of integrals with respect to parameters. The following result is extremely useful. For instance we shall use it in the next chapter when examining integral transforms.

DIFFERENTIATION WITH RESPECT TO PARAMETERS

**Theorem.** Consider a continuous function  $f(x, y)$  defined for all  $x$  from a finite interval  $[a, b]$  and for all  $y$  in another finite interval  $[c, d]$ , a point  $z \in [c, d]$ , and the integral

$$F(y) = \int_a^b f(x, y) dx.$$

If there exists the continuous derivative  $\frac{d}{dy} f$  on a neighbourhood of the point  $z$ , then  $\frac{d}{dy} F(z)$  exists as well and

$$\frac{d}{dy} F(z) = \int_a^b \frac{d}{dy} f(x, y)|_{y=z} dx.$$

**PROOF.** By the assumed continuity of all functions and the already known continuous dependence of integrals on parameters, some knowledge about univariate antiderivatives can be used. The result is then a simple consequence of the Fubini theorem. Denote

$$G(y) = \int_a^b \frac{d}{dy} f(x, y) dx, \quad F(y) = \int_a^b f(x, y) dx$$

and compute, invoking Fubini theorem, the antiderivative

$$\begin{aligned} H(y) &= \int_{y_0}^y G(z) dz = \int_{y_0}^y \left( \int_a^b \frac{d}{dz} f(x, z) dx \right) dz \\ &= \int_a^b \left( \int_{y_0}^y \frac{d}{dz} f(x, z) dz \right) dx \\ &= \int_a^b (f(x, y) - f(x, y_0)) dx \\ &= F(y) - F(y_0). \end{aligned}$$

Finally, differentiating with respect to  $y$  yields

$$G(y) = \frac{d}{dy} H(y) = \frac{dF}{dy}(y),$$

as desired.  $\square$

<sup>8</sup>Actually, this is the way how we shall define the Riemann integral in more variables in Chapter 8.

which implies that

$$\sup_{x \in [0,1]} |f_n(x) - f(x)| = \sup\{1, 0\} = 1.$$

Therefore,  $\lim_{n \rightarrow \infty} \sup_{x \in [0,1]} |f_n(x) - f(x)| = 1 \neq 0$ , and  $(x^n)_{n \in \mathbb{Z}_+}$  is not uniformly convergent on  $[0, 1]$ .  $\square$

**6.C.5.** Demonstrate that the sequence  $(f_n)_{n \in \mathbb{Z}_+}$  of non-negative functions defined by the given graph, pointwise converges to 0, yet it does not converge uniformly on  $[0, +\infty)$ .

**6.C.6.** Show that the sequence  $(f_n)_{n \in \mathbb{Z}_+}$  of functions defined by

$$f_n : \mathbb{R} \rightarrow \mathbb{R}, \quad f_n(x) = \sqrt{x^2 + \frac{1}{n^2}},$$

converges uniformly on  $\mathbb{R}$ .

**6.C.7.** (a) Provide an example of sequences  $(f_n), (g_n)$  that converge uniformly on a set  $I$ , but the product sequence  $(f_n \cdot g_n)$  does not converge uniformly on  $I$ .

(b) Suppose that the sequences  $(f_n), (g_n)$  converge uniformly to  $f, g$ , respectively, on a set  $I$ . Assume also that there exists some  $M > 0$  such that  $|f(x)| < M$  and  $|g(x)| < M$  for all  $x \in I$ . Show that the sequence  $(f_n \cdot g_n)$  uniformly converges to  $f \cdot g$  on  $I$ .

**6.C.8.** Inspect which of the sequences  $(f_n)_{n \in \mathbb{Z}_+}$  given below, converge uniformly on the given domain.

*Similarly with uniform convergence of sequences of functions, we can explore series of functions which converge uniformly on an interval. This is the case when the sequence of the partial sums converges uniformly. Uniform convergence of series has many applications. For instance, in Chapter 7 we will discuss the uniform convergence of trigonometric series, specifically focusing on Fourier series.*

**6.C.9.** Decide whether the series

$$\sum_{n=1}^{\infty} \frac{\sqrt{x} \cdot n}{n^4 + x^2}$$

converges uniformly on the interval  $(0, +\infty)$ .

**Solution.** Using the denotation

**6.3.14. The Riemann–Stieltjes integral.** To end this chapter, we mention briefly some other concepts of integration. Mostly we confine ourselves to remarks and comments. Readers interested in a thorough explanation can find another source.

First, a modification of the Riemann integral, which is useful when discussing probability and statistics. In the discussion of integration, we summed infinitely many linearized (infinitely) small increments of the area given by a function  $f(x)$ . We omitted the possibility that for different values of  $x$  we could take the increments with different weights. This can be arranged at the infinitesimal level by exchanging the differential  $dx$  for  $\varphi(x)dx$  for some suitable function  $\varphi$ , or we could even take some single points as adding the weight independently of the size of our intervals in the partitions.

Imagine that at some point  $x_0$ , the increment of the integrated quantity is given by  $\alpha f(x_0)$  independently of the size of the increment of  $x$ . For example, we may observe the probability that the amount of alcohol per mille in the blood of a driver at a test will be at most  $x$ . We might like to integrate over the possible values in the interval  $[0, x]$ . With quite a large probability the value is 0. Thus for any integral sum, the segment containing zero contributes by a constant nonzero contribution, independent of the norm of the partition.

We cannot simulate such behaviour by multiplying the differential  $dx$  by some real function. Instead we generalize the Riemann integral in the following way:

#### RIEMANN–STIELTJES INTEGRAL

Choose a real (usually) nondecreasing function  $g$  on a finite interval  $[a, b]$ . For every partition  $\Xi$  with representative  $\xi_i$  and points of the partition

$$a = x_0, x_1, \dots, x_n = b$$

the Riemann–Stieltjes integral sum of function  $f(x)$  is

$$S_{\Xi} = \sum_{i=1}^n f(\xi_i)(g(x_i) - g(x_{i-1})).$$

The Riemann–Stieltjes integral

$$I = \int_a^b f(x)dg(x)$$

exists and its value is  $I$ , if for every real  $\varepsilon > 0$  there exists a norm of the partition  $\delta > 0$  such that for all partitions  $\Xi$  with norm smaller than  $\delta$ ,

$$|S_{\Xi} - I| < \varepsilon.$$

For example, choose  $g(x)$  on interval  $[0, 1]$  as a piecewise constant function with finitely many discontinuities  $c_1, \dots, c_k$  and “jumps”

$$\alpha_i = \lim_{x \rightarrow c_i+} g(x) - \lim_{x \rightarrow c_i-} g(x),$$

$$f_n(x) = \frac{\sqrt{x} \cdot n}{n^4 + x^2}, \quad x > 0, \quad n \in \mathbb{N},$$

we have

$$f'_n(x) = \frac{n(n^4 - 3x^2)}{2\sqrt{x}(n^4 + x^2)^2}, \quad x > 0, \quad n \in \mathbb{N}.$$

From now on, let  $n \in \mathbb{N}$  be arbitrary. The inequalities  $f'_n(x) > 0$  for  $x \in (0, n^2/\sqrt{3})$  and  $f'_n(x) < 0$  for  $x \in (n^2/\sqrt{3}, +\infty)$  imply that the maximum of function  $f_n$  is attained exactly at the point  $x = n^2/\sqrt{3}$ . Since

$$f_n\left(\frac{n^2}{\sqrt{3}}\right) = \frac{\sqrt[4]{27}}{4n^2} \quad \text{a} \quad \sum_{n=1}^{\infty} \frac{\sqrt[4]{27}}{4n^2} = \frac{\sqrt[4]{27}}{4} \sum_{n=1}^{\infty} \frac{1}{n^2} < +\infty,$$

according to the Weierstrass test, the series  $\sum_{n=1}^{\infty} f_n(x)$  converges uniformly on the interval  $(0, +\infty)$ .  $\square$

**6.C.10.** For  $x \in [-1, 1]$ , add

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n(n+1)} x^{n+1}.$$

**Solution.** First notice that by the symbol for an indefinite integral, we'll denote one specific primitive function (while preserving the variable), which should be understood as a so called function of the upper limit, while the lower limit is zero. Using the theorem about integration of a power series for  $x \in (-1, 1)$ , we'll obtain

$$\begin{aligned} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n(n+1)} x^{n+1} &= \sum_{n=1}^{\infty} \left( \frac{(-1)^{n+1}}{n} \int x^n dx \right) \\ &= \int \sum_{n=1}^{\infty} \left( \frac{(-1)^{n+1}}{n} x^n \right) dx \\ &= \int \sum_{n=1}^{\infty} ((-1)^{n+1} \int x^{n-1} dx) dx \\ &= \int \left( \int \sum_{n=1}^{\infty} (-x)^{n-1} dx \right) dx = \int \left( \int 1 - x + x^2 - x^3 + \dots dx \right) dx \\ &= \int \left( \int \frac{1}{1+x} dx \right) dx = \int \ln(1+x) + C_1 dx. \end{aligned}$$

Since

$$\int \sum_{n=1}^{\infty} \left( \frac{(-1)^{n+1}}{n} x^n \right) dx = \int \ln(1+x) + C_1 dx,$$

we know from the continuity of the given functions that

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} x^n = \ln(1+x) + C_1, \quad x \in (-1, 1).$$

The choice  $x = 0$  then yields  $0 = \ln 1 + C_1$ , i.e.  $C_1 = 0$ . Next,

$$\begin{aligned} \int \ln(1+x) dx &= \text{per partes} \\ &= \left| \begin{array}{ll} u = \ln(1+x) & u' = \frac{1}{1+x} \\ v' = 1 & v = x \end{array} \right| \\ &= x \ln(1+x) - \int \frac{x}{1+x} dx = x \ln(1+x) - \int 1 - \frac{1}{1+x} dx \\ &= x \ln(1+x) - x + \ln(1+x) + C_2 \\ &= (x+1) \ln(x+1) - x + C_2. \end{aligned}$$

Since the given series converges at the point  $x = 0$  with a sum of 0, analogously as for  $C_1$ ,

$$0 = 1 \cdot \ln 1 - 0 + C_2$$

implies that  $C_2 = 0$ . In total, we have for  $x \in (-1, 1)$ :

then the Riemann–Stieltjes integral exists for every continuous  $f(x)$  and equals

$$I = \int_0^1 f(x) dg(x) = \sum_{i=1}^k \alpha_i f(c_i).$$

By the same technique as used for the Riemann integral, we define upper and lower sums and upper and lower Riemann–Stieltjes integral. For bounded functions they always exist, and their values coincide if and only if the Riemann–Stieltjes integral in the above sense exists.

We have already encountered problems with the Riemann integration of functions that are “too jumpy”. For a function  $g(x)$  on a finite interval  $[a, b]$  define its *variation* by

$$\text{var}_a^b g = \sup_{\Xi} \sum_{i=1}^n |g(x_i) - g(x_{i-1})|,$$

where the supremum is taken over all partitions  $\Xi$  of the interval  $[a, b]$ . If the supremum is infinite, we say that  $g(x)$  has unbounded variation on  $[a, b]$ . Otherwise we say that  $g$  is a function with bounded variation on  $[a, b]$ . A function is of bounded variation if and only if it can be written as the difference of two monotonic functions. We shall not provide a proof here.

As in the discussion of the Riemann integral, we derive the following theorem.

PROPERTIES OF THE RIEMANN–STIELTJES INTEGRAL

**Theorem.** Let  $f(x)$  and  $g(x)$  be real functions on a finite interval  $[a, b]$ .

- (1) Suppose  $g(x)$  is non-decreasing and continuously differentiable. Then the Riemann integral on the left hand side and the Riemann–Stieltjes integral on the right hand side either both exist or do not exist. In the former case, their values are equal

$$\int_a^b f(x)g'(x)dx = \int_a^b f(x)dg(x)$$

- (2) If  $f(x)$  is continuous and  $g(x)$  is a function with finite variation, then the integral  $\int_a^b f(x)dg(x)$  exists.

We invite the reader to add the details of its proof. The main tools are the mean theorem, the uniform continuity of continuous functions on closed bounded intervals. The variation of  $g$  over the interval  $[a, b]$  plays the role of the length of the interval in the earlier proofs dealing with Riemann integration.

**6.3.15. Kurzweil–Henstock integral.** The last topic in this chapter is a modification of the Riemann integral, which fixes the unfortunate behaviour at the third point in the paragraph 6.3.1. That is, the limits of the non-decreasing sequences of integrable functions are again integrable. Then we can interchange the order

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n(n+1)} x^{n+1} = (x+1) \ln(x+1) - x.$$

Moreover, according to Abel's theorem (see 6.3.9), the sum of the given series equals the (potentially improper) limit of the function  $(x+1) \ln(x+1) - x$  at points  $-1$  and  $1$ . In our case, both limits are proper (at point  $1$ , the function is even continuous and the value of the limit at point  $1$  then equals the value of the function  $2 \ln 2 - 1$ ). For computing the value of the limit at point  $-1$ , we'll use L'Hospital's rule:

$$\begin{aligned} \lim_{x \rightarrow -1^+} (x+1) \ln(x+1) - x &= \lim_{t \rightarrow 0^+} t \ln t + 1 \\ &= \lim_{t \rightarrow 0^+} \frac{\ln t}{\frac{1}{t}} + 1 = \lim_{t \rightarrow 0^+} \frac{\frac{1}{t}}{-\frac{1}{t^2}} + 1 \\ &= \lim_{t \rightarrow 0^+} -t + 1 = 1. \end{aligned}$$

Of course, the convergence of the series at points  $\pm 1$  can be verified directly. It's even possible to directly deduce that  $\sum_{n=1}^{\infty} \frac{1}{n(n+1)} = 1$  (by writing out  $\frac{1}{n(n+1)} = \frac{1}{n} - \frac{1}{n+1}$ ).  $\square$

**6.C.11. Sum of a series.** Using theorem 6.3.5 "about the interchange of a limit and an integral of a sequence of uniformly convergent functions", we'll now add the number series

$$\sum_{n=1}^{\infty} \frac{1}{n2^n}.$$

We'll use the fact that  $\int_2^{\infty} \frac{dx}{x^{n+1}} = \frac{1}{n2^n}$ .

**Solution.** On interval  $(2, \infty)$ , the series of functions  $\sum_{n=1}^{\infty} \frac{1}{x^{n+1}}$  converges uniformly. That is implied for example by the Weierstrass test: each of the function  $\frac{1}{x^{n+1}}$  is decreasing on interval  $(2, \infty)$ , thus their values are at most  $\frac{1}{2^{n+1}}$ ; the series  $\sum_{n=1}^{\infty} \frac{1}{2^{n+1}}$  is convergent though (it's a geometric series with quotient  $\frac{1}{2}$ ). Hence according to the Weierstrass test, the series of functions  $\sum_{n=1}^{\infty} \frac{1}{x^{n+1}}$  converges uniformly. We can even write the resulting function explicitly. Its value at any  $x \in (2, \infty)$  is the value of the geometric series with quotient  $\frac{1}{x}$ , so if we denote the limit by  $f(x)$ , we have

$$f(x) = \sum_{n=1}^{\infty} \frac{1}{x^{n+1}} = \frac{1}{x^2} \frac{1}{1 - \frac{1}{x}} = \frac{1}{x(x-1)}.$$

By using (6.3.7) (3), we get

$$\begin{aligned} \sum_{n=1}^{\infty} \frac{1}{n2^n} &= \sum_{n=1}^{\infty} \int_2^{\infty} \frac{dx}{x^{n+1}} = \int_2^{\infty} \left( \sum_{n=1}^{\infty} \frac{1}{x^{n+1}} \right) dx \\ &= \int_2^{\infty} \frac{1}{x(x-1)} dx = \lim_{\delta \rightarrow \infty} \int_2^{\delta} \frac{1}{x-1} - \frac{1}{x} dx \\ &= \lim_{\delta \rightarrow \infty} [(\ln(\delta-1) - \ln(\delta) - \ln(1) + \ln 2)] \\ &= \lim_{\delta \rightarrow \infty} \left[ \ln \left( \frac{\delta-1}{\delta} \right) \right] + \ln(2) \\ &= \ln \left( \lim_{\delta \rightarrow \infty} \frac{\delta-1}{\delta} \right) + \ln 2 = \ln 2 \end{aligned}$$

of the limit process and integration in these cases, just as with uniform convergence.

Notice what is the essence of the problem. Intuitively we assume that very small sets must have zero size. Thus the changes of values of the functions on such sets should not change the integral. Moreover, a countable union of such sets which are "negligible for the purpose of integration" should also have zero size. We would expect for example that the set of rational numbers inside a finite interval would have this property, hence its characteristic function should be integrable and the value of such an integral should be zero.

We say that a set  $A \subset \mathbb{R}$  has *zero measure*, if for every  $\varepsilon > 0$  there is a covering of the set  $A$  by a countable system of open intervals  $J_i, i = 1, 2, \dots$  such that

$$\sum_{i=1}^{\infty} m(J_i) < \varepsilon.$$

$m(J_i)$  means the length of the interval  $J_i$ .

In the sequel, the statement "function  $f$  has the given property on a set  $B$  almost everywhere" means that  $f$  has this property at all points except for a subset  $A \subset B$  of zero measure. For example, the characteristic function of rational numbers is zero almost everywhere. A piece-wise continuous function is continuous almost everywhere.

Now we modify the definition of the Riemann integral so that restrictions on the Riemann sums are permitted, eliminating the effect of the values of the integrated function on sets of measure zero. This is achieved by a finer control of the size of the segments in the partition in the vicinity of problematic points.

A positive real function  $\delta$  on a finite interval  $[a, b]$  is called a *gauge*. A partition  $\Xi$  of interval  $[a, b]$  with representatives  $\xi_i$  is  $\delta$ -gauged, if

$$\xi_i - \delta(\xi_i) < x_{i-1} \leq \xi_i \leq x_i < \xi_i + \delta(\xi_i)$$

for all  $i$ .

The norm  $\delta$  of the partition used in the Riemann integration is a special case of constant gauges  $\delta(x) = \delta > 0$ . In order to restrict the Riemann sums to a gauged partition with representatives in the definition of the integral, it is necessary to know that for every gauge  $\delta$ , a  $\delta$ -gauged partition with representatives exists. Otherwise the condition in the definition could be satisfied in a vacuous way. This statement is called *Cousin's lemma*. It is proved by exploiting the standard properties of suprema:

For a given gauge  $\delta$  on  $[a, b]$ , denote by  $M$  the set of all points  $x \in [a, b]$  such that a  $\delta$ -gauged partition with representatives can be found on  $[a, x]$ .  $M$  is nonempty and bounded, thus it has a supremum  $s$ . If  $s \neq b$ , then there is a gauged partition with representatives at  $s$ , where  $s$  is in the interior of the last segment. This leads to a contradiction. Thus the supremum is  $b$ , but then the gauge  $\delta(b) > 0$  and thus  $b$  itself belongs to the set  $M$ .

**6.C.12.** Consider function  $f(x) = \sum_{n=1}^{\infty} ne^{-nx}$ . Determine

$$\int_{\ln 2}^{\ln 3} f(x) dx.$$

**Solution.** Similarly as in the previous case, the Weierstrass test for uniform convergence implies that the series of functions  $\sum_{n=1}^{\infty} ne^{-nx}$  converges uniformly on interval  $(\ln 2, \ln 3)$ , since each of the functions  $ne^{-nx}$  is lesser than  $\frac{n}{2^n}$  on  $(\ln 2, \ln 3)$  and the series  $\sum_{n=1}^{\infty} \frac{n}{2^n}$  converges, which can be seen for example from the ratio test for convergence of series:

$$\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n \rightarrow \infty} \frac{(n+1)2^{-(n+1)}}{n2^n} = \lim_{n \rightarrow \infty} \frac{1}{2} \frac{n+1}{n} = \frac{1}{2}.$$

In total, according to (6.3.7) (3), we have

$$\begin{aligned} \int_{\ln 2}^{\ln 3} f(x) dx &= \int_{\ln 2}^{\ln 3} \sum_{n=1}^{\infty} ne^{-nx} dx = \sum_{n=1}^{\infty} \int_{\ln 2}^{\ln 3} ne^{-nx} dx \\ &= \sum_{n=1}^{\infty} [-e^{-nx}]_{\ln 2}^{\ln 3} = \sum_{n=1}^{\infty} \left( \frac{1}{2^n} - \frac{1}{3^n} \right) = 1 - \frac{1}{2} = \frac{1}{2}. \end{aligned}$$

**6.C.13.** Determine the following limit (give reasons for the procedure of computation):

$$\lim_{n \rightarrow \infty} \int_0^{\infty} \frac{\cos\left(\frac{x}{n}\right)}{\left(1 + \frac{x}{n}\right)^n} dx.$$

**Solution.** First we'll determine  $\lim_{n \rightarrow \infty} \frac{\cos\left(\frac{x}{n}\right)}{\left(1 + \frac{x}{n}\right)^n}$ . The sequence of these functions converges pointwise and we have

$$\lim_{n \rightarrow \infty} \frac{\cos\left(\frac{x}{n}\right)}{\left(1 + \frac{x}{n}\right)^n} = \frac{1}{\lim_{n \rightarrow \infty} \left(1 + \frac{x}{n}\right)^n} \stackrel{??}{=} \frac{1}{e^x}$$

It can be shown that the given sequence converges uniformly. Then according to (6.3.5),

$$\begin{aligned} \lim_{n \rightarrow \infty} \int_0^{\infty} \frac{\cos\left(\frac{x}{n}\right)}{\left(1 + \frac{x}{n}\right)^n} dx &= \int_0^{\infty} \left[ \lim_{n \rightarrow \infty} \frac{\cos\left(\frac{x}{n}\right)}{\left(1 + \frac{x}{n}\right)^n} \right] dx \\ &= \int_0^{\infty} \frac{1}{e^x} dx = 1 \end{aligned}$$

We leave the verification of uniform convergence to the reader (we only point out that the discussion is more complicated than in the previous cases).

**6.C.14.** Find the analytic function whose Taylor series is

$$x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \dots,$$

for  $x \in [-1, 1]$ .

**6.C.15.** From the knowledge of the sum of a geometric series, derive the Taylor series of function

$$y = \frac{1}{5+2x}$$

Now we can state the following generalization of the Riemann integral. Call it the *K-integral*<sup>9</sup>.

KURZWEIL-HENSTOCK INTEGRAL

**Definition.** A function  $f$  defined on a finite interval  $[a, b]$  has a *Kurzweil-Henstock integral*

$$I = \int_a^b f(x) dx,$$

if for every  $\varepsilon > 0$ , there exists a gauge  $\delta$  such that for every  $\delta$ -gauged partition with representatives  $\Xi$ , the inequality  $|S_{\Xi} - I| < \varepsilon$  is true for the corresponding Riemann sum  $S_{\Xi}$ .

**6.3.16. Basic properties.** When defining the K-integral, only the set of all partitions is bounded, for which the Riemann sums are taken into account. Hence if the function is Riemann integrable, then it is K-integrable, and the two integrals are equal.

For the same reason, the argumentation in Theorem 6.2.8 about simple properties of the Riemann integral applies. This verifies that the K-integral behaves in the same way. In particular, a linear combination of integrable function  $cf(x) + dg(x)$  is again integrable and its integral is  $c \int_a^b f(x) dx + d \int_a^b g(x) dx$  etc. To prove this, it suffices only to think through some modifications when discussing the refined partitions, which moreover should be  $\delta$ -gauged.

The Kurzweil integral behaves as anticipated with respect to the sets of zero measure:

**Theorem.** Consider a function  $f$ , defined on the interval  $[a, b]$ . If  $f$  is zero almost every, then the K-integral  $\int_a^b f(x) dx$  exists and is zero.

**PROOF.** The proof is an illustration of the idea that the influence of values on a "small" set can be removed by a suitable choice of gauge. Denote by  $M$  the corresponding set of zero measure, outside of which  $f(x) = 0$  and write  $M_k \subset [a, b]$ ,  $k = 1, \dots$ , for the subset of the points for which  $k - 1 < |f(x)| \leq k$ . Because all the sets  $M_k$  have zero measure, each of them can be covered by a countable system of pairwise disjoint open intervals  $J_{k,i}$  such that the sum of their lengths is arbitrarily small.

Define the gauge  $\delta(x)$  for  $x \in J_{k,i}$  so that the intervals  $(x - \delta(x), x + \delta(x))$  are still contained in  $J_{k,i}$ . Outside of  $M$ ,  $\delta$  is defined arbitrarily.

<sup>9</sup>There are many equivalent definitions and thus also names for this K-integral. A complicated approach was coined by Arnaud Denjoy around 1912. Thus the space of real functions integrable on an interval  $[a, b]$  in this sense is often called *Denjoy space*. Other people involved were Nikolai Luzin and Oskar Perron. We can find the integral under their names. The simple and beautiful definition was introduced by Jaroslav Kurzweil, a Czech mathematician still living in 1957. Much of the theory was developed by Ralph Henstock (1923-2007), an English mathematician.

for  $x \in [-1, 1]$ . ○

**6.C.25.** From the knowledge of the sum of a geometric series, derive the Taylor series of function

$$y = \frac{1}{5+2x}$$

centered at the origin. Then determine its radius of convergence. ○

For any  $\delta$ -gauged partition  $\Xi$  of the interval  $[a, b]$  the bound on the corresponding Riemann sum is given as

$$\begin{aligned} \left| \sum_{j=0}^{n-1} f(\xi_n)(x_{i+1} - x_i) \right| &= \left| \sum_{\substack{j=0 \\ \xi_i \in M}}^{n-1} f(\xi_n)(x_{i+1} - x_i) \right| \\ &\leq \sum_{k=1}^{\infty} \sum_{\substack{j=0 \\ \xi_i \in M_k}}^{n-1} |f(\xi_n)|(x_{i+1} - x_i) \\ &\leq \sum_{k=1}^{\infty} k \left( \sum_{\substack{j=0 \\ \xi_i \in M_k}}^{n-1} m(J_{k,j}) \right). \end{aligned}$$

To guarantee that this bound is smaller than a given  $\varepsilon$ , it suffices to choose the covering by the intervals  $J_{k,j}$  so that

$$\sum_{j=1}^{\infty} m(J_{k,j}) \leq \frac{\varepsilon}{k2^k}.$$

Since  $\sum_{k=1}^{\infty} 2^{-k} = 1$ , the result follows. □

**Corollary.** *If the values of  $f(x)$  are changed on a set of zero measure, the  $K$ -integrability of  $f(x)$  is not changed, and neither is the value of its integral.*

**6.3.17. The fundamental theorems of Calculus.** We conclude this chapter with a few remarks on the properties of integration procedures from the point of view of expectations and reality.<sup>10</sup>

In 6.2.9, we deal with the relation between the derivatives  $f(t)$  and the antiderivatives (integrals)  $F(t)$ . Since  $f(t)$  is assumed continuous, two essential claims collapse into one, resulting in

$$F(t) = \int_{t_0}^t f(x) dx$$

up to the choice of the value of  $F(t_0)$ . In particular,

$$\int_{t_0}^t F'(dx) dx = F(t) - f(t_0)$$

for all choices of  $F$ .

More generally, this can be split into two claims which hold for the  $K$ -integral under much milder conditions:

<sup>10</sup>A very good and elementary exposition of the  $K$ -integral can be found in the short paper *Return to the Riemann Integral*. The American Mathematical Monthly, Vol. 103, No. 8 (1996), 625-632. by Robert G. Bartle.

**Theorem.** (1) Suppose the K-integral  $\int_a^b f(x) dx$  exists. Then  $F(t) = \int_a^t f(x) dx$  is continuous. The derivative  $F'(t)$  exists and equals  $f(t)$  almost everywhere.  
 (2) Suppose  $F(t)$  is a continuous function on  $[a, b]$  and suppose  $f(t) = F'(t)$  exists for all but countably many exceptional points  $t$  in  $[a, b]$ . If  $f(t)$  is defined arbitrarily at those points, then  $F(t) = \int_a^t f(x) dx$  exists for all  $t \in [a, b]$  and equals to  $F(t) - F(a)$ .

We have no space here to go into proofs. Notice, the statements of the theorem are characteristic for the K-integrals, i.e. this is the only integration concept on  $\mathbb{R}$  for which these two theorems hold true.

**6.3.18. K-integrability and Lebesgue measure.** We illustrate the claims in the latter theorem on the indicator function  $\chi_{\mathbb{Q}}$  of the rational numbers. Clearly its K-integral

$$F(t) = \int_a^t \chi_{\mathbb{Q}}(x) dx$$

exists ( $\chi_{\mathbb{Q}}$  is zero almost everywhere) and equals zero. Its derivative  $F'(t)$  is identically zero, and equals  $\chi_{\mathbb{Q}}$  nearly everywhere. This is a good example of a bounded function which is not Riemann integrable, but is integrable in the more general sense.

There are many more K-integrable functions than Riemann integrable functions. There is no difference between proper and improper integrals. More precisely, the K-integral  $\int_a^b f(x) dx$  exists if and only if the one-sided limit

$$\lim_{t \rightarrow a-} \int_t^b f(x) dx$$

is well defined and their values coincide, and similarly for the upper limit  $b$ . This is due to the freedom in the choice of the gauges.

There is only an indirect proof that there are bounded functions on a compact interval which are not K-integrable, based on some set-theoretic arguments, but there are no explicit constructions of such functions available.

We say that a set of real numbers  $M$  is measurable if the K-integral of its indicator function  $\chi_M$  exists. The assignment  $m : M \mapsto \int_a^b \chi_M(x) dx$  for all sets  $M \subset [a, b]$  has the properties of a *measure*. The set of such measurable sets  $M$  is closed under finite intersections and countable unions. The measure  $m$  is additive with respect to unions of at most countable systems of pairwise disjoint sets.

This measure coincides with the *Lebesgue measure*. This measure is used in another concept of integration, which is extremely useful in higher dimensional applications, the *Lebesgue integral*. We do not go into more details here. We remark that a real function  $f$  is Lebesgue integrable if and only if its absolute value is K-integrable.

A big advantage of the K-integral compared to other concepts is the possibility of integrating many functions which are not integrable in absolute value. Compare the concepts of convergence and absolute convergence of series.

A typical example is the sinus integral over all reals. The K-integral of the sinc function  $\int_0^\infty \frac{\sin x}{x} dx$  exists, while the absolute value  $g(x) = |\text{sinc}(x)|$  is not Lebesgue integrable. Such integrals are important in models for signal processing where it is necessary to aggregate potentially infinite many interferences canceling each other by different signs.

**6.3.19. The convergence theorems.** We have dealt with uniform convergence and Riemann integrability. With the K-integral, there is a much nicer and stronger theorem available. A special case is the monotone convergence theorem for uniformly bounded functions  $f_0(x) \leq f_1(x) \leq \dots$ .

#### DOMINATED CONVERGENCE THEOREM

**Theorem.** *Suppose  $f_0, f_1, f_2, \dots$  are K-integrable functions on an interval  $[a, b]$ , converging pointwise to the limit function  $f$ . If there are two K-integrable functions  $g$  and  $h$  satisfying*

$$g(x) \leq f_n \leq h(x),$$

*for all  $n \in \mathbb{N}$  and  $x \in [a, b]$ , then  $f$  is K-integrable too, and*

$$\int_a^b f(t) dt = \lim_{n \rightarrow \infty} \int_a^b f_n(t) dt.$$

For monotone convergence, there is a stronger result saying that a sufficient and necessary condition for the K-integrability of the pointwise limit is  $\sup_n \int_a^b f_n(x) dx < \infty$ .

This theorem could not be applied in our third example in 6.3.2. There the functions  $f_n$  have a "bump" which gets larger but narrower when close to the origin. The functions cannot be dominated by an integrable function.

With the Riemann integral, a similar dominated convergence theorem can be proved, except that we have to guarantee the integrability of the pointwise limit  $f$ .

**D. Additional exercises for the whole chapter**

Next we will describe some extra material on the notions that we have analyzed so far in Chapter 6. We begin with additional exercises on higher-order derivatives, Taylor polynomials, Taylor series and other tasks related to differentiation. Some of them are technical, and some other require a bit of our imagination.

**A) MATERIAL ON DERIVATIVES OF HIGHER ORDERS**

**6.D.1.** Prove that  $n$ th derivative of the function  $f(x) = \frac{1}{x+1}$  with  $x \in A = \mathbb{R} \setminus \{-1\}$ , is given by  $f^{(n)}(x) = \frac{(-1)^n n!}{(x+1)^{n+1}}$  for all  $x \in A$ .

**Solution.** For any  $x$  in the domain of  $f$  we have  $f'(x) = -\frac{1}{(x+1)^2}$ . Thus for  $n = 1$  the given relation holds. Assume that  $f^{(k)}(x) = \frac{(-1)^k k!}{(x+1)^{k+1}}$  for some positive integer  $k$ . Then we see that

$$\begin{aligned} f^{(k+1)}(x) &= \left( \frac{(-1)^k k!}{(x+1)^{k+1}} \right)' = (-1)^k k! \left( \frac{1}{(x+1)^{k+1}} \right)' = (-1)^k k! \left( \frac{-(k+1)(x+1)^k (x+1)'}{(x+1)^{2(k+1)}} \right) \\ &= \frac{(-1)^{k+1} (k+1)!}{(x+1)^{k+2}}, \end{aligned}$$

for all  $x \in A$ , where we used the identity  $k!(k+1) = (k+1)!$ . This shows that  $f^{(k+1)}(x) = \frac{(-1)^{k+1} (k+1)!}{(x+1)^{k+2}}$  and the claim follows by the principle of induction.  $\square$

**6.D.2.** Compute the  $n$ th derivative of the function  $f(x) = \frac{1}{x(1-x)}$  with  $x \in \mathbb{R} \setminus \{0, 1\}$ .

**Solution.** For all  $x$  in the domain of  $f$  one can write  $f(x) = g(x) + h(x)$ , where  $g(x) = \frac{1}{x}$  and  $h(x) = \frac{1}{1-x}$ , respectively. Thus it follows that  $f^{(n)}(x) = g^{(n)}(x) + h^{(n)}(x)$  for all  $x$ , and it suffices to compute the  $n$ th derivatives of the functions  $g, h$ . For  $g$  we see that

$$g'(x) = -x^{-2}, \quad g''(x) = 2x^{-3}, \quad g'''(x) = -6x^{-4} = -1 \cdot 2 \cdot 3x^{-4}, \quad g^{(4)}(x) = 24x^{-5} = 1 \cdot 2 \cdot 3 \cdot 4x^{-5}.$$

Hence clearly we have

$$g^{(n)}(x) = (-1)^n n! x^{-(n+1)} = \frac{(-1)^n n!}{x^{n+1}},$$

which easily follows by induction. Similarly, for  $h(x)$  we can prove that  $h^{(n)}(x) = \frac{n!}{(1-x)^{n+1}}$ . Thus finally we deduce that

$$f^{(n)}(x) = n! \left( \frac{(-1)^n}{x^{n+1}} + \frac{1}{(1-x)^{n+1}} \right), \quad x \in \mathbb{R} \setminus \{0, 1\}.$$

$\square$

**6.D.3.** Consider the function  $f(x) = 1/x$ , with  $x \in \mathbb{R} \setminus \{0\}$ , and let  $n$  be a positive integer. Compute the limit  $\lim_{x \rightarrow +\infty} |f^{(n)}(x)|$ , for all  $x \neq 0$ . Next confirm your answer via Sage by combining the commands `limit` and `assume`.

**Solution.** First we need to compute the  $n$ th derivative. We see that

$$f'(x) = -x^{-2}, \quad f''(x) = 2x^{-3}, \quad f'''(x) = -2 \cdot 3x^{-4}, \quad f^{(4)}(x) = 2 \cdot 3 \cdot 4x^{-5}, \quad \dots, \quad f^{(n)}(x) = (-1)^n n! x^{-n-1}.$$

Hence  $f^{(n)}(x) = (-1)^n n! x^{-n-1}$  and we leave as practice the proof by induction over  $n$ . To compute the given limit one may use the ratio test:

$$\lim_{n \rightarrow +\infty} \left| \frac{f^{(n+1)}(x)}{f^{(n)}(x)} \right| = \lim_{n \rightarrow +\infty} \left| \frac{(-1)^{n+1} (n+1)! x^{-n-2}}{(-1)^n n! x^{-n-1}} \right| = \lim_{n \rightarrow +\infty} \frac{(n+1)}{|x|} = +\infty.$$

As for a Sage verification, it is necessary to use the command `assume` as follows

```
var("n"); assume(x>1)
limit(abs((-1)^n*(factorial(n))*(x**(-n-1))), n=oo)
```

Otherwise, Sage prints out an error, suggesting the use of further restrictions.  $\square$

**6.D.4.** Determine the Taylor expansion of third order around the point  $a = 0$  of the following functions:

$$g(x) = \frac{1}{\cos(x)}, \quad h(x) = e^{-\frac{x^2}{2}}, \quad k(x) = \sin(\sin(x)).$$

Next verify your answers in Sage.  $\circ$

**6.D.5.** For the function  $f(x) = e^{\sin(x)}$  with  $x \in \mathbb{R}$  compute the Taylor polynomials  $T_a^k f(x)$ , where  $k = 1, 2, 3, 4$  and  $a = 0$ . Deduce that  $T_0^3 f(x) = T_0^2 f(x)$  for all  $x$ . Moreover, use Sage to plot the graphs of these Taylor extensions together with the graph of  $f$ .

**Solution.** We have  $f(0) = e^0 = 1$ , and compute

$$f'(0) = \cos(x) e^{\sin(x)} \Big|_{x=0} = 1, \quad f''(0) = \left[ e^{\sin(x)} (\cos^2(x) - \sin(x)) \right] \Big|_{x=0} = 1,$$

$$f'''(0) = \left[ e^{\sin(x)} (\cos^3(x) - 3 \cos(x) \sin(x) - \cos(x)) \right] \Big|_{x=0} = 1 - 1 = 0,$$

$$f^{(4)}(0) = \left[ e^{\sin(x)} (\cos^4(x) - 6 \cos^2(x) \sin(x) - 4 \cos^2(x) + 3 \sin^2(x) + \sin(x)) \right] \Big|_{x=0} = 1 - 4 = -3.$$

Thus

$$T_0^1 f(x) = 1 + x, \quad T_0^2 f(x) = 1 + x + \frac{1}{2}x^2, \quad T_0^3 f(x) = T_0^2 f(x), \quad T_0^4 f(x) = 1 + x + \frac{1}{2}x^2 - \frac{1}{8}x^4.$$

In the figure below we present the graphs of these polynomials.

To produce this figure in Sage (together with a confirmation of the expressions of  $T_0^k f(x)$  for  $k = 1, \dots, 4$ ) we applied the following block:

```
f(x)=exp(sin(x))
p=plot(f(x), x, -2*pi, 2*pi, thickness=1.5, legend_label=r"$f$")
T1(x)=taylor(f(x), x, 0, 1)
p1=plot(T1(x), x, -2*pi, 2*pi, color="green", linestyle="--", legend_label=r"$T^1_{0}$")
T2(x)=taylor(f(x), x, 0, 2)
p2=plot(T2(x), x, -2*pi, 2*pi, color="red", linestyle="-.", legend_label=r"$T^2_{0}$")
T3(x)=taylor(f(x), x, 0, 3)
p3=plot(T3(x), x, -2*pi, 2*pi, color="purple", linestyle="-.", legend_label=r"$T^3_{0}$")
T4(x)=taylor(f(x), x, 0, 4)
p4=plot(T4(x), x, -pi, pi, color="black", linestyle=":", legend_label=r"$T^4_{0}$")
show(p+p1+p2+p3+p4)
```

□

**6.D.6.** Consider the function  $f(x) = \ln(1+x^2)/(1-\cos(x))$ . Using the Taylor series centered at 0 of the numerator and dominator of  $f$ , compute  $\lim_{x \rightarrow 0} f(x)$ . Next present a confirmation of your result based on the l'Hopital's rule.

**Solution.** Recall that the Taylor series centered at 0 of  $\ln(1+x)$  and  $\cos(x)$  are respectively given by

$$\ln(1+x) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^n}{n}, \quad |x| < 1, \quad \cos(x) = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} \quad x \in \mathbb{R}.$$

Thus, the Taylor series around 0 of  $\ln(1+x^2)$  has the form

$$\ln(1+x^2) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} x^{2n} = x^2 - \frac{x^4}{2} + \frac{x^6}{3} - \frac{x^8}{4} + \dots, \quad |x| < 1,$$

while

$$1 - \cos(x) = 1 - \left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} - \dots\right) = \frac{x^2}{2!} - \frac{x^4}{4!} + \frac{x^6}{6!} - \frac{x^8}{8!} + \dots, \quad x \in \mathbb{R}.$$

We can now use these two formulas to compute the limit at hand:

$$\begin{aligned} \lim_{x \rightarrow 0} f(x) &= \lim_{x \rightarrow 0} \frac{\ln(1+x^2)}{1-\cos(x)} = \lim_{x \rightarrow 0} \frac{x^2 - \frac{x^4}{2} + \frac{x^6}{3} - \frac{x^8}{4} + \dots}{\frac{x^2}{2!} - \frac{x^4}{4!} + \frac{x^6}{6!} - \frac{x^8}{8!} + \dots} = \lim_{x \rightarrow 0} \frac{x^2 \left(1 - \frac{x^2}{2} + \frac{x^4}{3} - \frac{x^6}{4} + \dots\right)}{x^2 \left(\frac{1}{2} - \frac{x^2}{4!} + \frac{x^4}{6!} - \frac{x^6}{8!} + \dots\right)} \\ &= \lim_{x \rightarrow 0} \frac{1 - \frac{x^2}{2} + \frac{x^4}{3} - \frac{x^6}{4} + \dots}{\frac{1}{2} - \frac{x^2}{4!} + \frac{x^4}{6!} - \frac{x^6}{8!} + \dots} = \frac{1}{\frac{1}{2}} = 2. \end{aligned}$$

To confirm this result by an alternative method, apply the l'Hopital rule twice:

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\ln(1+x^2)}{1-\cos(x)} &\stackrel{0}{=} \lim_{x \rightarrow 0} \frac{(\ln(1+x^2))'}{(1-\cos(x))'} = \lim_{x \rightarrow 0} \frac{\frac{2x}{1+x^2}}{\sin(x)} = \lim_{x \rightarrow 0} \frac{2x}{(1+x^2)\sin(x)} \\ &\stackrel{0}{=} \lim_{x \rightarrow 0} \frac{(2x)'}{((1+x^2)\sin(x))'} = \lim_{x \rightarrow 0} \frac{2}{2x\sin(x) + (1+x^2)\cos(x)} = \frac{2}{0+1} = 2. \end{aligned}$$

□

**6.D.7.** Consider the function  $f(x) = \frac{e^x - e^{-x} - 2x}{x^2 - x \ln(x+1)}$ . Using appropriately the theory of Taylor series to evaluate the limit  $\lim_{x \rightarrow 0} f(x)$ . Next confirm your computation by Sage.

**Solution.** Observe that limit that we need to compute has the indeterminate form 0/0. We have

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots + \frac{x^n}{n!} + \dots, \quad e^{-x} = 1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \dots + \frac{(-1)^n x^n}{n!} + \dots$$

Thus,  $e^x - e^{-x} = 2x + \frac{2x^3}{3!} +$  higher order terms. This implies that the numerator  $e^x - e^{-x} - 2x$  is dominated by the term  $\frac{2x^3}{3!}$ , as  $x \rightarrow 0$ . Similarly,

$$x \ln(x+1) = x \left(x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots\right) = x^2 - \frac{x^3}{2} + \frac{x^4}{3} - \frac{x^5}{4} + \dots.$$

Thus the dominator  $x^2 - x \ln(1+x)$  is dominated by the term  $\frac{x^3}{2}$ , as  $x \rightarrow 0$ . Combining these two observations we get  $\lim_{x \rightarrow 0} f(x) = 2/3$ .

In Sage to confirm the result give the cell

```
f(x) = (e^x - e^(-x) - 2*x) / (x^2 - x*ln(1+x)); limit(f(x), x=0)
```

□

**6.D.8.** Consider the function

$$f(x) = \begin{cases} 1/x^2, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases}$$

Determine the intervals of monotonicity and find the extremes points of  $f$ , if any.

**Solution.** The domain of  $f$  is the whole real line, but  $f$  is not continuous at  $x = 0$ , since

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^-} f(x) = \infty,$$

and  $f(0) = 0$  (try to plot the graph of  $f$ ). Recall in Sage we can get the same, just by the cell

```
show(lim(1/x^2, x=0, dir="left")); show(lim(1/x^2, x=0, dir="right"))
```

Hence,  $f$  is neither differentiable at  $x = 0$ , i.e.,  $f'(0)$  does not exist. Now, for all  $x \neq 0$  we have  $f'(x) = -2/x^3$  and hence  $f$  is strictly increasing for  $x < 0$  and strictly decreasing for  $x > 0$ . However, at  $x = 0$  the function  $f$  does not a maximum, since it is discontinuous at this point. □

**6.D.9.** Find the asymptotes of the following functions:

$$(a) y = 2 \arctan \left( \left| \frac{x}{x^2 - 1} \right| \right), \quad x \in \mathbb{R} \setminus \{\pm 1\}, \quad (b) y = \ln \left( \frac{3e^{2x} + e^x + 10}{e^x + 1} \right), \quad x \in \mathbb{R}.$$

○

**6.D.10.** Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be a differentiable function satisfying  $f(x) + e^{f(x)} = x + 1$ , for all  $x \in \mathbb{R}$ .

(a) Show that  $f(0) = 0$ .

(b) Does  $f$  have some critical points? Show that  $f$  is strictly increasing.

(c) Show that  $f$  is positive for  $x > 0$  and negative for  $x < 0$ .

(d) Prove the inequality  $\frac{x}{2} \leq f(x) \leq xf'(x)$ , for all  $x \in \mathbb{R}$ .

**Solution.** (a) The defining equation  $f(x) + e^{f(x)} = x + 1$  for  $x = 0$  gives

$$f(0) + e^{f(0)} - 1 = 0. \quad (*)$$

Suppose that  $f(0) = y \in \mathbb{R}$  and consider the function  $g(y) = y + e^y - 1$ . Obviously,  $y = 0$  is root of  $g$ , i.e.,  $g(0) = 0$ . On the other hand, the first derivative of  $g$  is given by  $g'(y) = 1 + e^y$  and we have  $g'(y) > 0$  for all  $y \in \mathbb{R}$ . Thus the function  $g$  is strictly increasing, which implies that  $y = 0$  is its unique root. Thus  $f(0) = 0$ .

Another solution: For  $y = f(0)$  and  $g(y) = y + e^y - 1$  the relation (\*) is written as  $g(f(0)) = 0$ . However,  $g$  is injective since  $g$  is strictly increasing. Therefore, the relation  $g(f(0)) = 0$  gives  $f(0) = 0$ .

(b) By differentiating the relation  $f(x) + e^{f(x)} = x + 1$  with respect to  $x$  we get  $f'(x)(1 + e^{f(x)}) = 1$ . Thus

$$f'(x) = \frac{1}{1 + e^{f(x)}} > 0, \quad x \in \mathbb{R}. \quad (**)$$

Hence  $f$  has no critical points, and in particular is strictly increasing.

(c) To obtain this claim one can rely on the monotonicity of  $f$  and use (a). In particular, we have

$$x > 0 \Leftrightarrow f(x) > f(0) = 0, \quad x < 0 \Leftrightarrow f(x) < f(0) = 0.$$

(d) Here we will use the second derivative of  $f$ , given by

$$f''(x) = \left( \frac{1}{1 + e^{f(x)}} \right)' = -\frac{f'(x) e^{f(x)}}{(1 + e^{f(x)})^2} = -\frac{e^{f(x)}}{(1 + e^{f(x)})^3} < 0,$$

for all  $x \in \mathbb{R}$ . Notice also by (\*\*) that  $f'(0) = 1/2$ . Now, for  $x > 0$  the given inequality holds as an equality. For  $x > 0$  consider the set  $[0, x]$ . On this set  $f$  satisfies the conditions of the mean value theorem, hence there exist  $\xi \in (0, x)$  such that

$$f'(\xi) = \frac{f(x) - f(0)}{x - 0} = \frac{f(x)}{x}, \quad (\#)$$

where we used (a) to replace  $f(0)$  by 0. On the other hand we saw that  $f'$  is strictly decreasing (since  $f''(x) < 0$  for all  $x$ ). Thus, in combination with (#) we obtain the following equivalences:

$$0 < \xi < x \Leftrightarrow f'(x) > f'(\xi) > f'(0) \Leftrightarrow f'(x) > \frac{f(x)}{x} > \frac{1}{2} \Leftrightarrow xf'(x) > f(x) > \frac{x}{2}$$

which proves the given formula for  $x > 0$ . For  $x < 0$  one proceeds similarly by applying the mean value theorem on the set  $[x, 0]$ . □

**6.D.11.** Study the local behaviour of the function  $f(x) = \sqrt[3]{|x|^3 + 1}$ , with  $x \in \mathbb{R}$ .

**Solution.** It is easy to deduce that  $f$  is continuous everywhere on  $\mathbb{R}$ . Also,  $f(x) \geq 1$  and  $f(-x) = f(x)$  for all  $x \in \mathbb{R}$ , i.e., the function  $f$  is positive and even. As for the limit behavior of  $f$  at  $\pm\infty$ , we compute (see also below the graph of  $f$ )

$$\lim_{x \rightarrow \pm\infty} \sqrt[3]{|x|^3 + 1} = \lim_{x \rightarrow \pm\infty} \sqrt[3]{|x|^3} = \lim_{x \rightarrow \pm\infty} |x| = +\infty.$$

For the first derivative of  $f$  we compute

$$f'(x) = \begin{cases} \frac{x^2}{\sqrt[3]{(x^3+1)^2}}, & \text{for } x > 0, \\ 0, & \text{for } x = 0, \\ -\frac{x^2}{\sqrt[3]{(-x^3+1)^2}}, & \text{for } x < 0. \end{cases}$$

Notice for computing  $f'(0)$  we used the one-side limits

$$\lim_{x \rightarrow 0^+} \frac{x^2}{\sqrt[3]{(x^3+1)^2}} = 0 = \lim_{x \rightarrow 0^-} -\frac{x^2}{\sqrt[3]{(-x^3+1)^2}}.$$

We deduce that  $f'(x) > 0$  for all  $x > 0$  and  $f'(x) < 0$  for all  $x < 0$ . This implies that  $f$  is strictly increasing on the interval  $(0, +\infty)$ , increasing on  $[0, +\infty)$ , strictly decreasing for all  $x \in (-\infty, 0)$ , and increasing on the interval  $(-\infty, 0]$  (recall that  $f$  is an even function). It follows that  $f$  has only one local minimum at point  $x_0 = 0$ , which is a global minimum with value  $f(0) = 1$ .

Next we will prove that  $f$  is convex for any  $x \in \mathbb{R}$ . Indeed, the second derivative of  $f$  is given by

$$f''(x) = \begin{cases} \frac{2x}{\sqrt[3]{(x^3+1)^5}}, & \text{if } x > 0; \\ 0, & \text{if } x = 0; \\ -\frac{2x}{\sqrt[3]{(-x^3+1)^5}}, & \text{if } x < 0. \end{cases}$$

Thus we deduce that  $f''(x) > 0$  for all  $x \in (-\infty, 0) \cup (0, \infty)$ , so  $f$  is strictly convex on this interval. In total, we obtained that  $f$  is convex on its whole domain (it doesn't have some inflection points).

Let us finally determine the asymptotes of  $C_f$ . Recall that a line  $y = ax + b$  is an inclined asymptote for  $x \rightarrow \infty$ , if and only if both (proper) limits

$$\lim_{x \rightarrow \infty} \frac{f(x)}{x} = a, \quad \lim_{x \rightarrow \infty} (f(x) - ax) = b,$$

exist. Analogous statement holds for  $x \rightarrow -\infty$ . Hence the limits

$$\begin{aligned} \lim_{x \rightarrow \infty} \frac{f(x)}{x} &= \lim_{x \rightarrow \infty} \frac{\sqrt[3]{x^3+1}}{x} = \lim_{x \rightarrow \infty} \frac{\sqrt[3]{x^3}}{x} = 1, \\ \lim_{x \rightarrow \infty} (f(x) - 1 \cdot x) &= \lim_{x \rightarrow \infty} \left( \sqrt[3]{x^3+1} - x \right) = \lim_{x \rightarrow \infty} \left( \left[ \sqrt[3]{x^3+1} - x \right] \frac{\sqrt[3]{(x^3+1)^2} + x\sqrt[3]{x^3+1} + x^2}{\sqrt[3]{(x^3+1)^2} + x\sqrt[3]{x^3+1} + x^2} \right) \\ &= \lim_{x \rightarrow \infty} \frac{x^3+1-x^3}{\sqrt[3]{(x^3+1)^2} + x\sqrt[3]{x^3+1} + x^2} = \lim_{x \rightarrow \infty} \frac{1}{3x^2} = 0, \end{aligned}$$

imply that the line  $y = x$  is an asymptote at  $+\infty$ . Since  $f$  is even, we immediately obtain the line  $y = -x$  as an asymptote at  $-\infty$ . Let us finally present the graph of  $f$  together with the asymptotes  $y = \pm x$ :

□

**6.D.12.** Using Sage as a tool, examine the local behaviour of the function  $f(x) = \arctan\left(\frac{x}{2-x}\right)$ .

**Solution.** The given function is defined on  $A = \mathbb{R} \setminus \{2\}$ . Its graph does not have special symmetry. The only point of intersection of  $C_f$  with the axes is the origin  $[0, 0]$ , while  $f$  is positive exactly on the open interval  $(0, 2)$ . In Sage the roots of  $f$  occur by the command

```
f(x)=arctan(x/(2-x)); show(solve(f(x)==0, x))
```

while one can verify that  $f$  is not even/odd by adding the cell

```
show(bool(f(-x)==f(x))); show(bool(f(-x)==-f(x)))
```

where for both cases Sage returns False. The function is everywhere continuous on  $A$ , and at  $x_0 = 2$  the graph of  $f$  has a jump of size  $\pi$ . This follows from the limits  $\lim_{x \rightarrow 2^-} f(x) = \frac{\pi}{2}$  and  $\lim_{x \rightarrow 2^+} f(x) = -\frac{\pi}{2}$ , see also the graph  $C_f$  of  $f$  below:

This illustration occurs by adding in the initial block the cell

```
p=plot(f(x), x, -10, 10, exclude=[2], color="black", thickness=2)
p+=text(r"$f(x)=\arctan(\frac{x}{2-x})$", (5.1, 1.45), fontsize=14, color="black")
p+=line([(2, -1.6), (2, 1.6)], rgbcolor=(0.2,0.2,0.2), linestyle="--")
p.show(figsize=6)
```

Moreover we see that  $\lim_{x \rightarrow -\infty} f(x) = -\frac{\pi}{4} = \lim_{x \rightarrow +\infty} f(x)$ , and thus the range of  $f$  is the set  $(-\pi/2, \pi/2) \setminus \{-\pi/4\}$ . Moreover, the only asymptote of  $C_f$  is the line  $y = -\pi/4$  at  $\pm\infty$ . We also compute

$$f'(x) = \frac{1}{x^2 - 2x + 2}, \quad f''(x) = \frac{2(1-x)}{(x^2 - 2x + 2)^2}, \quad x \in \mathbb{R} \setminus \{2\}.$$

The limits posed above together with the first two derivatives can be confirmed by adding in the initial block the cell

```
show(lim(f(x), x=2, dir="+")); show(lim(f(x), x=2, dir="-"))
show(lim(f(x), x=oo,)); show(lim(f(x), x=-oo))
show(diff(f, x).factor()); show(diff(f, x, 2).factor())
```

It is easy to see that  $f'(x) > 0$  for all  $x \in A$  and hence  $f$  is increasing at every point of its domain, see also the graph of  $f'(x)$  above (which is coloured by green). This claim can be confirmed in Sage by adding the cell

```
A=RealSet(x!=2); bool(diff(f, x)>0 for x in A)
```

Notice the first command in this cell declares the domain  $A$  of  $f$ . Finally, the function  $f$  is convex on the interval  $(-\infty, 1)$ , and concave on the interval  $(1, 2)$ ,  $(2, +\infty)$ . In the figure at the right we included the graph of  $f''(x)$ , which provides a graphical proof of these claims. The point  $x_1 = 1$  is the unique point of inflection with  $f(1) = \pi/4$ , which we can easily confirm by adding the cell `solve(diff(f, x, 2) == 0, x)`.  $\square$

**6.D.13.** Study the local behaviour of the function  $f(x) = -\frac{x^2}{x+1}$ , with  $x \in \mathbb{R} \setminus \{-1\}$  and use Sage to sketch the graph of  $f$  together with its asymptotes. ○

**6.D.14.** Study the local behaviour of the function  $f(x) = \frac{x^3 - 3x^2 + 3x + 1}{x - 1}$  and use Sage to confirm most of your computations. ○

**6.D.15.** Study the local behaviour of the function  $f(x) = \sqrt[3]{x}e^{-x}$ . ○

Consider a set of  $n$  functions  $\{f_1(t), \dots, f_n(t)\}$  which are  $(n - 1)$  times differentiable. The Wronski matrix associated to this set is defined by

$$W(f_1, \dots, f_n) = \begin{pmatrix} f_1(t) & f_2(t) & \dots & f_n(t) \\ f_1'(t) & f_2'(t) & \dots & f_n'(t) \\ f_1''(t) & f_2''(t) & \dots & f_n''(t) \\ \vdots & \vdots & \vdots & \vdots \\ f_1^{(n-1)}(t) & f_2^{(n-1)}(t) & \dots & f_n^{(n-1)}(t) \end{pmatrix}.$$

One can prove that the set of functions  $\{f_1(t), \dots, f_n(t)\}$  is linearly independent if and only if  $\det(W) \neq 0$ . Let us describe an application of this result, which relates linear algebra with calculus.

**6.D.16. Wronki matrix.** Consider the following set  $B = \{\sin(t), \cos(t), e^t\}$ .

(a) Show that  $B$  consists of linearly independent functions.

(b) If  $V$  is the real vector space of functions spanned by  $B$ , let  $\mathcal{D} : V \rightarrow V$  be the linear operator defined by  $\mathcal{D}(f) = f'(t) = \frac{d f(t)}{dt}$ . Compute the matrix of  $\mathcal{D}$  with respect to the basis  $B$ . Moreover, find its kernel and its image.

**Solution.** For the set  $B = \{\sin(t), \cos(t), e^t\}$  we compute

$$\det(W(\sin, \cos, \exp)) = \begin{vmatrix} \sin(t) & \cos(t) & e^t \\ \cos(t) & -\sin(t) & e^t \\ -\sin(t) & -\cos(t) & e^t \end{vmatrix} = -2e^t \neq 0,$$

hence  $B$  consists of linearly independent vectors. We can easily verify the computation of the determinant in Sage, by typing

```
t = var("t")
W = matrix(SR, 3, 3, [[sin(t), cos(t), exp(t)], [cos(t), -sin(t), exp(t)], [-sin(t), -cos(t), exp(t)]])
W; w=W.det (); w.full_simplify ()
```

which returns the desired answer  $-2 * e^t$ .

(b) For the matrix of the linear operator  $\mathcal{D}$  with respect to the basis  $B$  we see that

$$\mathcal{D}(\sin(t)) = 0 \sin(t) + 1 \cos(t) + 0e^t, \quad \mathcal{D}(\cos(t)) = -1 \sin(t) + 0 \cos(t) + 0e^t, \quad \mathcal{D}(e^t) = 0 \sin(t) + 0 \cos(t) + 1e^t.$$

Then the coordinates of  $\mathcal{D}(\sin(t))$ ,  $\mathcal{D}(\cos(t))$  and  $\mathcal{D}(e^t)$  give the columns of the matrix of  $\mathcal{D}$ , that is,  $\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ .

Let us now quickly compute the kernel of  $\mathcal{D}$  via Sage:

```
D = matrix(SR, 3, 3, [[0, -1, 0], [1, 0, 0], [0, 0, 1]])
D.right_kernel ()
```

which prints out

```
Vector space of degree 3 and dimension 0 over Symbolic Ring
Basis matrix:
[]
```

This essentially means that  $\text{Ker}(\mathcal{D}) = \{0\}$ . For the image use the command `D.image ()`. It gives<sup>5</sup>

```
Vector space of degree 3 and dimension 3 over Symbolic Ring
Basis matrix:
[1 0 0]
[0 1 0]
[0 0 1]
```

Thus the image of  $\mathcal{D}$  is spanned by the standard basis of  $\mathbb{R}^3$ . □

*We proceed with material on parametrized curves and surfaces.*

**6.D.17.** Find the points on the cycloid given in 6.A.45 where the tangent lines are vertical/parallel. ○

*In differential calculus there is a plethora of important inequalities. Among them there is one with many applications, the so called Jensen inequality, This is about convex and concave functions, as we will see below.*

**6.D.18. Jensen inequality.** For a strictly convex function  $f$  on interval  $I$  and for arbitrary points  $x_1, \dots, x_n \in I$  and real numbers  $c_1, \dots, c_n > 0$  such that  $c_1 + \dots + c_n = 1$ , the inequality

$$f\left(\sum_{i=1}^n c_i x_i\right) \leq \sum_{i=1}^n c_i f(x_i)$$

holds, with equality occurring if and only if  $x_1 = \dots = x_n$ . Notice the Jensen inequality can be also formulated in a more intuitive way: “the centroid of mass points placed upon a graph of a strictly convex function lies above this graph.”

**Solution.** Could be proven easily by induction: for  $n = 2$  it is just the definition of the convex function, for the induction step

$$f\left(\sum_{i=1}^{k+1} c_i x_i\right) = f\left(c_1 x_1 + (1 - c_1) \sum_{i=2}^{k+1} \frac{c_i}{1 - c_1} x_i\right) \leq c_1 f(x_1) + (1 - c_1) f\left(\sum_{i=2}^{k+1} \frac{c_i}{1 - c_1} x_i\right)$$

<sup>5</sup>Recall that the basis computed by Sage is “row reduced”.

$$\leq c_1 f(x_1) + (1 - c_1) \left( \sum_{i=2}^{k+1} \frac{c_i}{1 - c_1} f(x_i) \right) = \sum_{i=1}^{k+1} c_i f(x_i).$$

Notice above we used the inequality first for  $n = 2$  and then for  $n = k$ .  $\square$

**6.D.19.** Prove that among all (convex)  $n$ -gons inscribed into a circle, the regular  $n$ -gon has the largest area (for arbitrary  $n \geq 3$ ).

**Solution.** Clearly it suffices to consider the  $n$ -gons inside of which lies the center of the circle. We'll divide each such  $n$ -gon inscribed into a circle with radius  $r$  to  $n$  triangles with areas  $S_i, i \in \{1, \dots, n\}$  according to the figure. With regard to the fact that

$$\sin \frac{\varphi_i}{2} = \frac{x_i}{r}, \quad \cos \frac{\varphi_i}{2} = \frac{h_i}{r}, \quad i \in \{1, \dots, n\},$$

we have

$$S_i = x_i h_i = r^2 \sin \frac{\varphi_i}{2} \cos \frac{\varphi_i}{2} = \frac{1}{2} r^2 \sin \varphi_i, \quad i \in \{1, \dots, n\}.$$

This implies that the area of the hole  $n$ -gon is

$$S = \sum_{i=1}^n S_i = \frac{1}{2} r^2 \sum_{i=1}^n \sin \varphi_i.$$

Thus we want to maximize the sum  $\sum_{i=1}^n \sin \varphi_i$ , while for values  $\varphi_i \in (0, \pi)$  we clearly have

$$(1) \quad \varphi_1 + \dots + \varphi_n = \sum_{i=1}^n \varphi_i = 2\pi.$$

The function  $y = \sin x$  is strictly concave on the interval  $(0, \pi)$ , which means, that the function  $y = -\sin x$  is strictly convex on this interval. Then according to Jensen's inequality for  $c_i = 1/n$  and  $x_i = \varphi_i$ , we have

$$-\sin \left( \sum_{i=1}^n \frac{1}{n} \varphi_i \right) \leq -\sum_{i=1}^n \frac{1}{n} \sin \varphi_i, \quad \text{tj.} \quad \sin \left( \sum_{i=1}^n \frac{1}{n} \varphi_i \right) \geq \sum_{i=1}^n \frac{1}{n} \sin \varphi_i.$$

Moreover, we know the equality occurs exactly for  $\varphi_1 = \dots = \varphi_n$ . If we express (using (1))

$$S = \frac{r^2 n}{2} \sum_{i=1}^n \frac{1}{n} \sin \varphi_i \leq \frac{r^2 n}{2} \sin \left( \sum_{i=1}^n \frac{1}{n} \varphi_i \right) = \frac{r^2 n}{2} \sin \frac{2\pi}{n},$$

we can see that  $S$  can attain at most the value on the right hand side. But that happens if and only if  $\varphi_1 = \dots = \varphi_n$  (we chose  $x_i = \varphi_i$ ). Hence the regular  $n$ -gon is the one with the maximum area, because it satisfies  $\varphi_1 = \dots = \varphi_n = 2\pi/n$ .  $\square$

**6.D.20. Isoperimetric quotient.** For a closed curve in plane enclosing a planar region, we define its isoperimetric quotient as the number

$$IQ := \frac{S}{\pi \left(\frac{o}{2\pi}\right)^2} = \frac{4\pi S}{o^2},$$

where  $S$  denotes the area of the region and  $o$  its perimeter (i.e. the length of the curve). Hence the isoperimetric quotient determines the ratio of the area of the region and the area of a circle with the same perimeter as the given region. The notation  $IQ$  is therefore not only an English abbreviation for the isoperimetric quotient, but can be also thought of as the "intelligence of the region", with which it uses its perimeter for attaining as big area as possible. The isoperimetric theorem then states that for every closed curve,  $IQ \leq 1$ , with equality occurring only for a circle, or ("the circle is the smartest").

Determine  $IQ$  for a regular polygon and a circle and find the sector of a circle, for which its boundary has the largest  $IQ$

**Solution.** First notice that the value of  $IQ$  doesn't change with a change of scale on the axes (same on both). Because when the proportions of the region get  $a$  times bigger (for arbitrary  $a > 0$ ), the perimeter also gets  $a$  times bigger and the area  $a^2$  times (it's a square measure). Hence  $IQ$  doesn't depend on the size of the region, but only on its shape. Thus we can consider a regular  $n$ -gon inscribed into a unit circle. According to the figure,

$$h = \cos \varphi = \cos \frac{\pi}{n}, \quad \frac{x}{2} = \sin \varphi = \sin \frac{\pi}{n},$$

which yields

$$o_n = n \cdot x = 2n \sin \frac{\pi}{n}$$

and

$$S_n = n \cdot \frac{1}{2} hx = n \cos \frac{\pi}{n} \sin \frac{\pi}{n}.$$

Thus for a regular  $n$ -gon, we have

$$IQ = \frac{4\pi n \cos \frac{\pi}{n} \sin \frac{\pi}{n}}{4n^2 \sin^2 \frac{\pi}{n}} = \frac{\pi}{n} \cotg \frac{\pi}{n},$$

which we can verify for example for a square ( $n = 4$ ) with a side of length  $a$ , where

$$IQ = \frac{4\pi a^2}{(4a)^2} = \frac{\pi}{4} = \frac{\pi}{4} \cotg \frac{\pi}{4}.$$

Using the limit transition for  $n \rightarrow \infty$  and the limit

$$\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1,$$

we get the isoperimetric quotient for a circle:

$$IQ = \lim_{n \rightarrow \infty} \frac{\pi}{n} \cotg \frac{\pi}{n} = \lim_{n \rightarrow \infty} \frac{\cos \frac{\pi}{n}}{\sin \frac{\pi}{n}} = \frac{\cos 0}{1} = 1.$$

Of course, for a circle with radius  $r$ , we could have also directly computed

$$IQ = \frac{4\pi S}{o^2} = \frac{4\pi(\pi r^2)}{(2\pi r)^2} = 1.$$

For the boundary  $a$  of sector of a circle with radius  $r$  and central angle  $\varphi \in (0, 2\pi)$ , we have

$$IQ = \frac{4\pi S}{o^2} = \frac{4\pi \frac{\varphi r^2}{2}}{(2r+r\varphi)^2} = \frac{2\pi\varphi}{(2+\varphi)^2}.$$

Hence we're looking for a maximum of the function

$$f(\varphi) := \frac{2\pi\varphi}{(2+\varphi)^2}, \quad \varphi \in (0, 2\pi).$$

By computing

$$f'(\varphi) = 2\pi \frac{(2+\varphi)^2 - 2\varphi(2+\varphi)}{(2+\varphi)^4} = 2\pi \frac{2-\varphi}{(2+\varphi)^3}, \quad \varphi \in (0, 2\pi)$$

we easily obtain that

$$f'(\varphi) > 0, \quad \varphi \in (0, 2), \quad f'(\varphi) < 0, \quad \varphi \in (2, 2\pi).$$

Hence function  $f$  attains its maximal value for  $\varphi_0 = 2$  and for a central angle  $\varphi_0 = 2$  (radians), we get the largest

$$IQ = \frac{2\pi\varphi_0}{(2+\varphi_0)^2} = \frac{\pi}{4}.$$

For the sake of completeness, for a solid in three-dimensional space (more precisely, for the closed surface which is its boundary), we define

$$IQ := \frac{V}{\frac{4\pi}{3} \left(\frac{S}{4\pi}\right)^{\frac{3}{2}}},$$

where  $V$  is the volume and  $S$  the surface of the solid. Thus we compare the volume of the solid with a given surface with the volume of the ball with the same space.  $\square$

**6.D.21.** A string of length  $l$  is given. The task is to cut it into  $n$  parts so that it's possible to create boundaries of geometric figures given in advance (for example a square, a triangle, a circle, a halfcircle) with the least sum of areas from the  $n$  smaller strings.

**Solution.** To solve this problem, we'll use the isoperimetric quotient of curves and Jensen's inequality (stated in previous examples). For the geometric figures given in advance, denote the values of their isoperimetric quotients as

$$\frac{1}{\lambda_i} := \frac{4\pi S_i}{o_i^2}, \quad i \in \{1, \dots, n\},$$

where  $S_i$  is the area and  $o_i$  the perimeter of the  $i$ -th figure. We'll also use the denotation

$$\Lambda := \sum_{i=1}^n \lambda_i.$$

Recall that the isoperimetric quotient is given only by the shape of the figure and doesn't depend on its size. In particular, the value  $\Lambda$  is constant (it's determined by the shapes of the given figures).

Our task is to minimize the sum  $\sum_{i=1}^n S_i$  with  $\sum_{i=1}^n o_i = l$ . Because

$$S_i = \frac{o_i^2}{4\pi\lambda_i}, \quad i \in \{1, \dots, n\},$$

we need to minimize the expression

$$S := \frac{1}{4\pi} \sum_{i=1}^n \frac{o_i^2}{\lambda_i}.$$

Using Jensen's inequality for the strictly convex function  $y = x^2$  (on the whole real axis), we obtain

$$\left( \sum_{i=1}^n c_i x_i \right)^2 \leq \sum_{i=1}^n c_i x_i^2$$

for  $x_i \in \mathbb{R}$  and  $c_i > 0$  with the property  $c_1 + \dots + c_n = 1$ . Moreover we know that the equality occurs if and only if  $x_1 = \dots = x_n$ . By choosing

$$c_i = \frac{\lambda_i}{\Lambda}, \quad x_i = \frac{o_i}{\lambda_i}, \quad i \in \{1, \dots, n\},$$

we then get

$$\left(\sum_{i=1}^n \frac{\lambda_i}{\Lambda} \frac{o_i}{\lambda_i}\right)^2 \leq \sum_{i=1}^n \frac{\lambda_i}{\Lambda} \left(\frac{o_i}{\lambda_i}\right)^2.$$

By several simplifications, we obtain the inequality

$$\frac{1}{\Lambda^2} \left(\sum_{i=1}^n o_i\right)^2 \leq \frac{1}{\Lambda} \sum_{i=1}^n \frac{o_i^2}{\lambda_i}$$

and then (notice that  $\sum_{i=1}^n o_i = l$ )

$$\frac{l^2}{\Lambda} \leq \sum_{i=1}^n \frac{o_i^2}{\lambda_i},$$

with equality again occurring for

$$(1) \quad x_1 = \dots = x_n, \quad \text{tj.} \quad \frac{o_1}{\lambda_1} = \dots = \frac{o_n}{\lambda_n}.$$

This implies that  $S$  the smallest, if and only if (1) holds. This smallest value of  $S$  is  $l^2/(4\pi\Lambda)$ . Now we only need to determine the lengths of the cut parts  $o_i$ . If (1) holds, then clearly  $o_i = k\lambda_i$  for all  $i \in \{1, \dots, n\}$  and certain constant  $k > 0$ . From

$$\sum_{i=1}^n o_i = l \quad \text{and simultaneously} \quad \sum_{i=1}^n o_i = k \sum_{i=1}^n \lambda_i = k\Lambda,$$

we can immediately see that  $k = l/\Lambda$ , i.e.

$$o_i = \frac{\lambda_i}{\Lambda} l, \quad i \in \{1, \dots, n\}.$$

Let's take a look at a specific situation where we are to cut a string of length 1 m into two smaller ones and then create a square and a circle from them so that the sum of their areas is the smallest possible. For a square and a circle (in order), we have (see the example called Isoperimetric quotient)

$$\lambda_1 = \frac{4}{\pi}, \quad \lambda_2 = 1, \quad \text{tj.} \quad \Lambda = \lambda_1 + \lambda_2 = \frac{4+\pi}{\pi}.$$

Then the lengths of the respective parts are (in metres)

$$o_1 = \frac{\frac{4}{\pi}}{\frac{4+\pi}{\pi}} \cdot 1 = \frac{4}{4+\pi} \doteq 0,56, \quad o_2 = \frac{1}{\frac{4+\pi}{\pi}} \cdot 1 = \frac{\pi}{4+\pi} \doteq 0,44.$$

The area of a square with perimeter 0,56 m (with a side of length  $a = 0,14$  m) is 0,0196 m<sup>2</sup> and the area of a circle with perimeter 0,44 m (and radius  $r \doteq 0,07$  m) is approximately 0,0154 m<sup>2</sup>. We can verify that (in m<sup>2</sup>)

$$\frac{l^2}{4\pi\Lambda} = \frac{1}{4(4+\pi)} \doteq 0,035 = 0,0196 + 0,0154.$$

□

A) MATERIAL ON INTEGRATION

**6.D.22.** Based on Sage, evaluate the integrals  $\int f(x) dx$ , where:

- (1)  $f(x) = x^4 + e^x + 5 \ln(x)$ , with  $x > 0$ ;
- (2)  $f(x) = \sqrt{x}(1 + x^3)$ , with  $x > 0$ ;
- (3)  $f(x) = x/\sqrt{x+1}$ , with  $x > -1$ .

○

**6.D.23.** Using any basic formula, and your pencil, determine a primitive function for the following functions:

- (a)  $f(x) = \sqrt{x} \sqrt{x} \sqrt{x}$ , with  $x \in (0, +\infty)$ ;
- (b)  $g(x) = (2^x + 3^x)^2$ , with  $x \in \mathbb{R}$ ;
- (c)  $h(x) = \frac{1}{\sqrt{4-4x^2}}$ , with  $x \in (-1, 1)$ ;
- (d)  $k(x) = \frac{\cos x}{1 + \sin x}$ , with  $x \in (-\frac{\pi}{2}, \frac{3\pi}{2})$ .

Then, confirm your computations via Sage.

○

**6.D.24.** Find a primitive function for the function  $f(x) = e^x + \frac{3}{\sqrt{4-x^2}}$  on the open interval  $(-2, 2)$ .

○

**6.D.25.** Evaluate the integral  $\int \frac{dx}{x(\ln(x))^2 + 2025x}$  with an appropriate substitution.

○

**6.D.26.** Evaluate the integral  $\int \frac{e^x}{e^x + 2024} dx$  with an appropriate substitution.

○

**6.D.27.** Apply integration by parts to compute the integral  $A = \int \cos(3x + 2025)(x + 2026) dx$ , with  $x \in \mathbb{R}$ .

**Solution.** In terms of 6.2.4, it is convenient to set  $F(x) = (x + 2026)$ , such that  $F'(x) = 1$ . Then  $G'(x) = \cos(3x + 2025)$  and  $G$  must have the form  $G(x) = \frac{1}{3} \sin(3x + 2025)$ , such that  $G'(x) = \frac{(3x)' \cos(3x+2025)}{3} = \cos(3x + 2025)$ . Then we get

$$\begin{aligned} A &= \int (x + 2026) \cos(3x + 2025) dx = \int (x + 2026) \left( \frac{\sin(3x + 2025)}{3} \right)' dx = \\ &= \frac{1}{3} (x + 2026) \sin(3x + 2025) - \frac{1}{3} \int (x + 2026)' \sin(3x + 2025) dx = \\ &= \frac{1}{3} (x + 2026) \sin(3x + 2025) - \frac{1}{3} \int \sin(3x + 2025) dx = \\ &= \frac{1}{3} (x + 2026) \sin(3x + 2025) + \frac{1}{3} \cdot \frac{\cos(3x + 2025)}{3} + C, \end{aligned}$$

for some constant  $C$ . A direct verification in Sage occurs as usual:

```
show(integral(cos(3*x+2025)*(x+2026), x).factor())
```

□

**6.D.28.** Compute the integral  $A = \int \sin(2024x) \cos(x) dx$ , formally first and next in Sage.

**Solution.** Recall the identities

$$\sin(\alpha + \beta) = \sin(\alpha) \cos(\beta) + \sin(\beta) \cos(\alpha), \quad \sin(\alpha - \beta) = \sin(\alpha) \cos(\beta) - \sin(\beta) \cos(\alpha).$$

Adding these two relations we get  $2 \sin(\alpha) \cos(\beta) = \sin(\alpha + \beta) + \sin(\alpha - \beta)$ , an identity that one can apply to compute the integral at hand. In particular,

$$\begin{aligned} A &= \int \sin(2024x) \cos(x) dx = \frac{1}{2} \int (\sin(2024x+x) + \sin(2024x-x)) dx = \frac{1}{2} \int \sin(2025x) dx + \frac{1}{2} \int \sin(2023x) dx = \\ &= -\frac{1}{4050} \cos(2025x) - \frac{1}{4046} \cos(2023x) + C. \end{aligned}$$

In Sage to confirm this just type the command `show(integrate(sin(2024*x)*cos(x), x))`. □

**6.D.29.** Compute the integral  $I = \int \sqrt{1-x^2} dx$ , with  $x \in (-1, 1)$ , in two different ways.

**Solution.** In terms of integration by parts (6.2.4), we have  $F(x) = \sqrt{1-x^2}$ ,  $F'(x) = \frac{-x}{\sqrt{1-x^2}}$ ,  $G'(x) = 1$  and  $G(x) = x$ .

Thus, up to a constant we have that

$$\begin{aligned} I &= \int \sqrt{1-x^2} dx = x \sqrt{1-x^2} + \int \frac{x^2}{\sqrt{1-x^2}} dx = x \sqrt{1-x^2} - \int \frac{1-x^2-1}{\sqrt{1-x^2}} dx = \\ &= x \sqrt{1-x^2} - \int \sqrt{1-x^2} dx + \int \frac{1}{\sqrt{1-x^2}} dx = x \sqrt{1-x^2} - \int \sqrt{1-x^2} dx + \arcsin(x). \end{aligned}$$

This implies that

$$2 \int \sqrt{1-x^2} dx = x \sqrt{1-x^2} + \arcsin(x) + C \implies I = \int \sqrt{1-x^2} dx = \frac{1}{2} (x \sqrt{1-x^2} + \arcsin(x)) + C,$$

for some constant  $C \in \mathbb{R}$ .

Let us now compute  $I$  by an appropriate substitution. Set  $x = \sin(t)$  such that  $dx = \cos(t) dt$  and  $x = \arcsin(t)$ . Notice that  $t \in (-\pi/2, \pi/2)$  for  $x \in (-1, 1)$ , and among other things, one has

$$0 < \cos(t) = |\cos(t)| = \sqrt{\cos^2(t)} = \sqrt{1 - \sin^2(t)}.$$

Therefore our integral  $I$  can be written as

$$I = \int \sqrt{1-x^2} dx = \int \sqrt{1-\sin^2(t)} \cos(t) dt = \int \cos^2(t) dt = \frac{1}{2} (t + \sin(t) \cos(t)) + C,$$

for some constant  $C$ , where for the final equality one is based on our previous computation from 6.B.8. Thus

$$I = \frac{1}{2} \left( \sin(t) \sqrt{1-\sin^2(t)} + t \right) + C = \frac{1}{2} \left( x \sqrt{1-x^2} + \arcsin(x) \right) + C, \quad C \in \mathbb{R}.$$

□

**6.D.30.** Compute the limit  $\lim_{x \rightarrow +\infty} \frac{F'(x)}{x^4 + 1}$ , where  $F(x) = \int_1^x (t \sin(t) + 4 \cos(4t)) dt$ .

**Solution.** Let us express  $F$  as  $F(x) = \int_1^x f(t) dt$ , with  $f(t) = t \sin(t) + 4 \cos(4t)$ , for  $t \in \mathbb{R}$ . Since  $f$  is continuous the function  $F$  is differentiable, with  $F'(x) = x \sin(x) + 4 \cos(4x)$  for all  $x \in \mathbb{R}$ . Now for all  $x > 0$  the function  $g(x) = \frac{F'(x)}{x^4 + 1} = \frac{x \sin(x) + 4 \cos(4x)}{x^4 + 1}$  satisfies

$$|g(x)| = \left| \frac{x \sin(x) + 4 \cos(4x)}{x^4 + 1} \right| \leq \frac{|x \sin(x)| + 4 |\cos(4x)|}{x^4 + 1} \leq \frac{|x| + 4}{x^4 + 1} = \frac{x + 4}{x^4 + 1}.$$

It follows that  $\lim_{x \rightarrow +\infty} g(x) = 0$  (since  $\lim_{x \rightarrow +\infty} \frac{x+4}{x^4+1} = 0$ ).  $\square$

**6.D.31.** Suppose that the function  $f : \mathbb{R} \rightarrow \mathbb{R}$  has continuous second derivative on  $\mathbb{R}$  and attains a local extreme at  $x_0 = 1$ . Moreover, assume that the graph  $C_f$  of  $f$  passes through the point  $P = [0, 3] \in \mathbb{R}^2$ . If

$$\int_0^1 (x f''(x) + 4 f'(x)) dx = \alpha$$

for some real number  $\alpha$ , find  $\alpha$  such that  $f(1) = 1/3$ .

**Solution.** By assumption at  $x_0 = 1$  the function  $f$  attains a local extreme, thus  $f'(1) = 0$ . Moreover, we have  $f(0) = 3$ . Thus,

$$\begin{aligned} \int_0^1 (x f''(x) + 4 f'(x)) dx &= \int_0^1 x f''(x) dx + 4 \int_0^1 f'(x) dx = [x f'(x)]_0^1 - \int_0^1 (x') f'(x) dx + 4 [f(x)]_0^1 = \\ &= (1 \cdot f'(1) - 0 \cdot f'(0)) + 3 [f(x)]_0^1 = 0 + 3(f(1) - f(0)) = 3(f(1) - 3) = 3f(1) - 9. \end{aligned}$$

Thus  $3f(1) - 9 = \alpha$ , from where it follows that  $f(1) = (\alpha + 9)/3$ , and since it should be  $f(1) = 1/3$  we get  $\alpha = -8$ .  $\square$

Suppose that for some rational function  $f$  we want to compute the integral  $\int f(\sin(x), \cos(x)) dx$ . Then, usually we apply the substitution method, and here are some hints:

- If  $f(\sin(x), -\cos(x)) = -f(\sin(x), \cos(x))$ , then apply the substitution  $t = \sin(x)$ ;
- If  $f(-\sin(x), \cos(x)) = -f(\sin(x), \cos(x))$ , then set  $t = \cos(x)$ ;
- If  $f(-\sin(x), -\cos(x)) = f(\sin(x), \cos(x))$ , then set  $t = \tan(x)$ ;
- If none of these equalities hold, then try to use the substitution  $t = \tan(x/2)$ .

**6.D.32.** Integrate the following functions, with  $x \in (-\frac{\pi}{2}, \frac{\pi}{2})$  for all the cases:

(a)  $f(x) = \frac{\sin^3(x)}{1 + 4 \cos^2(x) + 3 \sin^2(x)}$ ;

(b)  $g(x) = \frac{1}{1 + \sin^2(x)}$ ;

(c)  $h(x) = \frac{1}{2 - \cos(x)}$ .

**Solution.** For  $f(x)$ , in the denominator it appears the function  $\beta(x) = 1 + 4 \cos^2(x) + 3 \sin^2(x)$ , which can be rewritten as  $\beta(x) = 4 + \cos^2(x)$ , and in the numerator only the sine function to an odd power. Thus, the substitution  $t = \cos(x)$  with  $dt = -\sin(x) dx$ , allows the replacement of all the sines and cosines. Indeed,

$$\begin{aligned} \int \frac{\sin^3(x)}{\beta(x)} dx &= \int \frac{\sin(x) (1 - \cos^2(x))}{4 + \cos^2(x)} dx = \int \frac{-(1 - t^2)}{4 + t^2} dt = \int \left(1 - \frac{5}{4 + t^2}\right) dt = t - \frac{5}{2} \arctan\left(\frac{t}{2}\right) + C \\ &= \cos(x) - \frac{5}{2} \arctan\left(\frac{\cos(x)}{2}\right) + C. \end{aligned}$$

For  $g(x)$ , because both the sine and cosine appear to an even power, we may use the substitution  $t = \tan(x)$ , and hence  $x = \arctan(t)$ . This leads to the relations

$$\sin^2(x) = \frac{\tan^2(x)}{1 + \tan^2(x)} = \frac{t^2}{1 + t^2}, \quad \cos^2(x) = \frac{1}{1 + \tan^2(x)} = \frac{1}{1 + t^2}.$$

Combining them with the relation  $dx = \frac{1}{1+t^2} dt$ , we get

$$\int \frac{dx}{1 + \sin^2(x)} = \int \frac{\frac{1}{1+t^2}}{1 + \frac{t^2}{1+t^2}} dt = \int \frac{1}{1+2t^2} dt = \frac{\sqrt{2}}{2} \arctan(\sqrt{2}t) + C = \frac{\sqrt{2}}{2} \arctan(\sqrt{2} \tan(x)) + C.$$

Finally, for  $h(x)$  one can apply the universal substitution  $t = \tan\left(\frac{x}{2}\right)$ , with

$$\sin(x) = \frac{2t}{1+t^2}, \quad \cos(x) = \frac{1-t^2}{1+t^2}, \quad dx = \frac{2}{1+t^2} dt.$$

In such terms we have

$$\int \frac{dx}{2 - \cos x} = \int \frac{\frac{2}{1+t^2}}{2 - \frac{1-t^2}{1+t^2}} dt = 2 \int \frac{dt}{1+3t^2} = \frac{2\sqrt{3}}{3} \arctan(\sqrt{3}t) + C = \frac{2\sqrt{3}}{3} \arctan\left(\sqrt{3} \tan\left(\frac{x}{2}\right)\right) + C.$$

□

**6.D.33.** Evaluate the integral  $I = \int \frac{1}{\sin(x)} dx$  with  $x \in (0, \frac{\pi}{2})$ , in at least two alternative ways.

**Solution.** We may rewrite the integrand as  $\frac{1}{\sin(x)} = \frac{\sin(x)}{\sin^2(x)} = \frac{\sin(x)}{1 - \cos^2(x)}$ . Thus,  $I = \int \frac{\sin(x)}{1 - \cos^2(x)} dx$  and we may set  $t = \cos(x)$  with  $dt = -\sin(x) dx$ , which gives  $I = -\int \frac{dt}{1-t^2}$ . However, it is easy to prove that  $-\frac{1}{1-t^2} = -\frac{1}{2(t+1)} + \frac{1}{2(t-1)}$ , hence we deduce that

$$\begin{aligned} I &= \frac{1}{2} \int \left( \frac{1}{t-1} - \frac{1}{t+1} \right) dt = \frac{1}{2} \ln|t-1| - \frac{1}{2} \ln|t+1| + C = \frac{1}{2} \ln \left| \frac{t-1}{t+1} \right| + C = \frac{1}{2} \ln \left| \frac{\cos(x)-1}{\cos(x)+1} \right| + C = \\ &= \frac{1}{2} \ln \left| \tan^2\left(\frac{x}{2}\right) \right| + C = \frac{1}{2} \ln \left| \tan\left(\frac{x}{2}\right) \right|^2 + C = \ln \left| \tan\left(\frac{x}{2}\right) \right| + C, \quad C \in \mathbb{R}. \end{aligned}$$

Here we applied the formulas  $\tan\left(\frac{x}{2}\right) = \sqrt{\frac{1-\cos(x)}{1+\cos(x)}}$  and  $|x|^2 = |x^2|$ .

Probably, the quickest way to compute the integral at hand is the substitution  $t = \tan\left(\frac{x}{2}\right)$  (see also 6.D.32), with

$$\sin(x) = \frac{2 \tan\left(\frac{x}{2}\right)}{1 + \tan^2\left(\frac{x}{2}\right)} = \frac{2t}{1+t^2}, \quad dx = \frac{2}{1+t^2} dt.$$

In such terms we immediately get  $I = \int \frac{1}{\frac{2t}{1+t^2}} \cdot \frac{2}{1+t^2} dt = \int \frac{1}{t} dt = \ln|t| + C = \ln \left| \tan\left(\frac{x}{2}\right) \right| + C, C \in \mathbb{R}$ . Notice may exist many other alternatives based on different trigonometric identities. For instance, one may use the identity

$$\tan\left(\frac{x}{2}\right) + \frac{1}{\tan\left(\frac{x}{2}\right)} = \tan\left(\frac{x}{2}\right) + \cot\left(\frac{x}{2}\right) = \frac{2}{\sin(x)}, \quad x \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right),$$

which you may verify either by your pencil, or by Sage and the command

```
bool(2/sin(x)==(tan(x/2)+(1/tan(x/2)))) for x in RealSet(-pi/2, pi/2)
```

□

*Then next few tasks involve the integration of rational functions.*

**6.D.34.** Consider the rational function  $Q(x) = \frac{1}{x^3 - 1}$ , with  $x \neq 1$ .

(a) Present the decomposition of  $Q$  into partial fractions, and then verify your answer by Sage.

(b) Evaluate the integral  $A = \int Q(x) dx$ .

○

**6.D.35.** Determine the integral  $\int \frac{3x+5}{x^2+4x+8} dx$ , where  $x \in \mathbb{R}$ .

○

**6.D.36.** Compute the indefinite integral of the function  $f(x) = \frac{1}{(x^2+x+1)^2}$ , with  $x \in \mathbb{R}$ .

○

**6.D.37.** Determine the indefinite integral  $\int \frac{dx}{x^3+1}$ , where  $x \in \mathbb{R} \setminus \{-1\}$ .

○

Next, we present additional material related to the integration of irrational expressions. In particular, for a few, we will focus on integrals of the form

$$\int f(x, \sqrt{ax^2 + bx + c}) dx,$$

where  $f$  is a rational expression and we expect  $a \neq 0$ ,  $b^2 - 4ac \neq 0$  for otherwise arbitrary numbers  $a, b, c \in \mathbb{R}$ . In this case one can distinguish two cases, related with the existence/non-existence of real roots for the quadratic polynomial  $ax^2 + bx + c$ .

- If  $a > 0$  and the polynomial  $ax^2 + bx + c$  has real roots  $x_1, x_2$ , use the representation

$$\sqrt{ax^2 + bx + c} = \sqrt{a} \sqrt{(x - x_1)^2 \frac{x - x_2}{x - x_1}} = \sqrt{a} |x - x_1| \sqrt{\frac{x - x_2}{x - x_1}}$$

and set  $t^2 = \frac{x - x_2}{x - x_1}$ .

- If  $a < 0$  and the polynomial  $ax^2 + bx + c$  has real roots  $x_1 < x_2$ , use the representation

$$\sqrt{ax^2 + bx + c} = \sqrt{-a} \sqrt{(x - x_1)^2 \frac{x_2 - x}{x - x_1}} = \sqrt{-a} (x - x_1) \sqrt{\frac{x_2 - x}{x - x_1}}$$

and set  $t^2 = \frac{x_2 - x}{x - x_1}$ .

- Finally, if the polynomial  $ax^2 + bx + c$  does not have real roots (necessarily for  $a > 0$ ), choose the substitution

$$\sqrt{ax^2 + bx + c} = \pm \sqrt{a} \cdot x \pm t$$

with any choice of the signs. Of course, here we choose the signs so that we result to as easy expression to integrate, as possible. As one can expect, for all these cases the corresponding substitutions lead to rational functions.

**6.D.38.** Determine the antiderivative of the following functions:

(a)  $f(x) = \frac{1}{(x + 4)\sqrt{x^2 + 3x - 4}}$ , with  $x \in (-\infty, -4) \cup (1, +\infty)$ ;

(b)  $g(x) = \frac{1}{(x - 1)\sqrt{x^2 + x + 1}}$ , with  $x \neq 1$ .

Next confirm the computations using Sage.

**Solution.** (a) According to the discussion above one can proceed as follows:

$$\int \frac{dx}{(x + 4)\sqrt{x^2 + 3x - 4}} = \int \frac{dx}{(x + 4)\sqrt{(x - 1)(x + 4)}} = \int \frac{dx}{(x + 4)|x + 4| \sqrt{\frac{x - 1}{x + 4}}} = \left| \begin{array}{l} t^2 = \frac{x - 1}{x + 4} \\ x = \frac{5}{1 - t^2} - 4 \\ dx = \frac{10t}{(1 - t^2)^2} dt \end{array} \right| = \int \frac{\frac{10t}{(1 - t^2)^2}}{\left(\frac{5}{1 - t^2}\right) \left|\frac{5}{1 - t^2}\right| t} dt = \int \frac{2}{5} \frac{|1 - t^2|}{1 - t^2} dt = \frac{2}{5} \text{sign}(1 - t^2) \int 1 dt = \frac{2}{5} \text{sign}\left(\frac{5}{x + 4}\right) t + C = \frac{2}{5} \text{sign}(x) \sqrt{\frac{x - 1}{x + 4}} + C.$$

In Sage giving the cell

```
f(x)=1/((x+4)*sqrt(x^2+3*x-4)); show(integral(f(x), x).factor())
```

we get the answer  $\frac{2\sqrt{x^2 + 3x - 4}}{5(x + 4)}$  (recall that  $x^2 + 3x - 4 = (x + 4)(x - 1)$ ). Hence Sage's answer does not contain the sign of  $x$ , but obviously our solution is correct.

(b) Here we see that

$$\int \frac{dx}{(x - 1)\sqrt{x^2 + x + 1}} = \left| \begin{array}{l} \sqrt{x^2 + x + 1} = x + t \\ x^2 + x + 1 = x^2 + 2xt + t^2 \\ x = -\frac{t^2 + 2t - 2}{2t - 1} + 1 \\ dx = \frac{-2(t^2 - t + 1)}{(2t - 1)^2} dt \end{array} \right| = \int \frac{\frac{-2(t^2 - t + 1)}{(2t - 1)^2}}{\frac{-t^2 + 2t - 2}{2t - 1} \frac{t^2 - t + 1}{2t - 1}} dt = \int \frac{2}{t^2 + 2t - 2} dt = \int \left( \frac{\sqrt{3}}{3} \frac{1}{t + 1 - \sqrt{3}} - \frac{\sqrt{3}}{3} \frac{1}{t + 1 + \sqrt{3}} \right) dt = \frac{\sqrt{3}}{3} \ln |t + 1 - \sqrt{3}| - \frac{\sqrt{3}}{3} \ln |t + 1 + \sqrt{3}| + C = \frac{\sqrt{3}}{3} \ln \left| \frac{t + 1 - \sqrt{3}}{t + 1 + \sqrt{3}} \right| + C = \frac{\sqrt{3}}{3} \ln \left| \frac{\sqrt{x^2 + x + 1} - x + 1 - \sqrt{3}}{\sqrt{x^2 + x + 1} - x + 1 + \sqrt{3}} \right| + C.$$

□

**6.D.39.** Using a suitable substitution, compute

$$\int \frac{dx}{x + \sqrt{x^2 + x - 1}} dx, \quad x \in \left(-\infty, \frac{-\sqrt{5}-1}{2}\right) \cup \left(\frac{\sqrt{5}-1}{2}, +\infty\right).$$

**Solution.** Even though the quadratic polynomial under the root has real roots  $x_1, x_2$ , we won't solve this problem by substitution  $t^2 = \frac{x-x_2}{x-x_1}$ . We could proceed that way, but we will rather use a method we introduced for the complex roots case. This is because this method yields a very simple integral of a rational function, as can be seen from the calculation

$$\begin{aligned} \int \frac{dx}{x + \sqrt{x^2 + x - 1}} &= \left| \begin{array}{l} \sqrt{x^2 + x - 1} = x + t \\ x^2 + x - 1 = x^2 + 2xt + t^2 \\ x = \frac{t^2+1}{1-2t} \\ dx = \frac{-2t^2+2t+2}{(1-2t)^2} dt \end{array} \right| = \int \frac{-2t^2 + 2t + 2}{(t+2)(1-2t)} dt = \\ &= \int \left(1 - \frac{2}{t+2} - \frac{1}{2} \frac{1}{t-\frac{1}{2}}\right) dt = t - 2 \ln |t+2| - \frac{1}{2} \ln \left|t - \frac{1}{2}\right| + C = \\ &= \sqrt{x^2 + x - 1} - x - 2 \ln \left(\sqrt{x^2 + x - 1} - x + 2\right) - \frac{1}{2} \ln \left|\sqrt{x^2 + x - 1} - x - \frac{1}{2}\right| + C. \end{aligned}$$

for some constant  $C$ . Notice an undeniable advantage of the recommended substitutions is their universality though: by using them, one can compute all integrals of the respective type.  $\square$

**6.D.40.** For  $x > 0$  determine

$$(a) \int \frac{(2+5x)^3}{\sqrt[4]{x^3}} dx, \quad (b) \int \frac{\sqrt[3]{1+\sqrt[4]{x}}}{\sqrt{x}} dx, \quad (c) \int \frac{1}{\sqrt[4]{1+x^4}} dx.$$

**Solution.** All three given integrals are binomial, i.e. they can be written as

$$\int x^m (a + bx^n)^p dx, \quad \text{for some } a, b \in \mathbb{R}, \text{ and } m, n, p \in \mathbb{Q}.$$

The binomial integrals are usually solved by applying the substitution method. If  $p \in \mathbb{Z}$  (not necessarily  $p < 0$ ), we choose the substitution  $x = t^s$ , where  $s$  is the common denominator of numbers  $m$  and  $n$ ; if  $\frac{m+1}{n} \in \mathbb{Z}$  and  $p \notin \mathbb{Z}$ , we choose  $a + bx^n = t^s$ , where  $s$  is the denominator of number  $p$ ; and if  $\frac{m+1}{n} + p \in \mathbb{Z}$  ( $p \notin \mathbb{Z}$ ,  $\frac{m+1}{n} \notin \mathbb{Z}$ ), we choose  $a + bx^n = t^s x^n$ , where  $s$  is the denominator of  $p$ . In these three cases, a reduction to an integration of a rational function is guaranteed.

Hence we can easily compute

(a)

$$\begin{aligned} \int \frac{(2+5x)^3}{\sqrt[4]{x^3}} dx &= \int x^{-\frac{3}{4}} (2+5x)^3 dx = \left| \begin{array}{l} p \in \mathbb{Z} \\ x = t^4 \\ dx = 4t^3 dt \end{array} \right| = 4 \int (2+5t^4)^3 dt = 4 \int (8 + 60t^4 + 150t^8 + 125t^{12}) dt = \\ &= 4 \left(8t + 12t^5 + \frac{50}{3}t^9 + \frac{125}{13}t^{13}\right) + C = 4 \left(8\sqrt[4]{x} + 12\sqrt[4]{x^5} + \frac{50}{3}\sqrt[4]{x^9} + \frac{125}{13}\sqrt[4]{x^{13}}\right) + C. \end{aligned}$$

(b)

$$\begin{aligned} \int \frac{\sqrt[3]{1+\sqrt[4]{x}}}{\sqrt{x}} dx &= \int x^{-\frac{1}{2}} \left(1+x^{\frac{1}{4}}\right)^{\frac{1}{3}} dx = \left| \begin{array}{l} p \notin \mathbb{Z}, \frac{m+1}{n} \in \mathbb{Z} \\ 1+x^{\frac{1}{4}} = t^3 \\ x = (t^3-1)^4 \\ dx = 12t^2(t^3-1)^3 dt \end{array} \right| = 12 \int t^3(t^3-1) dt = 12 \int t^6 - t^3 dt = \\ &= 12 \left(\frac{t^7}{7} - \frac{t^4}{4}\right) + C = 12\sqrt[3]{(1+\sqrt[4]{x})^4} \left(\frac{1+\sqrt[4]{x}}{7} - \frac{1}{4}\right) + C. \end{aligned}$$

(c)

$$\begin{aligned} \int \frac{1}{\sqrt[4]{1+x^4}} dx &= \int (1+x^4)^{-\frac{1}{4}} dx = \left| \begin{array}{l} p \notin \mathbb{Z}, \frac{m+1}{n} \notin \mathbb{Z}, \frac{m+1}{n} + p \in \mathbb{Z} \\ 1+x^4 = t^4 x^4 \\ x = (t^4-1)^{-\frac{1}{4}} \\ dx = -t^3(t^4-1)^{-\frac{5}{4}} dt \end{array} \right| = - \int \frac{t^2}{t^4-1} dt = - \int \frac{t^2}{(t-1)(t+1)(t^2+1)} dt = \\ &= -\frac{1}{4} \int \left(\frac{1}{t-1} - \frac{1}{t+1} + \frac{2}{t^2+1}\right) dt = -\frac{1}{4} (\ln |t-1| - \ln |t+1| + 2 \arctg t) + C = \\ &= -\frac{1}{4} \left[ \ln \frac{\sqrt[4]{\frac{1}{x^4}+1}-1}{\sqrt[4]{\frac{1}{x^4}+1}+1} + 2 \arctg \left(\sqrt[4]{\frac{1}{x^4}+1}\right) \right] + C. \end{aligned}$$

□

Next, we focus on definite integrals and related applications.

**6.D.41.** Compute the definite integrals given below:

$$A = \int_{\frac{\pi}{4}}^{\frac{\pi}{2}} \frac{\sin t}{1 - \cos^2 t} dt, \quad B = \int_0^{\ln 2} \frac{dx}{e^{2x} - 3e^x}, \quad C = \int_0^{\frac{\pi}{2}} \sin(x) \sin(2x) dx.$$

○

**6.D.42.** Use 6.B.36, to compute the integral  $\int_0^{50} \{x\} dx$ , where  $\{ \}$  is the fractional part function.

**Solution.** (c) Recall by 5.E.57 that the fractional part function is defined by  $\{x\} = x - \lfloor x \rfloor$ , and clearly this function is periodic with period  $T = 1$ . The integral at hand corresponds to the grey area in the following figure, which equals to  $10 \cdot \frac{1}{2} = 5$  (obviously, this is the area of 10 half square boxes with sides of length 1).

Indeed,

$$\int_0^{10} \{x\} dx = 10 \int_0^1 \{x\} dx = 10 \int_0^1 x dx = 10 \left[ \frac{x^2}{2} \right]_0^1 = 5.$$

For your convenience, here is the code used in Sage to produce the previous figure and confirm the result:

```
fract(x)=x-floor(x)
p=plot(fract, x, 0, 10, color="black", aspect_ratio=1, fill=True, fillcolor="grey", figsize=8); show(p)
integral(fract, x, 0, 10)
```

□

**6.D.43.** For some parameter  $\alpha \in \mathbb{R}$ , consider the function

$$f(x) = \begin{cases} e^x \cos(2x), & \text{if } x \in [-\pi/2, 0], \\ \sqrt{\alpha + \sin(4x)}, & \text{if } x \in (0, 3\pi/8]. \end{cases}$$

(a) Determine  $\alpha$  such that  $f$  is continuous for any  $x$  in its domain. Then use your answer and Sage to execute the following:

- Indicate the whole domain of  $f$  but also the domains of the two components of  $f$ .
- Sketch the graph of  $f$  via the piecewise method in Sage (see also 5.C.5).

(b) Compute the area in between the graph of  $f$  and the  $x$ -axis, bounded from the vertical lines  $x = \pm \frac{\pi}{4}$ .

(c) Use Sage in order to

- Confirm your result in (b), in a “manual way”.
- Compute the error that one obtains, if any, integrating the function  $f$ , as introduced via the piecewise method.

**Solution.** At  $x_0 = 0$  we see that  $\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (e^x \cos(2x)) = 1 = f(0)$ . Hence we need

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} \sqrt{\alpha + \sin(4x)} = 1 \iff \sqrt{\alpha + \lim_{x \rightarrow 0^+} \sin(4x)} = 1,$$

that is,  $\sqrt{\alpha + 0} = 1$  and hence  $\alpha = 1$ . Thus  $f$  is continuous everywhere in its domain if and only if  $\alpha = 1$  (obviously,  $f$  is continuous on the intervals  $[-\pi/2, 0)$  and  $(0, 3\pi/8]$ ). From now fix  $\alpha = 1$  and observe that  $f(-\pi/4) = 0$  and  $f(3\pi/8) = 0$ .

Sage has built-in commands to indicate the domain of a piecewise function and of its components, given by `domain` and `domains`, respectively. Hence we may type

```
f1(x)=(e^x)*cos(2*x); f2(x)=sqrt(1+sin(4*x))
f=piecewise([[(-pi/2, 0), f1(x)], [(0, 6*pi/16), f2(x)]])
f.domain(); f.domains()
```

Sage returns the obvious answers, i.e.,  $(-1/2 * \pi, 0) \cup (0, 3/8 * \pi)$ , and  $((-1/2 * \pi, 0), (0, 3/8 * \pi))$ , respectively.

Let us now present the graph of  $f$ , where we have included the two vertical lines from the question in (b), and shaded the region whose area needs to be computed.

The code to construct this figure relies on many different steps, and some advanced options from 2D-graphics in Sage, as for example the command `polygon` to shade the region in question.

In general, when one wants to integrate a function  $f$  from  $a$  to  $b$  and compute the area between  $f$  and the  $x$ -axis, with bounds the vertical lines passing from  $a, b$ , then can follow the summary given here:

- Step 1 introduce the function  $f$ ;  
 Step 2 declare the points  $a, b$   
 Step 3 sketch the graph of  $f$ , e.g., add the command

```
q= plot(f, (x, a-0.5, b+0.5), thickness=2)
```

- Step 4 graph the two vertical lines, which can be done by adding the syntax

```
q+= line([(a, 0), (a, f(a))], color='black')
q+= line([(b, 0), (b, f(b))], color='black')
```

- Step 5 shade the area at hand, via the `polygon` method:

```
q += polygon([(a, 0), (a, f(a))] + [(x, f(x)) for x in [a, a+0.005, ..., b]] + [(b, 0), (a, 0)],
            rgbcolor=(0.2, 0.4, 0.7), aspect_ratio="automatic")
```

- Step 6 produce the figure, which can be done by adding `show(q)` (we may specify further options here, as `ymin`, `ymax`, `ticks`, `figsize`, and other, hence instead one may type `q.show()`, and add inside the parentheses the appropriate options).

For our example this method becomes a few more complicated, since we have a piecewise function, and hence we use first the `piecewise` method to introduce  $f$ . Here is the full implementation combining both methods.

```
f1(x)=(e^x)*cos(2*x); f2(x)=sqrt(1+sin(4*x))
f=piecewise([( (-pi/2, 0), f1(x)), [(0, 6*pi/16), f2(x) ]])
p=plot(f(x), x, -pi/2, 6*pi/16, color="black", thickness=1.2)
p+=plot(f2(x), x, 0, 6*pi/16, color="darkgreen", thickness=1.2)
p+= text (" $f(x)$ ", (pi/16, 1.47), color="black", fontsize="12")
a=-pi/4; b=pi/4
p+=line([(a, 0), (a, 1)], color="black")
p+=line([(b, 0), (b, f(N(b)))]), color="black")
p+=polygon([( (-pi/4, 0), (-pi/4, f(N(-pi/4))) )]+[(x, f(N(x)))]
            for x in [-pi/4, -pi/4+0.005, ..., pi/4]]+[(b, 0), (a, 0)],
            rgbcolor=(0.5, 0.7, 0.8), aspect_ratio="automatic")
p.show(ticks=pi/4, tick_formatter=pi, ymin=-0.25, ymax=1.5)
```

Notice this technique requires the values introduced in  $f$  to be in numerical expression, and this is the reason behind the appearance of  $f(N(b))$ ,  $f(N(x))$ , etc. Otherwise Sage returns errors. However, as we will see below this method produces a small error in the computation of the given area; this is because the `piecewise` method uses approximations of  $a, b$ , which effect on the integration.

(b) Let us denote by  $E$  the shaded area. By definition we have

$$E = \int_{-\pi/4}^{\pi/4} |f(x)| dx = \int_{-\pi/4}^{\pi/4} f(x) dx = \int_{-\pi/4}^0 (e^x \cos(2x)) dx + \int_0^{\pi/4} \sqrt{1 + \sin(4x)} dx = E_1 + E_2.$$

For the first integral, recall that  $\left(\frac{\sin(2x)}{2}\right)' = \cos(2x)$  and  $\left(-\frac{\cos(2x)}{2}\right)' = \sin(2x)$ . Thus, by applying integration by parts twice we get

$$\begin{aligned} E_1 &= \int_{-\pi/4}^0 e^x \left(\frac{\sin(2x)}{2}\right)' dx = \frac{1}{2} [e^x \sin(2x)]_{-\pi/4}^0 - \frac{1}{2} \int_{-\pi/4}^0 e^x \sin(2x) dx = \\ &= \frac{1}{2} \left( e^0 \cdot \sin(0) - e^{-\pi/4} \cdot \sin\left(-\frac{2\pi}{4}\right) \right) + \frac{1}{4} \int_{-\pi/4}^0 e^x (\cos(2x))' dx = \\ &= \frac{1}{2} e^{-\pi/4} \cdot \sin\left(\frac{\pi}{2}\right) + \frac{1}{4} [e^x \cos(2x)]_{-\pi/4}^0 - \frac{1}{4} \int_{-\pi/4}^0 e^x \cos(2x) dx. \end{aligned}$$

Thus

$$E_1 = \frac{1}{2} e^{-\pi/4} + \frac{1}{4} \left( e^0 \cdot \cos(0) - e^{-\pi/4} \cdot \cos\left(-\frac{2\pi}{4}\right) \right) - \frac{1}{4} E_1,$$

or equivalently  $E_1 = \frac{2e^{-\pi/4} + 1}{5} \approx 0.382375$ .

For  $E_2$ , we use the identities  $\sin(2y) = 2 \sin(y) \cos(y)$  and  $\sin^2(y) + \cos^2(y) = 1$ , for any  $y \in \mathbb{R}$ , where we replace  $y$  by  $2x$ . Thus we can write

$$\begin{aligned} E_2 &= \int_0^{\pi/4} \sqrt{\sin^2(2x) + \cos^2(2x) + 2 \sin(2x) \cos(2x)} dx = \int_0^{\pi/4} \sqrt{(\sin(2x) + \cos(2x))^2} dx = \\ &= \int_0^{\pi/4} (\sin(2x) + \cos(2x)) dx = \left[ -\frac{\cos(2x)}{2} + \frac{\sin(2x)}{2} \right]_0^{\pi/4} = \frac{1}{2} + \frac{1}{2} = 1. \end{aligned}$$

Thus all together  $E = E_1 + E_2 = \frac{2e^{-\pi/4} + 1}{5} + 1 = \frac{2e^{-\pi/4} + 6}{5} \approx 1.382375$ .

(c) A confirmation of the result above, occurs easily, without using the piecewise method to introduce  $f$ , and from the mathematical point of view it relies on the relation  $E = E_1 + E_2$ . Hence we can type

```
f1(x)=e^(x)*cos(2*x); f2(x)=sqrt(1+sin(4*x))
show(integral(f1(x), x, -pi/4, 0))
show(integral(f2(x), x, 0, pi/4))
```

and this is what we mean “manually”. Execute this cell yourself to check Sage’s output.

On the other hand, introducing the function  $f$  (in Sage) via the piecewise method, gives us the ability to directly integrate  $f$ , as follows:

```
f1(x)=(e^x)*cos(2*x); f2(x)=sqrt(1+sin(4*x))
f=piecewise([[(-pi/2, 0), f1(x)], [(0, 6*pi/16), f2(x)]])
f.integral(x, N(-pi/4), N(pi/4))
```

However, since this still requires to introduce the certain values  $a = -\pi/4$  and  $b = \pi/4$  numerically, some error will appear. Indeed, executing this block, Sage prints out 1.16777341450385, which differs from the result in (b). The same time, we cannot replace in this certain example the last command by `f.integral(x, -pi/4, pi/4)`, which is a pitfall of Sage.  $\square$

**6.D.44.** Compute the area  $S$  of a figure composed of two parts of plane bounded by lines  $x = 0$ ,  $x = 1$ ,  $x = 4$ , the  $x$  axis and the graph of a function

$$y = \frac{1}{\sqrt[3]{x-1}}.$$

**Solution.** First realize that

$$\frac{1}{\sqrt[3]{x-1}} < 0, \quad x \in [0, 1), \quad \frac{1}{\sqrt[3]{x-1}} > 0, \quad x \in (1, 4]$$

and

$$\lim_{x \rightarrow 1^-} \frac{1}{\sqrt[3]{x-1}} = -\infty, \quad \lim_{x \rightarrow 1^+} \frac{1}{\sqrt[3]{x-1}} = +\infty.$$

The first part of the figure (below the  $x$  axis) is thus bounded by the curves

$$y = 0, \quad x = 0, \quad x = 1, \quad y = \frac{1}{\sqrt[3]{x-1}}$$

with an area given by the improper integral

$$S_1 = -\int_0^1 \frac{1}{\sqrt[3]{x-1}} dx;$$

while the second part (above the  $x$  axis), which is bounded by the curves

$$y = 0, \quad x = 1, \quad x = 4, \quad y = \frac{1}{\sqrt[3]{x-1}},$$

has an area of

$$S_2 = \int_1^4 \frac{1}{\sqrt[3]{x-1}} dx.$$

Since

$$\int \frac{1}{\sqrt[3]{x-1}} dx = \frac{3}{2} \sqrt[3]{(x-1)^2} + C,$$

the sum  $S_1 + S_2$  can be gotten as

$$S = - \lim_{x \rightarrow 1^-} \left( \frac{3}{2} \sqrt[3]{(x-1)^2} - \frac{3}{2} \right) + \lim_{x \rightarrow 1^+} \left( \frac{3}{2} \sqrt[3]{9} - \frac{3}{2} \sqrt[3]{(x-1)^2} \right) = \frac{3}{2} (1 + \sqrt[3]{9}).$$

We have shown among other things, that the given figure has a finite area, even though it's unbounded (both from the top and the bottom). (If we approach  $x = 1$  from the right, eventually from the left, its altitude grows beyond measure.) Recall here the indefinite expression of type  $0 \cdot \infty$ . Namely, the figure is bounded if we limit ourselves to  $x \in [0, 1 - \delta] \cup [1 + \delta, 4]$  for an arbitrarily small  $\delta > 0$ .  $\square$

**6.D.45.** Determine the surface and volume of a circular paraboloid created by rotating a part of the parabola  $y = 2x^2$  for  $x \in [0, 1]$  around the  $y$  axis.

**Solution.** The formulas stated in the texts are true for rotating the curves around the  $x$  axis! Hence it's necessary either to integrate the given curve with respect to variable  $y$ , or to transform. This gives

$$V = \int_0^2 \frac{x}{2} dx = \pi \quad \text{and} \quad S = 2\pi \int_0^2 \sqrt{\frac{x}{2}} \sqrt{1 + \frac{1}{8x}} dx = 2\pi \int_0^2 \sqrt{\frac{x}{2} + \frac{1}{16}} dx = \pi \frac{17\sqrt{17} - 1}{24}.$$

$\square$

A) MATERIAL ON SEQUENCES, SERIES AND LIMIT PROCESSES

*We begin with additional material related to uniform convergence of sequence of functions and of series.*

**6.D.46. Uniform convergence.** Let  $(f_n)$  be a sequence of functions defined on an interval  $I$  such that  $\lim_{n \rightarrow \infty} f_n(x) = f(x)$  for all  $x \in I$ . Prove that  $(f_n)$  uniformly converges to  $f$  on  $I$  if and only if  $\lim_{n \rightarrow \infty} a_n = 0$ , where  $a_n := \sup_{x \in I} |f_n(x) - f(x)|$ .

**Solution.** Suppose that  $(f_n)$  is uniformly convergent to  $f$  on  $I$ . Then, given  $\varepsilon > 0$  there exists an integer  $N$  such that for any  $n \geq N$  and  $x \in I$  we have  $|f_n(x) - f(x)| < \varepsilon$ . Therefore we also have  $a_n := \sup_{x \in I} |f_n(x) - f(x)| \leq \varepsilon$  for all  $n \geq N$  and thus  $a_n \rightarrow 0$  as  $n \rightarrow \infty$ . Conversely, assume that  $\lim_{n \rightarrow \infty} a_n = 0$ , where  $a_n$  is defined as above. Then, for any  $\varepsilon > 0$  there exists an integer  $N$  such that  $a_n < \varepsilon$  for all  $n \geq N$ , that is,

$$\sup_{x \in I} |f_n(x) - f(x)| < \varepsilon, \quad \text{for all } n \geq N.$$

By the definition of supremum,

$$|f_n(x) - f(x)| \leq \sup_{x \in [a,b]} |f_n(x) - f(x)| < \varepsilon,$$

for sufficiently large  $n$  and for all  $x \in I$ . Thus  $(f_n)$  uniformly converges to  $f$  on  $I$ .  $\square$

**6.D.47. Natural logarithm.** Expand the natural logarithm  $f(x) = \ln(1+x)$  into a power series around 0 and 1, and next determine all  $x \in \mathbb{R}$  for which these series converge.

**Solution.** First we will determine the expansion around point 0. To expand a function into a power series at a given point is the same as to determine its Taylor expansion at that point. We can easily see that

$$f^{(n)}(x) = [\ln(x+1)]^{(n)} = (-1)^{n+1} \frac{(n-1)!}{(x+1)^n},$$

so after computing the derivatives at zero, we have

$$f(x) = \ln(x+1) = \ln 1 + \sum_{n=1}^{\infty} a_n x^n,$$

where the coefficients  $a_n$  are given by

$$a_n = \frac{(-1)^{n+1} (n-1)!}{n!} = \frac{(-1)^{n+1}}{n}.$$

Therefore, one can write

$$\begin{aligned} f(x) = \ln(x+1) &= x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots \\ &= \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} x^n. \end{aligned}$$

For the radius of convergence, we can then use the limit of the quotient of the following coefficients of terms of the power series:

$$r = \frac{1}{\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right|} = \frac{1}{\lim_{n \rightarrow \infty} \frac{\frac{1}{n+1}}{\frac{1}{n}}} = 1.$$

Hence the series converges for arbitrary  $x \in (-1, 1)$ . For  $x = -1$  we get the harmonic series (with a negative sign), while for  $x = 1$  we get the alternating harmonic series, which converges by the Leibniz criterion. Thus the given series converges exactly for  $x \in (-1, 1]$ .

Analogously, for the expansion at point 1, we get

$$\begin{aligned} f(x) = \ln(x+1) &= \ln(2) + \frac{1}{2}(x-1) - \frac{1}{8}(x-1)^2 \\ &\quad + \frac{1}{3 \cdot 2^3}(x-1)^3 - \dots \\ &= \ln(2) + \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n \cdot 2^n} (x-1)^n, \end{aligned}$$

and for the radius of convergence of this series we get

$$r = \frac{1}{\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right|} = \frac{1}{\lim_{n \rightarrow \infty} \frac{\frac{1}{2^{n+1}(n+1)}}{\frac{1}{2^n n}}} = 1.$$

□

- 6.D.48.** Expand the function  $\cos^2(x)$  into a power series at 0, and determine for which  $x \in \mathbb{R}$  it converges.
- 6.D.49.** Expand the function  $\sin^2(x)$  into a power series at 0 and determine for which  $x \in \mathbb{R}$  it converges.
- 6.D.50.** Expand the function  $\ln(x^3 + 3x^2 + 3x + 1)$  into a power series at 0 and determine for which  $x \in \mathbb{R}$  it converges.
- 6.D.51.** Expand the function  $\ln(\sqrt{x})$  into a power series at 1 and determine for which  $x \in \mathbb{R}$  it converges.

Now is the time to demonstrate various ways to combine the theory of Taylor series with differentiation and integration. Further similar tasks are presented in Section D (see for example 6.D.58). To make the description more engaging, we will also utilize Sage.

- 6.D.52.** On the interval of convergence  $(-1, 1)$ , determine the sum of the series

$$\sum_{n=1}^{\infty} n(n+1)x^n.$$

Next confirm your answer in Sage.

**Solution.** We have

$$\begin{aligned} \sum_{n=1}^{\infty} n(n+1)x^n &= \sum_{n=1}^{\infty} n(x^{n+1})' = \left( \sum_{n=1}^{\infty} n x^{n+1} \right)' \\ &= \left( \sum_{n=1}^{\infty} n x^{n-1} x^2 \right)' = \left[ x^2 \sum_{n=1}^{\infty} (x^n)' \right]' \\ &= \left[ x^2 \left( \sum_{n=1}^{\infty} x^n \right)' \right]' = \left[ x^2 \left( -1 + \sum_{n=0}^{\infty} x^n \right)' \right]' \\ &= \left[ x^2 \left( -1 + \frac{1}{1-x} \right)' \right]' = \left[ x^2 \cdot \frac{1}{(1-x)^2} \right]' = \frac{2x}{(1-x)^3}, \end{aligned}$$

for all  $x \in (-1, 1)$ . To confirm the result in Sage use the `sum` command, as follows:

```
var("n")
show(sum(n*(n+1)*x^n, n, 1, oo).factor())
```

□

**6.D.53.** Use the Taylor series of  $f(x) = \cos(\sqrt{x})$  centered at 0 to approximate the integral  $I = \int_0^1 \cos(\sqrt{x}) dx$ . Then use Sage to compute the real value of  $I$ , and compare the two results. ○

**6.D.54. Taylor series of arctan.** Consider the function  $f(x) = 1/(1+x^2)$ ,  $x \in (-1, 1)$ . Use the Taylor series of  $f$  centered at 0 and the notion of definite integrals to compute the power series of  $\arctan(x)$  around 0.

**Solution.** Recall that for  $|x| < 1$  we have  $\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n$ . Thus the replacement of  $x$  by  $-x^2$  gives (see also 5.E.142)

$$\frac{1}{1+x^2} = \sum_{n=0}^{\infty} (-1)^n x^{2n}, \quad |x| < 1.$$

Hence, for all  $t \in (-1, 1)$  we have

$$\arctan'(t) = \frac{1}{1+t^2} = \sum_{n=0}^{\infty} (-t^2)^n = \sum_{n=0}^{\infty} (-1)^n t^{2n}.$$

Now, for all  $x \in (-1, 1)$  we have  $\int_0^x \arctan'(t) dt = \arctan(x) - \arctan(0) = \arctan(x)$ . On the other side

$$\int_0^x \left( \sum_{n=0}^{\infty} (-1)^n t^{2n} \right) dt = \sum_{n=0}^{\infty} \left( (-1)^n \int_0^x t^{2n} dt \right) = \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} x^{2n+1},$$

and thus  $\arctan(x) = \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} x^{2n+1}$  for all  $x \in (-1, 1)$ . □

**6.D.55.** Find the Maclaurin series of the function

$$A(x) = \int_0^x t \cos(t^2) dt.$$

**Solution.** The Maclaurin series of  $\cos(t)$  is

$$1 - \frac{t^2}{2!} + \frac{t^4}{4!} - \dots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} t^{2n}.$$

Using this we see that

$$t \cos(t^2) = t \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n}}{(2n)!} = \sum_{n=0}^{\infty} (-1)^n \frac{t^{4n+1}}{(2n)!}.$$

Therefore,

$$\begin{aligned} A(x) &= \int_0^x t \cos(t^2) dt = \int_0^x \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} t^{4n+1} dt \\ &= \sum_{n=0}^{\infty} \left[ \frac{(-1)^n}{(2n)!} \int_0^x t^{4n+1} dt \right] \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(4n+2)(2n)!} x^{4n+2}. \end{aligned}$$

Let us write down the first few terms of  $A$ ,

$$A(x) = \frac{1}{2}x^2 - \frac{1}{12}x^6 + \frac{1}{240}x^{10} - \frac{1}{10080}x^{14} + \dots$$

A confirmation of this expression via Sage is based on the method presented in 6.A.17. However, one should now combine this method with the command `integral(g(t), t, 0, x)`, to introduce a function of the form  $\int_0^x g(t) dt$ , where  $g(t) = t \cos(t^2)$ .

Thus the implementation goes as follows:

```
var("t"); assume(x>0)
f(x)=integral(t*cos(t^2), t, 0, x)
tf=taylor(f, x, 0, 6)
T=tf.power_series(QQ); show(T)
```

□

**6.D.56.** For the convergent series

$$\sum_{n=0}^{\infty} \frac{(-1)^n}{\sqrt{n+100}}$$

estimate the error of the approximation of its sum by the partial sum  $s_{9999}$ .

○

**6.D.57.** Approximate the expression given below with an error lesser than  $1/10$ :

$$\int_1^2 \left( x - \frac{\cos^{10}(x)}{10} \right) \ln(x) dx.$$

○

**6.D.58.** Find the Maclaurin series of the function  $F(x) = \int_0^x \frac{\sin(t)}{t} dt$ , with  $x \in \mathbb{R}$ . Next check your answer via Sage, and plot the graph of the function  $F$  for certain  $x$  in the domain of  $F$ .

**Solution.** Recall that  $\sin(t) = t - \frac{t^3}{3!} + \frac{t^5}{5!} - \dots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} t^{2n+1}$  for all  $t \in \mathbb{R}$ , hence

$$\frac{\sin(t)}{t} = 1 - \frac{t^2}{3!} + \frac{t^4}{5!} - \dots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} t^{2n}.$$

By integrating this series we get the series expansion of  $F(x)$ , i.e.,

$$\begin{aligned} F(x) &= \int_0^x \frac{\sin(t)}{t} dt = \int_0^x \left[ \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} t^{2n} \right] dt = \sum_{n=0}^{\infty} \left[ \frac{(-1)^n}{(2n+1)!} \int_0^x t^{2n} dt \right] = \sum_{n=0}^{\infty} \left[ \frac{(-1)^n}{(2n+1)!} \frac{t^{2n+1}}{(2n+1)} \right]_0^x \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)(2n+1)!} x^{2n+1}. \end{aligned}$$

Hence the series expansion of  $F$  is given by

$$F(x) = x - \frac{x^3}{3 \cdot 3!} + \frac{x^5}{5 \cdot 5!} - \dots + \frac{(-1)^n}{(2n+1)(2n+1)!} x^{2n+1} + \dots$$

We can easily check this result in Sage by the method described in 6.A.17 and 6.D.55, that is,

```
var("t"); assume(x>0); F(x)=integral(sin(t)/t, t, 0, x)
tF=taylor(F, x, 0, 7); T=tF.power_series(QQ); show(T)
```

This cell prints out the following expression:  $x - \frac{1}{18}x^3 + \frac{1}{600}x^5 - \frac{1}{35280}x^7 + O(x^8)$ , hence verifies our answer. In order to plot the graph of  $F$  for certain  $x$  we can for example add in the above cell the command `show(plot(F, x, -10, 10))`.

**6.D.59.** Find the function  $f$  to which, for  $x \in \mathbb{R}$ , the sequence of functions

$$f_n(x) = \frac{n^2 x^3}{n^2 x^2 + 1}, \quad n \in \mathbb{N}.$$

converges. Is this convergence uniform on  $\mathbb{R}$ ?

**6.D.60.** Does the series

$$\sum_{n=1}^{\infty} \frac{nx}{n^4 + x^2}, \quad \text{kde } x \in \mathbb{R},$$

converge uniformly on the real line?

**6.D.61.** Approximate

(a) the cosine of ten degrees with accuracy of at least  $10^{-5}$ ;

(b) the definite integral  $\int_0^{1/2} \frac{dx}{x^4 + 1}$  with accuracy of at least  $10^{-3}$ .

**6.D.62.** Determine the power series centered at  $x_0 = 0$  of the function

$$f(x) = \int_0^x e^{t^2} dt, \quad x \in \mathbb{R}.$$

**6.D.63.** Using the integral test, find the values  $a > 0$  for which the series

$$\sum_{n=1}^{\infty} \frac{1}{n^a}$$

converges.

**6.D.64.** For which  $x \in \mathbb{R}$  does the series

$$\sum_{n=1}^{\infty} \frac{\ln(n!)}{n^x}$$

converge?

**6.D.65.** Determine whether the series

$$\sum_{n=1}^{\infty} (-1)^{n-1} \tan \frac{1}{n\sqrt{n}}$$

converges absolutely, converges conditionally, diverges to  $+\infty$ , diverges to  $-\infty$ , or none of the above. (such a series is sometimes said to be oscillating).

**6.D.66.** Calculate the series

$$\sum_{n=1}^{\infty} \frac{1}{n \cdot 3^n}$$

with the help of an appropriate power series.

Solutions of the exercises

**6.A.5.** For all  $x \in (-1, 1)$  we have  $\ln \frac{1+x}{1-x} = \ln(1+x) - \ln(1-x)$ . Therefore, it is useful to consider the auxiliary function

$$\varphi(x) := \ln(ax+1), \quad x \in (-1, 1), \quad a = \pm 1.$$

For this function we easily compute

$$\varphi'(x) = \frac{a}{ax+1}, \quad \varphi''(x) = \frac{-a^2}{(ax+1)^2}, \quad \varphi^{(3)}(x) = \frac{2a^3}{(ax+1)^3}, \quad \varphi^{(4)}(x) = \frac{-6a^4}{(ax+1)^4},$$

for all  $x \in (-1, 1)$ . Motivated by these formulas, one may guess that

$$\varphi^{(n)}(x) = \frac{(-1)^{n-1}(n-1)!a^n}{(ax+1)^n}, \quad x \in (-1, 1), \quad n \in \mathbb{N}. \quad (*)$$

Let us use the principle of mathematical induction to prove (\*). As we have seen, it holds for  $n = 1, 2, 3, 4$  and we assume that (\*) holds for some other  $k \in \mathbb{N}$ . Then, a direct computation shows that

$$\varphi^{(k+1)}(x) = (\varphi^{(k)}(x))' = \left( \frac{(-1)^{k-1}(k-1)!a^k}{(ax+1)^k} \right)' = \frac{(-1)^{k-1}(k-1)!a^k(-k)a}{(ax+1)^{k+1}} = \frac{(-1)^k k! a^{k+1}}{(ax+1)^{k+1}},$$

and hence the relation (\*) is true for all  $n \in \mathbb{N}$ . Let us now return back to our initial task. By (\*) we may compute the  $n$ th derivative of  $\ln(1 \pm x)$ , that is,

$$\ln^{(n)}(1+x) = \frac{(-1)^{n-1}(n-1)!}{(x+1)^n}, \quad \ln^{(n)}(1-x) = -\frac{(n-1)!}{(-x+1)^n}, \quad x \in (-1, 1).$$

Therefore, we finally deduce that

$$\left( \ln \frac{1+x}{1-x} \right)^{(n)} = (n-1)! \left( \frac{1}{(1-x)^n} - \frac{(-1)^n}{(1+x)^n} \right)$$

for all  $x \in (-1, 1)$  and  $n \in \mathbb{N}$ .

**6.A.6.** The answer is  $f^{(12)}(x) = 2^{12} e^{2x} + \cos(x)$ .

**6.A.7.** The answer is  $f^{(26)}(x) = -\sin(x) + 2^{26} e^{2x}$ .

**6.A.8.** Recall that the third-order Taylor expansion of a function  $f$  around the point  $a = 0$ , is given by

$$T_0^3 f(x) = f(0) + f'(0)x + \frac{f''(0)}{2}x^2 + \frac{f^{(3)}(0)}{6}x^3.$$

For the sine function  $f(x) = \sin(x)$  we have  $f'(0) = \cos(0) = 1$ ,  $f^{(2)}(0) = -\sin(0) = 0$ ,  $f^{(3)}(0) = -\cos(0) = -1$ , and  $f(0) = 0$ . Thus we get

$$T_0^3 \sin(x) = x - \frac{1}{6}x^3 = x - \frac{x^3}{3!}.$$

In a similar way we obtain

$$T_0^3 \cos(x) = 1 - \frac{x^2}{2}, \quad T_0^3 e^x = 1 + x + \frac{x^2}{2} + \frac{x^3}{6}, \quad T_0^3 \ln(x+1) = x + \frac{x^2}{2} - \frac{x^3}{3}.$$

**6.A.10.** The answer is

$$T_1^4 f(x) = 2(x-1) - (x-1)^2 + \frac{2}{3}(x-1)^3 - \frac{1}{2}(x-1)^4.$$

To obtain this expression via Sage, we may type

```
f(x)=ln(x^2); T(x)=taylor(f(x), x, 1, 4); show(T(x))
```

Adding in this cell the command

```
p=plot(f(x), x, 0, 2, color="black", thickness=1.1)
p+=plot(T(x), x, 0, 2, linestyle="--", thickness=1.1);
p+=text(r"$f$", (1.95,1.8), fontsize=14, color="black")
p+=text(r"$T$", (1.95,0.8), fontsize=14, color="blue")
show(p)
```

one can produce the required graphs which we present here (the graph of the Taylor polynomial is coloured blue).

Observe that the approximation is accurate enough. In fact, try to verify yourself that as the degree of the Taylor polynomials increases, the approximations become more accurate.

**6.A.13.** Consider the exponential function  $f(x) = e^x$  restricted on the closed interval  $[0, x]$ . The third-order degree Taylor polynomial of  $f(x) = e^x$ , centered at  $a = 0$  has the form

$$T_0^3 e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!}.$$

Now,  $f$  is a smooth function and according to the theorem in 6.1.3 there exists some  $c \in (0, x)$  such that

$$f(x) = e^x = T_0^3 e^x + R(x), \quad R(x) = \frac{x^{3+1}}{(3+1)!} f^{(3+1)}(c).$$

We have  $f^{(4)}(x) = e^x$  and hence we see that  $R(x) = \frac{x^4}{4!} e^c > 0$ . Thus  $f(x) - T_0^3 f(x) \geq 0$  which proves our claim.

**6.A.14.** In this case we have  $k = 2$  and hence we compute the error  $\frac{-x^3}{3(1+x)^3}$ .

**6.A.15.** We compute  $T_0^4 \sin(x) = x - \frac{x^3}{6}$ . In Sage the task can be solved by the block

```
f(x)=sin(x); F=plot(f(x), x, -pi, pi)
T4(x)=taylor(f(x), x, 0, 4); show(T4(x))
T=plot(T4(x), x, -pi, pi, color="black"); show(F+T)
```

This confirms the expression of  $T_0^4 \sin(x)$  and produces the graphs of  $f, T_0^4 f$ , which we present in the figure below (in this figure, with blue is coloured the graph of  $f$ )

Next we may approximate  $\sin 1^\circ$  by the expression  $\sin 1^\circ \approx \frac{\pi}{180} - \frac{\pi^3}{6 \cdot 180^3}$ .

**6.A.16.** The answer is  $1 - \frac{\pi^2}{10^2 \cdot 2} + \frac{\pi^4}{10^4 \cdot 4!}$ .

**6.A.18.** One can use the known formula  $\frac{1}{1+x} = \sum_{n=0}^{\infty} (-x)^n = \sum_{n=0}^{\infty} (-1)^n x^n$  corresponding to geometric series. By differentiating it, we obtain

$$-\frac{1}{(1+x)^2} = \left( \sum_{n=0}^{\infty} (-1)^n x^n \right)' = \sum_{n=1}^{\infty} (-1)^n n x^{n-1}.$$

Thus we see that

$$\frac{1}{(1+x)^2} = \sum_{n=1}^{\infty} (-1)^{n+1} n x^{n-1} = 1 - 2x + 3x^2 - 4x^3 + 5x^4 - 6x^5 + 7x^6 - 8x^7 + \dots$$

for all  $x \in (-1, 1)$ . Finally, to confirm this expression by Sage we use the same method as in 6.A.17, i.e.,

```
f(x)=1/(1+x)^2; tf=taylor(f, x, 0, 10); T=tf.power_series(QQ); show(T)
```

Sage's answer has the form

$$1 - 2x + 3x^2 - 4x^3 + 5x^4 - 6x^5 + 7x^6 - 8x^7 + 9x^8 - 10x^9 + 11x^{10} + O(x^{11}).$$

**6.A.19.** The first limit equals to  $-1/6$ , while the second limit takes the value  $-1$ .

**6.A.22.** An example is given by  $f(x) = x^4$ . The point  $x_0 = 0$  is a local minimum of  $f$  but  $f'(0) = 0$  and  $f''(0) = 0$ .

**6.A.26.** For the solution one can adopt the method presented in 6.A.25, which means that we should use appropriately the commands `find_local_maximum(f, a, b)` and `find_local_minimum(f, a, b)`. The implementation takes the form

```
f(x)=(1/8)*x^8-(3/5)*x^5-3*x+9
fp=plot(f(x), x, -2, 2, color="black", legend_label=r"$f(x)$")
show(fp)
show(find_local_maximum(f, -2, 2))
show(find_local_minimum(f, -2, 2))
g(x)=x^2-(1/6)*x^3
gp=plot(g(x), x, -2, 2, color="black", legend_label=r"$g(x)$")
show(gp)
show(find_local_maximum(g, -2, 2))
show(find_local_minimum(g, -2, 2))
h(x)=x/sqrt(x^2+4)
hp=plot(h(x), x, -2, 2, color="black", legend_label=r"$h(x)$")
show(hp)
show(find_local_maximum(h, -2, 2))
show(find_local_minimum(h, -2, 2))
k(x)=ln(x^3+8)
kp=plot(k(x), x, -2, 2, color="black", legend_label=r"$k(x)$")
show(kp)
show(find_local_maximum(k, -2, 2))
show(find_local_minimum(k, -2, 2))
```

Sage's answers look like as follows:

For  $f$  : (66.19999293835187, -1.9999999605494494) , (3.1326992998650347, 1.525960530898268) .

For  $g$  : (5.333333096630033, -1.9999999605494494) , (9.947977045494631  $\times 10^{-19}$ , 9.97395460544528e-10) .

For  $h$  : (0.7071067742126095, 1.9999999605494494) , (-0.7071067742126095, -1.9999999605494494) .

For  $k$  : (2.7725886926518686, 1.9999999605494494) , (-14.563311203591136, -1.9999999605494494) .

Here, recall that Sage first presents the maximal/minimum value  $f(x_0)$  at the extreme point  $x_0$ , and next the point  $x_0$  itself. It also produces the plots of the functions at hand, which are listed below.

**6.A.29.** The function  $f(x) = x^a$  is twice differentiable on  $(0, +\infty)$  with  $f'(x) = ax^{a-1}$  and  $f''(x) = a(a-1)x^{a-2}$ . By assumption we have  $a > 0$  and  $(a-1) < 0$ . It is also easy to see that  $x^{a-2} > 0$  for all  $x > 0$ . Thus  $f''(x) < 0$  for all  $x > 0$  which means that  $f$  is concave on  $(0, +\infty)$ .

**6.A.30.** Based on the cell

```
f(x)=x/(x^2-1)
a=lim(f(x), x=1, dir="right")
b=lim(f(x), x=1, dir="left")
c=lim(f(x), x=-1, dir="right")
d=lim(f(x), x=-1, dir="left")
show(a, ', ', b, ', ', c, ', ', d)
```

we see that

$$a := \lim_{x \rightarrow 1^+} f(x) = +\infty, \quad b := \lim_{x \rightarrow 1^-} f(x) = -\infty, \quad c := \lim_{x \rightarrow -1^+} f(x) = +\infty, \quad d := \lim_{x \rightarrow -1^-} f(x) = -\infty.$$

Thus, the lines  $x = \pm 1$  are vertical asymptotes of  $f$ . It is also easy to see that the  $x$ -axis  $y = 0$  is the unique horizontal asymptote of  $f$  (this is because  $\lim_{x \rightarrow \infty} f(x) = 0 = \lim_{x \rightarrow -\infty} f(x)$ ). However, asymptotes with slope cannot exist, since  $f(x) = x/(x^2 - 1) = g(x)/h(x)$ , and the degree of  $g(x)$  is smaller than the degree of  $h(x)$ .

Recall that using Sage, to plot a rational function it is wise to restrict the  $y$ -values. On the other hand, Sage often sketches the vertical asymptotes via the option `detect_poles`, which we should appropriately include inside the command `plot`. In particular, the cell

```
p=plot(x/(x^2-1), x, -5, 5, ymin=-10, ymax=10,
detect_poles="show")
```

produces the figure posed above. However, one has the chance to set `detect_poles` to "True", (or "False"), to obtain only the graph of  $f$ . For an example with horizontal asymptotes see the [6.A.31](#).

**6.A.31.** (a) The given function is continuous and differentiable on  $\mathbb{R}$  as a fraction of differentiable functions. We see that its first derivative is everywhere positive,

$$f'(x) = \frac{2e^x}{(e^x + 1)^2} > 0, \quad x \in \mathbb{R}.$$

This implies that  $f$  is strictly increasing for all  $x \in \mathbb{R}$ . In case you want to verify this claim in Sage, use the cell

```
f(x) = (exp(x) - 1)/(exp(x) + 1); d1(x) = diff(f, x).factor(); bool(d1(x) > 0)
```

Now, since the domain of  $f$  is the whole real line,  $f$  cannot have vertical asymptotes. On the other hand, the lines  $y = \pm 1$  are horizontal asymptotes of  $f$  since

$$\lim_{x \rightarrow +\infty} \frac{e^x - 1}{e^x + 1} = \lim_{x \rightarrow +\infty} \frac{e^x}{e^x} = 1, \quad \lim_{x \rightarrow -\infty} \frac{e^x - 1}{e^x + 1} = \frac{0 - 1}{0 + 1} = -1.$$

Combining these conclusions one deduces that the range is the open interval  $(-1, 1)$ , see also the graph of  $f$  below.

It seems that Sage has not an “built-in” method for horizontal asymptotes. But we can proceed “manually” and introduce these lines via the command line. For instance, to sketch the graph of  $f$ , together with its asymptotes  $y = \pm 1$ , use the cell

```
f(x)=(exp(x)-1)/(exp(x)+1)
gf=plot(f, x, -5, 5, ymin=-1.1, ymax=1.1, color="black")
a1 = line([(5,1), (-5,1)], linestyle="--", thickness =0.8)
a2 = line([(5,-1), (-5,-1)], linestyle="--", thickness =0.8)
(gf+a1+a2).show(ticks=1,tick_formatter =1)
```

Executing this block, you will get the following figure

In this figure we have restricted the  $y$ -values, by the options  $ymin = -1.1$ , and  $ymax = 1.1$ , though not necessary (more experienced programmers could jump this step).

(b) We know that  $f$  is strictly increasing in  $\mathbb{R}$ , hence it does not admit (local/global) extremes. The second derivative of  $f$  is given by  $f''(x) = \frac{2(1-e^x)e^x}{(e^x+1)^3}$ , for all  $x \in \mathbb{R}$ . Thus,  $x = \ln(1) = 0$  is the unique solution of the equation  $f''(x) = 0$  and we have

- $f''(x) > 0$  for all  $x \in (-\infty, 0)$ ,
- $f''(x) < 0$  for all  $x \in (0, +\infty)$ .

Therefore,  $f$  is strictly convex for all  $x \in (-\infty, 0)$  and strictly concave for all  $x \in (0, +\infty)$ , and since  $f$  is continuous on 0 and its graph there changes from convex to concave,  $x = 0$  is the unique inflection point of  $f$  (with value  $f(0) = 0$ ).

Some of the previous conclusions occur really easy in Sage, as well. For instance, by typing

```
f(x)=(exp(x)-1)/(exp(x)+1)
d2(x)=diff(f, x, 2); show(solve(d2(x)==0, x))
```

we confirm the inflection point of  $f$ .

**6.A.34.** By assumption,  $f$  is differentiable on  $\mathbb{R}$ . Hence, if  $a \in \mathbb{R}$  is a stationary point of  $f$  we have  $f'(a) = 0$ . On the other hand, a differentiation of the defining equation gives

$$2f(x)f'(x) - f(x) - xf'(x) + 4x = 0, \quad x \in \mathbb{R}. \quad (*)$$

By replacing  $x = a$  in this equation, we find that  $f(a) = 4a$ . Combining this with the defining equation, the replacement  $x = a$  gives  $f^2(a) - af(a) + 2a^2 - 7 = 0$ , that is,  $(4a)^2 - 4a^2 + 2a^2 - 7 = 0$ , which is equivalent to  $14a^2 = 7$ . Thus  $a^2 = \frac{1}{2}$ , i.e.,  $a = \pm \frac{\sqrt{2}}{2}$ .

Next,  $f$  is twice differentiable. Hence, if  $x = b \in \mathbb{R}$  is an inflection point of  $f$  we should have  $f''(b) = 0$ . Now, taking the derivative of  $(*)$ , we see that

$$2(f'(x))^2 + 2f(x)f''(x) - 2f'(x) - xf''(x) + 4 = 0, \quad x \in \mathbb{R}.$$

For  $x = b$  this relation reduces to  $(f'(b))^2 - f'(b) + 2 = 0$ , which has negative discriminant,  $\Delta = -7 < 0$ . This implies that  $f$  does not admit inflection points.

**6.A.35.** We have  $f'(x) = 2x e^{x^2}$ ,  $g'(x) = \frac{2x}{x^2+1}$ , and  $k'(x) = \frac{e^x}{e^{2x}+1}$ , for all  $x \in \mathbb{R}$ . Thus, we get  $df(x) = (2x e^{x^2}) dx$ ,  $dg(x) = \frac{2x}{x^2+1} dx$ , and  $dk(x) = \frac{e^x}{e^{2x}+1} dx$ , respectively. An implementation of these differentials in Sage, essentially relies on the command `diff` (or `derivative`). For instance, a cell based on this method and which includes  $dx$  as a symbolic variable has the form

```
var("x, dx")
f(x)=e**(x**2); f1(x)=diff(f, x)
df(x)=f1*dx #declare the differential of f
g(x)=ln(x**2+1); g1(x)=diff(g, x)
dg(x)=g1*dx #declare the differential of g
k(x)=arctan(e^x); k1(x)=diff(k, x)
dk(x)=k1*dx #declare the differential of k
show(df(x), " ", dg(x), " ", dk(x))
```

Chek yourself Sage's output.

**6.A.41.** First we need to introduce  $f$  and use the command `plot` to sketch it. We also need to indicate the nodes  $x$ ,  $x+h$ ,  $f(x)$  and  $f(x+h)$ , and draw the slopes corresponding to forward/backward differences, together with the tangent line. Hence, we may appropriately use the commands `point` and `line` (recall that these are build-in functions in Sage for the construction of points and lines, respectively). To keep our code simple, we agree to distinguish the slopes via colours. So, let us use green and red colours to illustrate the forward/backward difference slopes, and orange colour for the tangent line of  $f$  trough  $x$ . We can now encode the solution, by the following block:

```
f(x)=exp(x^(2))-0.9
p=plot(f(x), x, -0.4, 0.5, ticks=[0.1,None])
p+=point((0.2, f(0.2)), size=30)
p+=point((0.3, f(0.3)), size=30)
p+=point((0.2, 0), size=30)
p+=point((0.3, 0), size=30)
p+=line([(0.2, f(0.2)), (0.3, f(0.3))], color="green")
p+=line([(0.2, 0), (0.2, f(0.2))],
linestyle="--", rgbcolor=(0.2,0.2,0.2))
p+=line([(0.3, 0), (0.3, f(0.3))],
linestyle="--", rgbcolor=(0.2,0.2,0.2))
p+=point((0.1, 0), size=30)
p+=point((0.1, f(0.1)), size=40)
p+=line([(0.1, f(0.1)), (0.2, f(0.2))], color="red")
p+=line([(0.1, 0), (0.1, f(0.1))],
linestyle="--", rgbcolor=(0.2,0.2,0.2))
f1=diff(f(x), x)(x=0.2); l1(x)=f(0.2)+f1*(x-0.2)
p+=plot(l1(x), x, 0.01, 0.45, color="orange")
p+=text(r"$x$", (0.22, 0.01), fontsize=12)
p+=text(r"$x+h$", (0.335, 0.01), fontsize=12)
p+=text(r"$x-h$", (0.14, 0.01), fontsize=12)
p+=text(r"$f(x)$", (0.19, 0.16), fontsize=12)
p+=text(r"$f(x+h)$", (0.24, 0.20), fontsize=12)
p+=text(r"$f(x-h)$", (0.07, 0.128), fontsize=12)
p+=text(r"$y=f(x)$", (0.35, 0.31), fontsize=12)
show(p)
```

This block has as output the following figure:

**6.A.42.** The central difference approximation of the value  $f'(0.2) = 0.4163243$  with step  $h = 0.01$  is given by

$$\frac{f(0.2 + 0.01) - f(0.2 - 0.01)}{0.02} \approx 0.4163671.$$

This proves the claim, comparing with the results in 6.A.40.

**6.A.43.** The axes of the given ellipse are the coordinate axes  $x$  and  $y$ , and its vertices are the points

$$P = [\sqrt{2}, 0], Q = [-\sqrt{2}, 0], R = [0, 1], S = [0, -1],$$

see also the given figure below.

Let us first compute the curvature at  $R$ . We can consider the coordinate  $y$  as a function of  $x$  (determined uniquely in a neighbourhood of  $R$ ). Thus by differentiating the equation of the ellipse with respect to  $x$  we get  $2x + 4yy' = 0$ . Hence  $y' = -\frac{x}{2y}$ . Differentiating this equation once more with respect to  $x$  we obtain the second derivative,

$$y'' = -\frac{1}{2} \left( \frac{1}{y} - \frac{xy'}{y^2} \right).$$

At the point  $R$ , we see that  $y'(R) = 0$  and  $y''(R) = -\frac{1}{2}$ . According to 6.1.13, the radius of the osculation circle will be given by the expression

$$\frac{(1 + (y')^2)^{\frac{3}{2}}}{(y'')^2}$$

evaluated at the point in question. This gives the values  $\pm 2$  (the sign tells us the circle will be “below” the graph of the function). Now, the ideas in 6.1.13 and 6.1.16 imply that the centre will be in the direction opposite to the normal line of this curve, i.e., on the  $y$ -axis. Since the radius is 2, the centre will be at the point  $[0, 1 - 2] = [0, -1]$ . In total, the equation of the osculation circle of the given ellipse at  $R$  will be  $x^2 + (y + 1)^2 = 4$ . Analogously, we can determine the equation of the osculation circle at the point  $S$ , where we get the equation  $x^2 + (y - 1)^2 = 4$ . Finally, the curvatures of the ellipse at these points equals to  $\frac{1}{2}$  (the absolute value of the curvature of the graph of the function).

For determining the osculation circle at the point  $[\sqrt{2}, 0]$ , we’ll consider the equation of the ellipse as a formula for the variable  $x$  depending on the variable  $y$ , i.e.,  $x$  as a function of  $y$ , determined uniquely, so we cannot use the previous procedure - technically it would end up by dividing by zero). Then, by differentiation we obtain:  $2xx' + 4y = 0$ , thus  $x' = -2\frac{y}{x}$ , and  $x'' = -2\left(\frac{1}{x} - \frac{yx'}{x^2}\right)$ . Hence at point  $[\sqrt{2}, 0]$ , we have  $x' = 0$  and  $x'' = -\sqrt{2}$  and the radius of the circle of osculation is  $\rho = -\frac{1}{\sqrt{2}} = \frac{\sqrt{2}}{2}$  according to 6.1.13. The normal line is heading to  $-\infty$  along the  $x$  axis at point  $[\sqrt{2}, 0]$ , thus the center

of the osculation circle will be on the  $x$  axis on the other side at distance  $\frac{\sqrt{2}}{2}$ , hence at the point  $[\sqrt{2} - \frac{\sqrt{2}}{2}, 0] = [\frac{\sqrt{2}}{2}, 0]$ . In total, the equation of the circle of osculation at vertice  $[\sqrt{2}, 0]$  will be  $(x - \frac{\sqrt{2}}{2})^2 + y^2 = \frac{1}{2}$ . The curvature at both of these vertices equals  $\sqrt{2}$ .

Note that the vertices of an ellipse (more generally the vertices of a closed smooth curve in plane) can be defined as the points at which the function of curvature has an extreme. The ellipse having four vertices isn't a coincidence. The so called "four vertices theorem" states that a closed curve of the class  $C^3$  has at least four vertices. A curve of the class  $C^3$  is locally given parametrically by points  $[f(t), g(t)] \in \mathbb{R}^2$ ,  $t \in (a, b) \subset \mathbb{R}$ , where  $f$  and  $g$  are functions of the class  $C^3(\mathbb{R})$ . Thus the curvature of the ellipse at its any point is between its curvatures at its vertices, i.e. between  $\frac{1}{2}$  and  $\sqrt{2}$ .

**6.A.44.** (a) Since the functions  $x = x(t)$  and  $y = y(t)$  are differentiable, by the chain rule one has

$$y'(t) = \frac{dy}{dt} = \frac{dy}{dx} \frac{dx}{dt} \implies \frac{dy}{dx} = \frac{dy/dt}{dx/dt},$$

assuming that  $x'(t) = 0$  for all  $t \in I$ .

(b) For  $\alpha(t)$  we have

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{6t^2}{1} = 6t^2.$$

Thus  $\frac{dy}{dx}|_{t=0} = 0$  and  $\frac{dy}{dx}|_{t=2} = 24$ . Alternatively, we have  $x = 1 + t$ , thus  $t = x - 1$  and hence  $y = 2(x - 1)^3$ . Thus  $y'(x) = \frac{dy}{dx} = 6(x - 1)^2 = 6t^2$ .

Next, for  $\beta(t)$  we have

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = -\frac{(1+t^2)^2}{2t(1+t)}. \quad (b)$$

However in this case we don't have  $x'(t) \neq 0$  for all  $t \in I$ , in particular, the derivative  $\frac{dy}{dx}$  is not defined at  $t = 0$ . However, at  $t = 2$  one gets  $\frac{dy}{dx}|_{t=2} = -25/12$ . To confirm the situation in an alternative way, we need to eliminate  $t$  which can be done by the first parametric equation  $x = 1/(1+t^2)$ . We get  $t = \sqrt{\frac{1-x}{x}}$  (notice that  $x = 1$  for  $t = 0$  and  $x = 1/5$  for  $t = 2$ ). Thus,  $y(x) = \ln\left(1 + \sqrt{\frac{1-x}{x}}\right)$  and now one can directly differentiate  $y$  with respect to  $x$ . Lets do this quickly in Sage:

```
var("t")
f(x)=ln(1+sqrt((1-x)/x))
show(diff(f, x))
show(diff(f, x)(x=1/5))
show(diff(f, x)(x=1))
show(diff(f(x), x)(x=1/(1+t^2)).full_simplify())
```

The very first show command returns the derivative  $y'(x)$  (in terms of  $x$ ), the second the value  $y'(1/5) = -25/12$  while the third one returns an error, since there  $y'(x)$  is not defined. Finally, the last command confirms the expression given in (b).

(c) Let us now pose the code for solving this task:

```
var("t")
F1(t)=(diff(2*t^3, t)/diff(t^2+1, t)).factor(); show(F1)
F2(t)=(diff(ln(1+t), t)/diff(1/(1+t^2), t)).factor(); show(F2)
p=parametric_plot((t^2+1, 2*t^3), (t,0,2), legend_label=r"\alpha(t)", color="black", thickness=2)
p+=parametric_plot((1/(1+t^2), ln(1+t)), (t,0,2), legend_label=r"\beta(t)", color="grey", thickness=2)
p+=plot(F1(t), t, 0, 2, color="black", linestyle="--", thickness=1.5,
legend_label=r"\left(\frac{dy}{dt}\right)_{\alpha}")
p+=plot(F2(t), t, 0, 2, color="darkgrey", linestyle="--", thickness=1.5,
legend_label=r"\left(\frac{dy}{dt}\right)_{\beta}")
p.show(ymin=-4, ymax=4, xmax=4, aspect_ratio=1/2)
```

This block confirms the given expressions of the derivatives  $\frac{dy}{dx}$  and produces the graphs of the curves  $\alpha, \beta$ , together with the graphs of the corresponding derivatives.

**6.A.46.** Let us present the block with some comments within:

```
var("t, s, r")
x(t)=t-sin(t); y(t)=1-cos(t)
show(diff(y, t)/diff(x, t)) # declare the slope of the cycloid at general point
y0=y(2*pi/3);show(y0) # declare the y-coordinate of the point P
x0=x(2*pi/3);show(x0) # declare the x-coordinate of the point P
k=diff(y, t)(t=2*pi/3)/(diff(x, t)(t=2*pi/3)); show(k) # declare the slope of the cycloid at 2pi/3
l(s)=y0+k*s-k*x0; show(l) #declare the tangent line passing through P
y00=y(4*pi/3); show(y00) # declare the y-coordinate of the point Q
x00=x(4*pi/3); show(x00) # declare the x-coordinate of the point Q
kk=diff(y, t)(t=4*pi/3)/(diff(x, t)(t=4*pi/3)); show(kk) # declare the slope of the cycloid at 4pi/3
L(r)=y00+kk*r-kk*x00; show(L) #declare the tangent line passing through Q
show(solve(l(r)-L(r)==0, r)) #declare the intersection point of the 2 tangent lines
p=parametric_plot((x(t), y(t)), (t,0,2*pi), color="black", thickness=2)
p+=plot(l(s), -0.5, 4, color="darkgrey")
p+=plot(L(r), 2, 6, color="grey")
p+=point([x(2*pi/3), y(2*pi/3)], size=30) # the point P
p+=point([x(4*pi/3), y(4*pi/3)], size=30) # the point Q
p+=point([pi, l(pi)], size=30) # the intersection point R
p+=text(r"$P$", (x0, y0+0.2), fontsize=14, rgbcolor=(0.1,0.2,0.5))
p+=text(r"$Q$", (x00, y00+0.2), fontsize=14, rgbcolor=(0.1,0.2,0.5))
p+=text(r"$R$", (pi, l(pi)+0.2), fontsize=14, rgbcolor=(0.1,0.2,0.5))
p.show(gridlines="true")
```

**6.B.2.** By definition, we have  $F'(x) = f(x)$  for all  $x \in \mathbb{R}$ . Combining this with the relation  $4F(x) = f(x)$  we get  $F'(x) = 4F(x)$ , that is,  $\frac{F'(x)}{F(x)} = 4$  (since  $F(x) = (1/4)f(x) \neq 0$  for all  $x \in \mathbb{R}$ ). An integration then gives

$$\int \frac{F'(x)}{F(x)} dx = \int 4 dx \iff \ln |F(x)| = 4x + c \iff |F(x)| = e^{4x+c},$$

for some constant  $c$ . Thus  $F(x) = e^{4x+c}$  or  $F(x) = -e^{4x+c}$ . Because  $F(4) = \frac{f(4)}{4} = 1 > 0$  the second case is omitted. In particular, the relation  $F(4) = 1$  gives  $e^{16+c} = 1 = e^0$ , that is,  $16 + c = 0$  or equivalently  $c = -16$ . Thus  $F(x) = e^{4(x-4)}$  and  $f(x) = F'(x) = 4e^{4(x-4)}$ .

**6.B.4.** One can use the identities  $\sin^2(x) = (1 - \cos(2x))/2$  and  $\cos^2(x) = (1 + \cos(2x))/2$ . In particular, we see that

$$\begin{aligned} A &= \int \left( \frac{1 - \cos(2x)}{2} \right) \left( \frac{1 + \cos(2x)}{2} \right) dx = \int \frac{1 - \cos^2(2x)}{4} dx = \frac{1}{4} \int dx - \frac{1}{4} \int \cos^2(2x) dx \\ &= \frac{x}{4} - \frac{1}{4} \int \left( \frac{1 + \cos(4x)}{2} \right) dx = \frac{x}{4} - \frac{1}{8} \int dx - \frac{1}{8} \int \cos(4x) dx = \frac{x}{8} - \frac{\sin(4x)}{32} + C. \end{aligned}$$

**6.B.7.** (a) We have  $(\sin(x))' = \cos(x)$  and hence

$$K = \int x(\sin(x))' dx = x \sin(x) - \int (x)' \sin(x) dx = x \sin(x) + \cos(x) + C, \quad C \in \mathbb{R}.$$

(b) Recall that  $(x^2 - x)' = 2x - 1$  and hence

$$M = \int (x^2 - x)' \ln(x) dx = (x^2 - x) \ln(x) - \int (x^2 - x)(\ln(x))' dx = (x^2 - x) \ln(x) - \int (x - 1) dx = (x^2 - x) \ln(x) + x - \frac{x^2}{2} + C.$$

(c) In this case we will use the relations  $(-\frac{1}{\beta} \cos(\beta x))' = \sin(\beta x)$  and  $(\frac{1}{\beta} \sin(\beta x))' = \cos(\beta x)$ , for all  $x \in \mathbb{R}$ . Thus

$$N = \int e^x \sin(\beta x) dx = \int e^x (-\frac{1}{\beta} \cos(\beta x))' dx = -\frac{1}{\beta} e^x \cos(\beta x) + \frac{1}{\beta} \nu, \quad (*)$$

where  $\nu = \int e^x \cos(\beta x) dx$ . In the same vein we see that

$$\nu = \int e^x (\frac{1}{\beta} \sin(\beta x))' dx = \frac{1}{\beta} e^x \sin(\beta x) - \frac{1}{\beta} N. \quad (**)$$

Therefore, a combination of (\*) and (\*\*) gives

$$N + \frac{1}{\beta^2} N = -\frac{1}{\beta} e^x \cos(\beta x) + \frac{1}{\beta^2} e^x \sin(\beta x) + C,$$

that is,  $N = \frac{\beta}{\beta^2 + 1} e^x (\frac{1}{\beta} \sin(\beta x) - \cos(\beta x)) + C$ ,  $C \in \mathbb{R}$ .

A word of caution: One should remember to identify multiples of  $C$  with  $C$  itself, as we did in cases (b) and (d), for example. Moreover, we could even write  $N(x) = \frac{\beta}{\beta^2 + 1} e^x (\frac{1}{\beta} \sin(\beta x) - \cos(\beta x)) + C$ ,  $x \in \mathbb{R}$ , and similarly for the previous cases (we avoid this to save some space).

**6.B.8.** All the solutions can be obtained by applying the rule  $\int F(x)G'(x) dx = F(x)G(x) - \int F'(x)G(x) dx$  (integration by parts). Notice the first non-trivial part in this rule is the function  $G(x)$ , which we should “guess” using its first derivative  $G'(x)$ . Next we should be able to compute the integral  $\int F'(x)G(x) dx$ .

(a) We have  $F(x) = x$ ,  $F'(x) = 1$ ,  $G'(x) = \frac{1}{\cos^2(x)}$  and hence  $G(x) = \tan(x)$ , such that  $(\tan(x))' = \frac{1}{\cos^2(x)}$ . Therefore, an application of the preceding rule gives

$$\begin{aligned} \int \frac{x}{\cos^2(x)} dx &= \int x(\tan(x))' dx = x \tan(x) - \int \tan(x) dx = x \tan(x) + \int \frac{-\sin(x)}{\cos(x)} dx \\ &= x \tan(x) + \int \frac{(\cos(x))'}{\cos(x)} dx = x \tan(x) + \ln |\cos(x)| + C. \end{aligned}$$

Above, in the final step we applied the identity  $\int \frac{f'(x)}{f(x)} dx = \ln |f(x)| + C$ , for some constant  $C$  (see 6.2.3).

(b) In this case we have  $F(x) = x^2$ ,  $F'(x) = 2x$ ,  $G'(x) = e^{-3x}$  and hence  $G(x) = -\frac{1}{3} e^{-3x}$ . Therefore, at a first step we obtain

$$\int x^2 e^{-3x} dx = \int x^2 (-\frac{1}{3} e^{-3x})' dx = -\frac{1}{3} x^2 e^{-3x} + \frac{2}{3} \int x e^{-3x} dx.$$

Next we see that

$$\int x e^{-3x} dx = \int x (-\frac{1}{3} e^{-3x})' dx = -\frac{1}{3} x e^{-3x} + \frac{1}{3} \int e^{-3x} dx = -\frac{1}{3} x e^{-3x} - \frac{1}{9} e^{-3x} + C,$$

for some constant  $C \in \mathbb{R}$ , where in the final step we used the relation  $\int e^{ax} dx = \frac{e^{ax}}{a} + C$  (see 6.2.3). A combination of these two relations gives

$$\int x^2 e^{-3x} dx = -\frac{1}{3} x^2 e^{-3x} + \frac{2}{3} \left( -\frac{1}{3} x e^{-3x} - \frac{1}{9} e^{-3x} \right) + C = -\frac{1}{3} e^{-3x} \left( x^2 + \frac{2}{3} x + \frac{2}{9} \right) + C,$$

for some constant  $C \in \mathbb{R}$ .

(c) In this case we have  $F(x) = \cos(x)$ ,  $F'(x) = -\sin(x)$ ,  $G'(x) = \cos(x)$  and hence  $G(x) = \sin(x)$ . If we set for convenience  $M = \int \cos^2(x) dx$ , we thus have

$$\begin{aligned} M &= \int \cos^2(x) dx = \int \cos(x) \cos(x) dx = \int \cos(x) (\sin(x))' dx = \cos(x) \sin(x) + \int \sin^2(x) dx \\ &= \cos(x) \sin(x) + \int (1 - \cos^2(x)) dx = \cos(x) \sin(x) + \int 1 dx - \int \cos^2(x) dx = \cos(x) \sin(x) + x - M + C, \end{aligned}$$

that is,  $2M = \cos(x)\sin(x) + x + C$  or equivalently,  $M = \frac{1}{2}(\cos(x)\sin(x) + x) + C$ , for some constant  $C \in \mathbb{R}$ . We emphasise that usually suitable simplifications or substitutions, lead to the desired result faster than integration by parts. For instance, by using the identity

$$\cos^2(x) = \frac{1}{2}(1 + \cos(2x)), \quad x \in \mathbb{R}$$

we easily obtain

$$\int \cos^2(x) dx = \int \frac{1}{2} dx + \int \frac{1}{2} \cos(2x) dx = \frac{x}{2} + \frac{\sin(2x)}{4} + C = \frac{x}{2} + \frac{2\sin(x)\cos(x)}{4} + C = \frac{1}{2}(x + \sin(x) \cdot \cos(x)) + C,$$

for some constant  $C \in \mathbb{R}$ .

**6.B.10.** Set  $t = x^3 + 4$  such that  $dt = 3x^2 dx$ . Thus  $dx = \frac{dt}{3x^2}$  and

$$\int e^{x^3+4} x^2 dx = \frac{1}{3} \int e^t dt = \frac{e^t}{3} + C = \frac{e^{x^3+4}}{3} + C,$$

for some constant  $C$ . In Sage one can type

```
show(integral((e^(x^3+4))*x^2, x))
```

**6.B.11.** The main idea of the so called *first substitution method* is writing the integral in the form of

$$\int f(\varphi(x)) \varphi'(x) dx, \quad (\star)$$

for certain functions  $f$  and  $\varphi$ . Then the substitution  $y = \varphi(x)$  gives that  $dy = \varphi'(x) dx$ , and the integral above reads as

$$\int f(y) dy.$$

Based on this idea let us set  $y = \cos(x)$ , such that  $dy = -\sin(x) dx$ . Then we obtain

$$\int \cos^5(x) \sin(x) dx = - \int \cos^5(x) (-\sin(x)) dx = - \int y^5 dy = -\frac{y^6}{6} + C = -\frac{\cos^6(x)}{6} + C,$$

for some arbitrary constant  $C \in \mathbb{R}$ .

**6.B.12.** We will use the so called *second substitution method*, which means a reduction of  $\int f(y) dy$  to the form  $(\star)$  presented in the previous task [6.B.11](#), for  $y = \varphi(x)$ . In particular, in our example we want to determine the primitive function of function  $f(x) = \tan^4(x)$ . Thus it is sensible to consider the substitution  $u = \tan(x)$ , and hence  $x = \arctan(u)$ . This gives  $dx = \frac{du}{1+u^2}$ , and hence we get

$$\int \frac{\sin^4(x)}{\cos^4(x)} dx = \int \frac{u^4}{1+u^2} du = \int u^2 - 1 + \frac{1}{u^2+1} du = \frac{u^3}{3} - u + \arctan(u) + C = \frac{\tan^3(x)}{3} - \tan(x) + x + C,$$

for some constant  $C \in \mathbb{R}$ .

**6.B.13.** Let us include the solutions in one cell:

```
show(integral((cos(x))^5*sin(x), x)); show(integral((sin(x))^4/((cos(x))^4), x))
```

Check yourself that this verifies the given answers in [6.B.11](#) and [6.B.12](#), respectively.

**6.B.14.** This is based on appropriate substitution, in particular

$$\begin{aligned} \int \cos^5(x) \sin^2(x) dx &= \int (\cos^2(x))^2 \sin^2(x) \cos(x) dx = \int ((1 - \sin^2(x))^2 \sin^2(x) \cos(x) dx \\ &\stackrel{t=\sin(x)}{dt=\cos(x) dt} \int (1 - t^2)^2 t^2 dt = \int (1 - 2t^2 + t^4) t^2 dt = \int (t^6 - 2t^4 + t^2) dt \\ &= \frac{t^7}{7} - 2\frac{t^5}{5} + \frac{t^3}{3} + C = \frac{\sin^7(x)}{7} - 2\frac{\sin^5(x)}{5} + \frac{\sin^3(x)}{3} + C, \end{aligned}$$

for some constant  $C$ .

**6.B.15.** (a) The substitution method leads to the integral

$$\int x^3 e^{-x^2} dx = \left| \begin{array}{l} t = -x^2 \\ dt = -2x dx \end{array} \right| = \frac{1}{2} \int t e^t dt,$$

which can be easily computed by integrating by parts, yielding

$$\frac{1}{2} \int t e^t dt = \left| \begin{array}{l} F(t) = t \\ G'(t) = e^t \end{array} \right| \left| \begin{array}{l} F'(t) = 1 \\ G(t) = e^t \end{array} \right| = \frac{1}{2} t e^t - \frac{1}{2} \int e^t dt = \frac{1}{2} t e^t - \frac{1}{2} e^t + C = -\frac{1}{2} e^{-x^2} (x^2 + 1) + C, \quad C \in \mathbb{R}.$$

(b) Similarly, we obtain

$$\begin{aligned} \int x \arcsin(x^2) dx &= \left| \begin{array}{l} t = x^2 \\ dt = 2x dx \end{array} \right| = \frac{1}{2} \int \arcsin(t) dt = \left| \begin{array}{l} F(t) = \arcsin(t) \\ G'(t) = 1 \end{array} \right| \left| \begin{array}{l} F'(t) = \frac{1}{\sqrt{1-t^2}} \\ G(t) = t \end{array} \right| \\ &= \frac{1}{2} t \arcsin(t) - \frac{1}{2} \int \frac{t}{\sqrt{1-t^2}} dt = \left| \begin{array}{l} u = 1-t^2 \\ du = -2t dt \end{array} \right| = \frac{1}{2} t \arcsin(t) + \frac{1}{4} \int \frac{du}{\sqrt{u}} \\ &= \frac{1}{2} t \arcsin(t) + \frac{1}{2} \sqrt{u} + C = \frac{1}{2} t \arcsin(t) + \frac{1}{2} \sqrt{1-t^2} + C \\ &= \frac{1}{2} x^2 \arcsin(x^2) + \frac{1}{2} \sqrt{1-x^4} + C, \quad C \in \mathbb{R}. \end{aligned}$$

(c) In this case let us first use the substitution  $y = \sqrt{x}$  to get rid of the root from the argument of the exponential function. This leads to the integral

$$\int e^{\sqrt{x}} dx = \left| \begin{array}{l} y^2 = x \\ 2y dy = dx \end{array} \right| = 2 \int y e^y dy.$$

Based now on integration by parts, we obtain

$$\int y e^y dy = \left| \begin{array}{l} F(y) = y \\ G'(y) = e^y \end{array} \right| \left| \begin{array}{l} F'(y) = 1 \\ G(y) = e^y \end{array} \right| = y e^y - \int e^y dy = y e^y - e^y + C, \quad C \in \mathbb{R}.$$

In total this gives

$$\int e^{\sqrt{x}} dx = 2y e^y - 2e^y + C = 2e^{\sqrt{x}} (\sqrt{x} - 1) + C, \quad C \in \mathbb{R}.$$

**6.B.17.** Integration by parts gives

$$\begin{aligned} \int \sin^n(x) dx &= \int \sin^{n-1}(x) \sin(x) dx = \int \sin^{n-1}(x) (-\cos(x))' dx \\ &= -\sin^{n-1}(x) \cos(x) + (n-1) \int \sin^{n-2}(x) \cos^2(x) dx \\ &= -\sin^{n-1}(x) \cos(x) + (n-1) \int \sin^{n-2}(x) (1 - \sin^2(x)) dx \\ &= -\sin^{n-1}(x) \cos(x) + (n-1) \int \sin^{n-2}(x) dx - (n-1) \int \sin^n(x) dx \\ &= -\sin^{n-1}(x) \cos(x) + (n-1) I_{n-2} - (n-1) I_n. \end{aligned}$$

Thus for any positive integer  $n$  we get

$$n I_n = -\sin^{n-1}(x) \cos(x) + (n-1) I_{n-2} \iff I_n = -\frac{1}{n} \sin^{n-1}(x) \cos(x) + \frac{n-1}{n} I_{n-2}.$$

Now, we have  $I_0 = x$  and  $I_1 = -\cos(x)$ . Thus based on the recurrence relation and using the identity  $\sin(2x) = 2 \sin(x) \cos(x)$ , we get

$$I_2 = \int \sin^2(x) dx = -\frac{1}{2} \sin(x) \cos(x) + \frac{1}{2} I_0 = -\frac{1}{2} \sin(x) \cos(x) + \frac{1}{2} x = -\frac{1}{4} \sin(2x) + \frac{1}{2} x.$$

Similarly,

$$\begin{aligned} I_3 &= \int \sin^3(x) dx = -\frac{1}{3} \sin^2(x) \cos(x) + \frac{2}{3} I_1 = -\frac{1}{3} \sin^2(x) \cos(x) - \frac{2}{3} \cos(x) = -\frac{1}{3} (1 - \cos^2(x)) \cos(x) - \frac{2}{3} \cos(x) \\ &= \frac{1}{3} \cos^3(x) - \cos(x). \end{aligned}$$

**6.B.18.** We can solve this by substitution, which we will encode in a more “compact” but less informative way, as follows:

$$\int \frac{6}{x-2} dx = \left| \begin{array}{l} y = x-2 \\ dy = dx \end{array} \right| = \int \frac{6}{y} dy = 6 \ln |y| + C_1 = 6 \ln |x-2| + C_1, \quad C_1 \in \mathbb{R}.$$

Similarly, we have

$$\int \frac{6}{(x+4)^3} dx = \left| \begin{array}{l} y = x+4 \\ dy = dx \end{array} \right| = \int \frac{6}{y^3} dy = \frac{6}{-2y^2} + C_2 = -\frac{3}{(x+4)^2} + C_2, \quad C_2 \in \mathbb{R}.$$

**6.B.19.** Setting  $w = ax + b$  we get  $dw = a dx$ , that is,  $dx = \frac{dw}{a}$ . Hence

$$\int \frac{dx}{(ax+b)^n} = \int \frac{dw}{aw^n} = \frac{1}{a} \int w^{-n} dw = \frac{1}{a} \left( \frac{w^{-n+1}}{-n+1} \right) + C = -\frac{1}{a(n-1)w^{n-1}} + C,$$

and the result follows.

Next observe that  $9x^2 + 6x + 1 = (3x + 1)^2$ . Thus  $\int \frac{dx}{9x^2 + 6x + 1} = \int \frac{dx}{(3x + 1)^2}$ , and by applying the relation that we proved in (a), it follows that  $\int \frac{dx}{(3x + 1)^2} = -\frac{1}{3(3x + 1)} + C$ , for some constant  $C$ .

**6.B.20.** Recall that  $P(x) = ax^2 + bx + c = a \left(x + \frac{b}{2a}\right)^2 - \frac{\Delta}{4a}$ , and since  $\Delta = 0$  we get  $P(x) = a \left(x + \frac{b}{2a}\right)^2$ . Therefore,  $\int \frac{dx}{P(x)} = \int \frac{dx}{a \left(x + \frac{b}{2a}\right)^2}$ . Let us set  $u = x + \frac{b}{2a}$ , such that  $du = dx$ . Then we see that

$$\int \frac{dx}{a \left(x + \frac{b}{2a}\right)^2} = \frac{1}{a} \int \frac{du}{u^2} = \frac{1}{a} \int u^{-2} du = -\frac{1}{au} + C = -\frac{1}{a \left(x + \frac{b}{2a}\right)} + C = -\frac{2}{2ax + b} + C,$$

for some constant  $C$ . We leave the other confirmation to the reader.

**6.B.27.** By the discussion in 6.2.7 we can assume that

$$Q(x) = \frac{2x^4 + 2x^2 - 5x + 1}{x(x^2 - x + 1)^2} = \frac{A}{x} + \frac{B_1x + C_1}{x^2 - x + 1} + \frac{B_2x + C_2}{(x^2 - x + 1)^2},$$

for some  $A, B_1, C_1, B_2, C_2$ , to be specified. By equating coefficients and solving the corresponding system one gets  $A = 1, B_1 = 1, C_1 = 3, B_2 = 1$  and  $C_2 = -6$ , and thus

$$Q(x) = \frac{1}{x} + \frac{x + 3}{x^2 - x + 1} + \frac{x - 6}{(x^2 - x + 1)^2}.$$

Recall that you can use Sage to get a quick confirmation of the obtained fractional decomposition of  $Q$ , just by typing

```
Q(x)=(2*x^4+2*x^2-5*x+1)/(x*(x^2-x+1)^2); show(Q.partial_fraction())
```

The fractional decomposition of  $Q$  implies that the integral in question splits in three parts:

$$\int Q(x) dx = \int \frac{2x^4 + 2x^2 - 5x + 1}{x(x^2 - x + 1)^2} dx = \int \frac{1}{x} dx + \int \frac{x + 3}{x^2 - x + 1} dx + \int \frac{x - 6}{(x^2 - x + 1)^2} dx. \quad (\star)$$

Let us focus on the last two integrals which are more difficult. To simplify our notation, we will compute them up to a constant (as Sage does). We begin with  $\Lambda := \int \frac{x + 3}{x^2 - x + 1} dx$ . Since  $x^2 - x + 1$  has complex roots one can apply a method similar to those presented in 6.B.22. Hence we get

$$\Lambda = \int \frac{x + 3}{x^2 - x + 1} dx = \frac{1}{2} \int \frac{2x - 1}{x^2 - x + 1} dx + \frac{7}{2} \int \frac{1}{x^2 - x + 1} dx = \Lambda_1 + \Lambda_2,$$

and we need to evaluate the integrals  $\Lambda_1$  and  $\Lambda_2$ . We have (up to a constant)

$$\Lambda_1 = \frac{1}{2} \int \frac{2x - 1}{x^2 - x + 1} dx \stackrel{t=x^2-x+1}{\underset{dt=(2x-1)dx}{=}} \frac{1}{2} \int \frac{dt}{t} = \frac{1}{2} \ln |t| = \frac{1}{2} \ln(t) = \frac{1}{2} \ln(x^2 - x + 1). \quad (\alpha)$$

Next

$$\begin{aligned} \Lambda_2 &= \frac{7}{2} \int \frac{dx}{x^2 - x + 1} = \frac{7}{2} \int \frac{dx}{\left(x - \frac{1}{2}\right)^2 + \frac{3}{4}} = \frac{7}{2} \int \frac{dx}{\left(x - \frac{1}{2}\right)^2 + \left(\frac{\sqrt{3}}{2}\right)^2} \stackrel{u=x-\frac{1}{2}}{\underset{du=dx}{=}} \frac{7}{2} \int \frac{du}{u^2 + \left(\frac{\sqrt{3}}{2}\right)^2} = \\ &= \frac{7}{2} \cdot \frac{1}{\frac{\sqrt{3}}{2}} \arctan\left(\frac{u}{\frac{\sqrt{3}}{2}}\right) = \frac{7}{\sqrt{3}} \arctan\left(\frac{2u}{\sqrt{3}}\right) = \frac{7\sqrt{3}}{3} \arctan\left(\frac{\sqrt{3}(2x-1)}{3}\right). \quad (\beta) \end{aligned}$$

A combination of  $(\alpha)$  and  $(\beta)$  gives

$$\Lambda = \Lambda_1 + \Lambda_2 = \frac{1}{2} \ln(x^2 - x + 1) + \frac{7\sqrt{3}}{3} \arctan\left(\frac{\sqrt{3}(2x-1)}{3}\right). \quad (A)$$

In the second integral  $M := \int \frac{x - 6}{(x^2 - x + 1)^2} dx$  the dominator appears in the second power. Hence one can apply a similar technique to those presented in 6.B.24. We have

$$M = \int \frac{x - 6}{(x^2 - x + 1)^2} dx = \frac{1}{2} \int \frac{2x - 1}{(x^2 - x + 1)^2} dx - \frac{11}{2} \int \frac{dx}{(x^2 - x + 1)^2} = M_1 + M_2.$$

Then, up to a constant we get

$$M_1 = \frac{1}{2} \int \frac{2x-1}{(x^2-x+1)^2} dx \stackrel{t=x^2-x+1}{dt=(2x-1)dx} \frac{1}{2} \int \frac{dt}{t^2} = -\frac{1}{2t} = -\frac{1}{2(x^2-x+1)}, \quad (\gamma)$$

and

$$\begin{aligned} M_2 &= -\frac{11}{2} \int \frac{dx}{(x^2-x+1)^2} = -\frac{11}{2} \int \frac{dx}{\left(\left(x-\frac{1}{2}\right)^2 + \left(\frac{\sqrt{3}}{2}\right)^2\right)^2} = -\frac{11}{2} \cdot K_2 \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right) = \\ &= -\frac{11}{2} \cdot \frac{1}{\frac{3}{4}} \left( \frac{1}{2} K_1 \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right) + \frac{x-\frac{1}{2}}{2\left(\left(x-\frac{1}{2}\right)^2 + \frac{3}{4}\right)} \right) = -\frac{11}{2} \cdot \frac{4}{3} \left( \frac{1}{2} \cdot \frac{1}{\frac{\sqrt{3}}{2}} \arctan \left(\frac{x-\frac{1}{2}}{\frac{\sqrt{3}}{2}}\right) + \frac{\frac{2x-1}{2}}{2(x^2-x+1)} \right) = \\ &= -\frac{22}{3} \left( \frac{\sqrt{3}}{3} \arctan \left(\frac{\sqrt{3}(2x-1)}{3}\right) + \frac{2x-1}{4(x^2-x+1)} \right) = -\frac{22\sqrt{3}}{9} \arctan \left(\frac{\sqrt{3}(2x-1)}{3}\right) - \frac{11(2x-1)}{6(x^2-x+1)}. \quad (\delta) \end{aligned}$$

Therefore by  $(\gamma)$  and  $(\delta)$  we obtain

$$M = M_1 + M_2 = -\frac{1}{2(x^2-x+1)} - \frac{22\sqrt{3}}{9} \arctan \left(\frac{\sqrt{3}(2x-1)}{3}\right) - \frac{11(2x-1)}{6(x^2-x+1)}. \quad (B)$$

Combining now  $(\star)$  with  $(A)$  and  $(B)$  we finally deduce that

$$\begin{aligned} \int Q(x) dx &= \ln|x| + \frac{1}{2} \ln(x^2-x+1) + \frac{7\sqrt{3}}{3} \arctan \left(\frac{\sqrt{3}(2x-1)}{3}\right) - \frac{1}{2(x^2-x+1)} \\ &\quad - \frac{22\sqrt{3}}{9} \arctan \left(\frac{\sqrt{3}(2x-1)}{3}\right) - \frac{11(2x-1)}{6(x^2-x+1)} + C, \end{aligned}$$

or equivalently

$$\int Q(x) dx = \ln \left| x \sqrt{x^2-x+1} \right| - \frac{\sqrt{3}}{9} \arctan \left(\frac{\sqrt{3}(2x-1)}{3}\right) - \frac{11x-4}{3(x^2-x+1)} + C,$$

for some constant  $C$ . For a confirmation (and much faster computation) via Sage, just type

```
Q(x)=(2*x^4+2*x^2-5*x+1)/(x*(x^2-x+1)^2); show(Q.integrate(x))
```

Or you may like to verify the integrals  $A_1, A_2, M_1, M_2$  presented above, which can be done in a similar way:

```
show((1/2)*integral((2*x-1)/(x^2-x+1), x)); show((7/2)*integral(1/(x^2-x+1), x))
show((1/2)*integral((2*x-1)/(x^2-x+1)^2, x)); show((-11/2)*integral(1/(x^2-x+1)^2, x))
```

**6.B.28.** An appropriate substitution is given by  $t = e^x$ , hence  $x = \ln(t)$  and  $dx = \frac{1}{t} dt$ . This will allow us to convert the function  $Q(x) = \frac{1}{e^{2x}-4e^x}$  to a rational function, hence we can apply the theory described above. In particular,

$$\int Q(x) dx = \int \frac{1}{e^{3x}-2e^{2x}} dx = \int \frac{dt}{(t^3-2t^2)t} = \int \frac{dt}{t^3(t-2)}.$$

Now, suppose that

$$\frac{1}{t^3(t-2)} = \frac{A}{t} + \frac{B}{t^2} + \frac{C}{t^3} + \frac{D}{t-2}, \quad \text{for some } A, B, C, D \in \mathbb{R}.$$

This gives the relation

$$1 = t^2(t-2)A + t(t-2)B + (t-2)C + t^3D \iff 1 = t^3(A+D) + t^2(-2A+B) + t(-2B+C) - 2C.$$

Thus we get the system

$$-2C = 1, \quad -2B + C = 0, \quad -2A + B = 0, \quad A + D = 0,$$

which has the tuple  $\{A = -1/8, B = -1/4, C = -1/2, D = 1/8\}$  as a unique solution. This means that

$$\frac{1}{t^3(t-2)} = -\frac{1}{8t} - \frac{1}{4t^2} - \frac{1}{2t^3} + \frac{1}{8(t-2)}, \quad (*)$$

which can be easily confirmed in Sage by the usual method, that is,

```
var("t"); show((1/(t^4-2*t^3)).partial_fraction())
```

Based on  $(*)$  we may finally compute the integral at hand:

$$\int \frac{dt}{t^3(t-2)} = \int \left( \frac{1}{8(t-2)} - \frac{1}{8t} - \frac{1}{4t^2} - \frac{1}{2t^3} \right) dt = \frac{1}{8} (\ln|t-2| - \ln|t|) + \frac{1}{4t} + \frac{1}{4t^2} + C =$$

$$= \frac{1}{8} (\ln |e^x - 2| - \ln(e^x)) + \frac{1}{4e^x} \left(1 + \frac{1}{e^x}\right) + C = \frac{\ln |e^x - 2|}{8} - \frac{x}{8} + \frac{1}{4} e^{-2x} (1 + e^x) + C,$$

for some constant  $C$ . For a quick confirmation of this result try the command

```
show(integral(1/(e**(3*x)-2*e**(2*x)), x))
```

**6.B.31.** For all  $x \neq \frac{\pi}{2} + k\pi$ , with  $k \in \mathbb{Z}$ , we see that

$$\int \frac{1}{\cos^2(x)} dx = \int_{dt=dx/\cos^2(x)}^{t=\tan(x)} dt = t + C = \tan(x) + C,$$

for some constant  $C$ . Therefore, with the help of the table given in 5.A.3 one computes

$$\begin{aligned} \int_{\pi/6}^{\pi/3} \tan^2(x) dx &= \int_{\pi/6}^{\pi/3} \frac{\sin^2(x)}{\cos^2(x)} dx = \int_{\pi/6}^{\pi/3} \frac{1 - \cos^2(x)}{\cos^2(x)} dx = \int_{\pi/6}^{\pi/3} \left( \frac{1}{\cos^2(x)} - 1 \right) dx = \left[ \tan(x) - x \right]_{\pi/6}^{\pi/3} \\ &= \sqrt{3} - \frac{\pi}{3} - \left( \frac{1}{\sqrt{3}} - \frac{\pi}{6} \right) = \frac{2\sqrt{3}}{3} - \frac{\pi}{6}. \end{aligned}$$

An alternative for computing this integral occurs by the substitution  $u = \tan(x)$ , with

$$du = \frac{dx}{\cos^2(x)}, \quad \sin^2(x) = \frac{\tan^2(x)}{1 + \tan^2(x)} = \frac{u^2}{1 + u^2}.$$

This is also based on the integral  $\int \frac{1}{1+u^2} du = \arctan(u) + C$  and left as an easy challenge.

Notice, to confirm the result in Sage we may type

```
show(integral(tan(x)*tan(x), x, pi/6, pi/3))
```

For the second integral recall by 6.B.8 that integration by parts gives

$$\int \frac{x}{\cos^2(x)} dx = x \tan(x) + \ln |\cos(x)| + C,$$

for all  $x \neq \frac{\pi}{2} + k\pi$ ,  $k \in \mathbb{Z}$ , where  $C$  is some constant. Thus

$$\int_0^{\pi/4} \frac{x}{\cos^2(x)} dx = \left[ x \tan(x) + \ln(\cos(x)) \right]_0^{\pi/4} = \frac{\pi}{4} + \ln \frac{\sqrt{2}}{2} = \frac{\pi}{4} - \frac{\ln(2)}{2}.$$

Again we can confirm this result in Sage, as before, i.e.,

```
show(integral(x/(cos(x)*cos(x)), x, 0, pi/4))
```

**6.B.32.** (a) Set  $y = 1 - x^2$  with  $dy = -2dx$ . For  $x = 0$  we have  $y = 1$  and for  $x = 1$  we have  $y = 0$ . Thus

$$\int_0^1 \frac{x}{\sqrt{1-x^2}} dx = - \int_1^0 \frac{y^{-1/2}}{2} dy = \int_0^1 \frac{y^{-1/2}}{2} dy = \left[ \sqrt{y} \right]_0^1 = 1.$$

(b) Set  $t = x + \sqrt{x^2 - 1}$ , so that  $dt = \frac{\sqrt{x^2-1}+x}{\sqrt{x^2-1}} dx$ . For  $x = 1$  we get  $t = 1$  and for  $x = 2$  we get  $t = 2 + \sqrt{3}$ . Thus,

$$\int_1^2 \frac{dx}{\sqrt{x^2-1}} = \int_1^{2+\sqrt{3}} \frac{1}{t} dt = \left[ \ln(t) \right]_1^{2+\sqrt{3}} = \ln(2 + \sqrt{3}).$$

**6.B.33.** Using Sage we see that the integral at hand equals to  $-1/2$ . This can be done in the usual way, i.e., the cell

```
integral(sin(3*x)*cos(x), x, pi/4, pi)
```

One method to verify this result formally is based on the identity  $\sin(\alpha + \beta) + \sin(\alpha - \beta) = 2 \sin(\alpha) \cos(\beta)$  which for our case applies as  $2 \sin(3x) \cos(x) = \sin(3x + x) + \sin(3x - x)$ . Thus we get

$$\begin{aligned} \int_{\pi/4}^{\pi} \sin(3x) \cos(x) dx &= \frac{1}{2} \int_{\pi/4}^{\pi} (\sin(3x + x) + \sin(3x - x)) dx = \frac{1}{2} \int_{\pi/4}^{\pi} \sin(4x) dx + \frac{1}{2} \int_{\pi/4}^{\pi} \sin(2x) dx \\ &= -\frac{1}{8} \left[ \cos(4x) \right]_{\pi/4}^{\pi} - \frac{1}{4} \left[ \cos(2x) \right]_{\pi/4}^{\pi} = -\frac{1}{8} (1 - (-1)) - \frac{1}{4} (1 - 0) = -\frac{1}{4} - \frac{1}{4} = -\frac{1}{2}. \end{aligned}$$

**6.B.34.** (a) Because  $0 \leq \frac{x^9}{\sqrt{2}} \leq \frac{x^9}{\sqrt{1+x}} \leq x^9$  for all  $x \in [0, 1]$  the geometric meaning of the definite integral implies

$$\frac{\sqrt{2}}{20} = \int_0^1 \frac{x^9}{\sqrt{2}} dx \leq \int_0^1 \frac{x^9}{\sqrt{1+x}} dx \leq \int_0^1 x^9 dx = \frac{1}{10}.$$

(b) Because  $0 < x < \pi/2$  we have  $0 < \frac{2}{\pi} < \frac{1}{x}$ . Also we have  $0 \leq \sin(x) \leq 1$  for all  $x \in (0, \pi/2)$ . Thus

$$\int_0^{\pi/2} \frac{2}{\pi} dx < \int_0^{\pi/2} \frac{\sin(x)}{x} < \int_0^{\pi/2} 1 dx,$$

or equivalently  $\frac{2}{\pi} \cdot \frac{\pi}{2} < \int_0^{\pi/2} \frac{\sin(x)}{x} < \frac{\pi}{2}$ .

**6.B.35.** Recall that any continuous function  $f : [-a, a] \rightarrow \mathbb{R}$  satisfies the relation

$$\int_{-a}^a f(x) dx = \int_{-a}^0 f(x) dx + \int_0^a f(x) dx. \quad (*)$$

Set  $u = -x$  such that  $du = -dx$ . For  $x = -a$  we have  $u = a$  and for  $x = 0$  we have  $u = 0$ . Assume now that  $f$  is even. Then  $f(u) = f(-x) = f(x)$  and thus

$$\int_{-a}^0 f(x) dx = \int_a^0 f(u)(-du) = - \int_a^0 f(u) du = \int_0^a f(u) du = \int_0^a f(x) dx$$

and hence  $(*)$  gives  $\int_{-a}^a f(x) dx = 2 \int_0^a f(x) dx$ . Similarly is treated the case where  $f$  is odd.

**6.B.36.** (1) Since  $f$  is periodic with period  $T$ , for any  $a \in \mathbb{R}$  one can write

$$\int_a^{a+T} f(x) dx = \int_a^0 f(x) dx + \int_0^T f(x) dx + \int_T^{a+T} f(x-T) dx. \quad (\dagger)$$

Set now  $u = x - T$  with  $du = dx$ . For  $x = T$  we have  $u = 0$  and for  $x = a + T$  we have  $u = a$ . Thus,  $\int_T^{a+T} f(x-T) dx = \int_0^a f(u) du$ , and the result follows by  $(\dagger)$ .

An alternative relies on the primitive function  $F$  of  $f$ , which allows us to prove that

$$\begin{aligned} \int_0^T f(x) dx &= \int_0^a f(x) dx + \int_a^T f(x) dx = \int_0^a f(x) dx + F(T) - F(a) \\ &= \int_0^a f(x) dx + (F(a+T) - F(a)) - (F(a+T) - F(T)) \\ &= \int_0^a f(x) dx + \int_a^{a+T} f(x) dx - \int_T^{a+T} f(x) dx. \quad (\ddagger) \end{aligned}$$

Then, as above with the substitution  $t = x - T$  one can show that  $\int_T^{a+T} f(x) dx = \int_0^a f(x) dx$  and the result follows by  $(\ddagger)$ .

(2) Since  $f$  is periodic with period  $T$ , using induction over the naturals we can show that  $f(x) = f(x + nT) = f(x - nT)$ , for any  $n \in \mathbb{N}$ . This easily extends to  $n \in \mathbb{Z}$  (try to prove this claim). Using this periodicity property, for  $n \geq 0$  we get

$$\begin{aligned} \int_a^{a+nT} f(x) dx &= \int_a^0 f(x) dx + \sum_{k=0}^{n-1} \int_{kT}^{(k+1)T} f(x) dx + \int_{nT}^{a+nT} f(x) dx \\ &= \int_a^0 f(x) dx + \sum_{k=0}^{n-1} \int_{kT}^{(k+1)T} f(x - kT) dx + \int_{nT}^{a+nT} f(x - nT) dx \\ &= \int_a^0 f(x) dx + \sum_{k=0}^{n-1} \int_0^T f(x) dx + \int_0^T f(x) dx = \sum_{k=0}^{n-1} \int_0^T f(x) dx = n \int_0^T f(x) dx. \quad (*) \end{aligned}$$

Notice for the integral  $\int_{kT}^{(k+1)T} f(x - kT) dx$  we did the substitution  $t = x - kT$  with  $dt = dx$ , and  $t = 0$  for  $x = kT$ ,

$t = T$  for  $x = (k + 1)T$ . Similarly for  $\int_{nT}^{a+nT} f(x - nT) dx$ .

Suppose now that  $n < 0$ . Then we have

$$\int_a^{a+nT} f(x) dx = - \int_{a+nT}^a f(x) dx = - \int_{a+nT}^{a+nT+(-nT)} f(x) dx \stackrel{(*)}{=} - \left( -n \int_0^T f(x) dx \right) = n \int_0^T f(x) dx.$$

This proves our claim. Observe, that the identity in (1) for  $a = 0$  reduces to

$$\int_0^{nT} f(x) dx = n \int_0^T f(x) dx.$$

This says that the area under  $C_f$  for  $n$  periods equals  $n$  times the area under  $C_f$  for one period.

**6.B.38.** (a) The given function  $F$  is clearly the antiderivative of the function  $f(x) := x^5 \ln(x + 1)$  on the interval  $(-1, 1)$ . Thus,  $F'(x) = -x^5 \ln(x + 1)$ , see also the fundamental theorem of calculus in 6.2.9.

(b) We have  $F'(x) = x^2 \sin(x) + 4 \cos(4x)$  and we see that

$$|g(x)| = \left| \frac{x^2 \sin(x) + 4 \cos(4x)}{x^2 + 2} \right| \leq \frac{|x^2 \sin(x)| + 4|\cos(4x)|}{x^2 + 2} \leq \frac{|x^2| \cdot 1 + 4 \cdot 1}{x^2 + 2} = \frac{x^2 + 4}{x^2 + 1},$$

for all  $x \in (0, +\infty)$ . Thus, obviously  $\lim_{x \rightarrow \infty} \frac{x^2+4}{x^2+1} = 1$ , which you can confirm in Sage by the cell

```
var("x"); lim((x^2+4)/(x^2+1), x=oo)
```

**6.B.45.** For some real numbers  $a < b$  consider the set  $A = (a, b]$  and the function  $f : A \rightarrow \mathbb{R}$ , with  $f(x) = 1/(x - a)$ . Though  $f$  is continuous on  $A$ , it is not uniformly continuous, since  $A$  is *not* closed. Indeed, let  $(x_n)$  and  $(y_n)$  be the sequences defined by

$$x_n = a + \frac{b - a}{n}, \quad y_n = a + \frac{b - a}{n + 1}, \quad n \in \mathbb{Z}_+.$$

Then it is easy to see that  $(x_n - y_n) \rightarrow 0$  but  $f(x_n) - f(y_n)$  does not converge to 0. Hence, by 6.B.44 one deduces that  $f$  cannot be uniformly continuous on  $A$ .

As an example where the domain is *not* bounded, consider the parabola  $h : A \rightarrow \mathbb{R}$ ,  $h(x) = x^2$  defined on  $A = [0, +\infty)$ . The sequences  $(x_n = n)$  and  $(y_n = n - \frac{1}{n})$  with  $n \in \mathbb{Z}_+$ , they both belong to  $A$  and satisfy  $x_n - y_n = \frac{1}{n} \rightarrow 0$ , as  $n \rightarrow \infty$ . However,  $h(x_n) - h(y_n) = 2 - \frac{1}{n^2}$ , which obviously does not converge to 0. By 6.B.44 we deduce that  $h$  cannot be uniformly continuous on  $A$ .

**6.B.46.** Consider the sequences  $(x_n), (y_n)$  with general terms  $x_n = 1/(n + 1)$  and  $y_n = 1/n$ , respectively, with  $n \geq 2$ . They both belong to  $A = (0, 1)$  and satisfy  $x_n - y_n \rightarrow 0$ . However, it is easy to see that  $f(x_n) - f(y_n) = 1$  and hence  $\lim_{n \rightarrow \infty} (f(x_n) - f(y_n)) = 1 \neq 0$ . The assertion now follows by the statement in 6.B.44. Provide an alternative proof based on the  $\varepsilon$ - $\delta$ -definition of uniform continuity, given in 6.2.11.

**6.B.48.** The proof is analogous to 6.B.47 and we leave it to the reader for practice.

**6.B.49.** (a) For instance, consider the function  $f(x) = \sin\left(\frac{1}{x}\right)$  with  $x \in A = (0, 1]$ . It is not hard to see that  $f$  is continuous on  $A$ , but not uniformly continuous. Now, for any  $n \in \mathbb{N}$  we have  $n\pi + \frac{\pi}{2} \geq 1$  and hence the sequence  $(x_n)$  with general term

$$x_n = \frac{1}{n\pi + \pi/2}, \quad n \in \mathbb{N},$$

is a sequence in  $A$ . Since  $n\pi + \pi/2 \rightarrow +\infty$  we have  $x_n \rightarrow 0$ , as  $n \rightarrow +\infty$ . Thus  $(x_n)$  is convergent and thus a Cauchy sequence in  $A$ . However, the sequence  $(f(x_n)) = \left(\sin\left(\frac{1}{x_n}\right)\right)_{n \in \mathbb{N}}$  is not a Cauchy sequence. Why?.

(b) Let  $(x_n)$  be a Cauchy sequence with  $x_n \in A$  for all  $n$ . By assumption  $f$  is uniformly continuous on  $A$ , hence for every  $\varepsilon > 0$  there exists  $\delta = \delta(\varepsilon) > 0$  such that  $|f(x) - f(y)| < \varepsilon$ , for all  $x, y \in A$ , provided that  $|x - y| < \delta$ . However,  $(x_n)$  is Cauchy and since  $\delta > 0$  we can find some natural  $N = N(\delta)$  such that  $|x_n - x_m| < \delta$  for all  $n, m \geq N$ . But then we get  $|f(x_n) - f(x_m)| < \varepsilon$ , for all  $n, m \geq N$ , and the result follows.

**6.B.50.** The function  $f(x) = x^2$  is continuous on  $\mathbb{R}$  and hence also on  $A = [0, 1]$ . Since the set  $[0, 1]$  is a closed finite interval, the function  $f$  should be uniformly continuous, see the theorem in 6.2.11.

Suppose that the function  $g(x) = \tan(x)$  is uniformly continuous on  $B = [0, \pi/2)$ . The domain of  $g$  is a finite subset of  $\mathbb{R}$  and hence bounded. But then the function  $g$  should be also bounded.<sup>6</sup> However, it is easy to see that  $\tan(x_n) \rightarrow +\infty$  for  $x_n \in (0, \pi/2)$  with  $x_n \rightarrow \pi/2$ , which implies that  $g(x) = \tan(x)$  is not bounded (think also the graph of  $\tan(x)$ ). This gives a contradiction and hence  $g(x) = \tan(x)$  is not uniformly continuous on  $B$ .

Next, the function  $h(x) = x^2$  is not uniformly continuous on  $\mathbb{R}$ . For instance, consider the sequences  $(x_n = n)$  and  $(y_n = n + \frac{1}{n})$ , with  $x_n - y_n \rightarrow 0$ . Then we see that  $h(x_n) - h(y_n) = 2 + \frac{1}{n^2} \geq 2$  and thus  $\lim_{n \rightarrow +\infty} (h(x_n) - h(y_n)) \neq 0$ . Our assertion now follows by 6.B.44.

Finally, the function  $k(x) = x^3$  is also not uniformly continuous on  $\mathbb{R}$ . Here one may consider the sequences  $x_n = n + \frac{1}{n}$  and  $y_n = n$ . Then obviously  $x_n - y_n \rightarrow 0$  but we see that  $k(x_n) - k(y_n) \geq 3n$  for all  $n$ , which implies that  $\lim_{n \rightarrow +\infty} (k(x_n) - k(y_n)) = +\infty$ .

**6.B.52.** The improper integral represents the area of the region bounded by the graph of the positive function

$$f(x) = \frac{\arctan(x)}{x\sqrt{x}} = x^{-\frac{3}{2}} \arctan(x), \quad x \geq 1,$$

and the  $x$ -axis. From the left, this region is bounded by the line  $x = 1$ , see also the figure here:

Therefore, the integral is a positive real number, or equals  $+\infty$ . First we see that

$$\int_1^{+\infty} x^{-\frac{3}{2}} dx = \lim_{t \rightarrow +\infty} \int_1^t x^{-\frac{3}{2}} dx = \lim_{t \rightarrow +\infty} \left(2 - \frac{2}{\sqrt{t}}\right) = 2.$$

Moreover, we know that

$$\frac{\pi}{4} \leq \arctan(x) \leq \frac{\pi}{2}, \quad \forall x \in [1, +\infty),$$

and hence we get

$$\frac{\pi}{2} = \frac{\pi}{4} \int_1^{+\infty} x^{-\frac{3}{2}} dx \leq \int_1^{+\infty} \frac{\arctg x}{x\sqrt{x}} dx \leq \frac{\pi}{2} \int_1^{+\infty} x^{-\frac{3}{2}} dx = \pi.$$

Thus the integral at hand is a finite real number. In fact, with the aid of Sage one can compute this integral via the command `integral(arctan(x)/(x*sqrt(x)), x, 1, oo)`.

**6.B.57.** As usual you can use the `def` method and introduce a routine which you may call “`length_of_curve`”. Since we usually work with the variable  $t$  for a parametric curve  $c : [a, b] \rightarrow \mathbb{R}^2$ ,  $t$  should be declared as a symbolic variable, together with the endpoints  $a, b$ , that is, the limits of integration. Thus, the input of our routine can be a tuple  $(x, y, a, b)$ , corresponding to the curve  $c : [a, b] \rightarrow \mathbb{R}^2$  with  $c(t) = [x(t), y(t)]$  for all  $t \in [a, b]$ . Hence, though  $a, b$  are real number inputs,  $x, y : [a, b] \rightarrow \mathbb{R}$  are real-valued functions of  $t$  which it is necessary to introduce as symbolic functions. To control also the aspect ratio of the corresponding parametric plot (and take a better illustration), we will introduce one more symbolic variable, say `rt`, which for any curve we can specify so that the result will be the desired one. This means that finally the input of our routine will be the list  $(x, y, a, b, rt)$ , and the implementation goes as follows:

```
var("t, a, b, rt")
function("x")(t)
function("y")(t)
def length_of_curve(x, y, a, b, rt) :
    X(t)=diff(x, t)
```

<sup>6</sup>Show that any uniformly-continuous function  $f : A \rightarrow \mathbb{R}$  mapping a bounded interval to  $\mathbb{R}$ , is bounded.

```

Y(t)=diff(y, t)
l(t)=(X(t)*X(t)+Y(t)*Y(t)).factor()
s(t)=numerical_approx(integral(sqrt(l), t, a, b), digits=7)
show("The length of the curve c(t)=(x, y) on [a, b] equals to ", ":", s(t))
p=parametric_plot((x, y), (t, a, b))
p.show(figsize=6, aspect_ratio=rt)
return
    
```

To test the routine first we will confirm a known result based on the curve  $[e^t - t, 4e^{t/2}]$  of the previous task (see 6.B.56), with  $t \in [0, 1]$ . To confirm this case, now one can simply give the cell

```
length_of_curve(e^t-t, 4*e^(t/2), 0, 1, 1/2)
```

where notice that we fixed  $rt = 1/2$ . Sage returns the following answer:

The length of the curve  $c(t) = (-t + e^t, 4e^{(\frac{1}{2}t)})$  on  $[0, 1]$  equals to:2.718282

For the given cases one can proceed similarly (we present them case by case):

(1) For the curve  $c(t) = [\cos^3(t), \sin^3(t)]$  on  $[0, \pi/2]$  type

```
length_of_curve((cos(t))^3, (sin(t))^3, 0, pi/2, 1/2)
```

Here the output is

The length of the curve  $c(t) = (\cos(t)^3, \sin(t)^3)$  on  $[0, \frac{1}{2}\pi]$  equals to:1.500000

Indeed, we see that  $|c'(t)| = \sqrt{9\cos^4(t)\sin^2(t) + 9\sin^4(t)\cos^2(t)} = 3\cos(t)\sin(t)$  and thus

$$s_{c(t)} = \int_0^{\pi/2} 3\cos(t)\sin(t) dt = \frac{3}{2} \int_0^{\pi/2} \sin(2t) dt = \frac{3}{2} \left[ -\frac{\cos(2t)}{2} \right]_0^{\pi/2} = \frac{3}{2} \left[ -\frac{\cos(\pi)}{2} + \frac{\cos(0)}{2} \right] = \frac{3}{2}.$$

As for the graph of  $c(t)$ , Sage returns the figure given here:

(2) For the curve  $c(t) = [t, \ln(\cos(t))]$  on  $[0, \pi/4]$  type

```
length_of_curve(t, ln(cos(t)), 0, pi/4, 1)
```

Sage's output has the form

The length of the curve  $c(t) = (t, \log(\cos(t)))$  on  $[0, \frac{1}{4}\pi]$  equals to:0.8813736

and the corresponding plot has the form

To confirm Sage's result we compute

$$|c'(t)| = \sqrt{1 + \left(\frac{-\sin(t)}{\cos(t)}\right)^2} = \sqrt{1 + \tan^2(t)} = \sqrt{\sec^2(t)} = \sec(t),$$

where we used the identity  $\tan^2(x) = \sec^2(x) - 1$ . Thus

$$s_{c(t)} = \int_0^{\pi/4} |c'(t)| dt = \int_0^{\pi/4} \sec(t) dt.$$

Notice now that

$$\int \sec(x) dx = \int \frac{\sec(x)(\sec(x) + \tan(x))}{\sec(x) + \tan(x)} dx = \int \frac{\sec^2(x) + \sec(x)\tan(x)}{\sec(x) + \tan(x)} dx.$$

Setting  $u = \sec(x) + \tan(x)$  we compute

$$\begin{aligned} du &= (\sec(x) + \tan(x))' dx = \left( \left(\frac{1}{\cos(x)}\right)' + \tan'(x) \right) dx = \left( \frac{\sin(x)}{\cos^2(x)} + (1 + \tan^2(x)) \right) dx = \\ &= \left( \frac{1}{\cos(x)} \cdot \frac{\sin(x)}{\cos(x)} + \sec^2(x) \right) dx = (\sec(x)\tan(x) + \sec^2(x)) dx, \end{aligned}$$

and hence

$$\int \sec(x) dx = \int \frac{1}{u} du = \ln |u| + C, \quad C \in \mathbb{R}. \quad (\star)$$

Since we have  $u(0) = \sec(0) + \tan(0) = 1$  and  $u(\pi/4) = \sec(\pi/4) + \tan(\pi/4) = \sqrt{2} + 1$ , we finally deduce that

$$s_{c(t)} = \int_0^{\pi/4} \sec(t) dt = \int_1^{\sqrt{2}+1} \frac{du}{u} = \left[ \ln |u| \right]_1^{\sqrt{2}+1} = \ln(1 + \sqrt{2}) - \ln(1) = \ln(1 + \sqrt{2}) \approx 0.8813736.$$

(3) For the curve  $c(t) = [t \sin(t), t \cos(t)]$  on  $[0, 4\pi]$  type

```
length_of_curve(t*sin(t), t*cos(t), 0, 4*pi, 1)
```

which answers

The length of the curve  $c(t) = (t \sin(t), t \cos(t))$  on  $[0, 4\pi]$  equals to: 80.81931

and prints out the following figure

Let us present some hints helpful for verifying this result formally. First we compute

$$|c'(t)| = \sqrt{(\sin(t) + t \cos(t))^2 + (\cos(t) - t \sin(t))^2} = \sqrt{1 + t^2}$$

and thus we need to compute  $s_{c(t)} = \int_0^{4\pi} \sqrt{1 + t^2} dt$ . For this integral, using the relation  $(\star)$  from (2) we will first prove that

$$\int \sqrt{1 + x^2} dx = \frac{1}{2} x \sqrt{1 + x^2} + \frac{1}{2} \ln(x + \sqrt{1 + x^2}) + C. \quad (*)$$

Indeed, set  $x = \tan(\theta)$  with  $dx = \left(\frac{1}{\cos^2(x)}\right) d\theta = \sec^2(x) d\theta$ . Then

$$\int \sqrt{1 + x^2} dx = \int \sqrt{1 + \tan^2(\theta)} \sec^2(\theta) d\theta = \int \sqrt{\sec^2(\theta)} \sec^2(\theta) d\theta = \int \sec^3(\theta) d\theta.$$

We have  $(\tan(\theta))' = \sec^2(\theta)$  and  $(\sec(\theta))' = \sec(\theta) \tan(\theta)$  and integration by parts gives

$$\begin{aligned} \int \sec^3(\theta) d\theta &= \int \sec^2(\theta) \sec(\theta) d\theta = \int (\tan(\theta))' \sec(\theta) d\theta = \tan(\theta) \sec(\theta) - \int \tan(\theta) (\sec(\theta))' d\theta \\ &= \tan(\theta) \sec(\theta) - \int \tan^2(\theta) \sec(\theta) d\theta = \tan(\theta) \sec(\theta) - \int (\sec^2(\theta) - 1) \sec(\theta) d\theta \\ &= \tan(\theta) \sec(\theta) - \int \sec^3(\theta) d\theta + \int \sec(\theta) d\theta. \end{aligned}$$

Thus  $\int \sec^3(\theta) d\theta = \frac{1}{2}(\tan(\theta) \sec(\theta) + \int \sec(\theta) d\theta)$  and hence using (\*) we can write

$$\int \sqrt{1+x^2} dx = \int \sec^3(\theta) d\theta = \frac{1}{2} \tan(\theta) \sec(\theta) + \frac{1}{2} \ln |\sec(\theta) + \tan(\theta)| + C.$$

The desired formula (\*) appears now by replacing  $x = \tan(\theta)$  and  $\sec(\theta) = \sqrt{1+x^2}$ . The final computation of  $s_{c(t)}$  is now based on (\*) and left as an easy exercise.

(4) For the curve  $c(t) = [\sin^2(t), \cos^2(t)]$  with  $t \in [0, \frac{\pi}{2}]$ , similarly we the previous cases we can type

```
length_of_curve((sin(t))^2, (cos(t))^2, 0, pi/2, 1)
```

Sage returns<sup>7</sup>

The length of the curve  $c(t) = (\sin^2(t), \cos^2(t))$  on  $[0, \frac{1}{2}\pi]$  equals to: 1.414214

and the following illustration of the curve at hand:

For a formal computation, we see that

$$|c'(t)| = \sqrt{(2 \sin(t) \cos(t))^2 + (-2 \sin(t) \cos(t))^2} = \sqrt{(\sin(2t))^2 + (-\sin(2t))^2} = \sqrt{2 \sin^2(2t)}.$$

Thus

$$s_{c(t)} = \int_0^{\pi/2} |c'(t)| dt = \sqrt{2} \int_0^{\pi/2} \sin(2t) dt = \sqrt{2} \left[ -\frac{\cos(2t)}{2} \right]_0^{\pi/2} = \sqrt{2}.$$

In fact, the given curve is a part of the line  $y = 1 - x$  (since  $\sin^2(t) + \cos^2(t) = 1$ ), and in particular the segment with boundary points  $[0, 1]$  for  $t = 0$ , and  $[1, 0]$  for  $t = \frac{\pi}{2}$ , see also the figure given above. Hence one can immediately write its length,  $s_{c(t)} = \sqrt{2}$  (by the Pythagorean theorem).

**6.B.58.** It is easy to see that

$$f'(t) = -r \sin t + \frac{r}{2 \tan \frac{t}{2} \cdot \cos^2 \frac{t}{2}} = -r \sin t + \frac{r}{\sin t} = \frac{r \cos^2 t}{\sin t}, \quad g'(t) = r \cos t,$$

for any  $t \in [\pi/2, a]$ . Thus, for the length  $s_{\alpha(t)}$  we get

$$s_{\alpha(t)} = \int_{\pi/2}^a \sqrt{\frac{r^2 \cos^4 t}{\sin^2 t} + r^2 \cos^2 t} dt = \int_{\pi/2}^a \sqrt{\frac{r^2 \cos^2 t}{\sin^2 t}} dt = -r \int_{\pi/2}^a \frac{\cos t}{\sin t} dt = -r [\ln(\sin t)]_{\pi/2}^a = -r \ln(\sin a).$$

To plot the tractrix for the values  $r = 1, 2, \dots, 5$  one can use the block

<sup>7</sup>Be aware that in this case Sage does not type the curve  $c(t)$  properly.

```

var("r, t")
f(t, r)=r*cos(t)+r*ln(tan(t/2))
g(t, r)=r*sin(t)
a=parametric_plot((f(t, 1), g(t, 1)), (t, pi/2, pi/2+1), exclude=[pi], rgbcolor=(0.2,0.2,0.5),
title="The tractrix for several values of r")
a+=parametric_plot((f(t, 2), g(t, 2)), (t, pi/2, pi/2+1), exclude=[pi], rgbcolor=(0.2,0.5,0.2))
a+=parametric_plot((f(t, 3), g(t, 3)), (t, pi/2, pi/2+1), exclude=[pi], rgbcolor=(0.5,0.2,0.2))
a+=parametric_plot((f(t, 4), g(t, 4)), (t, pi/2, pi/2+1), exclude=[pi], rgbcolor=(0.4,0.4,0.2))
a+=parametric_plot((f(t, 5), g(t, 5)), (t, pi/2, pi/2+1), exclude=[pi], rgbcolor=(0.4,0.2,0.8))
a+=point([[0, r] for r in [1,2,..,5]], color="black")
a.show(aspect_ratio=4, figsize=6)
    
```

which produces the following figure

**6.B.64.** By separating the variables we can write

$$y^{-1/2} dy = e^{\sin(x)} \cos(x) dx,$$

and this implies that

$$\int y^{-1/2} dy = \int e^{\sin(x)} \cos(x) dx \iff 2y^{1/2} = \int e^{\sin(x)} \cos(x) dx + C$$

To compute the integral at the right hand side set  $t = \sin(x)$  with  $dt = \cos(x) dx$ . Then we get

$$2y^{1/2} = \int e^t dt + C \iff 2y^{1/2} = e^t + C = e^{\sin(x)} + C.$$

To compute  $C$  we use the initial condition. By assumption  $y(0) = 16$ , thus  $2 \cdot \sqrt{y(0)} = 2 \cdot \sqrt{16} = 2 \cdot 4 = 8 = e^{\sin(0)} + C$ , from where we get  $C = 7$ . Thus

$$y = y(x) = \left( \frac{e^{\sin(x)} + 7}{2} \right)^2.$$

**6.B.67.** Let us refer to our routine as `trapezoid_rule`. The input should be a function  $f$ , the reals numbers  $a, b$  representing the lower and upper limit of the integral and the number of steps  $n$ . Let us present the program and provide the necessary explanations below.

```

def trapezoid_rule(f, a, b, n):
    step = (b - a) / n
    valsf = [f(a + i * step) for i in range(n + 1)]
    return (step / 2) * (valsf[0] + 2 * sum(valsf[1:n]) + valsf[-1])
    
```

In this block we use the list `valsf`, which is generated by evaluating the function  $f$  at  $n + 1$  points (the latter should be evenly spaced between  $a$  and  $b$ ). Hence, for example, `valsf[i]` contains the function value at the  $i$ th point, i.e., `valsf[i] = f(a + i * step)`. In the return, `valsf[1:n]` selects the sublist containing all the intermediate function values, excluding the first and last points. This is because the trapezoid rule assigns a weight of 2 to the intermediate points between the start and end of the interval, while the first and last points are treated differently with a weight of 1. In our program, these are accessed separately as `valsf[0]` and `valsf[-1]`, respectively.

Let us now test our routine, by verifying, for instance, the result obtained in 6.B.66. It suffices to add the cell

```
n=4; a=0; b=pi; f(x)=sin(x)
print(trapezoid_rule(f, a, b, n).n())
```

Sage's result is 1.89611889793704.

For the estimation of the integral  $L$  by the trapezoid rule, we will first present a formal computation. We have  $a = \pi/2$ ,  $b = 3\pi/2$ ,  $n = 4$  and hence  $h = \pi/4$ . Moreover,

$$x_0 = a = \frac{\pi}{2}, \quad x_1 = x_0 + h = \frac{3\pi}{4}, \quad x_2 = x_0 + 2h = \pi, \quad x_3 = x_0 + 3h = \frac{5\pi}{4}, \quad x_4 = b = x_0 + 4h = \frac{3\pi}{2}.$$

Thus we obtain

$$\begin{aligned} L_{\text{trap}} &= \frac{h}{2} [f(x_0) + 2f(x_1) + 2f(x_2) + 2f(x_3) + f(x_4)] \\ &= \frac{\pi}{8} \left[ \cos\left(\frac{\pi}{2}\right) + 2\cos\left(\frac{3\pi}{4}\right) + 2\cos(\pi) + 2\cos\left(\frac{5\pi}{4}\right) + \cos\left(\frac{3\pi}{2}\right) \right] = \frac{\pi}{8} \left[ 0 - 2\frac{\sqrt{2}}{2} - 2 - 2\frac{\sqrt{2}}{2} + 0 \right] \\ &= -\frac{\pi(1 + \sqrt{2})}{4} \approx -1.896. \end{aligned}$$

We can now confirm this result by applying the `trapezoid_rule` routine:

```
n=4; a=pi/2; b=3*pi/2; f(x)=cos(x)
print(trapezoid_rule(f, a, b, n).n())
```

Sage's output is  $-1.89611889793704$

To compute the actual error we first see that

$$L = \int_{\pi/2}^{3\pi/2} \cos(x) dx = [\sin(x)]_{\pi/2}^{3\pi/2} = \sin(3\pi/2) - \sin(\pi/2) = -1 - 1 = -2.$$

Thus,  $|L - L_{\text{trap}}| = |-2 + 1.896| = |-0.104| = 0.104$ . For the theoretical error a simple computation gives that  $\frac{(b-a)h^2}{12} |f''| = \frac{\pi^3}{192} \approx 0.161$ .

It is easy to see that the cosine function is convex over the interval of integration and the trapezoid rule overestimates the integral (since  $-1.896 > -2$ ). This overestimation is characteristic of the trapezoid rule when applied to convex functions. In fact,  $\cos(x)$  is negative on  $[\pi/2, 3\pi/2]$ , and hence the trapezoids do not exceed the area under the curve. This gives the desired overestimation, as illustrated in the figure below.

**6.B.68.** Simpson's rule formula for an integral over  $[a, b]$  with  $n$  intervals, is given by (see 6.2.23)

$$I_{\text{Simp}} = \frac{h}{3} [f(x_0) + 4f(x_1) + 2f(x_2) + 4f(x_3) + \cdots + 2f(x_{n-2}) + 4f(x_{n-1}) + f(x_n)],$$

where  $h = \frac{b-a}{n}$ ,  $x_i = a + ih$  for  $i = 0, 1, \dots, n$ , and  $n$  is even! Hence, except of the starting and ending points  $x_0, x_n$ , for all odd indices  $i = 1, 3, 5, \dots$  the function values  $f(x_i)$  are multiplied by 4, and for all even indices  $i = 2, 4, 6, \dots$  the function values  $f(x_i)$  are multiplied by 2.

For our case, for  $h = \frac{1}{4}$  we get the equation  $\frac{1}{4} = \frac{a-b}{n} = \frac{1-0}{n}$ , which gives  $n = 4$ . Thus we have  $n + 1 = 5$  nodes:  $x_0 = 0, x_1 = 1/4, x_2 = 1/2, x_3 = 3/4$  and  $x_4 = 1$ , with values  $f(x_0) = 1, f(x_1) = 4/5, f(x_2) = 2/3, f(x_3) = 4/7$  and  $f(x_4) = 1/2$ , respectively. Thus

$$I_{\text{Simp}} = \frac{h}{3} [f(x_0) + 4f(x_1) + 2f(x_2) + 4f(x_3) + f(x_4)] = \frac{1}{12} \left( 1 + 4\frac{4}{5} + 2\frac{2}{3} + 4\frac{4}{7} + \frac{1}{2} \right) \approx 0.69325,$$

where we used Sage via the following basic command to do the final computation:

```
print(N((1/12)*(1+16/5+4/3+16/7+1/2)))
```

Let us now find the approximation by the trapezoid rule, where the corresponding nodes are the same. We have

$$I_{\text{trap}} = \frac{h}{2} [f(x_0) + 2f(x_1) + 2f(x_2) + 2f(x_3) + f(x_4)] = \frac{1}{8} \left( 1 + 2\frac{4}{5} + 2\frac{2}{3} + 2\frac{4}{7} + \frac{1}{2} \right) \approx 0.6970.$$

This result can be verified by using the program constructed in 6.B.67, for example. Hence we can type

```
def trapezoid_rule(f, a, b, n):
    step = (b - a) / n
    valsf = [f(a + i * step) for i in range(n + 1)]
    return (step / 2) * (valsf[0] + 2 * sum(valsf[1:n]) + valsf[-1])
n=4; a=0; b=1; f(x)=1/(1+x)
print(trapezoid_rule(f, a, b, n).n())
```

Running this block Sage prints out the number 0.697023809523809.

The exact value of  $I$  is given by  $I = \int_0^1 \frac{1}{1+x} dx = \ln(1+1) - \ln(1+0) = \ln(2) \approx 0.69314$ , and we may summarize the results about the errors in a table:

Method	Approximation	Actual error
Trapezoidal Rule	0.6970	$ 0.693147 - 0.6970  \approx 0.0039$
Simpson's Rule	0.693253	$ 0.693147 - 0.693253  \approx 0.000106$

Thus, the approximation given by Simpson's rule is significantly closer to the exact value of  $I$ , compared to the trapezoidal rule (Simpson's rule yields a smaller error).

Similarly is treated the case with  $h = 1/2$ , which corresponds to  $n = 2$  and  $n + 1 = 3$  nodes:  $x_0 = 0$ ,  $x_1 = 1/2$ , and  $x_2 = 1$ . We leave this for practice.

**6.B.69.** Recall that Simpson's rule requires  $n$  to be an even number, as the method involves pairing subintervals to fit a quadratic polynomial. To solve this task, we will use a method similar to the one presented in 6.B.67, and therefore, we will omit extensive explanations. Here is our routine:

```
def simpson_rule(f, a, b, n):
    if n % 2 != 0:
        raise ValueError("n must be even for Simpson's rule.")

    step = (b - a) / n
    valsf = [f(a + i * step) for i in range(n + 1)]
    return (step / 3) * (valsf[0] + 4 * sum(valsf[i] for i in range(1, n, 2))
        + 2 * sum(valsf[i] for i in range(2, n-1, 2)) + valsf[-1])
```

Let us now use the function  $f(x) = 1/(1+x)$  of the previous example, with  $h = 1/4$  to check our program:

```
n = 4; a = 0; b = 1; f(x) = 1 / (1 + x)
print(simpson_rule(f, a, b, n).n())
```

This verifies our computation, as Sage's output is the number 0.69325396825396. Note that if  $n$  is odd, Sage will display the error: " $n$  must be even for Simpson's rule." You can use this program to demonstrate additional examples of Simpson's rule in your Sage editor.

For  $h = 1/4$  and the interval  $I$  given in 6.B.68, the slight overestimation of Simpson's rule demonstrated above can be illustrated as follows:

To construct this figure we used the following block in Sage:

```
f(x) = 1 / (1 + x)
a = 0; b = 1; h = 1/4
n = int((b - a) / h)
# Generate x values and corresponding y values
x_values = [a + i*h for i in range(n + 1)]
y_values = [f(x) for x in x_values]
# Initialize the plot with the original function
p = plot(f, a, b, color="blue", legend_label="f(x) = 1/(1+x)", thickness=1.5)
# Create the piecewise quadratic approximation for Simpson's rule
for i in range(0, n, 2):
    x0, x1, x2 = x_values[i], x_values[i+1], x_values[i+2]
    y0, y1, y2 = y_values[i], y_values[i+1], y_values[i+2]
    # Shade the area under the curve for this segment using a polygon
    p += polygon([(x0, 0), (x0, y0), (x2, y2), (x2, 0)], color="darkgreen", alpha=0.3, fill=True)

# Highlight the points used in Simpson's rule
p += points([(x, f(x)) for x in x_values], color="black", size=30, marker="o")
# Show the plot with a larger range for visibility
p.show(legend_loc="upper right")
```

**6.B.70.** It is easy to see that the fourth derivative of  $f(x) = \frac{1}{1+x}$  is given by  $f^{(4)}(x) = \frac{24}{(1+x)^5}$ , for all  $x \in [0, 1]$ . Recall that we can verify this computation in Sage by the cell

```
f(x)=1/(1+x); dif4=diff(f, x, 4); show(dif4)
```

Since the fourth derivative  $f^{(4)}(x)$  is decreasing for all  $x \in [0, 1]$ , the maximum value of  $|f^{(4)}(x)|$  occurs at the left endpoint of the interval, i.e., at  $x = 0$ , and equals 24. Here is a short program in Sage that can verify this claim (you may also plot the graph of  $f^{(4)}(x)$ )

```
var("x"); f_4 = 24 / (1 + x)^5
a = 0; b = 1
# Evaluate f^{(4)} at the endpoints
f_4_a = f_4.subs(x=a)
f_4_b = f_4.subs(x=b)
# Find the maximum value of |f^{(4)}(x)| on the interval
max_value = max(f_4_a, f_4_b)
# Output the results
f^{(4)}(0) = {f_4_a}, f^{(4)}(1) = {f_4_b}, Maximum |f^{(4)}(x)| on [0, 1] = {max_value}"
```

Thus we compute

$$\frac{(b-a)^5}{180n^4} \max_{x \in [0,1]} |f^{(4)}(x)| \stackrel{n=4}{=} \frac{24}{180 \cdot 256} = \frac{1}{1920} \approx 0.00052.$$

The actual error 0.000106 computed above is indeed less than the theoretical error bound 0.00052. In this way one confirms that the theoretical error bound is valid, and provides an upper limit on the actual error.

**6.C.3.** (a) A typical example is the sequence  $(f_n)$  with  $f_n(x) = x^n$ ,  $x \in [0, 1]$ . In 5.B.3 we learned that for  $0 \leq x < 1$  the sequence  $(f_n(x)) = (x^n)$  converges to 0, while  $(f_n(1))$  converges to 1. Thus, the limit function of  $(f_n)$  on  $[0, 1]$  is given by

$$f(x) = \begin{cases} 0, & \text{if } x \in [0, 1), \\ 1, & \text{if } x = 1. \end{cases}$$

Although each member  $f_n$  is continuous, it is obvious that  $f$  is not continuous at  $x_0 = 1$  (it has a jump discontinuity there). Another example is given by the sequence  $(f_n)_{n \in \mathbb{Z}_+}$  defined by

$$f_n(x) = \begin{cases} 0, & \text{if } x < 0, \\ nx, & \text{if } 0 \leq x \leq \frac{1}{n}, \\ 1, & \text{if } x > \frac{1}{n}. \end{cases}$$

The graph of  $f_n$  has the following form:

This was made in Sage by the cell

```
var("n"); n=2
def f(x):
    if -2 <x<0:
        return 0
    elif 0<=x<=1/n:
        return n*x
    elif 1/n<x<2:
        return 1
p=plot(f, (-2, 2), thickness=1.5, color="black")
p+=point([1/2, 0], size=30, color="black")
p+=line([(1/2, 0), (1/2, 1)], linestyle="--", color="blue")
p+=text(r"\frac{1}{n}", (1/2+0.01, -0.05), color="darkblue", fontsize="16")
p.show(ticks=[[], None])
```

Now, it is easy to see that  $f_n(x)$  is continuous on  $\mathbb{R}$  (notice that  $\lim_{x \rightarrow (\frac{1}{n})^-} f(x) = \lim_{x \rightarrow (\frac{1}{n})^-} nx = 1 = \lim_{x \rightarrow (\frac{1}{n})^+} f(x)$ ). However, the pointwise limit function of this sequence is the discontinuous function

$$f(x) = \begin{cases} 1, & \text{if } x > 0, \\ 0, & \text{if } x \leq 0. \end{cases}$$

(b) Consider for instance the sequence  $(f_n(x) = e^{-nx^2})$  with  $n \in \mathbb{N}$  and  $x \in \mathbb{R}$ . For  $x = 0$  we obviously have  $f_n(0) = 1$  and  $\lim_{n \rightarrow \infty} f_n(0) = 1$ , for all  $n$ . For  $x \neq 0$  we have  $\lim_{n \rightarrow \infty} f_n(x) = 0$ , for all  $n$ . This is because of the inequality  $\frac{1}{e^t} < \frac{1}{1+t}$ , which holds for any  $t > 0$ .<sup>8</sup> This gives that

$$0 < f_n(x) = \frac{1}{e^{nx^2}} < \frac{1}{1+nx^2},$$

and our claim follows. Thus, the sequence  $(f_n)$  converges on  $\mathbb{R}$  to the function

$$f(x) = \begin{cases} 1, & \text{if } x = 0, \\ 0, & \text{if } x \neq 0. \end{cases}$$

<sup>8</sup>To see this, use the familiar inequality  $e^t > 1 + t$ ,  $t > 0$ .

Now it is obvious that though all members of  $(f_n)$  are differentiable functions over  $\mathbb{R}$ , the limit function  $f(x)$  is not differentiable at  $x = 0$ . Another such example is given in 6.C.6.

(c) Let us consider the sequence of functions  $(f_n : [0, 1] \rightarrow \mathbb{R})$  defined by

$$f_n(x) = \begin{cases} 0, & \text{for } x = 0, \\ n, & \text{for } 0 < x \leq \frac{1}{n}, \\ 1/x, & \text{if } \frac{1}{n} < x \leq 1, \end{cases}$$

It is not hard to prove that the pointwise limit function  $f : [0, 1] \rightarrow \mathbb{R}$  of  $(f_n)_{n \in \mathbb{Z}_+}$  is given by

$$f(x) = \begin{cases} 0, & \text{if } x = 0, \\ 1/x, & \text{if } 0 < x \leq 1, \end{cases}$$

To illustrate this result graphically, we just need to use Sage and plot some members of the sequence  $(f_n)$ . This can be accomplished in several different ways. For instance, you may use a bit of programming as demonstrated in the following block:

```
var("n")
n=5
def f(x):
    if x==0:
        return 0
    elif 0<x<=1/n:
        return n
    elif 1/n<x<=1:
        return 1/x
p=plot(f, (x, 0, 1), thickness=1.5, color="black")
show(p)
```

This will produce the plot of  $f_5(x)$  and for convenience below we present the graphs of  $f_5(x)$ ,  $f_{25}(x)$  and  $f_{50}(x)$ .

Let us now prove that any member  $f_n(x)$  is Riemann integrable on  $[0, 1]$ . It is easy to see that each  $f_n(x)$  is bounded on  $[0, 1]$  (for instance, on the interval  $(\frac{1}{n}, 1]$  we see that  $\frac{1}{x}$  is bounded since  $x > \frac{1}{n}$  implies  $\frac{1}{x} < n$ ). Next we need to understand the discontinuities of the functions  $f_n, n \in \mathbb{Z}_+$ . Obviously, at  $x = 0$  we have a (jump) discontinuity,  $\lim_{x \rightarrow 0^+} f_n(x) = n \neq 0 = f_n(0)$ , for all  $n \in \mathbb{Z}_+$ . At all the other points the functions  $f_n$  are continuous: e.g., at  $x = 1/n$  we get

$$\lim_{x \rightarrow (1/n)^-} f_n(x) = \lim_{x \rightarrow (1/n)^+} n = n = f_n(1/n), \quad \lim_{x \rightarrow (1/n)^+} f_n(x) = \lim_{x \rightarrow (1/n)^+} (1/x) = \frac{1}{1/n} = n.$$

To summarize, each member  $f_n$  is bounded and has a unique discontinuity at  $x = 0$  (so a finite number of discontinuities, and thus of measure zero). Therefore, each  $f_n$  is Riemann integrable. In fact, we can easily see that

$$\int_0^1 f_n(x) dx = \int_0^{1/n} n dx + \int_{1/n}^1 \frac{1}{x} dx = 1 + \ln(n).$$

In contrast, the limit function  $f$  is not bounded on  $[0, 1]$ , and thus cannot be integrable on  $[0, 1]$ .

**6.C.5.** The sequence of functions  $(f_n)$  defined by the given graph has the form

$$f_n(x) = \begin{cases} nx, & \text{for } x \in [0, \frac{1}{n}), \\ 2 - nx, & \text{for } x \in [1/n, 2/n], \\ 0, & \text{otherwise.} \end{cases}$$

If  $x = 0$  we have  $f_n(x) = 0$  for all  $n$ , and  $\lim_{n \rightarrow \infty} f_n(0) = 0$ . Suppose now that  $x > 0$  and in particular that  $x \in (0, \frac{1}{n})$  for some  $n$ . Then, we may find a sufficiently large integer  $n_0$  such that  $x \notin [0, \frac{1}{n_0})$ , which implies again that  $\lim_{n \rightarrow \infty} f_n(x) = 0$ .

If  $x \in [\frac{1}{n}, \frac{2}{n}]$  then similarly there exists a sufficiently large integer  $n_0$  such that  $x \notin [\frac{1}{n_0}, \frac{2}{n_0}]$ , which again implies that  $\lim_{n \rightarrow \infty} f_n(x) = 0$ . Hence the claim, i.e.,  $\lim_{n \rightarrow \infty} f_n(x) = f(x) = 0$  for all  $x \geq 0$ .

For the uniform convergence, let  $x_0 = \frac{1}{2n}$ . Since  $f_n(x_0) = f_n(\frac{1}{2n}) = n \cdot \frac{1}{2n} = \frac{1}{2}$  is non-zero (regardless how large  $n$  becomes), we also get  $|f_n(\frac{1}{2n}) - f(\frac{1}{2n})| = |\frac{1}{2} - 0| = \frac{1}{2}$ . Therefore, for any  $\varepsilon < \frac{1}{2}$  does not exist  $N$  such that  $|f_n(x)| < \varepsilon$  for all  $n \geq N$ . Consequently,  $(f_n(x))$  cannot converge uniformly to  $f(x) = 0$ .

**6.C.6.** Obviously,

$$\lim_{n \rightarrow \infty} f_n(x) = \lim_{n \rightarrow \infty} \sqrt{x^2 + \frac{1}{n^2}} = \sqrt{x^2 + \lim_{n \rightarrow \infty} \frac{1}{n^2}} = \sqrt{x^2 + 0} = \sqrt{x^2} = |x|,$$

that is, the limit function is given by  $f(x) = |x|$  with  $x \in \mathbb{R}$ . Now, for given  $\varepsilon > 0$ , choose  $N$  large enough such that  $\frac{1}{N} < \varepsilon$ . Then, for any  $n \geq N$  and  $x \in \mathbb{R}$  we have

$$\begin{aligned} |f_n(x) - f(x)| &= \left| \sqrt{x^2 + \frac{1}{n^2}} - |x| \right| = \left| \sqrt{x^2 + \frac{1}{n^2}} - |x| \right| \cdot \frac{\sqrt{x^2 + \frac{1}{n^2}} + |x|}{\sqrt{x^2 + \frac{1}{n^2}} + |x|} \\ &= \frac{\frac{1}{n^2}}{\sqrt{x^2 + \frac{1}{n^2}} + |x|} \leq \frac{\frac{1}{n^2}}{\sqrt{\frac{1}{n^2}}} = \frac{1}{n} < \varepsilon. \end{aligned}$$

This proves the claim. Observe that each member  $f_n(x)$  is continuous and differentiable for all  $x \in \mathbb{R}$ , but the limit function  $f(x) = |x|$ , though continuous, is not differentiable at  $x = 0$ .

**6.C.7.** (a) On the interval  $I = (0, 1)$  consider the sequences  $(f_n)$ ,  $(g_n)$ , defined by

$$f_n(x) = \frac{1}{x}, \quad g_n(x) = \frac{1}{n}, \quad n \in \mathbb{Z}_+.$$

Obviously,  $f_n \rightarrow f = \frac{1}{x}$  and  $g_n \rightarrow 0$ , as  $n \rightarrow \infty$ , and it is easy to see that we have uniform convergence on  $(0, 1)$ . Consider the sequence  $(f_n \cdot g_n)_{n \in \mathbb{Z}_+}$  with  $f_n(x)g_n(x) = \frac{1}{nx}$  for all  $x \in (0, 1)$ . Certainly,  $\frac{1}{nx} \rightarrow 0$  as  $n \rightarrow \infty$ , hence its pointwise limit function is the zero one. We will show however that the convergence is not uniform on  $(0, 1)$ .

For uniform convergence, given  $\varepsilon > 0$  we need to find some positive integer  $N$  such that  $|\frac{1}{nx} - 0| < \varepsilon$  for all  $n \geq N$  and  $x \in (0, 1)$ . This is also written as  $\frac{1}{nx} < \varepsilon$  or equivalently,  $n > \frac{1}{\varepsilon x}$ , which must hold for all  $x \in (0, 1)$ . However, no matter how large  $n$  is chosen, there will always be some  $x \in (0, 1)$  close enough to 0 such that  $\frac{1}{nx} \geq \varepsilon$  (notice that as  $x \rightarrow 0^+$ , the expression  $1/x$  grows without bound, making  $\frac{1}{nx}$  difficult to keep below any positive  $\varepsilon$  uniformly). In particular, we see that

$$\sup_{x \in (0, 1)} |f_n(x)g_n(x) - 0| = \sup_{x \in (0, 1)} \left| \frac{1}{nx} \right| = \sup_{x \in (0, 1)} \left( \frac{1}{nx} \right) = +\infty.$$

**6.C.8.**

**6.D.4.** We compute  $T_0^3(g(x)) = 1 + \frac{x^2}{2}$ ,  $T_0^3(h(x)) = 1 - \frac{x^2}{2}$  and  $T_0^3(k(x)) = x - \frac{x^3}{3}$ , respectively. In Sage we can verify these results as usual, that is, by typing

`show(taylor(1/cos(x), x, 0, 3)), show(taylor(exp(-x**2/2), x, 0, 3)), show(taylor(sin(sin(x)), x, 0, 3)),`  
respectively.

**6.D.9.** (a) The  $x$ -axis  $y = 0$  as  $x \rightarrow \pm\infty$ . (b) The lines  $y = \ln 10$ , and  $y = x + \ln 3$ .

**6.D.13.** The function  $f(x) = -x^2/(x+1)$  with  $x \in A = \mathbb{R} \setminus \{-1\}$  is not odd, neither even, nor periodic. Its range is the union  $(-\infty, 0] \cup [4, +\infty)$ . Moreover, the point  $x_0 = -1$  is an improper point, i.e.,  $f$  is not defined there and so it has a single discontinuity with

$$\lim_{x \rightarrow -1^+} f(x) = -\infty, \quad \lim_{x \rightarrow -1^-} f(x) = +\infty.$$

The function intersects the  $x$  axis only at the origin. It is positive for  $x < -1$  and not positive for  $x > -1$ . It can be shown easily that

$$\lim_{x \rightarrow -\infty} f(x) = +\infty, \quad \lim_{x \rightarrow +\infty} f(x) = -\infty, \quad f'(x) = -\frac{x^2 + 2x}{(x+1)^2}, \quad f''(x) = -\frac{2}{(x+1)^3}, \quad x \in \mathbb{R} \setminus \{-1\}.$$

Therefore,  $f$  is increasing on the intervals  $[-2, -1)$ ,  $(-1, 0]$  and decreasing on the intervals  $(-\infty, -2]$ ,  $[0, +\infty)$ , see also a sketch of its graph below. The function  $f$  has two stationary points  $x_1 = 0$  and  $x_2 = -2$ . We leave the characterization of these critical points to the reader. Moreover,  $f$  is convex on the interval  $(-\infty, -1)$  and concave on the interval  $(-1, +\infty)$ .

However, it does not have a point of inflection. The line  $x = -1$  is a vertical asymptote, the inclined asymptote at  $\pm\infty$  is the line  $y = -x + 1$ . For example,  $f(-3) = 9/2$ ,  $f'(-3) = -3/4$ ,  $f(1) = -1/2$ ,  $f'(1) = -3/4$ .

To graph of  $f$  together with its asymptotes is given below:

To obtain this illustration one may use the block

```
f(x) = (-x^2) / (x+1)
p=plot(f(x), x, -10, 10, exclude=[-1], ymin=-11, ymax=11, color="black", figsize=6)
p+=text(r"$f(x) = \frac{-x^2}{x+1}$", (-4.1, 9), fontsize=14, color="black")
p+=line([(-1, -12), (-1, 12)], rgbcolor=(0.2,0.2,0.5), linestyle="--")
p+=line([(-10, 11), (10, -9)], rgbcolor=(0.2,0.5,0.2), linestyle="--"); show(p)
```

Notice in the second line we have used the option `exclude = [-1]`, in order to exclude the point where  $f$  is not defined.

**6.D.14.** The function is defined on  $A = \mathbb{R} \setminus \{1\}$  and is everywhere continuous on  $A$ . It is not odd, neither even nor periodic. The points of intersection of the graph of  $f$  with the axes are the points  $[1 - \sqrt[3]{2}, 0]$  and  $[0, -1]$ . At  $x_0 = 1$ , the function has a discontinuity of the second kind and its range is  $\mathbb{R}$ , which follows from the limits

$$\lim_{x \rightarrow 1^-} f(x) = -\infty, \quad \lim_{x \rightarrow 1^+} f(x) = +\infty, \quad \lim_{x \rightarrow \pm\infty} f(x) = +\infty.$$

After the arrangement

$$f(x) = (x-1)^2 + \frac{2}{x-1}, \quad x \in \mathbb{R} \setminus \{1\},$$

it is not difficult to compute

$$f'(x) = 2 \frac{(x-1)^3 - 1}{(x-1)^2}, \quad x \in \mathbb{R} \setminus \{1\},$$

$$f''(x) = 2 \frac{(x-1)^3 + 2}{(x-1)^3}, \quad x \in \mathbb{R} \setminus \{1\}.$$

The only stationary point is  $x_1 = 2$ . The function  $f$  is increasing on the interval  $[2, +\infty)$ , decreasing on the intervals  $(-\infty, 1)$ ,  $(1, 2]$ . Hence at the point  $x_1$  it attains the local minimum  $y_1 = 3$ . It is convex on the intervals  $(-\infty, 1 - \sqrt[3]{2})$ ,  $(1, +\infty)$  and concave on the intervals  $(1 - \sqrt[3]{2}, 1)$ . The point  $x_2 = 1 - \sqrt[3]{2}$  is a point of inflection. The line  $x = 1$  is a horizontal asymptote. The function does not have any inclined asymptotes.

**6.D.15.** The function is defined on  $\mathbb{R}$  and is everywhere continuous. It is not odd, even nor periodic. It attains positive values on the positive half-axis, negative values on the negative half-axis. The point of intersection of the graph of  $f$  with the axes is only at the point  $[0, 0]$ . The derivative is:

$$f'(x) = \frac{e^{-x}}{3\sqrt[3]{x^2}} - \sqrt[3]{x} e^{-x}, \quad x \in \mathbb{R} \setminus \{0\}, \quad f'(0) = +\infty,$$

$$f''(x) = \sqrt[3]{x} e^{-x} - \frac{2e^{-x}}{3\sqrt[3]{x^2}} - \frac{2e^{-x}}{9\sqrt[3]{x^5}}, \quad x \in \mathbb{R} \setminus \{0\}.$$

The only zero point of the first derivative is the point  $x_0 = 1/3$ . The function  $f$  is increasing on the interval  $(-\infty, 1/3]$  and decreasing on the interval  $[1/3, +\infty)$ . Hence at the point  $x_0$ , it has an absolute maximum  $y_0 = 1/\sqrt[3]{3e}$ . Since  $\lim_{x \rightarrow -\infty} f(x) = -\infty$ , its range is  $(-\infty, y_0]$ . The points of inflection are

$$x_1 = \frac{1-\sqrt{3}}{3}, \quad x_2 = 0, \quad x_3 = \frac{1+\sqrt{3}}{3}.$$

It is convex on the intervals  $(x_1, x_2)$  and  $(x_3, +\infty)$ , concave on the intervals  $(-\infty, x_1)$ ,  $(x_2, x_3)$ . The only asymptote is the line  $y = 0$  at  $+\infty$ , i.e.  $\lim_{x \rightarrow +\infty} f(x) = 0$ .

**6.D.17.** Recall by 6.A.45 that the slope of the cycloid

$$x(t) = t - \sin(t), \quad y(t) = 1 - \cos(t), \quad t \in [0, 2\pi]$$

is given by

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{\sin(t)}{1 - \cos(t)}.$$

We see that  $\frac{dy}{dx} = 0$  if and only if  $\frac{dy}{dt} = 0$ , that is,  $\sin(t) = 0$ . This gives  $t = \pi$  where we have a parallel tangent line. The vertical tangents appear at the cusps of the cycloid, that is, at the point  $t = 0$  or  $t = 2\pi$ . These values of  $t$  solve the equation  $\frac{dx}{dt} = 0$ , that is,  $\cos(t) = 1$ . To calculate the slopes at these points we can use limits:

$$k_0 = \lim_{t \rightarrow 0^+} \frac{dy}{dx} = \lim_{t \rightarrow 0^+} \frac{\sin(t)}{1 - \cos(t)} = +\infty, \quad k_{2\pi} = \lim_{t \rightarrow 2\pi^-} \frac{dy}{dx} = \lim_{t \rightarrow 2\pi^-} \frac{\sin(t)}{1 - \cos(t)} = -\infty.$$

Thus the tangents at  $t = 0, 2\pi$  are vertical.

**6.D.22.** Here one should simply give the following block:

```
show(integral(x^4+e^x+5*ln(x), x)); show(integral(sqrt(x)*(1+x^3), x)); show(integral(x/sqrt(x+1), x))
```

Check yourself Sage's output.

**6.D.23.** (a)  $F(x) = \frac{8}{15} x \sqrt[8]{x^7}$ ;

(b)  $G(x) = \frac{4^x}{\ln 4} + 2 \frac{6^x}{\ln 6} + \frac{9^x}{\ln 9}$ ;

(c)  $H(x) = \frac{\arcsin(x)}{2}$ ;

(d)  $K(x) = \ln(1 + \sin(x))$ .

**6.D.24.** A primitive function is given by  $F(x) = e^x + 3 \arcsin\left(\frac{x}{2}\right)$ .

**6.D.25.** Set  $t = \ln(x)$  with  $dt = \frac{1}{x} dx$ . Then we see that

$$\int \frac{dx}{x(\ln(x))^2 + 2025x} = \int \frac{dx}{x((\ln(x))^2 + 2025)} = \int \frac{dt}{t^2 + 45^2} = \frac{1}{45} \arctan\left(\frac{t}{45}\right) + C = \frac{1}{45} \arctan\left(\frac{\ln(x)}{45}\right) + C,$$

for some constant  $C \in \mathbb{R}$ . If you like to verify the result in Sage just type

```
show(integral(1/(x*((ln(x))^2+2025)), x))
```

**6.D.26.** Set  $t = e^x$  such that  $dt = e^x dx = t dx$ , that is,  $dx = \frac{1}{t} dt$ . Then

$$\int \frac{e^x}{e^x + 2024} dx = \int \left( \frac{t}{t + 2024} \cdot \frac{1}{t} \right) dt = \int \frac{dt}{t + 2024} = \ln|t + 2024| + C = \ln(t + 2024) + C = \ln(e^x + 2024) + C.$$

**6.D.34.** To be written.

**6.D.35.** The answer is  $\frac{3}{2} \ln(x^2 + 4x + 8) - \frac{1}{2} \operatorname{arctg} \frac{x+2}{2} + C$ , for some  $C \in \mathbb{R}$ .

**6.D.36.** The answer is  $\frac{4}{3\sqrt{3}} \operatorname{arctg} \frac{2x+1}{\sqrt{3}} + \frac{2x+1}{3(x^2+x+1)} + C$ , with  $C \in \mathbb{R}$ .

**6.D.37.** The answer is  $\frac{1}{6} \ln \frac{(x+1)^2}{x^2-x+1} + \frac{\sqrt{3}}{3} \operatorname{arctg} \frac{2x-1}{\sqrt{3}} + C$ , with  $C \in \mathbb{R}$ .

**6.D.41.** We compute  $A = \frac{1}{2} \ln \left( \frac{2 + \ln 2}{2 - \ln 2} \right)$ ,  $B = -\frac{1}{6} - \frac{2}{9} \ln(2)$ , and  $C = 2/3$ .

**6.D.48.** The answer is

$$\sum_{i=0}^{\infty} (-1)^i \frac{2^{2n-1}}{(2n)!} x^{2n},$$

which converges for all real  $x$ .

**6.D.49.** The answer is

$$\sum_{n=1}^{\infty} (-1)^{n+1} \frac{2^{2n-1}}{(2n)!} x^{2n},$$

which converges for all real  $x$ .

**6.D.50.** The answer is

$$f(x) = \sum_{n=1}^{\infty} \frac{3(-1)^{n+1}}{n} x^n,$$

which converges for all  $x \in (-1, 1]$ .

**6.D.51.** One should first realize that we are expanding the function  $f(x) = \frac{1}{2} \ln(x)$ . Thus, we get

$$f(x) = \sum_{i=0}^{\infty} (-1)^{i+1} \frac{1}{2i} (x-1)^i,$$

which converges on the interval  $(0, 2]$ .

**6.D.53.** Recall from Chapter 5 (see for example 5.D.21) that  $\cos(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots$ , which makes sense for any  $x \in \mathbb{R}$ . Thus, replacing  $x$  by  $\sqrt{x}$  we get

$$\cos(\sqrt{x}) = 1 - \frac{(\sqrt{x})^2}{2!} + \frac{(\sqrt{x})^4}{4!} - \frac{(\sqrt{x})^6}{6!} + \dots = 1 - \frac{x}{2!} + \frac{x^2}{4!} - \frac{x^3}{6!} + \dots.$$

We can now approximate the integral at hand, as follows:

$$I = \int_0^1 \left(1 - \frac{x}{2!} + \frac{x^2}{4!} - \frac{x^3}{6!} + \dots\right) dx = \left[x - \frac{x^2}{2 \cdot 2!} + \frac{x^3}{3 \cdot 4!} - \frac{x^4}{4 \cdot 6!} + \dots\right]_0^1 = 1 - \frac{1}{2 \cdot 2!} + \frac{1}{3 \cdot 4!} - \frac{1}{4 \cdot 6!} + \dots$$

Hence we deduce that  $I = \int_0^1 \cos(\sqrt{x}) dx \approx 1 - \frac{1}{2 \cdot 2!} + \frac{1}{3 \cdot 4!} - \frac{1}{4 \cdot 6!} = 1 - \frac{1}{4} + \frac{1}{72} - \frac{1}{2880} = 733/960 \approx 0.7635416$ .

In Sage the real value of  $I$  is obtained by the cell

```
integral(cos(sqrt(x)), x, 0, 1)
N(integral(cos(sqrt(x)), x, 0, 1))
```

Here the first commands gives the answer  $2 \cos(1) + 2 \sin(1) - 2 \approx$  and the second prints out its decimal expression, 0.763546581352073. Hence the estimation based on the Maclaurin series has very small error.

**6.D.56.** The error belongs to the interval  $(0, 1/200)$ .

**6.D.57.** We find that

$$0 < \int_1^2 \frac{\cos^{10}(x)}{10} \ln(x) dx < \frac{1}{10}, \quad \int_1^2 x \ln x dx = \ln 4 - \frac{3}{4}.$$

## Continuous tools for modelling

*How do we manage non-linear objects?  
– mainly by linear tools again...*

A. Fourier series

*If we want to understand three-dimensional objects, we often use (one or more) two-dimensional plane projections of them. The orthogonal projections are special in providing the closest images of the points of the objects in the chosen plane.*

*Similarly, we can understand complicated functions in terms of simpler ones. We consider their projections into the (real) vector space generated by those chosen functions. Recall from Chapter 2 that the orthogonal projections were easily computed in terms of inner products. Now we do the same for the infinite dimensional spaces of functions.*

In this chapter, we mainly deal with applications of the tools of differential and integral calculus. We consider a variety of problems related to functions of one real variable.

The tools and procedures are similar to the ones shown in Chapter 3, i.e. we consider linear combinations of selected generators and linear transformations.

This chapter serves also as a useful consolidation of background material before considering functions of several variables, differential equations, and the calculus of variations.

We begin by asking how to approximate a given function by linear combinations from a given set of generators. Approximation considerations lead to the general concept of distance. We illustrate the concepts on rudiments of the Fourier series. Our intuition from the Euclidean spaces of low dimensions is extended to infinite dimensional spaces, particularly the concept of orthogonal projections.

The next part of this chapter focuses on integral operators. These are linear mappings on functions which are defined in terms of integrals. Especially, we pay attention to convolutions and Fourier analysis. Throughout all these considerations, we work with real or complex valued functions of one variable.

Only then do we introduce the elements of the theory of metric spaces. This should enlighten the concepts of convergence and approximation on infinite dimensional spaces of functions. It will also cover our needs in analysis on Euclidean spaces  $\mathbb{R}^n$  in the next chapter.

### 1. Fourier series

**7.1.1. Spaces of functions.** As usual, we begin by choosing appropriate sets of functions to use. We want enough functions so that our models can conveniently be applied in practice. At the same time, the functions must be sufficiently “smooth” so that we can integrate and differentiate as needed.

All functions are defined on an interval  $I = [a, b] \subset \mathbb{R}$ , where  $a < b$ . The interval may be bounded, (i.e., both  $a$  and  $b$  are finite), or unbounded (i.e., either  $a = -\infty$ , or  $b = +\infty$ , or both).

In this case the inner product mimics the product of scalars and provides the necessary tool to calculate the corresponding projections. The simplest way to define an inner product on appropriate vector spaces of functions takes the form

$$\langle f, g \rangle = \int_a^b f(x)g(x) dx.$$

We refer to this inner product as  $L_2$  and denote the corresponding norm by  $\| \cdot \|_2$ , see 7.1.1-7.1.3 for further details and its extension to complex functions.

**7.A.1. Orthogonal systems of functions.** Consider the subspace  $W = \langle f_1, f_2 \rangle$  of the space of real-valued functions defined on the interval  $[1, 2]$ , generated by the functions  $f_1(x) = 1/x$  and  $f_2(x) = x^2$ , endowed with the  $L_2$  product.

- (a) Complete the function  $f_1$  to an orthogonal basis of  $W$ .
- (b) Determine the orthogonal projection of  $f(x) = x$  onto  $W$  and compute the distance of  $f$  from  $W$ .

**Solution.** (a) The vector space  $W$  is generated by two linearly independent functions, thus its dimension is 2. All vectors belonging to  $W$  are of the form  $a \cdot f_1(x) + b \cdot f_2(x)$  for some  $a, b \in \mathbb{R}$ . According to the Gram-Schmidt process, we seek for a vector of the form  $h = x^2 + k \cdot \frac{1}{x}$ ,  $k \in \mathbb{R}$ , subject to the orthogonality condition  $0 = \langle \frac{1}{x}, x^2 + k \cdot \frac{1}{x} \rangle$ , which gives

$$k = -\frac{\langle \frac{1}{x}, x^2 \rangle}{\langle \frac{1}{x}, \frac{1}{x} \rangle} = -\frac{\int_1^2 \frac{1}{x} \cdot x^2 dx}{\int_1^2 \frac{1}{x} \cdot \frac{1}{x} dx} = -3.$$

Hence the requested orthogonal basis consists of the functions  $\frac{1}{x}$  and  $x^2 - \frac{3}{x}$ .

(b) The projection of the function  $f(x) = x$  onto  $W$  has the form (see ....)

$$\begin{aligned} p_x &= \frac{\langle x, \frac{1}{x} \rangle}{\langle \frac{1}{x}, \frac{1}{x} \rangle} \cdot \frac{1}{x} + \frac{\langle x, x^2 - \frac{3}{x} \rangle}{\langle x^2 - \frac{3}{x}, x^2 - \frac{3}{x} \rangle} \cdot (x^2 - \frac{3}{x}) \\ &= \frac{2}{x} + \frac{15}{34} (x^2 - \frac{3}{x}). \end{aligned}$$

Let us recall that the distance of a vector from the subspace is given by the norm of the difference between this vector and its projection. In this case we get

$$\begin{aligned} \|x - p_x\|_2 &= \left( \int_1^2 \left( x - \frac{2}{x} - \frac{15}{34} \left( x^2 - \frac{3}{x} \right) \right)^2 dx \right)^{\frac{1}{2}} \\ &= \frac{1}{\sqrt{408}} \approx 0.0495. \quad \square \end{aligned}$$

**7.A.2.** Let  $W$  be the the space generated by the functions  $\frac{1}{x}, \frac{1}{x^2}, \frac{1}{x^3}$ , defined on the interval  $[1, 2]$ . Assume that  $W$  is endowed with the  $L_2$  product. Complete the function  $\frac{1}{x}$  to an orthogonal basis of  $W$ . Next determine the projection of the functions  $f(x) = \frac{1}{x^4}$  and  $g(x) = x$  onto  $W$  and find their distances from  $W$ . ○

SPACES OF PIECEWISE SMOOTH FUNCTIONS

We denote by  $\mathcal{S}^0 = \mathcal{S}^0[a, b]$  the set of all piecewise continuous functions on  $I = [a, b]$  with real or complex values. Otherwise put, all functions  $f$  in  $\mathcal{S}^0 = \mathcal{S}^0[a, b]$  have only finitely many points of discontinuity on bounded intervals. Moreover,  $f$  has finite one-sided left and right limits at every point in  $[a, b]$ . In particular,  $f$  is bounded on all bounded subintervals.

For every natural number  $k \geq 1$ , we consider the set of all piecewise continuous functions  $f$  such that all their derivatives up to order  $k$  (inclusive) lie in  $\mathcal{S}^0$ . We denote this set by  $\mathcal{S}^k[a, b]$ , or briefly  $\mathcal{S}^k$ . Note that the derivatives of functions in  $\mathcal{S}^k$  need not exist at all points, but their one-sided limits must exist.

If the interval  $I$  is unbounded, we often consider only those functions with compact support. A function with compact support means that it is identically zero outside some bounded interval of the real line. For unbounded intervals, we denote by  $\mathcal{S}_c^k$  the subset of those functions in  $\mathcal{S}^k$  which have compact support.

Functions in  $\mathcal{S}^0$  are always Riemann integrable on the bounded interval  $I = [a, b]$ , with both

$$\int_a^b |f(x)| dx < \infty, \quad \text{and} \quad \int_a^b |f(x)|^2 dx < \infty.$$

Both integrals are finite for unbounded intervals if the function  $f$  has compact support.

**7.1.2. Distance between functions.** The properties of limits and derivatives ensure that  $\mathcal{S}^k$  and  $\mathcal{S}_c^k$  are vector spaces. In finite-dimensional spaces, the distance between vectors can be expressed by means of the differences of the coordinate components. In spaces of functions, we proceed analogously and utilize the absolute value of real or complex numbers and the Euclidean distance in the following way:

THE  $L_1$  DISTANCE OF FUNCTIONS

The  $L_1$ -distance between functions  $f$  and  $g$  in  $\mathcal{S}_c^0$  is defined by

$$\|f - g\|_1 = \int_a^b |f(x) - g(x)| dx.$$

If  $g = 0$ , then the distance from  $f$  to the zero function, namely  $\|f\|_1$ , is called the  $L_1$ -norm (i.e., length or size) of  $f$ .

The  $L_1$ -distance between functions  $f$  and  $g$  (when both are real valued) expresses the area enclosed by the graphs of these functions, regardless of which function takes greater values. We observe that  $\|f - g\|_1 \geq 0$ .

Since  $f$  and  $g$  are both piecewise continuous functions,  $\|f - g\|_1 = 0$  only if  $f$  and  $g$  differ in their values at most at the points of discontinuity, and hence at only finitely many points on any bounded interval. Recall that we can change

The next task involves a specific type of polynomials, known as “Chebyshev polynomials”. These are defined by  $T_n(x) = \cos(n \arccos(x))$ , or equivalently, given by

$$T_n(\cos(x)) = \cos(nx), \quad n \in \mathbb{N}.$$

Chebyshev polynomials are described by a plethora of equivalent ways, and have a distinguished role in approximation theory. Moreover, due to their simple definition are easily adapted to symbolic computations, and here we will explain how one can manipulate them via Sage.

**7.A.3. Chebyshev polynomials.** Show that  $T_n(x)$  is a polynomial for all  $n \in \mathbb{N}$ .

**Solution.** By the definition given above it is direct that

$$T_0(x) = 1, \quad T_1(x) = x.$$

Based now on the trigonometric identity

$$\cos(rz) \cos(sz) = \frac{1}{2}(\cos((r-s)z) + \cos((r+s)z)), \quad (\star)$$

we see that

$$\begin{aligned} T_{n+1}(x) + T_{n-1}(x) &= \\ &= \cos((n+1) \arccos(x)) + \cos((n-1) \arccos(x)) \\ &= 2 \cos(n \arccos(x)) \cos(\arccos(x)) = 2x T_n(x), \end{aligned}$$

that is,

$$T_{n+1}(x) = 2x T_n(x) - T_{n-1}(x),$$

for all positive integers  $n$ . This is the recurrent definition of Chebyshev polynomials, and the result follows.  $\square$

**7.A.4.** (a) Verify that for each interval  $I = [a, b] \subset \mathbb{R}$  and positive continuous function  $\omega$  on  $I$ , the formula

$$\langle f, g \rangle_\omega = \int_a^b f(x)g(x)\omega(x) dx$$

defines an inner product on the continuous functions on  $I$ .

(b) Choosing  $I = (-1, 1)$  and  $\omega(x) = \omega_0(x) = (1-x^2)^{-1/2}$ , deduce that the Chebyshev polynomials  $T_k(x)$ , ( $k \in \mathbb{N}$ ), form an orthogonal system of polynomials with respect to  $\langle \cdot, \cdot \rangle_{\omega_0}$ .

**Solution.** We compare the defining formula with the  $L_2$  inner product above: Consider the substitution  $x = \varphi(z)$ , where  $\varphi$  is the inverse function to  $z = \int_a^x \omega(t) dt$ . The inverse exists, since  $\omega$  is positive and so  $z$  is a strictly increasing function of  $x$ . Thus,  $dz = \omega(x)dx$  and

$$\begin{aligned} \langle f, g \rangle_\omega &= \int_a^b f(x)g(x)\omega(x) dx \\ &= \int_0^{\varphi^{-1}(b)} f(\varphi(z))g(\varphi(z)) dz. \end{aligned}$$

In particular, the “coordinate change”  $x = \varphi(z)$  identifies the vector space of continuous functions on  $I$  with the space of continuous function on another interval equipped with the  $L_2$  inner product and so  $\langle \cdot, \cdot \rangle_\omega$  is an inner product. We leave as an easy exercise to check that  $\langle \cdot, \cdot \rangle_\omega$  satisfies the properties of an inner product.

the value of any function at a finite number of points, without changing the value of the integral.

If in particular,  $f$  and  $g$  are both continuous on  $[a, b]$ , then  $\|f - g\|_1 = 0$  implies  $f(x) = g(x)$  for all  $x \in [a, b]$ . Indeed, if  $f(x_0) \neq g(x_0)$  at a point  $x_0$ ,  $a \leq x_0 \leq b$ , and if  $f$  and  $g$  are both continuous at  $x_0$ , then  $f$  and  $g$  also differ on some small neighbourhood of  $x_0$ , and this neighbourhood, in turn, contributes a non-zero value into the integral, so that then  $\|f - g\|_1 > 0$ .

If we have three functions  $f$ ,  $g$ , and  $h$ , then, of course,

$$\begin{aligned} \int_a^b |f(x) - g(x)| dx &= \int_a^b |f(x) - h(x) + h(x) - g(x)| dx \\ &\leq \int_a^b |f(x) - h(x)| dx + \int_a^b |h(x) - g(x)| dx, \end{aligned}$$

so the usual triangle inequality

$$\|f - g\|_1 \leq \|f - h\|_1 + \|h - g\|_1$$

holds. To derive this inequality, we used only the triangle inequality for the scalars; thus it is valid for functions  $f, g \in \mathcal{S}_c^0$  with complex values as well.

$\|f - g\|_1$  is not the only way to measure distance between two functions  $f$  and  $g$ . For another way:

#### THE $L_2$ -DISTANCE

The  $L_2$ -distance between functions  $f$  and  $g$  in  $\mathcal{S}_c^0$  is defined by

$$\|f - g\|_2 = \left( \int_a^b |f(x) - g(x)|^2 dx \right)^{1/2}.$$

If  $g = 0$ , then  $\|f\|_2$ , the distance from  $f$  to the zero function, is called the  $L_2$  norm of  $f$ .

Clearly  $\|f\|_2 \geq 0$ . Moreover,  $\|f\|_2 = 0$ , implies that  $f(x) = 0$  for all  $x$  except for a finite set of points in any bounded interval. As above for the  $L_1$  norm,  $\|f - g\|_2 = 0$  only if  $f$  and  $g$  differ in their values at most at the points of discontinuity, and hence at only finitely many points on any bounded interval. In particular, if  $f$  and  $g$  are both continuous for all  $x$ , then  $\|f - g\|_2 = 0$  implies  $f(x) = g(x)$  for all  $x$ .

The square of  $\|f\|_2$  for a function  $f$  is

$$\|f\|_2^2 = \int_a^b |f(x)|^2 dx$$

and it is related to the well-defined symmetric bilinear mapping of real or complex functions to scalars

$$\langle f, g \rangle = \int_a^b f(x)\overline{g(x)} dx$$

since

$$\langle f, f \rangle = \int_a^b f(x)\overline{f(x)} dx = \int_a^b |f(x)|^2 dx = \|f\|_2^2.$$

We can use therefore all the properties of inner products in unitary spaces as described in Chapter 3. In particular, the

(b) In this special case,  $\omega(x) = \frac{d}{dx}(\arccos(x))$ , and thus the above substitution yields

$$\langle T_r, T_s \rangle_\omega = \int_0^\pi \cos(rz) \cos(sz) \, dz.$$

We are dealing with improper Riemann integrals (integrating the unbounded function  $\omega$ ), but this does not cause any problem. In fact it is easy to evaluate the integral via the trigonometric formula ( $\star$ ) mentioned in 7.A.3. We see that it vanishes for all  $r \neq s$ .  $\square$

*Both Sage and Maple provide built-in functions for generating the Chebyshev polynomials. For instance, in Sage they can be accessed via the function `chebyshev_T(n, x)`, and in our notation this correspond to  $T_n(x)$ , see also below.*

**7.A.5.** (a) Use Sage and its function `chebyshev_T` to derive the first five Chebyshev polynomials. Next, plot them.

(b) Combine the recursive definition of Chebyshev polynomials with the `def` environment in Sage to present an alternative approach for integrating them into Sage.

**Solution.** (a) To write down the first five Chebyshev polynomials one can type

```
R = PolynomialRing(QQ, "x")
show([chebyshev_T(n, x) for n in [0..4]])
```

which returns the list

$$[1, x, 2x^2 - 1, 4x^3 - 3x, 8x^4 - 8x^2 + 1]$$

To plot them add the command

```
plot([chebyshev_T(n, x) for n in [0..4]])
```

(b) For this task, let us agree to call `T(n, x)` the desired routine. We can introduce it as follows:

```
def T(n, x):
    if n==0:
        return 1
    elif n==1:
        return x
    else:
        return expand(2*x*T(n-1, x) - T(n-2, x))
```

To test the routine you may type `T(3, x)` to get  $4x^3 - 3x$ , `T(4, x)` to get  $8x^4 - 8x^2 + 1$ , etc. Or you can directly compare the formula of `T(n, x)` with that of `chebyshev_T(n, x)`, for some  $n$ , by typing

```
bool(T(n, x)==chebyshev_T(n, x) for n in [0..10])
```

In this case Sage's answer is `True`.  $\square$

**7.A.6.** A good programmer is often interested in the efficiency of algorithms and programs. For example, you may like to check the efficiency of the routine in Sage presented in 7.A.5, which can be done via the command `timeit`. Hence, one may compare the execution time of the commands `chebyshev_T(n, x)` and `T(n, x)`, for certain values of  $n$ . To test the case  $n = 3$ , for example, add the cell

inner product satisfies both linearity in the first argument and the Hermitian symmetry

$$\langle f, g \rangle = \overline{\langle g, f \rangle}.$$

It is a symmetric bilinear mapping in the real case.

In the sequel, the  $L_2$  distance will be most important. Thus, to simplify notation, the norm symbol  $\| \cdot \|$  without subscript will mean  $\| \cdot \|_2$  in the subsequent paragraphs.

**7.1.3. Orthogonality.** In Chapters 2 and 3, we dealt with finite-dimensional real or complex vector spaces. Most properties derived there concerned pairs or finite sets of vectors. Now, we can do just the same with functions. We restrict our definition of the inner product to any vector subspace generated by only finitely many functions  $f_1, \dots, f_k$  (over real or complex numbers, according to our need). We again obtain a well-defined inner product on this finite-dimensional vector subspace and so all our considerations from the finite dimensional linear algebra apply again.

As an example, consider the monomial functions  $f_i(x) = x^i, i = 0, \dots, k$ . In  $\mathcal{S}^0$ , these generate the  $(k + 1)$ -dimensional vector subspace  $\mathbb{R}_k[x]$  of all polynomials of degree at most  $k$ . The inner product of two such polynomials is given by integration. Every polynomial of degree at most  $k$  is uniquely expressed as a linear combination of the generators  $f_0, \dots, f_k$ . Moreover, if we can arrange the choice of generators to satisfy

$$(1) \quad \langle f_i, f_j \rangle = \begin{cases} 0 & \text{for } i \neq j, \\ 1 & \text{for } i = j, \end{cases}$$

then the computations become much easier than they would otherwise.

Recall the Gram–Schmidt orthogonalization procedure, see 2.3.21. This procedure transforms any system of linearly independent generators  $f_i$  into new (again linearly independent) orthogonal generators  $g_i$  of the same subspace, i.e.  $\langle g_i, g_j \rangle = 0$  for all  $i \neq j$ . We can calculate them step by step. Put  $g_1 = f_1$ , and

$$g_{\ell+1} = f_{\ell+1} + a_1 g_1 + \dots + a_\ell g_\ell, \quad a_i = -\frac{\langle f_{\ell+1}, g_i \rangle}{\|g_i\|^2}$$

for  $\ell \geq 1$ .

To illustrate, we apply this procedure to the three polynomials  $1, x, x^2$  on the interval  $[-1, 1]$ . Put  $g_1 = 1$ , and generate the sequence

$$\begin{aligned} g_1 &= 1 \\ g_2 &= x - \frac{1}{\|g_1\|^2} \left( \int_{-1}^1 x \cdot 1 \, dx \right) \cdot g_1 = x - 0 = x \\ g_3 &= x^2 - \frac{1}{\|g_1\|^2} \left( \int_{-1}^1 x^2 \cdot 1 \, dx \right) \cdot g_1 - \\ &\quad \frac{1}{\|g_2\|^2} \left( \int_{-1}^1 x^2 \cdot x \, dx \right) \cdot g_2 = x^2 - \frac{1}{3}. \end{aligned}$$

```
print(timeit('chebyshev_T(3,x)', number=20))
print(timeit('T(3,x)', number=20))
```

Here the option `number=20` restricts the number of loops. The output appears as follows:

```
20 loops, best of 3: 81.2 μs per loop
20 loops, best of 3: 18 μs per loop
```

and what one looks for is the execution time, which here is measured in microseconds ( $\mu s$ ).<sup>1</sup> Note that each time the above two commands are executed, Sage returns slightly different execution times.

**7.A.7.** Show that the choice of the weight function  $\omega(x) = e^{-x}$  and the interval  $I = [0, \infty)$  in Problem 7.A.3, leads to an inner product for which the *Laguerre polynomials*

$$L_n(x) = \sum_{k=0}^n \binom{n}{k} \frac{(-1)^k}{k!} x^k$$

form an orthonormal system. ○

**7.A.8.** Check that the orthonormal systems obtained in the previous two examples coincide with the result of the corresponding Gram-Schmidt orthogonalisation procedure applied to the system  $1, x, x^2, \dots, x^n, \dots$ , using the inner products  $\langle \cdot, \cdot \rangle_\omega$ , possibly only up to signs. ○

**7.A.9.** Let  $\mathcal{S}^0([-\pi, \pi])$  be the (infinite-dimensional) vector space of  $\mathbb{F}$ -valued piecewise continuous functions defined on  $[-\pi, \pi]$ , where  $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ , and let us denote by  $\bar{g}$  the complex conjugate of a function  $g \in \mathcal{S}^0([-\pi, \pi])$ . Prove that for any  $f, g \in \mathcal{S}^0([-\pi, \pi])$  the rule

$$(f, g) := \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \overline{g(x)} dx$$

defines an inner product. Next show that the system of functions

$$\left\{ \frac{\sqrt{2}}{2}, \sin(x), \cos(x), \sin(2x), \cos(2x), \dots : n \in \mathbb{Z}_+ \right\}$$

is  $(\cdot, \cdot)$ -orthonormal. ○

The orthonormal system of functions discussed in 7.A.9 is an orthonormal version of the so-called “Fourier orthogonal system”, introduced in 7.1.6. In fact, a key point in 7.A.9 is the “periodicity” of the functions forming the orthonormal basis (each having period  $2\pi$ ).

Periodic functions occur frequently in engineering problems, and usually have a complicated form. Thus, it is often desirable to have a presentation of such periodic functions in terms of the simpler functions of sine and cosine. Building an orthogonal system of the periodic functions  $\sin(nx)$  and  $\cos(nx)$  leads to the classical concept of the Fourier series

<sup>1</sup>For the command `timeit` Sage’s output can include also the units nanoseconds (ns) and millisecond (ms). Recall that nanoseconds provide the smallest unit of the three, followed by microseconds and then milliseconds.

The corresponding orthogonal basis of the space  $\mathbb{R}_2[x]$  of all polynomials of degree less than three on the interval  $[-1, 1]$  is  $1, x, x^2 - 1/3$ . Rescaling by appropriate numbers so that the basis elements all have length 1, yields the orthonormal basis

$$h_1 = \sqrt{\frac{1}{2}}, \quad h_2 = \sqrt{\frac{3}{2}}x, \quad h_3 = \frac{1}{2}\sqrt{\frac{5}{2}}(3x^2 - 1).$$

For example,  $h_1 = g_1 / \|g_1\|$  and

$$\|g_1\|^2 = \int_{-1}^1 1^2 dx = 2.$$

We could easily continue this procedure in order to find orthonormal generators of  $\mathbb{R}_k[x]$ . The resulting polynomials are called *Legendre polynomials*.

Considering all Legendre polynomials  $h_i, i = 0, \dots$ , we have an infinite orthonormal set of generators such that polynomials of all degrees are uniquely expressed as their finite linear combinations.

**7.1.4. Orthogonal systems of functions.** Generalizing the latter example, suppose we have three polynomials  $h_1, h_2, h_3$  forming an orthonormal set. For any polynomial  $h$ , we can put

$$H = \langle h, h_1 \rangle h_1 + \langle h, h_2 \rangle h_2 + \langle h, h_3 \rangle h_3.$$

We claim that  $H$  is the (unique) polynomial which minimizes the  $L_2$ -distance  $\|h - H\|$ . See 3.4.3.

The coefficients for the best approximation of a given function by a function from a selected subspace are obtained by the integration introduced in the definition of the inner product.

This example of computing the best approximation of  $H$  by a linear combination of the given orthonormal generators suggests the following generalization:

**ORTHOGONAL SYSTEMS OF FUNCTIONS**

Every (at most) countable system of linearly independent functions in  $\mathcal{S}_c^0[a, b]$  such that the inner product of each pair of distinct functions is zero is called an *orthogonal system of functions*. Moreover, if the norm  $\|f\|_2 = 1$  for all  $f$  in an orthogonal system, we talk about an *orthonormal system of functions*.

Notice, all continuous functions have got compact supports on a finite interval  $[a, b]$ .

Consider an orthogonal system of functions  $f_n \in \mathcal{S}^0[a, b]$  and suppose that for (real or complex) constants  $c_n$ , the series

$$F(x) = \sum_{n=0}^{\infty} c_n f_n(x)$$

converges uniformly on a finite interval  $[a, b]$ . Notice that the limit function  $F(x)$  does not need to belong to  $\mathcal{S}^0[a, b]$ , but this is not our concern now.

for a  $2L$ -periodic function  $f$  that is integrable over an interval of length  $2L$ , say  $[-L, L]$ .<sup>2</sup> These are series of the form

$$F(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left( a_n \cos\left(\frac{n\pi x}{L}\right) + b_n \sin\left(\frac{n\pi x}{L}\right) \right),$$

where  $a_n$  and  $b_n$  are the Fourier coefficients, given by

$$a_n = \frac{1}{L} \int_{-L}^L f(x) \cos\left(\frac{n\pi x}{L}\right) dx, \quad n = 0, 1, \dots,$$

$$b_n = \frac{1}{L} \int_{-L}^L f(x) \sin\left(\frac{n\pi x}{L}\right) dx, \quad n = 1, 2, \dots,$$

respectively.

In many cases the period is  $2\pi$ , i.e.,  $L = \pi$ , but we are also interested in functions with arbitrary periods, which, in practice (applications), is the most common scenario. For instance, if  $f$  has period  $T$  then it may be defined on any interval of the form  $[0, T]$  or  $[-T/2, T/2]$ , i.e., of length  $T$ . Defining  $f$  on intervals of the form  $[-\pi, \pi]$  or  $[0, 2\pi]$  is useful however, since it simplifies the calculations and aligns with the standard form of the Fourier series, see 7.1.6. For the purpose of Fourier series the function  $f$  may be defined even on the open interval  $(-\pi, \pi)$ , where the key requirement is that  $f$  must be periodic of period  $2\pi$ , see for example the so-called ‘‘Heaviside function’’ in 7.1.9 (also known as the ‘‘square wave function’’).

Below, our goal is to illustrate all of this with a series of examples, most of which are implemented using Sage as well. For convenience, next we will denote by  $F_k(x)$  ( $k > 0$ ) the  $k$ th-partial sum of a given Fourier series  $F(x)$ .

**7.A.10.** Consider the  $2\pi$ -periodic extension of the function  $f(x) = x$ , with  $x \in (-\pi, \pi)$ . Describe the corresponding Fourier series  $F(x)$  and next confirm your answer via Sage. Moreover, confirm that as the number of terms in the series increases, the approximation improves significantly, except in a small neighbourhood around the discontinuity point. (Hint: For example, use Sage to plot the partial sums  $F_5(x)$ ,  $F_{10}(x)$ ,  $F_{20}(x)$  and  $F_{100}(x)$ ).

**Solution.** We see that  $f(-x) = -x = -f(x)$  for all  $x \in (-\pi, \pi)$ , which means that  $f$  is an odd function. Thus, the coefficients  $a_n$  vanish for all  $n = 0, 1, \dots$ , and the Fourier series of  $f$  is a sine series, that is,  $F(x) = \sum_{n=1}^{\infty} b_n \sin(nx)$ . On the other hand, the function  $g(x) = x \sin(nx)$  is even, i.e.,  $g(-x) = g(x)$  for all  $x \in (-\pi, \pi)$ . Hence, according to the statement in 6.B.35 we have

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} x \sin(nx) dx = \frac{2}{\pi} \int_0^{\pi} x \sin(nx) dx.$$

<sup>2</sup>The Fourier series are named in honour of the French mathematician and physicist Jean B. J. Fourier, in recognition of his seminal 1807 work ‘‘On the Propagation of Heat in Solid Bodies’’, which focused on the issue of heat conduction. Fourier introduced the concept of analyzing periodic functions using trigonometric series, a method that remains fundamental to mathematical physics and has numerous critical applications in engineering.

By uniform convergence, the inner product  $\langle F, f_n \rangle$  can be expressed in terms of the particular summands (see the corollary 6.3.7), obtaining

$$\langle F, f_n \rangle = \sum_{m=0}^{\infty} c_m \int_a^b f_m(x) \overline{f_n(x)} dx = c_n \|f_n\|^2,$$

since each term in the sum is 0 except when  $m = n$ . Exactly as in the example above, each finite sum  $\sum_{n=0}^k c_n f_n(x)$  is the best approximation of the function  $F(x)$  among the linear combinations of the first  $k + 1$  functions  $f_n$  in the orthogonal system.

Actually, we can generalize the definition further to any vector space of functions with an inner product. See the exercise 7.A.4 for such an example. For the sake of simplicity we confine ourselves to the  $L_2$  distance, but the reader can check that the proofs work in general.

We extend our results from finite-dimensional spaces to infinite dimensional ones. Instead of finite linear combinations of base vectors, we have infinite series of pairwise orthogonal functions. The following theorem gives us a transparent and very general answer to the question as to how well the partial sums of such a series can approximate a given function:

**7.1.5. Theorem.** Let  $f_n$ ,  $n = 1, 2, \dots$ , be an orthogonal sequence of (real or complex) functions in  $\mathcal{S}^0[a, b]$  and let  $g \in \mathcal{S}^0[a, b]$  be an arbitrary function. Put

$$c_n = \|f_n\|^{-2} \int_a^b g(x) \overline{f_n(x)} dx.$$

Then

(1) For any fixed  $n \in \mathbb{N}$ , the expression which has the least  $L_2$ -distance from  $g$  among all linear combinations of functions  $f_1, \dots, f_n$  is

$$h_n = \sum_{i=1}^n c_i f_i(x).$$

(2) The series  $\sum_{n=1}^{\infty} |c_n|^2 \|f_n\|^2$  always converges, and moreover

$$\sum_{n=1}^{\infty} |c_n|^2 \|f_n\|^2 \leq \|g\|^2.$$

(3) The equality  $\sum_{n=1}^{\infty} |c_n|^2 \|f_n\|^2 = \|g\|^2$  holds if and only if  $\lim_{n \rightarrow \infty} \|g - h_n\| = 0$ .

Before presenting the proof, we consider the meaning of the individual statements of this theorem. Since we are working with an arbitrarily chosen orthogonal system of functions, we cannot expect that all functions can be approximated by linear combinations of the functions  $f_i$ .

For instance, if we consider the case of Legendre orthogonal polynomials on the interval  $[-1, 1]$  and restrict ourselves to even degrees only, surely we can approximate only even

Keeping in mind the relations  $\cos(n\pi) = (-1)^n$  and  $\sin(n\pi) = 0$ , integration by parts gives

$$\begin{aligned} b_n &= \frac{2}{\pi} \int_0^\pi x \sin(nx) dx = \frac{2}{\pi} \left[ -\frac{x \cos(nx)}{n} + \frac{\sin(nx)}{n^2} \right]_0^\pi \\ &= \frac{2}{\pi} \cdot \frac{-\pi}{n} (-1)^n = \frac{2}{n} (-1)^{n+1}. \end{aligned}$$

Therefore, the Fourier series of  $f$  has the form

$$\begin{aligned} F(x) &= \sum_{n=1}^\infty \frac{2(-1)^{n+1}}{n} \sin(nx) = 2 \sin(x) - \sin(2x) \\ &\quad + \frac{2}{3} \sin(3x) - \frac{1}{2} \sin(4x) + \frac{2}{5} \sin(5x) - \dots \end{aligned}$$

In Sage it suffices to compute the Fourier coefficients  $a_n$  and  $b_n$ , which can be easily done by the block

```
f=lambda x:x; f=piecewise([( -pi, pi), f])
L=pi; n=var("n")
an=(1/L)*integral(x*cos(n*pi*x/L), x, -pi, pi)
show("a_n=", an)
bn=(1/L)*integral(x*sin(n*pi*x/L), x, -pi, pi)
show("b_n=", bn.expand())
```

Sage prints out the following expressions

$$a_n=0, \quad b_n = -\frac{2 \cos(\pi n)}{n} + \frac{2 \sin(\pi n)}{\pi n^2},$$

which, with a bit of effort, confirm the presented values of  $a_n, b_n$ , and consequently the given expression of  $F(x)$ .

In Sage the description of the  $k$ th-partial sum of the Fourier series corresponding to a periodic function  $f$ , relies on the syntax `f.fourier_series_partial_sum(k, L)`, where  $L$  denotes the half-period of  $f$ . For instance, the 5th partial sum of the Fourier series at hand can be explicitly described by adding in the previous cell the following:

```
FS = f.fourier_series_partial_sum(5, pi)
show("partial FS = ", FS)
```

To plot the suggested partial sums, together with  $f$ , you may add the block

```
FS5 = f.fourier_series_partial_sum(5, pi)
FS10 = f.fourier_series_partial_sum(10, pi)
FS20 = f.fourier_series_partial_sum(20, pi)
FS100 = f.fourier_series_partial_sum(100, pi)
a = f.plot(x, -pi, pi)
b5 = plot(FS5, x, -pi, pi, linestyle="--", tick_formatter=[2*pi, None])
b10 = plot(FS10, x, -pi, pi, linestyle="--", tick_formatter=[2*pi, None])
b20 = plot(FS20, x, -pi, pi, linestyle="--", tick_formatter=[2*pi, None])
b100 = plot(FS100, x, -pi, pi, linestyle="--", tick_formatter=[2*pi, None])
(a+b5).show(); (a+b10).show()
(a+b20).show(); (a+b100).show()
```

This procedure yields the figures presented below, illustrating the improvement in approximation as the number of terms is increased.

functions in a reasonable way. Nevertheless, the first statement of the theorem says that the best approximation possible (in the  $L_2$ -distance), is by the partial sums as described.

The second and third statements can be perceived as an analogy to the orthogonal projections onto subspaces in terms of Cartesian coordinates. Indeed, if for a given function  $g$ , the series  $F(x) = \sum_{n=1}^\infty c_n f_n(x)$  converges pointwise, then the function  $F(x)$  is, in a certain sense, the orthogonal projection of  $g$  into the vector subspace of all such series.

The second statement is called *Bessel's inequality* and it is an analogy of the finite-dimensional proposition that the size of the orthogonal projection of a vector cannot be larger than the original vector. The equality from the third statement is called *Parseval's theorem* and it says that if a given vector does not decrease in length by the orthogonal projection onto a given subspace, then it belongs to this subspace.

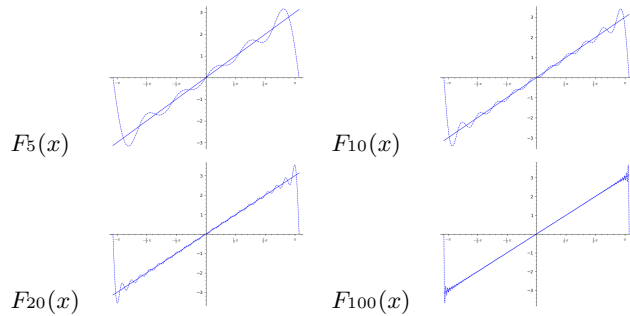

On the other hand, the theorem does not claim that the partial sums of the considered series need to converge pointwise to some function. There is no analogy to this phenomenon in the finite-dimensional world. In general, the series  $F(x)$  need not be convergent for some points  $x$ , even under the assumption of the equality in (3). However, if the series  $\sum_{n=1}^\infty |c_n|$  converges to a finite value, and if all the functions  $f_n$  are bounded uniformly on  $I$ , then, the series  $F(x) = \sum_{n=1}^\infty c_n f_n(x)$  converges at every point  $x$ . Yet it need not converge to the function  $g$  everywhere. We return to this problem later.

The proof of all of the three statements of the theorem is similar to the case of finite-dimensional Euclidean spaces. That is to be expected since the bounds for the distances of  $g$  from the partial sum  $f$  are constructed in the finite-dimensional linear hull of the functions concerned:

**PROOF OF THEOREM 7.1.5.** Choose any linear combination  $f = \sum_{n=1}^k a_n f_n$  and calculate its distance from  $g$ . We obtain

$$\begin{aligned} \|g - \sum_{n=1}^k a_n f_n\|^2 &= \int_a^b \left| g(x) - \sum_{n=1}^k a_n f_n(x) \right|^2 dx \\ &= \int_a^b |g(x)|^2 dx - \int_a^b \sum_{n=1}^k g(x) \overline{a_n f_n(x)} dx - \\ &\quad - \int_a^b \sum_{n=1}^k a_n f_n(x) \overline{g(x)} dx + \int_a^b \left| \sum_{n=1}^k a_n f_n(x) \right|^2 dx \\ &= \|g\|^2 - \sum_{n=1}^k \overline{a_n} c_n \|f_n\|^2 - \sum_{n=1}^k a_n \overline{c_n} \|f_n\|^2 + \sum_{n=1}^k a_n^2 \|f_n\|^2 \\ &= \|g\|^2 + \sum_{n=1}^k \|f_n\|^2 (|c_n - a_n|^2 - |c_n|^2). \end{aligned}$$

Since we are free to choose  $a_n$  as we please, we minimize the last expression by choosing  $a_n = c_n$ , for each  $n$ . This

□

**7.A.11. Triangle wave.** Find the Fourier series  $F(x)$  for the  $2\pi$ -periodic extension of the function  $f(x) = |x|$ , with  $x \in (-\pi, \pi)$ . Next present the 1st, 3rd and 6th partial sum of the Fourier series and use Sage to illustrate them for  $x \in (-4\pi, 4\pi)$ .

**Solution.** The given function corresponds to a sawtooth-shaped oscillation. Its expression as a Fourier series is very important in practice. The function  $g$  is even on  $(-\pi, \pi)$ , i.e.,  $f(-x) = f(x)$  for all  $x \in (-\pi, \pi)$ . Therefore, we have  $b_n = 0$  for all  $n \in \mathbb{Z}_+$ , and it suffices to determine  $a_n$ , for  $n \in \mathbb{N}$ . Combining the definition of  $a_n$  with 6.B.35, we get

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} g(x) dx = \frac{2}{\pi} \int_0^{\pi} x dx = \frac{2}{\pi} \left[ \frac{x^2}{2} \right]_0^{\pi} = \pi.$$

To compute  $a_n$  for  $n \in \mathbb{Z}_+$ , one can apply integration by parts:

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos(nx) dx = \frac{2}{\pi} \int_0^{\pi} x \cos(nx) dx \\ &= \frac{2}{\pi} \left[ \frac{x}{n} \sin(nx) \right]_0^{\pi} - \frac{2}{n\pi} \int_0^{\pi} \sin(nx) dx \\ &= \frac{2}{n^2\pi} [\cos(nx)]_0^{\pi} = \frac{2}{n^2\pi} ((-1)^n - 1). \end{aligned}$$

So

$$a_n = \begin{cases} -\frac{4}{n^2\pi}, & \text{for } n \text{ odd;} \\ 0, & \text{for } n \text{ even,} \end{cases}$$

and the Fourier series in question has the form

$$\begin{aligned} F(x) &= \frac{\pi}{2} + \frac{2}{\pi} \sum_{n=1}^{\infty} \left( \frac{(-1)^n - 1}{n^2} \cos(nx) \right) \\ &= \frac{\pi}{2} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos((2n-1)x)}{(2n-1)^2} \\ &= \frac{\pi}{2} - \frac{4}{\pi} \left( \cos x + \frac{\cos(3x)}{3^2} + \frac{\cos(5x)}{5^2} + \dots \right). \end{aligned}$$

completes the proof of the first statement. With this choice of  $a_n$ , we obtain *Bessel's identity*

$$\|g - \sum_{n=1}^k c_n f_n\|^2 = \|g\|^2 - \sum_{n=1}^k |c_n|^2 \|f_n\|^2.$$

Since the left-hand side is non-negative, it follows that:

$$\sum_{n=1}^k |c_n|^2 \|f_n\|^2 \leq \|g\|^2.$$

Let  $k \rightarrow \infty$ . Since every non-decreasing sequence of real numbers which is bounded from above has a limit, it follows that

$$\sum_{n=1}^{\infty} c_n^2 \|f_n\|^2 \leq \|g\|^2,$$

which is Bessel's inequality.

If equality occurs in Bessel's inequality, then statement (3) follows straight from the definitions and the Bessel's identity proved above. □

An orthogonal system of functions is called a *complete orthogonal system* on an interval  $I = [a, b]$  for some space of functions on  $I$  if and only if Parseval's equality holds for every function  $g$  in this space.

**7.1.6. Fourier series.** The coefficients  $c_n$  from the previous theorem are called the *Fourier coefficients* of a given function in the (abstract) *Fourier series*.

The previous theorem indicates that we are able to work with countable orthogonal systems of functions  $f_n$  in much the same way as with finite orthogonal bases of vector spaces.

There are, however, essential differences:

- It is not easy to decide what the set of convergent or uniformly convergent series

$$F(x) = \sum_{n=1}^{\infty} c_n f_n(x)$$

looks like.

- For a given integrable function, we can find only the "best approximation possible" by such a series  $F(x)$  in the sense of  $L_2$ -distance.

In the case when we have an orthonormal system of functions  $f_n$ , the formulae mentioned in the theorem are simpler, but still there is no further improvement in the approximations.

The choice of an orthogonal system of functions for use in practice should address the purpose for which the approximations are needed. The name "Fourier series" itself refers to the following choice of a system of real-valued functions:

FOURIER'S ORTHOGONAL SYSTEM

The following functions form an orthogonal system

$$1, \sin x, \cos x, \sin 2x, \cos 2x, \dots, \sin nx, \cos nx, \dots$$

Thus

$$F_1(x) = \frac{\pi}{2} - \frac{4 \cos(x)}{\pi},$$

$$F_3(x) = F_1(x) - \frac{4 \cos(3x)}{9\pi},$$

$$F_6(x) = F_3(x) - \frac{4 \cos(5x)}{25\pi}.$$

Below we illustrate  $F_1, F_3$  and  $F_6$  together in a single figure:

To better observe the convergence of the Fourier series in a small neighbourhood around the origin, we may zoom in on the graph at that point:

Notice the Fourier series described here could be derived by easier means, namely by integrating the Fourier series of the square wave function (Heaviside's function), see 7.1.9. □

**7.A.12.** Use Sage to provide a solution of the task in 7.A.11. Moreover, show that  $F_5(x) = F_6(x)$  for all  $x$ . ○

**7.A.13.** Compute the Fourier series of the  $2\pi$ -periodic extension of the sign function  $\text{sgn} : [-\pi, \pi] \rightarrow \mathbb{R}$ , where recall that

$$\text{sgn}(x) = \begin{cases} -1, & \text{for } -\pi \leq x < 0, \\ 0, & \text{for } x = 0, \\ 1, & \text{for } 0 < x \leq \pi. \end{cases} \quad \circ$$

An elementary exercise on integration by parts shows that this is an orthogonal system of functions on the interval  $[-\pi, \pi]$ .

These functions are periodic with common period  $2\pi$  (see the definition below). “Fourier analysis”, which builds upon this orthogonal system, allows us to work with all piecewise continuous periodic functions with extraordinary efficiency. Since many physical, chemical, and biological data are perceived, received, or measured, in fact, by frequencies of the signals (the measured quantities), it is really an essential mathematical tool. Biologists and engineers often use the word “signal” in the sense of “function”.

PERIODIC FUNCTIONS

A real or complex valued function  $f$  defined on  $\mathbb{R}$  is called a *periodic function* with period  $T > 0$  if  $f(x + T) = f(x)$  for every  $x \in \mathbb{R}$ .

It is evident that sums and products of periodic functions with the same period are again periodic functions with the same period.

We note that the integral  $\int_{x_0}^{x_0+T} f(x) dx$  of a periodic function  $f$  on an interval whose length equals the period  $T$  is independent of the choice of  $x_0 \in \mathbb{R}$ . To prove it, it is enough to suppose  $0 \leq x_0 < T$ , using a translation by a suitable multiple of  $T$ . Then,

$$\begin{aligned} \int_{x_0}^{x_0+T} f(x) dx &= \int_{x_0}^T f(x) dx + \int_T^{x_0+T} f(x) dx \\ &= \int_{x_0}^T f(x) dx + \int_0^{x_0} f(x) dx = \int_0^T f(x) dx. \end{aligned}$$

Next, remind the Fourier's orthogonal system with the norms over intervals of length  $2\pi$  equal to

$$\|\sin nx\|^2 = \|\cos nx\|^2 = \pi$$

(cf. 6.2.6). Using it to built series as in the theorem 7.1.5, we arrive at

FOURIER SERIES

The series of functions

$$F(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos(nx) + b_n \sin(nx))$$

with coefficients

$$a_n = \frac{1}{\pi} \int_{x_0}^{x_0+2\pi} g(x) \cos(nx) dx,$$

$$b_n = \frac{1}{\pi} \int_{x_0}^{x_0+2\pi} g(x) \sin(nx) dx,$$

is called the *Fourier series* of a function  $g$  on the interval  $[x_0, x_0 + 2\pi]$ .

The coefficients  $a_n$  and  $b_n$  are called *Fourier coefficients of the function*  $g$ .

**7.A.14.** Use Sage to describe the Fourier series of the  $2\pi$ -periodic extension of the function

$$f(x) = \begin{cases} 0, & x \in [-\pi, 0), \\ \sin(x), & x \in [0, \pi). \end{cases}$$

Additionally, plot the graphs of  $F_3, F_5, F_8$  and  $f$  in a single figure, and specify the 8th and 48th coefficients of the corresponding Fourier series.

**Solution.** We have  $T = 2\pi$  and we are interested in the interval  $[-\pi, \pi)$ . Let us begin by computing the Fourier coefficients of  $f$ , which can be done with the method applied above, involving the commands `piecewise` and `integral`:

```
f1(x)=0; f2(x)=sin(x)
f=piecewise([( -pi, 0), f1], [(0, pi), f2])
L=pi; n=var("n")
an=(1/L)*integral(f1(x)*cos(n*pi*x/L), x, -pi, 0)
+(1/L)*integral(f2(x)*cos(n*pi*x/L), x, 0, pi)
show("a_n=", an.expand())
bn=(1/L)*integral(f1(x)*sin(n*pi*x/L), x, -pi, 0)
+(1/L)*integral(f2(x)*sin(n*pi*x/L), x, 0, pi)
show("b_n=", bn.expand())
```

Running this, we get the answers

$$a_n = -\frac{\cos(\pi n)}{\pi(n^2 - 1)} - \frac{1}{\pi(n^2 - 1)}, \quad b_n = -\frac{\sin(\pi n)}{\pi(n^2 - 1)},$$

which both make sense for all  $n \neq 1$ . Thus, for all positive integers  $n \neq 1$  we have

$$a_n = -\frac{1}{\pi(n^2 - 1)}((-1)^n + 1), \quad b_n = 0$$

and moreover  $a_0 = \frac{2}{\pi}$ . For  $n = 1$  we have the integrals

$$a_1 = \frac{1}{2\pi} \int_0^\pi \sin(2x) dx, \quad b_1 = \frac{1}{\pi} \int_{-\pi}^\pi f(x) \sin(x) dx,$$

and it is easy to see that  $a_1 = 0$  and  $b_1 = 1/2$ . In this way we arrive at the Fourier series

$$F(x) = \frac{1}{\pi} + \frac{\sin x}{2} + \frac{1}{\pi} \sum_{n=2}^\infty \left( \frac{(-1)^n + 1}{1 - n^2} \cos(nx) \right).$$

Since  $(-1)^n + 1 = 0$  when  $n$  is odd, and  $(-1)^n + 1 = 2$  when  $n$  is even, put  $n = 2m$  to obtain the expression

$$F(x) = \frac{1}{\pi} + \frac{\sin x}{2} - \frac{2}{\pi} \sum_{m=1}^\infty \frac{\cos(2mx)}{4m^2 - 1}.$$

For the partial sums we see that

$$F_3(x) = \frac{1}{\pi} + \frac{\sin(x)}{2} - \frac{2 \cos(2x)}{3\pi},$$

$$F_5(x) = -\frac{2 \cos(4x)}{15\pi} + F_3(x),$$

$$F_8(x) = -\frac{2 \cos(8x)}{63\pi} - \frac{2 \cos(6x)}{35\pi} + F_5(x).$$

In Sage to obtain these expressions we may continue typing in the preceding block the syntax given here:

If  $T$  is the time taken for one revolution of an object moving round the unit circle at constant speed, then that constant speed is  $\omega = 2\pi/T$ . In practice, we often want to work with Fourier series with an arbitrary primary period  $T$  of the functions, not just  $2\pi$ . Then we should employ the functions  $\cos(\omega nx)$ ,  $\sin(\omega nx)$ , where  $\omega = \frac{2\pi}{T}$ . By substitution  $t = \omega x$ , we can verify the orthogonality of the new system of functions and recalculate the coefficients in the Fourier series  $F(x)$  of a function  $g$  on the interval  $[x_0, x_0 + T]$ :

$$F(x) = \frac{a_0}{2} + \sum_{n=1}^\infty (a_n \cos(n\omega x) + b_n \sin(n\omega x)),$$

which have values

$$a_n = \frac{2}{T} \int_{x_0}^{x_0+T} g(x) \cos(n\omega x) dx,$$

$$b_n = \frac{2}{T} \int_{x_0}^{x_0+T} g(x) \sin(n\omega x) dx.$$

**7.1.7. The complex Fourier coefficients.** Parametrize the unit circle in the form:

$$e^{i\omega t} = \cos \omega t + i \sin \omega t.$$

For all integers  $m, n$  with  $m \neq n$ ,

$$\begin{aligned} \int_{-\pi}^\pi e^{imx} e^{-inx} dx &= \int_{-\pi}^\pi e^{i(m-n)x} dx \\ &= \frac{1}{i(m-n)} [e^{i(m-n)x}]_{-\pi}^\pi = 0. \end{aligned}$$

Thus for  $m \neq n$ , the integral  $\langle e^{imx}, e^{inx} \rangle = 0$ .

FOURIER'S COMPLEX ORTHOGONAL SYSTEM

The following functions form a complex valued orthogonal system

$$e^{-in\omega t}, \dots, e^{-i\omega t}, 1, e^{i\omega t}, e^{i2\omega t}, \dots, e^{in\omega t}, \dots$$

Note that if  $m = n$ , then

$$\int_{-\pi}^\pi e^{imx} e^{-imx} dx = \int_{-\pi}^\pi dx = 2\pi.$$

The orthogonality of this system can be easily used to recover the orthogonality of the real Fourier's system: Rewrite the above result as

$$\int_{-\pi}^\pi (\cos mx + i \sin mx)(\cos nx - i \sin nx) dx = 0$$

By expanding and separating into real and imaginary parts we get both

$$\int_{-\pi}^\pi (\cos mx \cos nx + \sin mx \sin nx) dx = 0$$

$$\int_{-\pi}^\pi (\sin mx \cos nx - \cos mx \sin nx) dx = 0$$

```

FS3 = f.fourier_series_partial_sum(3,pi)
FS5 = f.fourier_series_partial_sum(5,pi)
FS8 = f.fourier_series_partial_sum(8,pi)
show("3rd partial sum = ",FS3)
show("5th partial sum = ",FS5)
show("8th partial sum = ",FS8)
a = f.plot(x, -pi, pi, thickness=2,
color="black", legend_label="$f$")
b = plot(FS3, x,-pi,pi,linestyle="--",
color="blue",legend_label="$F_3$")
c= plot(FS5, x,-pi,pi,linestyle="-.",
color="green", legend_label="$F_5$")
d= plot(FS8, x, -pi, pi, linestyle=":",
color="red", legend_label="$F_8$")
(a+b+c+d).show()

```

This block also constructs the required graphs, which we present below.

Finally, for calculating the Fourier coefficients Sage provides built-in functions. For instance, one can use the syntax `f.fourier_series_cosine_coefficient(k)`, which corresponds to the  $k$ th coefficient of the cosine Fourier series of our periodic function  $f$ . Notice that if you are interested in “sine coefficients”, then the right function is `f.fourier_series_sine_coefficient(k)`, and in this case one should ensure that uses the sine function correctly, see 7.D.8 for an example.

Now you may check yourselves the desired coefficients, by simply adding the following cell:

```

Fc8=f.fourier_series_cosine_coefficient(8)
show("8th coefficient = ",Fc8)
Fc48=f.fourier_series_cosine_coefficient(48)
show("48th coefficient = ",Fc48)

```

In 7.D.11 we will present an alternative method using the Sage functions introduced in this block to determine and illustrate certain partial sums of a Fourier series, without using the Sage function `fourier_series_partial_sum`. □

By replacing  $n$  with  $-n$ , we have also

$$\int_{-\pi}^{\pi} (\cos mx \cos nx - \sin mx \sin nx) dx = 0$$

$$\int_{-\pi}^{\pi} (\sin mx \cos nx + \cos mx \sin nx) dx = 0$$

and hence, with  $m \neq n$ ,

$$\int_{-\pi}^{\pi} \cos mx \cos nx dx = 0$$

$$\int_{-\pi}^{\pi} \sin mx \sin nx dx = 0$$

$$\int_{-\pi}^{\pi} \sin mx \cos nx dx = 0$$

which proves again the orthogonality of the real valued Fourier system.

Note the case  $m = n > 0$ , when we recovered again

$$\int_{-\pi}^{\pi} \cos^2 nx dx = \|\cos(nx)\|^2 = \pi,$$

$$\int_{-\pi}^{\pi} \sin^2 nx dx = \|\sin(nx)\|^2 = \pi.$$

If  $n = 0$ , then  $\|1\|^2 = 2\pi$ .

For a (real or complex) function  $f(t)$  with  $-T/2 \leq t \leq T/2$ , and all integers  $n$ , we can define, in this context, its *complex Fourier coefficients* by the complex numbers

$$c_n = \frac{1}{T} \int_{-T/2}^{T/2} f(t) e^{-i\omega n t} dt.$$

The relation between the coefficients  $a_n$  and  $b_n$  of the Fourier series (after recalculating the formulae for these coefficients for functions with a general period of length  $T$ ) and these complex coefficients  $c_n$  follow from the definitions. Clearly,  $c_0 = a_0/2$ , and for natural numbers  $n$ , we have

$$c_n = \frac{1}{2}(a_n - ib_n), \quad c_{-n} = \frac{1}{2}(a_n + ib_n).$$

If the function  $f$  is real valued,  $c_n$  and  $c_{-n}$  are complex conjugates of each other.

We note here that for real valued functions with period  $2\pi$ , the Bessel inequality in this notation becomes

$$\frac{1}{2}|a_0|^2 + \sum_{n=1}^{\infty} (|a_n|^2 + |b_n|^2) \leq \|f\|^2 = \frac{1}{\pi} \int_{-\pi}^{\pi} |f(t)|^2 dt.$$

We have expressed the Fourier series  $F(t)$  for a function  $f(t)$  in the form

$$F(t) = \sum_{n=-\infty}^{\infty} c_n e^{i\omega n t}.$$

In both cases of real or complex valued functions, the corresponding Fourier series can be written in this form. In general, the coefficients are complex. We return to this expression later, in particular when dealing with Fourier transforms.

For fixed  $T$ , the expression  $\omega = 2\pi/T$  describes how the frequency changes if  $n$  is increased by one.

**7.A.15. Fourier series over other intervals.** Consider the function  $g : [-1, 1) \rightarrow \mathbb{R}$ , defined by

$$g(x) = \begin{cases} 0, & \text{for } -1 \leq x < 0, \\ x + 1, & \text{for } 0 \leq x < 1. \end{cases}$$

- (a) Determine a 2-periodic extension  $\hat{g}$  of  $g$  for  $x \in [-3, 3)$  and next sketch its graph via Sage.
- (b) Find the corresponding Fourier series on  $[-1, 1)$ , and next confirm your result via Sage.
- (c) Use Sage to plot the partial sums  $F_5(x)$ , and  $F_{55}(x)$  together with  $\hat{g}$ , for  $x \in (-3, 3)$ .

**Solution.** (a) By assumption the period is  $T = 2$ , and on the interval  $[-3, 3)$  a 2-periodic extension of  $g$  has the form

$$\hat{g}(x) = \begin{cases} g(x+2), & \text{for } -3 \leq x < -1, \\ g(x), & \text{for } -1 \leq x < 1, \\ g(x-2), & \text{for } 1 \leq x < 3. \end{cases}$$

$$= \begin{cases} 0, & \text{for } -3 \leq x < -2, \\ x+3, & \text{for } -2 \leq x < -1, \\ 0, & \text{for } -1 \leq x < 0, \\ x+1, & \text{for } 0 \leq x < 1, \\ 0, & \text{for } 1 \leq x < 2, \\ x-1, & \text{for } 2 \leq x < 3. \end{cases}$$

In Sage we can use the `piecewise` command to plot  $\hat{g}$ , so one may try the following block:

```
g1(x)=0;g2(x)=x+1;g3(x)=x+3;g4(x)=x-1
g=piecewise([( (-3,-2),g1), [ (-2,-1),g3],
[ (-1,0),g1], [ (0,1),g2], [ (1,2),g1], [ (2,3),g4] ])
a = g.plot(x, -3, 3,thickness=3,
color="steelblue",
exclude=[-2, -1, 0, 1, 2],
legend_label=r"\hat{g}")
p0=point([-3, 0], size=30, color="black")
p1=point([-2, 1], size=30, color="black")
p2=point([-1, 0], size=30, color="black")
p3=point([0, 1], size=30, color="black")
p4=point([1, 0], size=30, color="black")
p5=point([2, 1], size=30, color="black")
show(a+p0+p1+p2+p3+p4+p5)
```

Let us present the result:

We wish to show that the Fourier orthogonal system is complete on  $\mathcal{S}^0[-\pi, \pi]$ . This needs a thorough technical preparation. So now, we only formulate the main result, and add some practical notes. The proof of the theorem will be discussed later, see 7.1.15.

**7.1.8. Theorem.** Consider a bounded interval  $[a, b]$  of length  $T = b - a$ . Let  $f$  be a real or complex valued function in  $\mathcal{S}^1[a, b]$  (i.e., a piecewise continuous function with a piecewise continuous first derivative), extended periodically on  $\mathbb{R}$ . Then:

- (1) The partial sums  $s_N$  of its Fourier series converge pointwise to the function

$$g(x) = \frac{1}{2} \left( \lim_{y \rightarrow x+} f(y) + \lim_{y \rightarrow x-} f(y) \right).$$

- (2) Moreover, if the periodic extension of  $f \in \mathcal{S}^1[a, b]$  is a continuous function on  $\mathbb{R}$ , then the pointwise convergence of its Fourier series is uniform.
- (3) The  $L_2$ -distance  $\|s_N - f\|$  converges to 0 for  $N \rightarrow \infty$ .

**7.1.9. Periodic extension of functions.** The Fourier series converges, of course, outside the original interval  $[-T/2, T/2]$ , since it is a periodic function on  $\mathbb{R}$ . The Heaviside function  $g$  is defined by

$$g(x) = \begin{cases} -1 & \text{if } -\pi < x < 0, \\ 1 & \text{if } 0 < x < \pi \end{cases}$$

(We do not need to define the values at zero and at the end points of the interval, because these do not effect the coefficients of the Fourier series.) The periodic extension of the Heaviside function onto all of  $\mathbb{R}$  is usually called the *square wave function*.

Since  $g$  is an odd function, the coefficients of the functions  $\cos(nx)$  are all zero. The coefficients of  $\sin(nx)$ , are given by

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} g(x) \sin(nx) dx = \frac{2}{\pi} \int_0^{\pi} \sin(nx) dx$$

$$= \frac{2}{n\pi} (1 - (-1)^n).$$

Thus the Fourier series of  $g$  is

$$g(x) = \frac{4}{\pi} \left( \sin(x) + \frac{1}{3} \sin(3x) + \frac{1}{5} \sin(5x) + \dots \right).$$

The partial sums of its first five and fifty terms, respectively, are shown in the following diagrams.

Notice that we have included the points where the jump discontinuities occur within the interval  $[-3, 3)$ , using the command point.

(b) In this task one should apply the general formulae given in 7.1.6. We have  $\omega = 2\pi/T = \pi$ , and

$$a_n = \frac{2}{T} \int_{x_0}^{x_0+T} g(x) \cos(n\omega x) dx, \forall n \in \mathbb{N},$$

$$b_n = \frac{2}{T} \int_{x_0}^{x_0+T} g(x) \sin(n\omega x) dx, \forall n \in \mathbb{Z}_+.$$

Now it is easy to see that  $a_0 = \int_{-1}^1 g(x) dx = \int_0^1 (x+1) dx = \frac{3}{2}$  and moreover

$$a_n = \int_{-1}^1 g(x) \cos(n\pi x) dx = \int_0^1 (x+1) \cos(n\pi x) dx$$

$$= \frac{(-1)^n - 1}{n^2\pi^2},$$

$$b_n = \int_{-1}^1 g(x) \sin(n\pi x) dx = \int_0^1 (x+1) \sin(n\pi x) dx$$

$$= \frac{1 - 2(-1)^n}{n\pi}.$$

In Sage to confirm these computations, it suffices to use only  $g$  (and not its extension), as follows:

```
g1(x)=0;g2(x)=x+1
g=piecewise([( -1, 0), g1], [(0, 1), g2])
T=2; n=var("n"); Om=pi
an=(2/T)*integral(g1(x)*cos(n*Om*x), x, -1, 0) \
+(2/T)*integral(g2(x)*cos(n*Om*x), x, 0, 1)
show("a_n=", an.expand())
bn=(2/T)*integral(g1(x)*sin(n*Om*x), x, -1, 0) \
+(2/T)*integral(g2(x)*sin(n*Om*x), x, 0, 1)
show("b_n=", bn.expand()); integral(x+1, x, 0, 1)
```

In this way we obtain the following expression of the Fourier series in question:

$$\frac{3}{4} + \sum_{n=1}^{\infty} \left( \frac{(-1)^n - 1}{n^2\pi^2} \cos(n\pi x) + \frac{1 - 2(-1)^n}{n\pi} \sin(n\pi x) \right),$$

and one can try to obtain refinements by considering odd/even cases.

(c) This task can be solved by the following block:

If the interval  $[-T/2, T/2]$  is chosen for the prime period  $T$  of such a square wave function, the resulting Fourier series is

$$g(x) = \frac{4}{\pi} \left( \sin(\omega x) + \frac{1}{3} \sin(3\omega x) + \frac{1}{5} \sin(5\omega x) + \dots \right).$$

The number  $\omega = \frac{2\pi}{T}$  is also called the *phase frequency* of the wave.

As the number of terms of the series increases, the approximation gets much better except in a (still shrinking) neighbourhood of the discontinuity point. There, the maximum of the deviation remains roughly the same. This is a general property of Fourier series and it is called the *Gibbs phenomenon*.

In accordance with 7.1.8(1), the Fourier series of the Heaviside function converges to the mean of the two one-sided limits at the points of discontinuity.

Of course, we cannot expect that the convergence of Fourier series for functions  $g$  with discontinuity points be uniform (then, the function  $g$  would have to be continuous itself, being a uniform limit of continuous functions).

**7.1.10. Utilizing symmetry of functions.** We consider the

problem of finding the Fourier series of the function  $f(x) = x^2$  on the interval  $[0, 1]$ . If we just periodically extend this function from the given interval  $[0, 1]$ , the resulting function would not be continuous, and so the convergence at integers would be as slow as in the case of a square wave function. However, we can easily extend the domain of  $f$  to the interval  $[-1, 1]$ , so that  $f(x) = x^2$  is an even function for  $-1 \leq x \leq 1$ . If we then extend periodically, the result is continuous. The resulting Fourier series then converges uniformly, and since then  $f$  is even, only the coefficients  $a_n$  are non-zero.

For  $n > 0$ , iterated application of integration by parts yields:

$$a_n = \frac{2}{2} \int_{-1}^1 x^2 \cos\left(\frac{2\pi nx}{2}\right) dx = 2 \int_0^1 x^2 \cos(\pi nx) dx$$

$$= \frac{4}{\pi^2 n^2} (-1)^n.$$

The remaining coefficient is

$$a_0 = \frac{2}{2} \int_{-1}^1 x^2 dx = 2 \int_0^1 x^2 dx = \frac{2}{3}.$$

The entire series giving the periodic extension of  $x^2$  from the interval  $[-1, 1]$  thus equals

$$g(x) = \frac{1}{3} + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \cos(\pi nx).$$

By the Weierstrass criterion, this series converges uniformly. Therefore,  $g(x)$  is continuous. By theorem 7.1.8,  $g(x) = f(x) = x^2$  on the interval  $[-1, 1]$ . Thus our series approximates the function  $x^2$  on the interval  $[0, 1]$  better (i.e. faster) than we could achieve with the periodic extension of the function from  $[0, 1]$  interval only. If we put  $x = 1$  and rearrange,

```
g1(x)=0;g2(x)=x+1;g3(x)=x+3;g4(x)=x-1
g=piecewise([(−3, −2), g1], [(−2, −1), g3], [(0, 1), g2], [(1, 2), g1], [(2, 3), g4]])
partS5 = g.fourier_series_partial_sum(5,1)
partS55 = g.fourier_series_partial_sum(55,1)
a = g.plot(x, −3, 3, thickness=3, color="steelblue",
exclude=[−2, −1, 0, 1, 2], legend_label=r"$f$")
s5=plot(partS5, x, −3, 3, linestyle="--",
```

we obtain the remarkable result

$$\frac{1}{4}(g(1) - \frac{1}{3}) = \frac{\pi^2}{6} = \sum_{n=1}^{\infty} \frac{(-1)^{2n}}{n^2} = \sum_{n=1}^{\infty} \frac{1}{n^2}.$$

We proceed with a further illustration. Let us try to differentiate the Fourier series for  $x^2$  term by term and, of course we hope to get the Fourier series of  $x$  on the interval  $-1 < x < 1$

$$x = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin(\pi nx).$$

If it was truly the series of  $x$ , it could not converge uniformly since the periodic extension of the function  $x$  from the interval  $[-1, 1]$  is not a continuous function. Thus our differentiation term by term is not guaranteed by the general theorem.

However, a straightforward computation of the Fourier coefficients shows, that this is the Fourier series of  $x$ .

The series for  $x^2$  converges uniformly, and so we can integrate it term by term obtaining

$$\frac{1}{3}x^3 = \frac{2}{3}x + \frac{4}{\pi^3} \sum_{n=1}^{\infty} \frac{(-1)^n}{n^3} \sin(\pi nx).$$

This is valid for  $-1 < x < 1$ . It is not valid for other values of  $x$ , since the series is periodic, but the other two terms are not. Of course, we may substitute the above Fourier series of the function  $x$  and thus obtain the Fourier series for  $x^3$  on the interval  $[-1, 1]$  this way. Notice, this will no more converge uniformly.

In this context, we use the following terminology for the Fourier series of even or odd functions:

THE SINE AND COSINE FOURIER SERIES

For a given (real or complex) valued function  $f$  on an interval  $[0, T)$  of length  $T > 0$ , the Fourier series of its even periodic extension (with period  $2T$ ) is called the *cosine Fourier series* of  $f$ , while the Fourier series of the odd periodic extension of  $f$  is called the *sine Fourier series* of the function  $f$ .

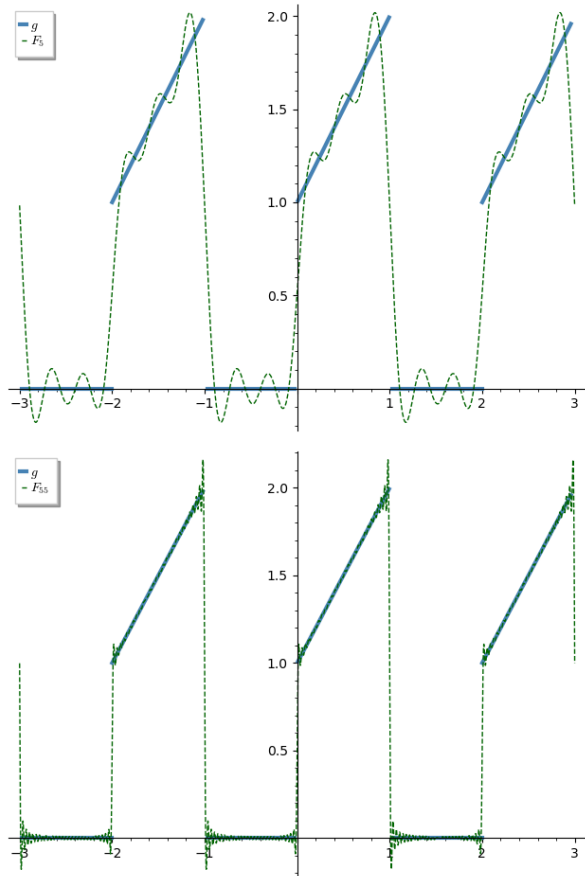

**7.1.11. General Fourier series and wavelets.** In the case of a general orthogonal system of functions  $f_n$  and the series generated from it, we often talk about the *general Fourier series* with respect to the orthogonal system of functions  $f_n$ .

Fourier series and further tools built upon them are used for processing various signals, images, and other data. In fact, these mathematical tools also underpin many fundamental models in science, including, for example, modeling of the function of the brain, as well as much of theoretical physics.

The periodic nature of the sine and cosine functions used in classical Fourier series, and their simple scaling by increasing the frequency by unit steps, limit their usability. In many

```
color="darkgreen", legend_label=r"$F_{5}$")
s55=plot(partS55, x, -3, 3, linestyle="--",
color="darkgreen", legend_label=r"$F_{55}$")
show(a+s5);show(a+s55)
```

Notice the resulting approximations are much slower comparing the situation in the previous examples. By the illustrations one can also demonstrate the “Gibbs phenomenon”. This is the overshooting in the jumps, which is proportional to the magnitudes of the jumps, see the figures here:

□

It is often convenient (and usually easier) to express the Fourier series using the complex coefficients  $c_n$  instead of the real coefficients  $a_n$  and  $b_n$ . This is a straightforward consequence of the facts

$$e^{in\omega x} = \cos(n\omega x) + i \sin(n\omega x) \quad \text{or, vice versa}$$

$$\cos(n\omega x) = \frac{1}{2}(e^{in\omega x} + e^{-in\omega x}),$$

$$\sin(n\omega x) = \frac{1}{2i}(e^{in\omega x} - e^{-in\omega x}).$$

The resulting series for a real or complex valued function  $g$  on the interval  $[-\pi, \pi]$  is  $F(x) = \sum_{n=-\infty}^{\infty} c_n e^{inx}$  with

$$c_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{-inx} g(x) dx.$$

applications, the nature of the data may suggest more convenient and possibly more efficient orthogonal systems of functions.

Requirements for fast numerical processing usually include quick scalability and the possibility of easy translations by constant values. In other words, we want to be able to zoom quickly in and out with respect to the frequencies and, at the same time, to localize in time.

Fast scalability can be achieved by having just one wavelet mother function<sup>1</sup>  $\psi$ , if possible with compact support, from which we create countably many functions  $\psi_{j,k}$ ,  $j, k \in \mathbb{Z}$ , by integer translations and dyadic dilations:

$$\psi_{j,k}(x) = 2^{j/2} \psi(2^j x - k).$$

It is wise to rescale and choose  $\psi$  with  $L_2$ -norm equal to one (as a function on  $\mathbb{R}$ ). Then the coefficients  $2^{j/2}$  ensure that the same is true for all  $\psi_{j,k}$ .

Of course, the shape of the mother wavelet  $\psi$  should match and cover all typical local behaviour of the data to be processed. We say that  $\psi$  is an orthogonal mother wavelet if the resulting countable system of functions  $\psi_{j,k}$  is orthogonal and, at the same time, it is “reasonably dense” in the space of functions with integrable squares. We come to this concept in more detail later on.

The effectivity of the wavelet analysis is another issue which needs further ideas and concepts to be built in. We do not have space here to go into details, but the readers may find many excellent specialized books in this fascinating area of applied Mathematics. Here we consider one simple example.

**7.1.12. The Haar wavelets.** Perhaps the first question to start with is, how to effectively approximate any given function with piecewise constant ones.

For various reasons, it is good if our mother wavelet  $\psi$  has zero mean, too. Thus we want to consider an analogue of the Heaviside function

$$\psi(x) = \begin{cases} 1 & x \in [0, 1/2) \\ -1 & x \in [1/2, 1). \end{cases}$$

As a straightforward exercise we may check that, indeed, the resulting system of functions  $\psi_{j,k}$  is orthonormal. Another exercise shows, using finite linear combinations of these functions, that we may approximate any constant function with given precision over a bounded interval. In an exercise we shall see ?? that this already verifies the density properties required for the orthogonal mother wavelet functions.

<sup>1</sup>The roots of wavelets go back to various attempts, how to localize the basic signals in both time and frequency, with diverse motivations from engineering and other applications. The name wavelet seems to be related to the idea of having a wave similar signal which begins and ends with zero amplitude. Since late 1970’s, these attempts were related to many names (e.g. Morlet, Meyer) and the wavelet theory became the main tool in signal analysis. Of course, first examples of wavelets are much older, the Haar’s construction goes back to 1909. Actually, many of the wavelet types do not represent orthogonal systems of functions, they rather share the idea of a combination of the high pass filters and low pass filters. The reader is advised to consult extremely rich literature, if interested in more details

Let us discuss a few examples and for more details see 7.1.7 (see also 7.D.10).

**7.A.16. Complex Fourier series.** (a) Determine the complex version of the Fourier series  $F(x)$  of the function  $f(x) = x$  with  $x \in (-\pi, \pi)$ . Next use the results from 7.A.10 to confirm that

$$c_n = \frac{1}{2}(a_n - ib_n), \quad c_{-n} = \overline{c_n}.$$

(b) Verify that the complex form of the Fourier series matches the result given in 7.A.10.

**Solution.** (a) By definition,  $F(x) = \sum_{n=-\infty}^{\infty} c_n e^{inx}$ , hence one needs to specify the complex Fourier coefficients  $c_n$ . We have

$$c_0 = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) dx = \frac{1}{2\pi} \int_{-\pi}^{\pi} x dx = 0,$$

since  $f(x) = x$  is an odd function. For  $n \neq 0$ , using integration by parts we get

$$\begin{aligned} c_n &= \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx} dx = \frac{1}{2\pi} \int_{-\pi}^{\pi} x e^{-inx} dx \\ &= \frac{1}{2\pi} \left[ -\frac{x e^{-inx}}{in} \right]_{-\pi}^{\pi} - \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{e^{-inx}}{-in} dx \\ &= -\frac{1}{2i\pi n} [x e^{-inx}]_{-\pi}^{\pi} + \frac{1}{2i\pi n} \int_{-\pi}^{\pi} e^{-inx} dx \\ &= -\frac{1}{2i\pi n} (\pi e^{-in\pi} + \pi e^{in\pi}) + \frac{1}{2i\pi n} \left[ -\frac{e^{-inx}}{in} \right]_{-\pi}^{\pi} \\ &= -\frac{2\pi \cos(n\pi)}{2\pi in} - \frac{1}{2\pi(in)^2} [e^{-inx}]_{-\pi}^{\pi} \\ &= -\frac{(-1)^n}{in} + \frac{1}{2\pi n^2} (e^{-in\pi} - e^{in\pi}) \\ &= -\frac{(-1)^n}{in} + \frac{-2i \sin(n\pi)}{2\pi n^2} = -\frac{(-1)^n}{in}. \end{aligned}$$

Here we used the identities  $i^2 = -1$ ,  $e^{-in\pi} + e^{in\pi} = 2 \cos(n\pi) = 2(-1)^n$  and  $e^{-in\pi} - e^{in\pi} = -2i \sin(n\pi) = 0$ .

Now, according to 7.A.10 we have  $a_n = 0$ ,  $b_n = \frac{2}{n}(-1)^{n+1}$ , and it should be

$$\begin{aligned} c_n &= \frac{1}{2}(a_n - ib_n) = \frac{1}{2} \left( 0 - i \frac{2}{n} (-1)^{n+1} \right) \\ &= \frac{-i(-1)^{n+1}}{n} = \frac{(-1)^{n+1}}{in}, \end{aligned}$$

since  $-i = \frac{1}{i}$ . This agrees with the result presented above and can be verified in Sage using the `bool` function. For example, you may type the cell

```
var("n")
bn=(2*(-1)^(n+1))/n; cn=(-(-1)^(n))/(i*n)
bool(cn==-(i*bn)/2)
```

which returns `True`. In a similar way, for  $c_{-n}$  one gets  $c_{-n} = \frac{(-1)^n}{in}$  and it is easy to see that  $c_n = \overline{c_{-n}}$ , that is,  $c_{-n}$  is the complex conjugate of  $c_n$ , see also 7.1.7.

Now we consider the question of effective treatment. Notice that we can also use the characteristic function  $\varphi$  of the interval  $[0, 1)$  and write

$$\psi(x) = \varphi(2x) - \varphi(2x-1) = \frac{1}{\sqrt{2}} \sqrt{2} \varphi_{1,0}(x) - \frac{1}{\sqrt{2}} \sqrt{2} \varphi_{1,1}(x).$$

The function  $\varphi$  plays the role of the *father wavelet function* and it itself satisfies

$$\varphi(x) = \varphi(2x) + \varphi(2x-1) = \frac{1}{\sqrt{2}} \sqrt{2} \varphi_{1,0}(x) + \frac{1}{\sqrt{2}} \sqrt{2} \varphi_{1,1}(x).$$

This can be interpreted as differencing and averaging the two consecutive values at the half scale.

With these properties, there is no need for an explicit analytic form of  $\psi$  and  $\varphi$ , since we can find their values recurrently in all dyadic points  $x$ . Indeed,

$$\varphi(2^{j-1}n) = \varphi(2^j n) + \varphi(2^j n - 1).$$

The function  $\varphi$  has another useful feature. Namely we can obtain the unit constant function by adding all its integer translations

$$\sum_{k=-\infty}^{\infty} \varphi_{0,k}(x) = 1$$

for all  $x \in \mathbb{R}$ .

Finally, nearly all the coefficients in the general Fourier series with the base  $\psi_{j,k}$  vanish for piecewise constant functions. On the contrary, the function  $\varphi$  "sees" the constants. In engineering terminology, this is an instance of the *high pass filter* and *low pass filter*.

**7.1.13. Example.** To illustrate the above considerations, we approximate the following function  $f(x)$  in  $\mathbb{R}$  by the Haar wavelets,

$$f(x) = \begin{cases} 0.3(x+3), & -2 \leq x \leq -1 \\ 0.7(x+1), & 0 \leq x \leq 1 \\ 0 & \text{otherwise} \end{cases}.$$

The function in question is not periodic and could not be approximated well by classical Fourier series. The individual functions  $\psi_{j,k}$  from 7.1.11 have compact support, but in order to approximate constant or linear behaviour, we still need a large number of them. The following illustrations have been acquired in Maple working with indices  $|j| \leq n$  and  $|k| \leq n$ , the first one with  $n = 5$ , the second one with  $n = 10$ .

The approximation on the sides of the interval is not as good as in the middle, because we do not include enough shifts, i.e. values of  $k$ . One of the motivations for the scaling

For the complex expression of  $F(x)$  we finally get

$$\begin{aligned} F(x) &= c_0 + \sum_{n=1}^{\infty} c_n e^{inx} + \sum_{n=1}^{\infty} c_{-n} e^{-inx} \\ &= 0 + \sum_{n=1}^{\infty} \frac{-(-1)^n}{in} e^{inx} + \sum_{n=1}^{\infty} \frac{(-1)^n}{in} e^{-inx} \\ &= \sum_{n=1}^{\infty} \frac{(-1)^n}{in} (e^{-inx} - e^{inx}). \quad (b) \end{aligned}$$

(b) This follows directly from (b), combined with the identity  $-2i \sin(nx) = e^{-inx} - e^{inx}$ , i.e.,

$$\begin{aligned} F(x) &= \sum_{n=1}^{\infty} \frac{(-1)^n}{in} (e^{-inx} - e^{inx}) \\ &= \frac{1}{i} \sum_{n=1}^{\infty} \frac{(-1)^n}{n} (-2i \sin(nx)) \\ &= \frac{i}{i} \sum_{n=1}^{\infty} \frac{2(-1)^{n+1}}{n} \sin(nx), \end{aligned}$$

which is the formula presented in 7.A.10. □

**7.A.17.** Compute the complex Fourier series of the  $2\pi$ -periodic extension of the exponential map  $f(x) = e^x$ , with  $x \in (-\pi, \pi)$ . Next use Sage to illustrate the 20th-partial sum of the Fourier series together with that of  $f$ . ○

When  $f$  is a periodic function with period  $2L$  for some  $L > 0$ , then the complex Fourier series for  $x \in (x_0, x_0 + 2L)$  has the form  $F(x) = \sum_{n=-\infty}^{\infty} c_n e^{\frac{i\pi n x}{L}}$ , where

$$c_n = \frac{1}{2L} \int_{x_0}^{x_0+2L} f(x) e^{-\frac{i\pi n x}{L}} dx.$$

The next task focuses on this case and is left as a challenge for you.

**7.A.18.** For the function  $f(x) = e^{-x}$  with  $x \in [-1, 1]$  and  $f(x) = f(x + 2)$  outside the interval  $[-1, 1]$ , compute the complex Fourier coefficients and derive the corresponding Fourier series. ○

Let  $f : [a, b] \rightarrow \mathbb{R}$  be a function for which  $f'$  exists. We say that  $f$  is piecewise differentiable if both  $f$  and  $f'$  are piecewise continuous on  $[a, b]$ . Suppose now that  $f$  is a  $2L$ -periodic piecewise differentiable function defined on an interval of length  $L$ , for some  $L > 0$ , and let  $F$  be the Fourier series of  $f$ . Assuming that  $\lim_{n \rightarrow \infty} F_n(x) = F(x)$ , the first part of the theorem in 7.1.8 (known as the “Dirichlet condition”, see 7.1.16) implies that at a point of continuity of  $f$ , the series  $F$  converges to the value of  $f$  at that point. Moreover, at a point of discontinuity the series  $F$  converges to the average of the left and right limits of  $f$  at that point. Thus, at a jump discontinuity  $x_0$  of  $f$ , the value of the Fourier series  $F$  does not depend on the value  $f(x_0)$ , but only on the left and right limits of  $f$  at  $x_0$ . This means that the behaviour of the Fourier series of  $f$  at discontinuity points is not effected

and shifting in the construction of wavelets is the hope for a small amount of non-zero coefficients. But this does not mean that most of the coefficients would be zero. In our case the percentage of non-zero coefficients for  $n = \{1, 2, \dots, 10\}$  is 55.6, 44., 38.8, 34.6, 32.2, 30.8, 29.8, 28.7, 28.0, 27.4.

**7.1.14. Concluding remarks.** A series of famous wavelets  $D_N$  has been called after Ingrid Debauchies. They are constructed by very similar recurrent averaging and differencing relations based on certain natural requirements. Just as an indication, consider the slightly more general recurrent relations

$$\begin{aligned} \varphi(x) &= \sqrt{2} \sum_{k=0}^N h_k \varphi(2x - k) \\ \psi(x) &= \sqrt{2} \sum_{k=0}^N g_k \varphi(2x - k) \end{aligned}$$

with yet unknown constants  $g_k$  and  $h_k$ . If we want the mother wavelet  $\psi(x-k)$  to have zero coefficients in the resulting series for all polynomials up to the order  $N-1$ , then we must ensure that

$$\int_{-\infty}^{\infty} x^k \psi(x) dx = 0$$

for all  $k = 0, 1, \dots, N-1$ . Similar conditions determine the Debauchies wavelets.

The standards of JPEG2000 are based on similar wavelets and such techniques provide tools for professional compression of visual data in film industry, or the format DjVu for compressed publications.

In the diagram below, there are the Daubechies  $D4$  mother and father wavelets.

In real applications, the orthogonality of the mother wavelet can be relaxed. As long as the functions  $\psi_{k,l}$  are linearly independent and generate the whole space of interest, we always get the dual basis with respect to the  $L_2$  inner product.

by the values of  $f$  there. On the other hand, recall that the continuity of  $f$  is a necessary and sufficient condition for the uniform convergence of  $F$  over the entire real line.

Let us describe a few examples and for further material on the convergence of Fourier series see the final section of this chapter (Section D).

**7.A.19.** Describe the implications of Dirichlet's condition for the Fourier series obtained in Problem 7.A.10.

**Solution.** Consider the function  $f(x) = x$ , with  $x \in (-\pi, \pi)$ , as in 7.A.10. The  $2\pi$ -periodic extension of  $f$  has discontinuities at  $x = \pm\pi, \pm3\pi, \pm5\pi, \dots$  and provides an example of a periodic piecewise differentiable function. At these discontinuities it is easy to see that the average of the left and right limits of  $f$  is zero. Therefore, by the result in 7.A.10 and Dirichlet's condition one deduces that

$$\sum_{n=1}^{\infty} \frac{2(-1)^{n+1}}{n} \sin(nx) = \begin{cases} x, & \text{if } -\pi < x < \pi, \\ 0, & \text{if } x = \pm\pi. \end{cases}$$

□

**7.A.20. Convergence of Fourier series.** Consider the square wave function (Heaviside's function, see also 7.1.9), defined this time on  $[-1, 1]$ , i.e.,

$$f(x) = \begin{cases} -1, & \text{if } -1 \leq x < 0, \\ 1, & \text{if } 0 < x \leq 1, \end{cases}$$

with  $f(x+2) = f(x)$  for all  $x$  outside the interval  $[-1, 1]$ . Determine the pointwise convergence of the corresponding Fourier series.

**Solution.** To answer the task we do not need the explicit expression of the Fourier series  $F$  of  $f$ . In particular,  $f$  satisfies Dirichlet's condition and hence  $F$  converges to  $f$  at all points where  $f$  is continuous. The discontinuities of  $f$  appear at  $x = 0$ , and  $x = \pm 1$ . In particular, for the endpoints we have  $f(-1) \neq f(1)$  and the 2-periodic extension of  $f$  has discontinuities at  $\pm 1, \pm 3, \dots$ . At these points the Fourier series converges to the average of the left-hand and right-hand limits, which all equal to zero. For instance, we see that  $f(0^+) = \lim_{x \rightarrow 0^+} f(x) = 1$  and  $f(0^-) = \lim_{x \rightarrow 0^-} f(x) = -1$ , hence

$$\frac{1}{2}(f(0^-) + f(0^+)) = \frac{1}{2}(-1 + 1) = 0.$$

The limits  $f(0^-)$  and  $f(0^+)$  can be verified also in Sage, by utilizing the `piecewise` and `limit` commands. It is important however to specify the option `algorithm = "giac"` within the `limit` command, as shown below:

```
f = piecewise([[(-1, 0), -1], [(0, 1), 1]])
show(f(x).limit(x=0, dir="+", algorithm="giac"))
show(f(x).limit(x=0, dir="-", algorithm="giac"))
```

Thus  $F(x)$  converges to  $f(x)$  for all  $x$ , except of  $x = 0, \pm 1$  where it converges to 0. □

**7.1.15. Proof of theorem 7.1.8 about Fourier series.** We

return to the detailed proof of the basic properties of the classical Fourier series. We shall need several concepts and technicalities related to abstract metric spaces. Thus, the reader could enjoy reading first the general context of metrics and convergence which we will introduce in the beginning of the last part of this chapter. In this perspective, reading first a few paragraphs starting by 7.3.1, and returning later might be a good idea. On the other hand, we do not need much from the general theory of metric spaces and so our considerations of various concepts of convergence in the proof could also be of assistance for the abstract developments later.

We do not worry here about necessary conditions for convergence, and many other formulations can be found in literature. On the other hand, the statement of theorem 7.1.8 is quite simple and deals with many useful situations, as we have seen already.

Although we need only the  $L_1$  and  $L_2$  norms now, we should observe that for general  $1 \leq p < \infty$ , the formula

$$\|f\|_p = \left( \int_a^b |f|^p \right)^{1/p}$$

defines also a norm. See the definition in 7.3.1 and the paragraph on the  $L_p$ -norms and Hölder inequality in 7.3.4 below. Moreover, there is the  $L_\infty$  norm given by the suprema of values of  $f$  over the interval in question.

For the sake of simplicity, we always work in the space  $S_c^0$  or  $S_c^1$  with respect to the corresponding norm (which always makes sense there).

Hölder's inequality (applied to the functions  $f$  and constant 1) yields the following bound on  $S^0[a, b]$ . Namely, for  $p > 1$  and  $1/p + 1/q = 1$ ,

$$\int_a^b |f(x)| dx \leq |b-a|^{1/q} \left( \int_a^b |f(x)|^p dx \right)^{1/p} \leq |b-a|^{1/q} \|f\|_p.$$

Replace  $f$  with  $f_n - f$ . It is then clear from the above bound that  $L_p$ -convergence  $f_n \rightarrow f$  implies, for any  $p > 1$ ,  $L_1$ -convergence. (The terminology  $L_p$ -convergence is stronger than  $L_1$ -convergence is sometimes used). With a modified bound, we can derive an even stronger proposition, namely that on a bounded interval,  $L_q$ -convergence is stronger than  $L_p$ -convergence whenever  $q > p$ ; try this by yourselves.

If uniform boundedness of the sequence of functions  $f_n$  is given, then there is a constant  $C$  independent of  $n$ , so that  $\|f_n\|_\infty \leq C$ .

Then we can assert that  $|f_n(x) - f(x)| \leq 2C$ , and it then follows that  $L_1$ -convergence implies  $L_p$ -convergence, since

**7.A.21.** Using the Fourier series of the  $2\pi$ -periodic extension of the function  $g(x) = |x|$ , with  $x \in [-\pi, \pi)$ , sum the series

$$\sum_{n=1}^{\infty} \frac{1}{(2n-1)^2}.$$

**Solution.** To determine the value of this series, one can successfully apply several known Fourier series. The Fourier series of the function  $g$  coincides with the Fourier series presented in 7.A.11, i.e.,

$$\frac{\pi}{2} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos((2n-1)x)}{(2n-1)^2}.$$

Since this function  $g$  is continuous on  $[-\pi, \pi)$  and  $|\cdot - \pi| = |\pi|$ , we have

$$|x| = \frac{\pi}{2} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos((2n-1)x)}{(2n-1)^2}, \quad x \in [-\pi, \pi].$$

Substituting  $x = 0$ , we get  $0 = \frac{\pi}{2} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^2}$ . Therefore

$$\sum_{n=1}^{\infty} \frac{1}{(2n-1)^2} = \frac{\pi^2}{8}.$$

□

**7.A.22.** Determine the convergence and uniform convergence of the Fourier series for the function  $g(x) = e^{-x}$ ,  $x \in [-1, 1)$ .

**Solution.** Again, it is unnecessary to calculate the corresponding Fourier series, since we wish only to check convergence. Let us consider the 2-periodic function  $s(x)$ , defined as follows:

$$s(x) = g(x) = e^{-x}, \quad x \in (-1, 1),$$

$$s(1) = \frac{g(-1) + \lim_{x \rightarrow 1^-} g(x)}{2} = \frac{e + e^{-1}}{2}.$$

According to 7.1.8, this function is the sum of the Fourier series in question. In other words, the Fourier series converges to  $s(x)$ . Moreover, this convergence is uniform on every closed interval which contains none of the points  $2k + 1$ ,  $k \in \mathbb{Z}$ . This follows from the continuity of the functions  $g$  and  $g'$  on  $(-1, 1)$ . On the other hand, the convergence cannot be uniform on any interval  $(c, d)$  such that  $[c, d]$  contains an odd integer. This is because the uniform limit of continuous functions is always a continuous function, and the periodic extension of  $s$  is not continuous at the odd integers. Thus, the series converges to the function  $g$  on  $(-1, 1)$ , yet this convergence is uniform only on the subintervals  $[c, d]$  which satisfy the restriction  $-1 < c < d < 1$ . □

**7.A.23.** Express the function  $g(x) = \pi^2 - x^2$  on the interval  $[-\pi, \pi]$  in the form of a Fourier series. Using this expression, sum the two series

then

$$\int_a^b |f(x) - f_n(x)|^p dx =$$

$$= \int_a^b |f(x) - f_n(x)|^{p-1} |f(x) - f_n(x)| dx$$

$$\leq (2C)^{p-1} \int_a^b |f(x) - f_n(x)| dx$$

which can be written

$$\|f - f_n\|_p \leq (2C)^{1/q} \|f - f_n\|_1^{1/p}.$$

It follows that the  $L_p$ -norms on the space  $S^0[a, b]$  are equivalent with respect to the convergence of uniformly bounded sequences of functions.

**7.1.16. Implications of the Dirichlet condition.** The most difficult (and most interesting) problem is to prove the first statement of the theorem 7.1.8, which in the literature is often referred to as the *Dirichlet condition*, which seems to have been derived as early as in 1824.

We begin by proving how this property of pointwise convergence implies the statements (2) and (3) of the theorem. Without loss of generality, we assume that we are working on the interval  $[-\pi, \pi]$ , i. e. with period  $T = 2\pi$ .

As the first step, we prepare simple bounds for the coefficients of the Fourier series. One bound is of course

$$|a_n| \leq \frac{1}{\pi} \int_{-\pi}^{\pi} |f(x)| dx,$$

and similarly for all the coefficients  $b_n$ . This is because both  $\cos(x)$  and  $\sin(x)$  are bounded by 1 in absolute value. However, if  $f$  is a continuous function in  $S^1[-\pi, \pi]$ , we can integrate by parts, thus obtaining (we write  $a_n(f)$  for the corresponding coefficient of the function  $f$ , and so on)

$$b_n(f) = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin(nx) dx$$

$$= \frac{-1}{n\pi} [f(x) \cos(nx)]_{-\pi}^{\pi} + \frac{1}{n\pi} \int_{-\pi}^{\pi} f'(x) \cos(nx) dx$$

$$= \frac{1}{n} a_n(f').$$

Notice  $f(-\pi) = f(\pi)$  by the continuity and thus the boundary term vanishes. Similarly we compute  $a_n(f) = -b_n(f')$ .

Iterating this procedure, we obtain a bound for functions  $f$  in  $S^{k+1}[-\pi, \pi]$  with continuous derivatives up to order  $k$  inclusive

$$|a_n(f)| \leq \frac{1}{n^{k+1}\pi} \int_{-\pi}^{\pi} |f^{(k+1)}(x)| dx,$$

and similarly for  $b_n(f)$ .

Thus we can see that the “smoother” a function is, the more rapidly the Fourier coefficients approach zero. For sufficiently smooth functions  $f$ , the  $n^k$ -multiples of their Fourier coefficients  $a_n$  and  $b_n$  are bounded by the  $L_1$ -norm of their  $k$ -th derivative  $f^{(k)}$ .

$$(1) \quad \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2}, \quad \sum_{n=1}^{\infty} \frac{1}{n^2}.$$

**Solution.** We could take advantage of the function  $g$  being even, and calculate the non-zero coefficients  $a_n$  by integration by parts. However, in 7.1.10 the Fourier series for the function  $f(x) = x^2$  on the interval  $[-1, 1]$  is derived. This proves the identity

$$f(x) = \frac{1}{3} + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n \cos(n\pi x)}{n^2}, \quad x \in (-1, 1),$$

valid also for  $x = \pm 1$ . By adding  $\pi^2$  and rescaling, it follows

$$g(x) = \pi^2 - \left( \frac{1}{3} + \frac{4}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n \cos \frac{n\pi x}{\pi}}{n^2} \right) \pi^2$$

that

$$= \frac{2}{3}\pi^2 + 4 \sum_{n=1}^{\infty} \frac{(-1)^{n+1} \cos(nx)}{n^2}, \quad x \in [-\pi, \pi].$$

Of course, one can also calculate the Fourier series of the function  $g$  directly.

Substituting  $x = 0$  and  $x = \pi$  then gives

$$\pi^2 = \frac{2}{3}\pi^2 + 4 \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2}, \quad \text{i.e.} \quad \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2} = \frac{\pi^2}{12},$$

and

$$0 = \frac{2}{3}\pi^2 + 4 \sum_{n=1}^{\infty} \frac{(-1)^{n+1}(-1)^n}{n^2}, \quad \text{i.e.} \quad \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}.$$

In other words,

$$\begin{aligned} \pi^2 &= 12 \left( 1 - \frac{1}{2^2} + \frac{1}{3^2} - \frac{1}{4^2} + \dots \right) \\ &= 6 \left( 1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \dots \right). \end{aligned}$$

□

We have seen that the Fourier series of a  $2L$ -periodic odd function involves only sine functions, whereas Fourier series of a  $2L$ -periodic even function involves only cosine functions. However, Fourier series are employed in many areas and often we are interested in functions that are only defined on intervals of the form  $[0, L]$ , for some  $L > 0$ . In particular, to get the cosine series expansion of  $f$  we may extend it to  $[-L, L]$  so that the extended function is an even  $2L$ -periodic function. In this case, by the result in 6.B.35 we will have

$$a_n = \frac{2}{L} \int_0^L f(x) \cos\left(\frac{n\pi x}{L}\right) dx, \quad b_n = 0.$$

This gives the cosine extension

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{L}\right).$$

Similarly, to get the sine series expansion of  $f$ , we may extend it to  $[-L, L]$  in such a way that the extended function is an odd  $2L$ -periodic function. Then we will have

$$a_n = 0, \quad b_n = \frac{2}{L} \int_0^L f(x) \sin\left(\frac{n\pi x}{L}\right) dx,$$

Let  $f$  be a continuous function in the space  $\mathcal{S}^1[a, b]$ . By the Dirichlet condition, its Fourier series converge pointwise to  $f$ . Then we can assert that

$$\begin{aligned} |s_N(x) - f(x)| &= \left| \sum_{k=N+1}^{\infty} (a_k \cos(kx) + b_k \sin(kx)) \right| \\ &\leq \sum_{k=N+1}^{\infty} (|a_k| + |b_k|). \end{aligned}$$

The right-hand side can further be estimated by the coefficients  $a'_n$  and  $b'_n$  of the derivative  $f'$ . By applying in succession the inequality above, then Hölder's inequality for infinite series (with  $p = q = 2$ ), and then with the arithmetic-geometric inequality, we obtain

$$\begin{aligned} |s_N(x) - f(x)| &\leq \sum_{k=N+1}^{\infty} \frac{1}{k} (|a'_k| + |b'_k|) \\ &\leq \left( \sum_{k=N+1}^{\infty} \frac{1}{k^2} \right)^{\frac{1}{2}} \left( \sum_{k=N+1}^{\infty} (|a'_k|^2 + 2|a'_k||b'_k| + |b'_k|^2) \right)^{\frac{1}{2}} \\ &\leq \left( \sum_{k=N+1}^{\infty} \frac{1}{k^2} \right)^{\frac{1}{2}} \left( \sum_{k=N+1}^{\infty} (2|a'_k|^2 + 2|b'_k|^2) \right)^{\frac{1}{2}} \\ &\leq \sqrt{2} \left( \int_N^{\infty} \frac{1}{x^2} dx \right)^{\frac{1}{2}} \frac{1}{\sqrt{\pi}} \|f'\|_2 \\ &= \left( \frac{\sqrt{2}}{\sqrt{\pi}} \|f'\|_2 \right) \cdot \frac{1}{\sqrt{N}}. \end{aligned}$$

Thus we have obtained not only a proof of the uniform convergence of our series to the anticipated value, but also a bound for the speed of the convergence:

#### UNIFORM CONVERGENCE UNDER THE DIRICHLET CONDITION

If  $f$  is a continuous function in  $\mathcal{S}^1[a, b]$ , then

$$\sup_{x \in \mathbb{R}} |s_N(x) - f(x)| \leq \left( \frac{\sqrt{2}}{\sqrt{\pi}} \|f'\|_2 \right) \cdot \frac{1}{\sqrt{N}}.$$

This proves the statement 7.1.8.(2), supposing the Dirichlet condition 7.1.8.(1) holds.

**7.1.17.  $L_2$ -convergence.** In the next step of our proof, we derive  $L_2$ -convergence of Fourier series. The proof utilizes the common technique of approximation objects which are not continuous by ones which are. We describe it without further details. Interested readers should be able to fill in the gaps by themselves without any difficulties. First, we formulate the statement we need.

**Lemma.** The subset of continuous functions  $f$  in  $\mathcal{S}^0[a, b]$  on a finite interval  $[a, b]$  is a dense subset in this space with respect to the  $L_2$ -norm.

which gives the sine extension

$$\sum_{n=1}^{\infty} b_n \sin\left(\frac{n\pi x}{L}\right),$$

see also at the end of the paragraph 7.1.10. Let us describe a few examples and for further material we refer to Section D.

**7.A.24.** Describe the cosine Fourier series for the sine function  $f(x) = \sin(x)$ , with  $x \in [0, \pi]$ . ○

**7.A.25.** Describe the sine Fourier series for the function  $f(x) = \cos(x)$ , with  $x \in [0, \pi]$ . ○

We end this section with a tasks on the so called “Parseval’s” identity, and some applications of Fourier series.

**7.A.26.** Using Parseval’s identity for Fourier’s orthogonal system (part (3) of the theorem 7.1.5), verify that

$$\sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} = \frac{\pi^4}{96}.$$

**Solution.** It is imperative to choose an appropriate Fourier series. For instance, consider the Fourier series

$$\frac{\pi}{2} - \frac{4}{\pi} \sum_{n=1}^{\infty} \frac{\cos((2n-1)x)}{(2n-1)^2},$$

which we obtained for the function  $g(x) = |x|$ ,  $x \in [-\pi, \pi]$  in 7.A.15(b). Parseval’s identity

$$\frac{a_0^2}{2} + \sum_{n=1}^{\infty} a_n^2 + \sum_{n=1}^{\infty} b_n^2 = \frac{2}{T} \int_{x_0}^{x_0+T} (g(x))^2 dx$$

says, substituting for the  $a$ ’s and  $b$ ’s from our particular series, that

$$\frac{\pi^2}{2} + \frac{16}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} = \frac{1}{\pi} \int_{-\pi}^{\pi} |x|^2 dx = \frac{2}{\pi} \int_0^{\pi} x^2 dx = \frac{2\pi^2}{3},$$

so,

$$\sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} = \left(\frac{2\pi^2}{3} - \frac{\pi^2}{2}\right) \frac{\pi^2}{16} = \frac{\pi^4}{96}.$$

There are other ways of obtaining this result, see for example (3) at the page 698. We recommend comparing the solutions of this exercise to the previous one.

We started our discussion of Fourier series with the simplest of periodic functions

$$f(t) = a \sin(\omega t + b)$$

for certain constants  $a, \omega > 0, b \in \mathbb{R}$ . They appear as the general solution to the homogeneous linear differential equation

$$(1) \quad y'' + \omega^2 y = 0$$

which arises in mechanics by Newton’s law of force for a moving particle. Recall the brief introduction to the simplest differential equations in 6.2.21 on page 552. Much more follows in Chapter 8.

**SKETCH OF THE PROOF.** Here “dense” means that for any  $g$  in  $S^0[a, b]$  and any  $\varepsilon > 0$ , there is some continuous  $f$  satisfying  $\|f - g\|_2 < \varepsilon$ . We deal with abstract topological concepts like this in the last part of this chapter.

The idea of the proof can be seen easily via the example of approximation of Heaviside’s function  $h$  on the interval  $[-\pi, \pi]$ . We recall that  $h(x) = -1$  for  $x < 0$ , and  $h(x) = 1$  for  $x > 0$ . For every  $\delta$  satisfying  $\pi > \delta > 0$ , we define the function  $f_\delta$  as  $x/\delta$  for  $|x| \leq \delta$  and  $f_\delta(x) = h(x)$  otherwise. All the functions  $f_\delta$  are continuous, in fact, piecewise linear. It can be calculated easily that  $\|h - f_\delta\|_2 \rightarrow 0$  so that  $h$  can be approximated in  $L_2$  norm by a sequence of continuous functions.

All discontinuity points of a general function  $f$  can be catered for in exactly the same way. There are only finitely many of them, and so all of the considered functions are limit points of sequences of continuous functions. □

Now, our proof of the  $L_2$  convergence (under the assumption of the Dirichlet condition) is already simple because for the given function  $f$ , the distance between the partial sums of its Fourier series can be bounded by using a sequence of continuous functions  $f_\varepsilon$  in this way (all norms in this paragraph are the  $L_2$  norms):

$$\|f - s_N(f)\| \leq \|f - f_\varepsilon\| + \|f_\varepsilon - s_N(f_\varepsilon)\| + \|s_N(f_\varepsilon) - s_N(f)\|$$

and the particular summands on the right-hand side can be controlled.

The first one of them is at most  $\varepsilon$ , and according to the uniform convergence for continuous functions (as just proved above), the second summand can be bounded also by  $\varepsilon$ , if  $N$  is big enough. Notice that the third term has the value of the partial sum of the Fourier series for  $f - f_\varepsilon$ . Thus (cf. Theorem 7.1.5(1)),

$$\|f - f_\varepsilon - s_N(f - f_\varepsilon)\| \leq \|f - f_\varepsilon\|.$$

Therefore by the triangle inequality,

$$\|s_N(f - f_\varepsilon)\| \leq \|s_N(f - f_\varepsilon) - f + f_\varepsilon\| + \|f - f_\varepsilon\| \leq 2\|f - f_\varepsilon\|.$$

Altogether,  $\|f - s_N(f)\| \leq 4\varepsilon$ .

This verifies the  $L_2$  convergence of the functions  $s_N(f)$  to  $f$  under the Dirichlet condition, which is we wanted to prove.

**7.1.18. Dirichlet kernel.** Finally, we arrive at the proof of the first statement of theorem 7.1.8. It follows from the definition of the Fourier series  $F(t)$  for a function  $f(t)$ , using its expression with the complex exponential in 7.1.7, that the partial sums  $s_N(t)$  can be written as

$$s_N(t) = \frac{1}{T} \sum_{k=-N}^N \int_{-T/2}^{T/2} f(x) e^{-i\omega kx} e^{i\omega kt} dx,$$

We mention that the function  $f$  has period  $T = 2\pi/\omega$ . In mechanics, one often talks about frequency  $1/T$ . The positive value  $a$  expresses the maximum displacement of the oscillating point from the equilibrium position and it is called the amplitude. The value  $b$  determines the position of the point at the initial time  $t = 0$  and it is called the initial phase, while  $\omega$  is the angular frequency of the oscillation.

Similarly, the function  $z \equiv g(t)$  describes the dependence of voltage upon time  $t$  in an electrical circuit with inductance  $L$  and capacity  $C$  and which is the solution of the differential equation

$$(2) \quad z'' + \omega^2 z = 0.$$

The only difference between the equations (1) and (2) (besides the dissimilar physical interpretation) is the constant  $\omega$ . In the equation (1), there is  $\omega^2 = k/m$  where  $k$  is the proportionality constant and  $m$  is the mass of the point, while in the equation (2), there is  $\omega^2 = (LC)^{-1}$ .

We illustrate how Fourier series can be applied in the theory of differential equations. Consider only the non-homogeneous (compare to (1)) differential equation

$$(3) \quad y'' + a^2 y = f(x)$$

with  $y$  an unknown in variable  $x \in \mathbb{R}$ , with a periodic, continuously differentiable function  $f : \mathbb{R} \rightarrow \mathbb{R}$  on the right-hand side and a constant  $a > 0$ . Let  $T > 0$  be the prime period of the function  $f$  and let its Fourier series on  $[-T/2, T/2]$  be known, i.e. we assume

$$(4) \quad f(x) = \frac{A_0}{2} + \sum_{n=1}^{\infty} \left( A_n \cos \frac{2\pi n x}{T} + B_n \sin \frac{2\pi n x}{T} \right).$$

**7.A.27.** Prove that if the equation (3) has a periodic solution on  $\mathbb{R}$ , then the period of this solution is also a period of the function  $f$ . Further, prove that the equation (3) has a unique periodic solution with period  $T$  if and only if

$$(1) \quad a \neq \frac{2\pi n}{T} \quad \text{for every } n \in \mathbb{N}.$$

**Solution.** Let a function  $y = g(x)$ ,  $x \in \mathbb{R}$ , be a solution of the equation (3) with  $f(x) \not\equiv 0$  and with period  $p > 0$ . In order to substitute the function  $g$  into a second-order differential equation, its second derivative  $g''$  must exist. Since the functions  $g, g', g'', \dots$  share the same period, the function

$$g''(x) + a^2 g(x) = f(x)$$

is also periodic with period  $p$ . In other words, the function  $f$  is periodic as a linear combination of functions with period  $p$ . Thus, we have proved the first statement claiming that  $p = lT$  for a certain  $l \in \mathbb{N}$ .

Suppose that the function  $y = g(x)$ ,  $x \in \mathbb{R}$ , is a periodic solution of the equation (3) with period  $T$  and that it is expressed by a Fourier series as follows:

$$(2) \quad g(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos(\omega n x) + b_n \sin(\omega n x)), \quad x \in \mathbb{R},$$

where  $T$  is the period we are working with and  $\omega = 2\pi/T$ . This expression can be rewritten as

$$(1) \quad s_N(t) = \int_{-T/2}^{T/2} K_N(t-x)f(x) dx,$$

where the function

$$K_N(y) = \frac{1}{T} \sum_{k=-N}^N e^{i\omega k y}$$

is called the *Dirichlet kernel*. The sum is a (finite) geometric series with common ratio  $e^{i\omega y}$ . By multiplying by  $e^{i\omega y}$  and then subtracting, we obtain

$$e^{i\omega y} K_N(y) = \frac{1}{T} \sum_{k=-N}^N e^{i\omega(k+1)y}$$

$$(1 - e^{i\omega y})K_N(y) = \frac{1}{T} \left( e^{-iN\omega y} - e^{i(N+1)\omega y} \right).$$

Provided  $\omega y$  is not a multiple of  $2\pi$ , we continue to obtain

$$\begin{aligned} K_N(y) &= \frac{1}{T} \frac{e^{-iN\omega y} - e^{i(N+1)\omega y}}{1 - e^{i\omega y}} \\ &= \frac{1}{T} \frac{1 - e^{-i(N+1/2)\omega y} + e^{i(N+1/2)\omega y}}{e^{i\omega y/2} - e^{-i\omega y/2}} \\ &= \frac{1}{T} \frac{\sin((N+1/2)\omega y)}{\sin(\omega y/2)} \end{aligned}$$

in which the key step was to multiply both the numerator and the denominator by  $-e^{-i\omega y/2}$ . When  $y = 0$ ,  $K_N(0) = \frac{1}{T}(2N+1)$ .

The last expression shows that  $K_N(y)$  is an even function. By l'Hospital's rule, applied at  $y = 0$ , it is continuous everywhere. Since all the partial sums of the series for the constant function  $f(x) = 1$  also equal 1, we obtain from the definition of the Dirichlet kernel, cf. (1), that

$$\int_{-T/2}^{T/2} K_N(x) dx = 1.$$

In the case of periodic functions, the integrals over intervals whose length equals the period are independent of the choice of the end points. Hence, changing the coordinates, we can also use the expression

$$s_N(x) = \int_{-T/2}^{T/2} K_N(y)f(x+y) dy$$

for the partial sums.

Finally, we are fully prepared. First, we consider the case when the function  $f$  is continuous (and piecewise differentiable) at the point  $x$ . We want to prove that in this case, the Fourier series  $F(x)$  for the function  $f$  converges to the value  $f(x)$  at the point  $x$ . We have

$$s_N(x) - f(x) = \int_{-T/2}^{T/2} (f(x+y) - f(x))K_N(y) dy.$$

where  $\omega = 2\pi/T$ . If  $g$  satisfies the equation (3), it has a continuous second derivative on  $\mathbb{R}$ . Therefore, for  $x \in \mathbb{R}$ ,

$$(3) \quad \begin{aligned} g'(x) &= \sum_{n=1}^{\infty} (\omega n b_n \cos(\omega n x) - \omega n a_n \sin(\omega n x)), \\ g''(x) &= \sum_{n=1}^{\infty} (-\omega^2 n^2 a_n \cos(\omega n x) - \omega^2 n^2 b_n \sin(\omega n x)), \end{aligned}$$

Substituting (4), (2) and (3) into (3) yields

$$\begin{aligned} a^2 \frac{1}{2} a_0 + \sum_{n=1}^{\infty} ((-\omega^2 n^2 a_n + a^2 a_n) \cos(n\omega x) + (-\omega^2 n^2 b_n + a^2 b_n) \sin(n\omega x)) \\ = \frac{A_0}{2} + \sum_{n=1}^{\infty} (A_n \cos(n\omega x) + B_n \sin(n\omega x)). \end{aligned}$$

It follows that

$$(4) \quad a^2 \frac{a_0}{2} = \frac{A_0}{2}, \quad \text{that is} \quad a^2 a_0 = A_0,$$

and for  $n \in \mathbb{N}$ ,

$$(5) \quad (-\omega^2 n^2 + a^2) a_n = A_n, \quad (-\omega^2 n^2 + a^2) b_n = B_n.$$

There is exactly one pair of sequences  $\{a_n\}_{n \in \mathbb{N} \cup \{0\}}$ ,  $\{b_n\}_{n \in \mathbb{N}}$  satisfying these conditions if and only if

$$-\omega^2 n^2 + a^2 = -\left(\frac{2\pi n}{T}\right)^2 + a^2 \neq 0 \quad \text{for every } n \in \mathbb{N},$$

i.e., if (1) holds. In this case, the only solution of (3) with period  $T$  is determined by the only solution

$$(6) \quad a_n = \frac{A_n}{-\omega^2 n^2 + a^2}, \quad b_n = \frac{B_n}{-\omega^2 n^2 + a^2}, \quad n \in \mathbb{N}$$

of the system (5). We emphasize that we utilized the uniform convergence of the series in (3).  $\square$

**7.A.28.** Using the solution of the previous problem, find all  $2\pi$ -periodic solutions of the differential equation

$$y'' + 2y = \sum_{n=1}^{\infty} \frac{\sin(nx)}{n^2}, \quad x \in \mathbb{R}.$$

**Solution.** The equation is in the form of (3) for  $a = \sqrt{2}$  and the continuously differentiable function

$$f(x) = \sum_{n=1}^{\infty} \frac{\sin(nx)}{n^2}, \quad x \in \mathbb{R}$$

with prime period  $T = 2\pi$ . According to problem 7.A.27, the condition  $\sqrt{2} \notin \mathbb{N}$  implies that there is exactly one  $2\pi$ -periodic solution. If we look for it as the value of the series

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos(nx) + b_n \sin(nx)), \quad x \in \mathbb{R},$$

we know also that (see (4) and (6))

$$a_0 = a_n = 0, \quad b_n = \frac{1}{n^2(2-n^2)}, \quad n \in \mathbb{N}.$$

Thus, the given equation has the unique  $2\pi$ -periodic solution

$$y = \sum_{n=1}^{\infty} \frac{\sin(nx)}{n^2(2-n^2)}, \quad x \in \mathbb{R}. \quad \square$$

The integrand can be rewritten

$$\begin{aligned} \frac{f(x+y) - f(x)}{\sin(\omega y/2)} \sin((N+1/2)\omega y) &= \\ = \varphi_x(y) (\cos(\omega y/2) \sin(N\omega y) + \sin(\omega y/2) \cos(N\omega y)), \end{aligned}$$

where

$$\varphi_x(y) = \frac{f(x+y) - f(x)}{\sin(\omega y/2)}$$

for  $y \neq 0$ . Moreover, we can compute the right and left limits of  $\varphi_x$  at the point  $y = 0$  using the L'Hospital's rule. Indeed, writing  $f'_{\pm}(x)$  for the right and left derivatives of  $f$ , we arrive at

$$\begin{aligned} \lim_{y \rightarrow 0^+} \varphi_x(y) &= \lim_{y \rightarrow 0^+} \frac{f(x+y) - f(x)}{y} \frac{y}{\sin(\omega y/2)} \\ &= \frac{2}{\omega} f'_+(x), \end{aligned}$$

and similiary for the left limit. Thus,  $\varphi_x(y)$  is piecewise continuous on the entire interval  $[-T/2, T/2]$ .

Next, we rewrite the integral expression for  $s_N - f$  in the form reminding coefficients of Fourier series:

$$\frac{2}{T} \int_{-T/2}^{T/2} (\psi_1(y) \sin(N\omega y) + \psi_2(y) \cos(N\omega y)) dy$$

with the piecewise continuous functions

$$\psi_1(y) = \frac{T}{2} \varphi_x(y) \cos(\omega y/2), \quad \psi_2(y) = \frac{T}{2} \varphi_x(y) \sin(\omega y/2).$$

Indeed, we deal with the Fourier coefficients of the functions  $\psi_1$  and  $\psi_2$ , but they have to converge to zero with  $N \rightarrow \infty$  by virtue of the general theorem on abstract Fourier series, see the Bessel inequality in 7.1.5(2). Hence

$$\lim_{N \rightarrow \infty} \int_{-T/2}^{T/2} \psi_1(y) \sin(N\omega y) dy = 0,$$

and

$$\lim_{N \rightarrow \infty} \int_{-T/2}^{T/2} \psi_2(y) \cos(N\omega y) dy = 0.$$

But this means  $\lim_{N \rightarrow \infty} s_N(x) - f(x) = 0$ , as desired.

Now suppose the function  $f$  has a discontinuity at  $x$ . Without loss of generality, we may assume  $x = 0$  (using constant shift of coordinates otherwise).

Since the function belongs to  $\mathcal{S}^1$ , it is already continuous and differentiable on a neighbourhood of the point  $x = 0$  (outside the point itself). Split  $f$  into its even part  $f_1$  and its odd part  $f_2$ . That is, write  $f(x) = f_1(x) + f_2(x)$ , where

$$f_1(x) = \frac{1}{2}(f(x) + f(-x)) \quad \text{for } x \neq 0$$

$$f_1(0) = \frac{1}{2} \left( \lim_{x \rightarrow 0^+} f(x) + \lim_{x \rightarrow 0^-} f(x) \right)$$

$$f_2(x) = \frac{1}{2}(f(x) - f(-x)).$$

Then the even part  $f_1(x)$  is continuous and piecewise differentiable at the point  $x = 0$  because of the existence of the one-sided limits, and so on a neighbourhood of the point  $x = 0$ .

**B. Integral operators and Fourier Transform**

Next we will focus on problems related with the notion of “convolution”, which is a typical integral operation that applies on two functions  $f, g$  and produces a new one, denote by  $(f \star g)$  and defined by

$$(f \star g)(y) = \int_{-\infty}^{\infty} f(x)g(y - x) dx.$$

The convolution integral is a fundamental concept in various fields, e.g., in statistics, signal processing, computer vision, and other. For its basic features and other basic facts, see 7.2.2.

**7.B.1.** Find the convolutions  $f \star g$  and  $f \star h$  of the following functions and in each case check the “smoothing” of  $f$ .

$$f(x) = \sin(x) + \frac{2}{5} [\sin(6x)]^2 - \frac{1}{5} \sin(60x),$$

$$g(x) = \begin{cases} \frac{1}{2\varepsilon} & \text{if } -\varepsilon < x < \varepsilon \\ 0 & \text{otherwise} \end{cases}, \quad \text{where } \varepsilon > 0,$$

$$h(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad \text{where } \mu, \sigma \in \mathbb{R}, \sigma > 0.$$

**Solution.** The function  $g$  is chosen to provide the mean of  $f$  over (small) intervals of length  $2\varepsilon$  and it is normalized so that the integral of  $g$  over all of  $\mathbb{R}$  is one. We should expect some smoothing of the oscillations of the function  $f(x)$ . Drawing the resulting functions by Maple shows:

The graph depicted in the upper left is the original  $f$ , while the graph in the upper right is of  $g$  with  $\varepsilon = 1/10$ . The two

Also  $f_2(0) = 0$ , and the Fourier series for  $f_2$  contains only the terms with  $\sin(n\omega x)$  and thus, vanishes at  $x = 0$ .

Thus we can refer to the previous continuous case and obtain, for the Fourier series  $F(x)$  of the function  $f$ , the equation

$$F(0) = \frac{1}{2} \left( \lim_{x \rightarrow 0^+} f(x) + \lim_{x \rightarrow 0^-} f(x) \right) + 0,$$

which is what we wanted to prove.

If we face more than one jump of  $f$  within the basic period of length  $T$ , we may express  $f$  as a sum of functions with exactly one discontinuity. For example, if points of discontinuity were  $x_0 < x_1$ , both in  $(-T/2, T/2)$ , and writing  $f(y_{\pm}) = \lim_{x \rightarrow y_{\pm}} f(x)$  for the one-sided limits, we can consider  $f = g_1 + g_2$  with

$$g_1(x) = \begin{cases} f(x) & x \in (-T/2, x_0) \\ f(x) - f(x_{0+}) + f(x_{0-}) & x \in (x_0, T/2) \end{cases}$$

$$g_2(x) = \begin{cases} 0 & x \in (-T/2, x_0) \\ f(x_{0+}) - f(x_{0-}) & x \in (x_0, T/2). \end{cases}$$

Clearly  $g_1$  has got the only discontinuity in  $x_1$  while the piecewise constant  $g_2$  jumps at  $x_0$  only. By the already proved behavior, the Fourier series of  $g_1$  and  $g_2$  converges at  $x_0$  to  $f(x_{0-})$  and  $\frac{1}{2}(f(x_{0+}) - f(x_{0-}))$ , respectively. Their sum provides the desired result. Similarly for the other discontinuity point.

This completes the proof. This also completes the proof of the statements (2) and (3) of theorem 7.1.8 where we required that the Dirichlet condition be true.

**2. Integral operators and Fourier transform**

This section provides a few glimpses towards a fascinating and useful area of mathematics exploiting the integration process in many practical ways. Unlike most of this book, we do not provide any general theory and our constructions will be rather illustrated by examples than by rigorous theorems with full proofs.

**7.2.1. Functionals.** In the case of finite-dimensional vector spaces, we can regard the vectors as mappings from a finite set of fixed generators into the space of coordinates. The sums of vectors and the scalar multiples of vectors were then given by the corresponding operations with such functions. We also worked with the vector spaces of functions of a real variable in the same way when their values were scalars (or vectors as well).

The simplest linear mapping  $\alpha$  between vector spaces maps vectors to scalars. It is called a linear form, or a linear functional (in particular when dealing with vector spaces of functions). In finite dimension, it is defined as the sum of products of coordinates  $x_i$  of vectors with fixed values  $\alpha_i = \alpha(e_i)$  at the generators  $e_i$ , i.e. by one-row matrices:

$$(x_1, \dots, x_n)^T \mapsto (\alpha_1, \dots, \alpha_n) \cdot (x_1, \dots, x_n)^T.$$

labels in drawings - proc ne, ale pripsat rukou, popis je ale v textu stejne ?

lower graphs show their convolution with (respectively) parameters for  $g$  selected as  $\varepsilon = 1/10$  and  $\varepsilon = 13/50$ . It is straightforward to compute the convolution explicitly, too:

$$f * g(y) = \frac{1}{2\varepsilon} \int_{y-\varepsilon}^{y+\varepsilon} \sin(x) + \frac{2}{5} \sin(6x)^2 - \frac{1}{5} \sin(60x) dx$$

$$= \frac{1}{2\varepsilon} \left[ -\cos(x) - \frac{1}{30} \sin(6x) \cos(6x) + \frac{1}{5}x + \frac{1}{300} \cos(60x) \right]_{y-\varepsilon}^{y+\varepsilon}$$

Similarly, the other function  $h$  is a typical smoothing function which gives much more weight to the values of  $f$  near the point  $y$ , and much less weight to the values of  $f$  further from  $y$ . This is the famous *Gaussian* function. We meet it frequently. Using Maple again, we see that the integral of  $h$  over  $\mathbb{R}$  is one (we prove this in 13.2.8). It is not easy to find the convolution analytically, but Maple can do it approximately. The resulting diagrams are as follows.

As before, the graph depicted in the upper left is the original  $f$ , while the graph in the upper right is of  $h$  with  $\mu = 0$ , and  $\sigma = 1/10$ . Below that, their convolutions are shown with parameters  $\mu = 0$ ,  $\sigma^2 = 1/60$  and (lower right)  $\mu = 0$ ,  $\sigma^2 = 5/60$ .

**7.B.2.** Determine the convolution  $f_1 * f_2$  where

$$f_1(x) = \frac{1}{x} \quad \text{for } x \neq 0$$

$$f_2(x) = \begin{cases} x & \text{for } x \in [-1, 1] \\ 0 & \text{otherwise} \end{cases}$$

**Solution.**

More complicated mappings, with values lying in the same space, are given similarly by square matrices. We approach linear operations on spaces of functions in an analogous way.

For simplicity, we work with the real vector space  $\mathcal{S}$  of all piecewise continuous real-valued functions having compact support and defined on the whole  $\mathbb{R}$  or on an interval  $I \neq \varepsilon[a, b]$ . Linear mappings  $\mathcal{S} \rightarrow \mathbb{R}$  are called (real) *linear functionals*. Such functionals can be defined in many diverse ways. For example, by evaluating the function's values (or its derivatives') at some fixed points or in terms of integration.

We can, for instance consider the functional  $L$  given by evaluating the function at a sole fixed point  $x_0 \in I$ , i. e.,

$$L(f) = f(x_0).$$

Or, we can have the functional given by integration of the product with a fixed function  $g(x)$ , i.e.,

$$L(f) = \int_a^b f(x)g(x) dx.$$

The function  $g(x)$  in the previous example is a function which weighs the particular values representing the function  $f(x)$  in the definition of the Riemann integral and the functional  $L$  is a perfect analogue of the linear forms on finite dimensional vector spaces mentioned above. The simplest case of such a functional is, of course, the Riemann integral itself, i. e. the case of  $g(x) = 1$  for all points  $x$ .

A good example is given by

$$g(x) = \begin{cases} 0 & \text{if } |x| \geq \varepsilon \\ \frac{1}{2\varepsilon} & \text{if } |x| < \varepsilon. \end{cases}$$

for any  $\varepsilon > 0$ . The integral of the function  $g$  over  $\mathbb{R}$  equals one, and our linear functional can be perceived as a (uniform) averaging of the values of the function  $f$  over the  $\varepsilon$ -neighbourhood of the origin. Similarly, we can work with the function

$$g(x) = \begin{cases} 0 & \text{if } |x| \geq \varepsilon \\ e^{\frac{1}{x^2 - \varepsilon^2} + \frac{1}{\varepsilon^2}} & \text{if } |x| < \varepsilon \end{cases}$$

which we used in the paragraph 6.1.9. This function is smooth on  $\mathbb{R}$  with compact support on the interval  $(-\varepsilon, \varepsilon)$ .

Our functional has the meaning of a weighted combination of the values, but this time, the weights of the input values decrease rapidly as their distance from the origin increases. The integral of  $g$  over  $\mathbb{R}$  is finite, but it is not equal to one. Dividing  $g$  by this integral would lead to a functional which would have the meaning of a non-uniform averaging of a given function  $f$ .

Another example is the Gaussian function

$$g(x) = \frac{1}{\sqrt{\pi}} e^{-x^2},$$

which also has its integral over  $\mathbb{R}$  equal to one (we verify this later). This time, all the input values  $x$  in the corresponding "average" have a non-zero weight, yet this weight becomes insignificantly small as the distance from the origin increases.

$$(f_1 * f_2)(t) = \int_{-\infty}^{\infty} f_1(x) f_2(t-x) dx = \int_{-\infty}^{\infty} \frac{1}{x} f_2(t-x) dx.$$

Since  $f_2(x) = 0$  outside the interval  $[-1, 1]$ , necessarily  $-1 \leq t-x \leq 1$  that is,  $t-1 \leq x \leq t+1$ . So

$$(f_1 * f_2)(t) = \int_{t-1}^{t+1} \frac{1}{x} (t-x) dx = t \int_{t-1}^{t+1} \frac{1}{x} dx - 2.$$

This last integral is improper if  $t-1 \leq 0 \leq t+1$ . For  $t$  outside that interval, the integration gives

$$(f_1 * f_2)(t) = t \ln \left| \frac{t+1}{t-1} \right| - 2.$$

If instead,  $-1 < t < 1$ , we can for small  $\varepsilon > 0$ , replace  $\int_{t-1}^{t+1} \frac{1}{x} dx$  with

$$\int_{\varepsilon}^{t+1} \frac{1}{x} dx + \int_{t-1}^{-\varepsilon} \frac{1}{x} dx$$

which computes to  $\ln |t+1| - \ln |\varepsilon| + \ln |-\varepsilon| - \ln |t-1|$ . The terms in  $\varepsilon$  cancel, so when we take the limit  $\varepsilon \rightarrow 0$ , we obtain the same answer for the integral as before.

Thus

$$(f_1 * f_2)(t) = t \ln \left| \frac{t+1}{t-1} \right| - 2$$

for all values of  $t$  except for  $t = 1$ , or for  $t = -1$ . □

We calculate the convolution of two functions both of which have a bounded support.

**7.B.3.** Determine the convolution  $f_1 * f_2$  where

$$f_1(x) = \begin{cases} 1-x^2 & \text{for } x \in [-1, 1], \\ 0 & \text{otherwise,} \end{cases}$$

$$f_2(x) = \begin{cases} x & \text{for } x \in [0, 1], \\ 0 & \text{otherwise.} \end{cases}$$

**Solution.** Since the integrand is zero when  $f_1(x) = 0$ ,

$$f_1 * f_2(t) = \int_{-\infty}^{\infty} f_1(x) f_2(t-x) dx$$

$$= \int_{-1}^1 (1-x^2) f_2(t-x) dx$$

But the integrand is also zero when  $f_2(t-x) = 0$ , so we need  $0 \leq t-x \leq 1$  ie.  $t-1 < x < t$  for the integrand to be non zero. So for a non zero value of  $f_1 * f_2(t)$ , we integrate over the intersection of the intervals  $[t-1, t]$  and

**7.2.2. Function convolution.** Integral functionals from the previous paragraph can easily be modified to obtain a “streamed averaging” of the values of a given function  $f$  near a given point  $y \in \mathbb{R}$ :

$$L_y(f) = \int_{-\infty}^{\infty} f(x) g(y-x) dx$$

CONVOLUTION OF FUNCTIONS OF A REAL VARIABLE

The free parameter  $y$  in the definition of the functional  $L_y(f)$  can be perceived as a new independent variable, and our operation  $L_y$  actually maps functions to functions again,  $f \mapsto \tilde{f}$ :

$$\tilde{f}(y) = L_y(f) = \int_{-\infty}^{\infty} f(x) g(y-x) dx.$$

This operation is called the *convolution of functions*  $f$  and  $g$ , denoted  $f * g$ .

The convolution is usually defined for real or complex valued functions on  $\mathbb{R}$  with compact support, or those with decay fast enough to ensure the integrability.

By the transformation  $t = z - x$ , we can easily calculate that

$$(f * g)(z) = \int_{-\infty}^{\infty} f(x) g(z-x) dx$$

$$= - \int_{\infty}^{-\infty} f(z-t) g(t) dt = (g * f)(z).$$

Thus the convolution, considered as a binary operation

$$* : \mathcal{S}_c \times \mathcal{S}_c \rightarrow \mathcal{S}_c$$

of pairs of functions having compact support, is commutative.

Similarly, convolutions can be considered with integration over a finite interval; we only have to guarantee that the functions participating in them are well-defined. In particular, this can be done for periodic functions, integrating over an interval whose length equals the period.

Convolution is an extraordinarily useful tool for modeling the way in which we observe the data of an experiment or the influence of a medium through which information is transferred. For instance, an analog audio or video signal affected by noise. The input value  $f$  is the transferred information. The function  $g$  is chosen so that it would express the influence of the medium or the technical procedure used for the signal processing or the processing of any other data.

**7.2.3. Gibbs phenomenon.** Actually, we have already seen a very useful case of convolution. In paragraph 7.1.18, we interpreted the partial sum of the Fourier series for a function  $f$  as a convolution with the Dirichlet kernel  $K_N(y) = \sum_{-T/2}^{T/2} e^{i\omega_k y}$ . The figure shows this convolution kernel with  $N = 5$  and  $N = 15$ .

$[-1, 1]$ . Consequently,

$$\begin{aligned} (f_1 * f_2)(t) &= 0, \text{ if } t > 2 \\ &= \int_{t-1}^1 (1-x^2)(t-x) dx = 4t/3 - t^2 + t^4/12, \\ &\hspace{10em} 1 \leq t \leq 2 \\ &= \int_{t-1}^t (1-x^2)(t-x) dx = -t^2/2 + 1/4 + 2t/3, \\ &\hspace{10em} 0 \leq t \leq 1 \\ &= \int_{-1}^t (1-x^2)(t-x) dx \\ &= -t^4/12 + t^2/2 + 1/4 + 2t/3, \\ &\hspace{10em} -1 \leq t \leq 0 \\ &= 0, \text{ if } t < -1. \end{aligned}$$

Notice that instead of integrals over the entire real line, we employ the integration over the basic period  $T$  of the periodic functions in question.

This interpretation allows us to explain the Gibbs phenomenon mentioned in paragraph 7.1.9. The point is that we know well the behaviour of the Dirichlet kernel near to the origin and thus, taken into account that the function  $f$  is bounded over the whole period and has all one-side limits of values and derivatives at each point of discontinuity, the effect of the convolution must be quite local. Consequently this leads to verification that the convolution with the Dirichlet kernel in the point  $x$  of jump of  $f$  behaves the same way as we computed explicitly for the Heaviside function at  $x = 0$ . There the overshooting by the Fourier sums can be computed explicitly and this explains the Gibbs effect in general.

We do not provide more details here. Readers may either work them out themselves (as a truly nontrivial exercise) or look them up in the literature.

**7.B.4.** Determine the convolution  $f_1 * f_2$  of the functions

$$\begin{aligned} f_1 &= \begin{cases} 1-x & \text{for } x \in [-2, 1], \\ 0 & \text{otherwise,} \end{cases} \\ f_2 &= \begin{cases} 1 & \text{for } x \in [0, 1], \\ 0 & \text{otherwise.} \end{cases} \end{aligned}$$

The next topic is the Fourier transform, which is another example of an integral operator. This time the kernel  $e^{-i\omega t}$  is complex (see 7.2.5 for the terminology). Thus the values on real functions are complex functions in general, see 7.2.5. This is a basic operation in mathematics, allowing the time and frequency analysis of signals and also the transitions between local and global behaviour.

**7.B.5.** Fix  $\Omega > 0$ . Recall that  $\text{sgn } t = 1$  if  $t > 0$ , and  $\text{sgn } t = -1$  if  $t < 0$ ,  $\text{sgn } 0 = 0$ .

Find the Fourier transform  $\mathcal{F}(f)$  and the inverse Fourier transform  $\mathcal{F}^{-1}$  of the functions:

- (a)  $f(t) = \text{sgn } t$  if  $t \in (-\Omega, \Omega)$ , and zero otherwise.
- (b)  $f(t) = 1$  if  $t \in (-\Omega, \Omega)$  and zero otherwise.

**Solution.** The case (a).

The Fourier transform of the given function is

$$\begin{aligned} \mathcal{F}(f)(\omega) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-i\omega t} dt \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\Omega}^{\Omega} \text{sgn } t (\cos(\omega t) - i \sin(\omega t)) dt \\ &= \frac{1}{\sqrt{2\pi}} \left( \int_0^{\Omega} (\cos(\omega t) - i \sin(\omega t)) dt - \int_{-\Omega}^0 (\cos(\omega t) - i \sin(\omega t)) dt \right). \end{aligned}$$

Since  $\cos$  and  $\sin$  are respectively even and odd functions,

**7.2.4. Integral operators.** In general, integral operators can depend on any number of values and derivatives of the function in its argument. For example, considering a function  $F$  depending on  $k + 2$  free arguments,

$$L(f)(y) = \int F(y, x, f(x), f'(x), \dots, f^{(k)}(x)) dx.$$

Convolution is one of many examples of a special class of such operators on spaces of functions

$$L(f)(y) = \int_a^b f(x)k(y, x) dx.$$

The function  $k(y, x)$ , dependent on two variables,

$$k : \mathbb{R}^2 \rightarrow \mathbb{R},$$

is called the *kernel of the integral operator*  $L$ .

The theory of integral operators is very useful and interesting. We focus only on an extraordinarily important special case, namely the *Fourier transform*  $\mathcal{F}$ , which has deep connections with Fourier series.

**7.2.5. Fourier transform.** Recall that a function  $f(t)$ , given by its converging Fourier series, equals

$$f(t) = \sum_{n=-\infty}^{\infty} c_n e^{i\omega_n t},$$

$$\mathcal{F}(f)(\omega) = \frac{2}{\sqrt{2\pi}} \int_0^{\Omega} -i \sin(\omega t) dt = \frac{2i}{\sqrt{2\pi}} \left[ \frac{\cos(\omega t)}{\omega} \right]_0^{\Omega} \\ = i \sqrt{\frac{2}{\pi}} \frac{\cos(\omega\Omega) - 1}{\omega}.$$

The inverse Fourier transform is given by almost the same integral, with the kernel  $e^{i\omega x}$  instead of  $e^{-i\omega x}$ . The integration is in the frequency domain with variable  $\omega$ . Thus, the only difference in the result is the sign:

$$\mathcal{F}^{-1}(f)(t) = \frac{2}{\sqrt{2\pi}} \int_0^{\Omega} i \sin(\omega t) d\omega = \frac{-2i}{\sqrt{2\pi}} \left[ \frac{\cos(\omega t)}{t} \right]_0^{\Omega} \\ = i \sqrt{\frac{2}{\pi}} \frac{1 - \cos(t\Omega)}{t}.$$

Case (b) is computed similarly:

$$\mathcal{F}(f)(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\Omega}^{\Omega} (\cos(\omega t) - i \sin(\omega t)) dt \\ = \frac{1}{\sqrt{2\pi}} \int_{-\Omega}^{\Omega} \cos(\omega t) dt = \frac{1}{\sqrt{2\pi}} \left[ \frac{\sin(\omega t)}{\omega} \right]_{-\Omega}^{\Omega} = \sqrt{\frac{2}{\pi}} \frac{\sin(\omega\Omega)}{\omega}.$$

The latter expression is often expressed by means of the function  $\text{sinc}(t) = \sin(t)/t$

$$\mathcal{F}(f)(\omega) = \frac{2\Omega}{\sqrt{2\pi}} \text{sinc}(\omega\Omega).$$

Here, the inverse Fourier transform has exactly the same result, because the sign change in the kernel does not affect the real part. Thus we only need to interchange the time and frequency variables:

$$\mathcal{F}^{-1}(f)(t) = \frac{2\Omega}{\sqrt{2\pi}} \text{sinc}(t\Omega).$$

□

The results are:

The first two diagrams below show the imaginary values of the Fourier image of the signum function from 7.B.5(a) with  $\Omega = 20$  and  $\Omega = 50$ . The next two diagrams do the same for the characteristic function of the interval  $|x| < \Omega$

where the numbers  $c_n$  are complex Fourier coefficients, and  $\omega_n = n2\pi/T$  with period  $T$ , see paragraph 7.1.7.

After fixing  $T$ , the expression  $\Delta\omega = 2\pi/T$  describes the change of the frequency caused by  $n$  being increased by one. Thus it is just the discrete step by which we change the frequencies when calculating the coefficients of the Fourier series. The coefficient  $1/T$  in the formula

$$c_n = \frac{1}{T} \int_{-T/2}^{T/2} f(x) e^{-i\omega_n x} dx$$

then equals  $\Delta\omega/2\pi$ , so the series for  $f(t)$  can be rewritten as

$$f(t) = \sum_{n=-\infty}^{\infty} \frac{1}{2\pi} \left( \Delta\omega \int_{-T/2}^{T/2} f(x) e^{-i\omega_n x} dx \right) e^{i\omega_n t}.$$

Now imagine the values  $\omega_n$  for all  $n \in \mathbb{Z}$  as the chosen representatives for small intervals  $[\omega_n, \omega_{n+1}]$  of length  $\Delta\omega$ . Then, our expression in the big inner parentheses in the previous formula for  $f(t)$ , restricting the sum to  $n \in [-N, N]$ , describes the summands of the Riemann sums for the integrals

$$\frac{1}{2\pi} \int_{-N}^N g(\omega) e^{i\omega t} d\omega,$$

where  $g(\omega)$  is a function which takes, at the points  $\omega_n$ , the values

$$g(\omega_n) = \int_{-T/2}^{T/2} f(x) e^{-i\omega_n x} dx.$$

Considering the limit for  $N \rightarrow \infty$  leads to the improper integral of  $g(\omega) e^{i\omega t}$ .

If the function  $f(x) e^{-i\omega_n x}$  is integrable over the entire  $\mathbb{R}$  (this is always the case if  $f$  is piecewise continuous with a compact support) then letting  $T \rightarrow \infty$ , the norm  $\Delta\omega$  of our subintervals in the Riemann sum decreases to zero. We obtain the integral

$$g(\omega) = \int_{-\infty}^{\infty} f(x) e^{-i\omega x} dx.$$

The previous reasonings indicates that there should be a large set of functions  $f$  on  $\mathbb{R}$  (e.g. all those with  $|f|$  integrable over  $\mathbb{R}$ ) for which we can define a pair of mutually inverse integral operators:

from 7.B.5(b). The longer the interval with the constant values is, the more the image is concentrated around the origin.

*We can always use directly the simpler version of the transform for the odd and even functions. If the argument  $f$  is odd, then only the sine part of the formula contributes and its Fourier transform is*

$$\mathcal{F}(f)(\omega) = \frac{-2i}{\sqrt{2\pi}} \int_0^{\infty} f(t) \sin(\omega t) dt.$$

Similarly, for even functions  $f$

$$\mathcal{F}(f)(\omega) = \frac{2}{\sqrt{2\pi}} \int_0^{\infty} f(t) \cos(\omega t) dt.$$

*In particular, the odd functions have pure imaginary images while the images of the even functions are real. More generally, every real function  $f$  decomposes in to its odd and even parts  $f = f_{\text{even}} + f_{\text{odd}}$  and the real and imaginary components of the Fourier image  $\tilde{f}$  are the images of these two parts, respectively.*

**7.B.6.** Discover how the Fourier transform and its inverse behave under the translation  $\tau_a$  in the variable,  $\tau_a f(x) = f(x+a)$ , and the phase shift  $\varphi_a$  defined as  $\varphi_a f(x) = e^{iax} f(x)$ , always with  $a \in \mathbb{R}$ .

**Solution.** Evaluate the compositions  $\mathcal{F} \circ \tau_a$  and  $\mathcal{F} \circ \varphi_a$ . This is easy:

$$\begin{aligned} \mathcal{F} \circ \tau_a f(\omega) &= \int_{-\infty}^{\infty} f(t+a) e^{-i\omega t} dt \\ &= \int_{-\infty}^{\infty} f(x) e^{-i\omega(x-a)} dx = e^{ia\omega} \mathcal{F}f(\omega). \end{aligned}$$

$$\begin{aligned} \mathcal{F} \circ \varphi_a f(\omega) &= \int_{-\infty}^{\infty} f(t) e^{iat} e^{-i\omega t} dt \\ &= \int_{-\infty}^{\infty} f(t) e^{-i(\omega-a)t} dt = \mathcal{F}f(\omega-a). \end{aligned}$$

Thus is proved the formulae

$$\mathcal{F} \circ \tau_a = \varphi_a \circ \mathcal{F}, \quad \mathcal{F} \circ \varphi_a = \tau_{-a} \circ \mathcal{F}.$$

Similarly,

$$\mathcal{F}^{-1} \circ \tau_a = \varphi_{-a} \circ \mathcal{F}^{-1}, \quad \mathcal{F}^{-1} \circ \varphi_a = \tau_a \circ \mathcal{F}^{-1}.$$

□

*The next problem displays the behaviour of the Fourier transform on the Gaussian function. This is a rare example, where the time and frequency forms are very similar. Again, we see the feature of exchanging the local and global properties in the time and frequency domains.*

**7.B.7.** Compute the Fourier transform  $\mathcal{F}(f)$  of the function

$$f(t) = e^{-at^2}, \quad t \in \mathbb{R},$$

where  $a > 0$  is a fixed parameter.

**Solution.** The task is to calculate

#### FOURIER TRANSFORM

For every real or complex valued function  $f$  on  $\mathbb{R}$  for which the following integrals exist (e.g. all those piecewise continuous with compact support or fast decay), we define

$$\begin{aligned} \mathcal{F}(f)(\omega) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-i\omega t} dt \\ \mathcal{F}^{-1}(f)(t) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(\omega) e^{i\omega t} d\omega. \end{aligned}$$

The function  $\tilde{f}(\omega) = \mathcal{F}(f)(\omega)$  is called the *Fourier transform* of the function  $f$ .

The previous ideas indicate that  $\mathcal{F}^{-1}(\mathcal{F}(f))(t) = f(t)$ , whenever both the improper (Riemann) integrals exist.

This says that the Fourier transform  $\mathcal{F}$  has an inverse operation  $\mathcal{F}^{-1}$ , which is called the *inverse Fourier transform*.

Notice, the Fourier transform and its inverse are integral operators with almost identical kernels

$$k(\omega, t) = e^{\pm i\omega t}.$$

The right choice of the function space (and integral type) ensuring the existence of Fourier transform and its inverse is a very subtle question. This is the main reason why we do not formulate theorems with formal proofs and just touch the problems based on examples here.

We hope this will motivate the readers to find more detailed answers in specialized literature.

**7.2.6. Simple properties.** The Fourier transform changes

the local and global behaviour of functions in an interesting way. We begin with a simple example in which there is a function  $f(t)$  which is transformed to the indicator function of the interval  $[-\Omega, \Omega]$ , i. e.,  $\tilde{f}(\omega) = 0$  for  $|\omega| > \Omega$ , and  $\tilde{f}(\omega) = 1$  for  $|\omega| \leq \Omega$ .

The inverse transform  $\mathcal{F}^{-1}$  gives

$$\begin{aligned} f(t) &= \frac{1}{\sqrt{2\pi}} \int_{-\Omega}^{\Omega} e^{i\omega t} d\omega = \frac{1}{\sqrt{2\pi}} \left[ \frac{1}{it} e^{i\omega t} \right]_{-\Omega}^{\Omega} \\ &= \frac{2}{\sqrt{2\pi} 2i} (e^{i\Omega t} - e^{-i\Omega t}) \\ &= \frac{2\Omega}{\sqrt{2\pi}} \frac{\sin(\Omega t)}{\Omega t}. \end{aligned}$$

Thus, except for a multiplicative constant and the scaling of the input variable, it is the very important function  $f(x) = \text{sinc}(t) = \frac{\sin t}{t}$ .

This function is not that easy to handle. Our construction of the Fourier transform suggests that  $\mathcal{F}(f)$  should be the indicator function of the interval  $[-\Omega, \Omega]$ . We verify this by direct computation in ???. Now, just notice that the sinc function is not integrable in absolute value over  $\mathbb{R}$ . It rather behaves as an alternating series of numbers.

But the local behavior of  $f$  is easy to see. Calculation of the limit at zero, by l'Hospital's rule or otherwise, gives  $f(0) = 2\Omega(2\pi)^{-1/2}$ . The closest zero points are at

$$\mathcal{F}(f)(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-at^2} e^{-i\omega t} dt.$$

A standard trick is to transform the problem into one of solving a (simple) differential equation. Hence:

Differentiating (with respect to  $\omega$ ) and then integrating by parts gives

$$\begin{aligned} (\mathcal{F}(f)(\omega))' &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} -it e^{-at^2} e^{-i\omega t} dt \\ &= \frac{1}{\sqrt{2\pi}} \left( \lim_{t \rightarrow \infty} \frac{i}{2a} e^{-at^2 - i\omega t} - \lim_{t \rightarrow -\infty} \frac{i}{2a} e^{-at^2 - i\omega t} \right. \\ &\quad \left. - \int_{-\infty}^{\infty} \frac{i(-i\omega)}{2a} e^{-at^2} e^{-i\omega t} dt \right) \\ &= \frac{1}{\sqrt{2\pi}} \left( \frac{i}{2a} \lim_{t \rightarrow \infty} e^{-at^2} - \frac{i}{2a} \lim_{t \rightarrow -\infty} e^{-at^2} \right. \\ &\quad \left. - \int_{-\infty}^{\infty} \frac{\omega}{2a} e^{-at^2} e^{-i\omega t} dt \right) \\ &= -\frac{\omega}{2a} \left( \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-at^2} e^{-i\omega t} dt \right) = -\frac{\omega}{2a} \mathcal{F}(f)(\omega). \end{aligned}$$

Therefore  $y(\omega) = \mathcal{F}(f)(\omega)$  satisfies the differential equation

$$\frac{dy}{d\omega} = -\frac{\omega}{2a} y, \quad \text{i.e.} \quad \frac{1}{y} dy = -\frac{\omega}{2a} d\omega,$$

unless  $y$  equals zero ( $y \equiv 0$  is a solution of the equation). Integration yields

$$\ln |y| = -\frac{\omega^2}{4a} - C, \quad \text{i.e.} \quad y = Ke^{-\frac{\omega^2}{4a}},$$

where  $C$  and  $K$  are constants. All solutions (including the zero solution) of the differential equation are given by the function

$$y(\omega) = Ke^{-\frac{\omega^2}{4a}}, \quad K \in \mathbb{R}.$$

To find  $K$ , begin with the well known fact (proved in ??)

$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi},$$

to obtain

$$\int_{-\infty}^{\infty} e^{-at^2} dt = \frac{1}{\sqrt{a}} \int_{-\infty}^{\infty} e^{-x^2} dx = \frac{\sqrt{\pi}}{\sqrt{a}}.$$

Therefore,  $\mathcal{F}(f)(0) = \frac{1}{\sqrt{2\pi}} \frac{\sqrt{\pi}}{\sqrt{a}} = \frac{1}{\sqrt{2a}}$  and  $\mathcal{F}(f)(0) = Ke^0 = K$ . So  $K = \frac{1}{\sqrt{2a}}$  and

$$\mathcal{F}(f)(\omega) = \frac{1}{\sqrt{2a}} e^{-\frac{\omega^2}{4a}}.$$

□

**7.B.8.** Determine the Fourier transform image of the Gaussian function

$$f(t) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(t-\mu)^2}{2\sigma^2}}.$$

**Solution.** Use the result of the previous problem with  $a = \frac{1}{2\sigma^2}$  and the composition with the variable shift  $\tau_a$  from the last but one problem. It follows that

$$\mathcal{F}(f)(\omega) = \frac{1}{\sqrt{2\pi}} e^{i\mu\omega} e^{-\sigma^2 \frac{\omega^2}{2}}.$$

□

$t = \pm\pi/\Omega$  and the function drops in value to zero quite rapidly away from the origin  $x = 0$ . This function is shown in the diagram by a wavy curve for  $\Omega = 20$ . Simultaneously, the area where our function  $f(t)$  keeps waving more rapidly as  $\Omega$  increases is also depicted by a curve.

The Fourier transform of the indicator function of the interval  $[-\Omega, \Omega]$  is also the above function  $f$ , see the explicit computation in 7.B.5 (the even function sinc does not see the change of sign in the kernel of the transform). Clearly, this function  $f$  takes significant positive values near zero, and the value taken at zero is a fixed multiple of  $\Omega$ . Therefore, as  $\Omega$  increases, the function  $f$  concentrates more and more near the origin.

Next, we derive the Fourier transform of the derivative  $f'(t)$  for a function  $f$ . We continue to suppose that all the integration makes sense (e.g.  $f$  has compact support), so that both  $\mathcal{F}(f')$  and  $\mathcal{F}(f)$  exist. By integration by parts,

$$\begin{aligned} \mathcal{F}(f')(\omega) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f'(t) e^{-i\omega t} dt \\ &= \frac{1}{\sqrt{2\pi}} [e^{-i\omega t} f(t)]_{-\infty}^{\infty} + \frac{i\omega}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-i\omega t} dt \\ &= i\omega \mathcal{F}(f)(\omega). \end{aligned}$$

Thus the Fourier transform converts the (limit) operation of differentiation to the (algebraic) operation of a multiplication by the variable. Of course, this procedure can be iterated, to obtain

$$\mathcal{F}(f^{(n)}) (\omega) = -\omega^2 \mathcal{F}(f), \dots, \mathcal{F}(f^{(n)}) = i^n \omega^n \mathcal{F}(f).$$

**7.2.7. The relation to convolutions.** There is another extremely important property to consider, namely the relation between convolutions and Fourier transforms.

We shall calculate the Fourier transform of the convolution  $h = f * g$ , where we again assume that all the integrals exist (e.g. assuming the functions to be piecewise continuous with compact supports).

Recall that we may change the order of integration, see 6.3.12. Then we change variable by the substitution  $t - x = u$ .

As mentioned, the most typical use of the Fourier transform is to analyse the frequencies in a signal. The next problem reveals the reason. For technical reasons we cut the signal by multiplication with the characteristic function  $h_\Omega$  of the interval  $(-\Omega, \Omega)$ .

**7.B.9.** Find the Fourier transform of the functions

$$f(t) = h_\Omega(t) \cos(nt), \quad g(t) = h_\Omega(t) \sin(nt).$$

**Solution.** By definition

$$\begin{aligned} \mathcal{F}(f)(\omega) &= \frac{1}{\sqrt{2\pi}} \int_{-\Omega}^{\Omega} \cos(nt) e^{-i\omega t} dt \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\Omega}^{\Omega} \frac{1}{2} (e^{int} + e^{-int}) e^{-i\omega t} dt \\ &= \frac{1}{2\sqrt{2\pi}} \left[ \frac{1}{i(n-\omega)} e^{i(n-\omega)t} \right]_{-\Omega}^{\Omega} \\ &\quad + \frac{1}{2\sqrt{2\pi}} \left[ \frac{-1}{i(n+\omega)} e^{-i(\omega+n)t} \right]_{-\Omega}^{\Omega} \\ &= \frac{\Omega}{\sqrt{2\pi}} (\text{sinc}((n-\omega)\Omega) + \text{sinc}((n+\omega)\Omega)). \end{aligned}$$

The same computation leads to the image of the sine signal, the only difference is one minus sign and an additional  $i$  in the formula:

$$\mathcal{F}(g)(\omega) = i \frac{\Omega}{\sqrt{2\pi}} (-\text{sinc}((n-\omega)\Omega) + \text{sinc}((n+\omega)\Omega))$$

□

**7.B.10.** Find the Fourier transform of the superposition of the  $\cos(nt)$  signals over the interval  $(-\Omega, \Omega)$ ,

$$f(t) = h_\Omega(t)(3 \cos(5t) + \cos(15t)).$$

What happens, if  $\Omega \rightarrow \infty$ ?

**Solution.** The Fourier transform is linear over scalars, thus we simply add the corresponding images from the previous problem with  $n = 1$  and  $n = 3$ , multiplied by the proper coefficients. The illustration of the image with  $\Omega = 20$  is

Each of the peaks behaves like the Fourier image of the characteristic function  $h_\Omega$ , shifted to the frequencies.

The result is

$$\begin{aligned} \mathcal{F}(h)(\omega) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \left( \int_{-\infty}^{\infty} f(x)g(t-x) dx \right) e^{-i\omega t} dt \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) \left( \int_{-\infty}^{\infty} g(t-x) e^{-i\omega t} dt \right) dx \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) \left( \int_{-\infty}^{\infty} g(u) e^{-i\omega(u+x)} du \right) dx \\ &= \frac{1}{\sqrt{2\pi}} \left( \int_{-\infty}^{\infty} f(x) e^{-i\omega x} dx \right) \cdot \left( \int_{-\infty}^{\infty} g(u) e^{-i\omega u} du \right) \\ &= \sqrt{2\pi} \mathcal{F}(f) \cdot \mathcal{F}(g) \end{aligned}$$

A similar calculation shows that the Fourier transform of a product is the convolution of the transforms, up to a multiplicative constant. In fact,

$$\mathcal{F}(f \cdot g) = \frac{1}{\sqrt{2\pi}} \mathcal{F}(f) * \mathcal{F}(g).$$

As we mentioned above, the convolution  $f * g$  often models the process of the observation of some quantity  $f$ . Using the Fourier transform and its inverse, the original values of this quantity are easily recognised if the convolution kernel  $g$  is known. We just calculate  $\mathcal{F}(f * g)$  and divide it by the image  $\mathcal{F}(g)$ . This yields the Fourier transform of the original function  $f$ , which can be obtained explicitly using the inverse Fourier transform. This is sometimes called *deconvolution*.

In real applications, the procedure often cannot be that straightforward since the Fourier image of the known convolution kernel might have zero values and therefore we hardly can divide by it as above. For example, take the convolution kernel  $\text{sinc}(t)$  whose image is an indicator function of some finite interval. So we need some more cunning techniques and there is a vast literature on them.

**7.2.8. The  $L_2$ -norm.** Now we are in position to verify that

the Fourier transform is actually an isometry with respect to the  $L_2$ -norm. The Fourier transform exists for all functions in  $L_1$ , i.e., with integrable absolute values. A simple observation reveals that  $\mathcal{F} : L_2 \rightarrow L_\infty$  satisfies

$$\|\mathcal{F}(f)\|_\infty \leq \|f\|_1.$$

Indeed,  $|e^{-i\omega x}| = 1$  and thus,  $|\mathcal{F}(f)(\omega)| \leq \int_{-\infty}^{\infty} |f(x)| dx$  for all  $\omega$ .

Now, assume  $f, g$  are two functions in  $L_2$  and write  $\hat{g}$  for the function  $\hat{g}(t) = \overline{g(-t)}$ . Notice

$$(f * \hat{g})(t) = \int_{-\infty}^{\infty} f(x) \hat{g}(t-x) dx = \int_{-\infty}^{\infty} f(x) \overline{g(x-t)} dx.$$

In particular, the scalar product is given by the formula

$$\langle f, g \rangle = (f * \hat{g})(0).$$

If  $\Omega$  increases to infinity, the image  $\tilde{f}$  has four peaks at the same positions corresponding to the frequencies  $\pm 5$  and  $\pm 15$ . But they become narrower and sharper. In the limit, this is no longer a function since the width of the peaks becomes zero. This is usually written

$$\mathcal{F}(\cos(nt))(\omega) = \sqrt{\frac{\pi}{2}}(\delta(n - \omega) + \delta(n + \omega))$$

with the special case

$$\mathcal{F}(1)(\Omega) = \sqrt{2\pi}\delta(\omega).$$

See 7.2.9 for comments on the *Dirac delta function*.  $\square$

**7.B.11.** Find the Fourier transform image of the convolution of the signals  $f(t)$  and  $g(t)$  from the Problem 7.B.1. Recall that  $f(t) = \sin(t) + 0.4 [\sin(6t)]^2 - 0.2 \sin(60t)$  and  $g$  is the characteristic function of the interval  $(-\varepsilon, \varepsilon)$ . Assume that the signal is nonzero only in the interval  $(-\Omega, \Omega)$ .

**Solution.** Once we note that  $\mathcal{F}(f * g) = \sqrt{2\pi}\mathcal{F}(f)\mathcal{F}(g)$ , we have all the ingredients ready. Indeed, in 7.B.5 and in the last two problems above, we already computed the Fourier image of  $g$  and of the sine and cosine functions on the interval  $(-\Omega, \Omega)$ .

Instead of writing the explicit formulae for the result, we display illustrations of the real components of  $\mathcal{F}(f)$  and  $\mathcal{F}(f * g)$  in the first line, and similarly the imaginary components in the second line, all with  $\Omega = 5, \varepsilon = 1/10$ .

The reader should compare the diagrams of  $f$  and  $f * g$  in 7.B.1 to see that the higher frequencies in  $f$  are effectively canceled by this convolution, as expected.  $\square$

Further, the definition of the Fourier transform yields

$$\begin{aligned} \langle f, g \rangle &= (\mathcal{F}^{-1} \mathcal{F}(f * \hat{g}))(0) \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathcal{F}(f * \hat{g}) e^{ix\omega} d\omega |_{x=0} \\ &= \int_{-\infty}^{\infty} \mathcal{F}f(\omega) \mathcal{F}\hat{g}(\omega) d\omega \end{aligned}$$

while

$$\mathcal{F}(\hat{g})(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \overline{g(-x)} e^{-i\omega x} dx = \overline{\mathcal{F}(g)}(\omega).$$

Consequently,  $\langle f, g \rangle = \langle \mathcal{F}(f), \mathcal{F}(g) \rangle$ . Thus, we have verified that the Fourier transform preserves the scalar product and so it also preserves the  $L_2$ -norm.

This also explains our choice of the constants in the definition.

**7.2.9. Dirac delta-function.** We return to the first example of the inverse transform to the indicator function  $f_\Omega$  of the interval  $[-\Omega, \Omega]$ . Let  $\Omega$  approach infinity and denote by  $\sqrt{2\pi}\delta(t)$  the desired “limit function” for  $\mathcal{F}^{-1}(f_\Omega)(t)$ .

The inverse image of a product with an arbitrary image  $\mathcal{F}(g)$  can be expressed using convolution:

$$\mathcal{F}^{-1}(f_\Omega \cdot \mathcal{F}(g))(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(t) \mathcal{F}^{-1}(f_\Omega)(z - t) dt.$$

As  $\Omega$  increases to  $\infty$ , the left-hand expression should approach  $\mathcal{F}^{-1}(\mathcal{F}(g))(z) = g(z)$ , while on the right-hand side, we get

$$g(z) = \int_{-\infty}^{\infty} g(t) \delta(z - t) dt.$$

The desired  $\delta(t)$  thus looks as a “function” which takes zero everywhere except the single point  $t = 0$  where it “has an infinite value”. Integrating the product of  $\delta(t)$  with any integrable function  $g$  gives just the value of  $g$  at the point  $t = 0$ . Of course, this is strictly not a function at all. Nevertheless it is a useful concept. It is called the *Dirac function*  $\delta$  and it can be described correctly as an example of what is known as a distribution. Since we do not have enough space and time, we do not pay further attention to distributions. We mention only that the Dirac  $\delta$  can be imagined as a unit impulse at a single point. In fact, we saw similar concepts under the name “measure” when dealing with the Riemann-Stieltjes and Henstock-Kurzweil integrals, cf. 6.3.18, 6.3.14 and we shall come back to them in Chapter 10 in the context of probability. In this sense, the Dirac function is the (probability) measure concentrated in the origin and it can be realized by the Riemann-Stieltjes integral with the piecewise constant function  $g$  with the single unit jump in the origin. Its Fourier transform is the constant function  $\mathcal{F}(\delta)(\omega) = \frac{1}{\sqrt{2\pi}}$ .

On the other hand, many functions which are not strictly integrable on  $\mathbb{R}$  are Fourier-transformed to expressions with

As discussed in 7.2.5, the Fourier transform has an inverse operation. This means that no information is lost when changing from the time behaviour of a signal to its frequency behaviour. This allows us to use Fourier transform for the solution of functional equations involving differentiation or integration. We stay with elementary observations only and return to differential equations in one and more variables in the following chapters.

**7.B.12.** By using the inverse Fourier transform solve the integral equation

$$\int_0^\infty f(t) \sin(xt) dt = e^{-x}, \quad x > 0$$

for an unknown function  $f$ .

**Solution.** Multiply both sides of the equation by  $\sqrt{2/\pi}$ , to obtain the sine Fourier transform on the left-hand side. Apply the inverse transform to both sides of the equation to get

$$f(t) = \frac{2}{\pi} \int_0^\infty e^{-x} \sin(xt) dx, \quad t > 0.$$

Integrating by parts twice shows that

$$\int e^{-x} \sin(xt) dx = \frac{e^{-x}}{1+t^2} [-\sin(xt) - t \cos(xt)] + C.$$

Hence

$$\begin{aligned} & \int_0^\infty e^{-x} \sin(xt) dx \\ &= \lim_{x \rightarrow \infty} \left( \frac{e^{-x}}{1+t^2} [-\sin(xt) - t \cos(xt)] \right) - \frac{e^0(-t)}{1+t^2} = \frac{t}{1+t^2}. \end{aligned}$$

So

$$f(t) = \frac{2}{\pi} \frac{t}{1+t^2}, \quad t > 0.$$

□

**7.B.13.** Use the Fourier transform to find solutions of the non-homogeneous linear differential equation

$$(1) \quad y' = ay + f$$

where  $a \in \mathbb{R}$  is a non-zero constant and  $f$  is a known function. Can all solutions be obtained in this way?

**Solution.** The key observation for this problem is the relation between the Fourier transform and the derivative

$$\mathcal{F}(f')(\omega) = i\omega \mathcal{F}(f)(\omega),$$

see 7.2.6. Thus, if the Fourier transform is applied to the equation (1), we get the algebraic equation for  $\tilde{y} = \mathcal{F}(y)$

$$i\omega \tilde{y} = a\tilde{y} + \tilde{f}.$$

If it is assumed that  $\mathcal{F}(f) = \tilde{f}$  exists and there is a solution  $y$  with the Fourier image  $\tilde{y}$ , then

$$\tilde{y} = \frac{1}{i\omega - a} \tilde{f}$$

the Dirac  $\delta$ . For instance,

$$\mathcal{F}(\cos(nt))(\omega) = \sqrt{\frac{\pi}{2}} (\delta(n - \omega) + \delta(n + \omega)),$$

which can be seen from the calculation of the Fourier transform of the function  $f_\Omega \cos(nx)$  and then letting  $\Omega$  approach  $\infty$ , see the solution to problem 7.B.10.

We can obtain the Fourier transform of the sine function in a similar way. We can take advantage of the fact that the transform of the derivative of this function differ only by a multiple of the imaginary unit and the new variable. Alternatively, we can also use the fact that the sine function is obtained from the cosine function by the phase shift of  $\pi/2$ .

These transforms are a basis for Fourier analysis of signals (see also problem 7.B.9): If a signal is a pure sinusoid of a given frequency, then this is recognized in the Fourier transform as two single-point impulses exactly at the positive and negative value of the frequency. If the signal is a linear combination of several such pure signals, then we obtain the same linear combination of single-point impulses. However, since we always process a signal in a finite time interval only, we get not single-point impulses, but rather a wavy curve similar to the function sinc with a strong maximum at the value of the corresponding frequency. The size of this maximum also yields information about the amplitude of the original signal.

Another good way how to approximate the Dirac delta function is to exploit the Gaussian functions. As seen in the solution to problem 7.B.7, the Fourier image of the Gaussian function

$$f(t) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{t^2}{2\sigma^2}}$$

is again Gaussian corresponding to the reciprocal values of  $\sigma$ . In the limit  $\sigma \rightarrow 0$ , the image converges fast to the multiple of constant function, see the illustrations on the picture, with  $\sigma = 3$  and  $\sigma = 1/10$ .

Notice that the rather large  $\sigma$  in the first illustration corresponds to a wide Gaussian, while the image is the slim one. The second illustration provides the opposite case. The preimage is the narrow Gaussian and the image is already reasonably close to the constant function. The Gaussians are chosen with  $L_1$ -norm equal to one, but the Fourier transform preserves the  $L_2$ -norm of the functions.

**7.2.10. Fourier sine and cosine transform.** If we apply the Fourier transform to an odd function  $f(t)$ , where  $f(-t) =$

and using the general relation  $\mathcal{F}^{-1}(g \cdot h) = \sqrt{2\pi}\mathcal{F}^{-1}f * \mathcal{F}^{-1}g$  between the product and convolutions from 7.2.7 we arrive at the final formula

$$y = \frac{1}{\sqrt{2\pi}}\mathcal{F}^{-1}\left(\frac{1}{i\omega - a}\right) * f.$$

So it is necessary to compute the inverse Fourier transform of the simple rational function  $(i\omega - a)^{-1}$ . Guess the solution in two steps.

Assume first  $a < 0$  and evaluate

$$\int_{-\infty}^0 e^{at} e^{-i\omega t} dt = \left[\frac{1}{a-i\omega} e^{(a-i\omega)t}\right]_{-\infty}^0 = \frac{1}{a-i\omega}.$$

Similarly for  $a > 0$

$$\int_0^{\infty} e^{at} e^{-i\omega t} dt = \left[\frac{1}{a-i\omega} e^{(a-i\omega)t}\right]_0^{\infty} = \frac{1}{i\omega - a}.$$

This provides the two desired results. Indeed, if the equation (1) comes with  $a > 0$ , we rewrite our rational function as  $-(a - i\omega)^{-1}$ . Next, the function  $-\sqrt{2\pi} e^{-at}$  for negative  $t$  provides the requested Fourier image. Immediately it is seen that the convolution

$$y(t) = -\int_{-\infty}^0 e^{ax} f(t-x) dx$$

is a solution. (The multiples  $\sqrt{2\pi}$  in the expression with the convolution cancel.) Similarly, if  $a < 0$  then

$$y(t) = \int_0^{\infty} e^{ax} f(t-x) dx$$

is a solution.

Not all solutions can be obtained in this way. For example,  $y' = y$  leads to  $y(t) = C e^t$  with an arbitrary constant  $C$ , but this is not a function with a Fourier image. With  $f(t) = 0$ , our procedure produces the zero function, which is just one of the solutions. Similarly, if we deal with the equation  $y' = y + t$ , then the particular solution suggested above is

$$y(t) = -\int_{-\infty}^0 e^x(t-x) dx = -t - 1. \quad \square$$

**7.B.14.** Check directly that the two functions  $y(t)$  found above are indeed solutions to the equation  $y' = ay + f$ .

○

**7.B.15.** As in the previous problem, solve the second order equation

$$y'' = ay + f.$$

**Solution.** Use the fact that  $\mathcal{F}(y'')(\omega) = -\omega^2\mathcal{F}(y)(\omega)$  and deduce the algebraic relation  $-\omega^2\tilde{y} = a\tilde{y} + \tilde{f}$ , for the Fourier images  $\tilde{y}$  and  $\tilde{f}$ . Hence

$$\tilde{y} = \frac{-1}{\omega^2 + a}\tilde{f}.$$

$-f(t)$ , the contribution in the integration of the product of  $f(t)$  and the function  $\cos(\pm\omega t)$  cancels for positive and negative values of  $t$ . Thus if  $f$  is odd, then

$$\mathcal{F}(f)(\omega) = \frac{-2i}{\sqrt{2\pi}} \int_0^{\infty} f(t) \sin \omega t dt.$$

The resulting function is odd again, hence for the same reason, the inverse transform can be determined similarly:

$$\mathcal{F}^{-1}(f)(\omega) = \frac{2i}{\sqrt{2\pi}} \int_0^{\infty} f(t) \sin \omega t dt.$$

Omitting the imaginary unit  $i$  (notice, this means we have to multiply the Fourier transform and its inverse by  $i$  and  $-i$ , respectively) inverse) gives mutually inverse transforms, which are called the *Fourier sine transform* for odd functions:

$$\tilde{f}_s(\omega) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(t) \sin(\omega t) dt,$$

$$f(t) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \tilde{f}_s(t) \sin(\omega t) dt.$$

Similarly, we can define the *Fourier cosine transform* for even functions:

$$\tilde{f}_c(\omega) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(t) \cos(\omega t) dt,$$

$$f(t) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \tilde{f}_c(t) \cos \omega t dt.$$

**7.2.11. Laplace transforms.** The Fourier transform can be mainly applied to functions which are integrable in absolute value over  $\mathbb{R}$ . The *Laplace transform* is similar to the Fourier transform and does apply to all functions whose growth is not too fast:

$$\mathcal{L}(f)(s) = \int_0^{\infty} f(t) e^{-st} dt.$$

The integral operator  $\mathcal{L}$  has a rapidly reducing kernel if  $s$  is a positive real number. Therefore, the Laplace transform is usually perceived as a mapping of suitable functions on the interval  $[0, \infty)$  to the function on the same or shorter interval. The image  $\mathcal{L}(p)$  exists, for example, for every polynomial  $p(t)$  and all positive numbers  $s$ .

Analogously to the Fourier transform, we obtain the formula for the Laplace transform of a differentiated function for  $s > 0$  by using integration by parts:

$$\begin{aligned} \mathcal{L}(f'(t))(s) &= \int_0^{\infty} f'(t) e^{-st} dt \\ &= [f(t) e^{-st}]_0^{\infty} + s \int_0^{\infty} f(t) e^{-st} dt \\ &= -f(0) + s\mathcal{L}(f)(s). \end{aligned}$$

The properties of the Laplace transform and many other transforms used in technical practice can be found in specialized literature. We provide a few examples in the other column starting with 7.B.17.

In order to guess the correct preimage of the rational function in question, first assume  $a > 0$  and compute

$$\begin{aligned} \int_{-\infty}^{\infty} e^{-a|x|} e^{-i\omega x} dx &= \left[ \frac{1}{a-i\omega} e^{a-i\omega x} \right]_{-\infty}^0 + \left[ \frac{-1}{a+i\omega} e^{-a-i\omega x} \right]_0^{\infty} \\ &= \frac{1}{a-i\omega} + \frac{1}{a+i\omega} = \frac{2a}{a^2 + \omega^2} \end{aligned}$$

Thus it is verified that

$$\mathcal{F}(e^{-\sqrt{a}|x|}) = \sqrt{\frac{a}{2\pi}} \frac{1}{a + \omega^2}.$$

Immediately (the factors  $\sqrt{2\pi}$  cancel)

$$y(t) = \frac{-1}{\sqrt{a}} e^{-\sqrt{a}|t|} * f(t) = \frac{-1}{\sqrt{a}} \int_{-\infty}^{\infty} e^{-\sqrt{a}|x|} f(t-x) dx.$$

The case  $a < 0$  is a little more complicated. But we may ask Maple or look up in the literature that the function

$$g(t) = \sin(b|t|)$$

has the Fourier image

$$\mathcal{F}(g)(\omega) = \frac{1}{2\pi} \frac{2b}{b^2 - \omega^2}.$$

We are nearly finished. The required preimage is

$$h(t) = \frac{\sqrt{2\pi}}{\sqrt{-4a}} \sin(\sqrt{-a}|t|)$$

and the resulting convolution is

$$y(t) = \frac{1}{\sqrt{-4a}} \int_{-\infty}^{\infty} \sin(\sqrt{-a}|x|) f(t-x) dx.$$

If we rewrite the equation as  $y'' + by = f$  with  $b > 0$ , the result says

$$y(t) = \frac{1}{2b} \int_{-\infty}^{\infty} \sin(b|x|) f(t-x) dx. \quad \square$$

**7.B.16.** Check directly that the two functions  $y(t)$  found above are indeed solutions to the equation  $y'' = ay + f$ .

○

 *The Laplace transfer is another integral transform which interchanges differentiation and algebraic multiplication. As with the Fourier transform, this is based on the properties of the exponential function, but this time we take the real exponential, see 7.2.11 for the formula. One advantage is that every polynomial has its Laplace image.*

**7.B.17.** Determine the Laplace transform  $\mathcal{L}(f)(s)$  for each of the functions

- (a)  $f(t) = e^{at}$ ;
- (b)  $f(t) = c_1 e^{a_1 t} + c_2 e^{a_2 t}$ ;
- (c)  $f(t) = \cos(bt)$ ;
- (d)  $f(t) = \sin(bt)$ ;
- (e)  $f(t) = \cosh(bt)$ ;
- (f)  $f(t) = \sinh(bt)$ ;
- (g)  $f(t) = t^k, k \in \mathbb{N}$ ,

**7.2.12. Discrete transforms.** Fourier analysis of signals mentioned in the previous paragraph are realized by special analog circuits in, for example, radio technology. Nowadays, we work only with discrete data when processing signals by computer circuits. Assume that there is a fixed (small) *sampling interval*  $\tau$  given in a (discrete) time variable and that, for a large natural number  $N$ , the signal repeats with period  $N\tau$ , which is the maximal period which can be represented in our discrete model.

We should not be surprised that our continuous models allow for a discrete analogy. Consider an  $N$ -dimensional vector, which can be imagined as the function  $r \mapsto f(r) \in \mathbb{C}$ , for  $r = 0, 1, \dots, N-1$ . Denote  $\Delta\omega = \frac{2\pi}{N}$  and  $\omega_k = k\Delta\omega$ . The simplest discrete approximation of the Fourier transform integral suggests that

$$\tilde{f}(k) = \frac{1}{N} \sum_{r=0}^{N-1} f(r) e^{-i\frac{2\pi}{N}kr}$$

should be a promising transformation  $f \mapsto \tilde{f}$ , whose inverse  $\tilde{f} \mapsto \hat{f}$  should not be far from

$$\hat{f}(k) = \sum_{r=0}^{N-1} \tilde{f}(r) e^{i\frac{2\pi}{N}kr}.$$

Actually, these are already the mutually inverse transformations:

**Theorem.** *The transformation above satisfies  $\hat{\tilde{f}}(k) = f(k)$  for all  $k = 0, 1, \dots, N-1$ .*

**PROOF.** Let

$$T = \sum_{r=0}^{N-1} e^{ir\frac{2\pi}{N}k}.$$

Then

$$e^{i\frac{2\pi}{N}k} T = \sum_{r=1}^N e^{ir\frac{2\pi}{N}k}$$

and so by subtraction,

$$(1 - e^{i\frac{2\pi}{N}k})T = 1 - e^{i2\pi k}.$$

The right hand side is 0 for all integers  $k$ . On the left side, the coefficient of  $T$  is not zero unless  $k$  is a multiple of  $N$ . Hence

$$T = \sum_{r=0}^{N-1} e^{ir\frac{2\pi}{N}k} = \begin{cases} N & \text{if } k \text{ is a multiple of } N \\ 0 & \text{otherwise.} \end{cases}$$

With  $k$  and  $s$  both confined to the range  $\{0, 1, 2, \dots, N-1\}$ ,  $k-s$  can only be a multiple of  $N$  when  $k = s$ . It follows that for such  $k$  and  $s$

$$\sum_{r=0}^{N-1} e^{ir\frac{2\pi}{N}(k-s)} = \delta_{ks} N$$

where the Kronecker delta  $\delta_{ks} = 0$  for  $k \neq s$  and  $\delta_{ks} = 1$  if  $k = s$ .

Finally, we compute:

where the constants  $b \in \mathbb{R}$  and  $a, a_1, a_2, c_1, c_2 \in \mathbb{C}$  are arbitrary. It is assumed that the positive number  $s \in \mathbb{R}$  is greater than the real parts of the numbers  $a, a_1, a_2 \in \mathbb{C}$ , and is greater than  $b$  in the problems (e) and (f).

**Solution.** The case (a). It follows directly from the definition of the Laplace transform that

$$\begin{aligned} \mathcal{L}(f)(s) &= \int_0^\infty e^{at} e^{-st} dt \\ &= \int_0^\infty e^{-(s-a)t} dt = \lim_{R \rightarrow \infty} \left( \frac{e^{-(s-a)R}}{-(s-a)} \right) - \frac{e^0}{-(s-a)} = \frac{1}{s-a}. \end{aligned}$$

The case (b). Using the result of the above case and the linearity of improper integrals, we obtain

$$\mathcal{L}(f)(s) = c_1 \int_0^\infty e^{a_1 t} e^{-st} dt + c_2 \int_0^\infty e^{a_2 t} e^{-st} dt = \frac{c_1}{s-a_1} + \frac{c_2}{s-a_2}.$$

The case (c). Since

$$\cos(bt) = \frac{1}{2} (e^{ibt} + e^{-ibt}),$$

the choice  $c_1 = 1/2 = c_2$ ,  $a_1 = ib$ ,  $a_2 = -ib$  in the previous case gives

$$\begin{aligned} \mathcal{L}(f)(s) &= \int_0^\infty \left( \frac{1}{2} e^{ibt} + \frac{1}{2} e^{-ibt} \right) e^{-st} dt = \\ &= \frac{1}{2(s-ib)} + \frac{1}{2(s+ib)} = \frac{s}{s^2+b^2}. \end{aligned}$$

The cases (d), (e), (f). Analogously, the choices

(d)  $c_1 = -i/2, c_2 = i/2, a_1 = ib, a_2 = -ib;$

(e)  $c_1 = 1/2 = c_2, a_1 = b, a_2 = -b;$

(f)  $c_1 = 1/2, c_2 = -1/2, a_1 = b, a_2 = -b$

lead to

(d)  $\mathcal{L}(f)(s) = \frac{b}{s^2+b^2};$

(e)  $\mathcal{L}(f)(s) = \frac{s}{s^2-b^2};$

(f)  $\mathcal{L}(f)(s) = \frac{b}{s^2-b^2}.$

Finally, the last one is obtained by a straightforward repetition of integration by parts:

$$\begin{aligned} \mathcal{L}(t^k)(s) &= \int_0^\infty t^k e^{-st} dt \\ &= \left[ -t^k \frac{1}{s} e^{-st} \right]_0^\infty + \frac{k}{s} \int_0^\infty t^{k-1} e^{-st} dt \\ &= \dots = \frac{k!}{s^k} \int_0^\infty e^{-st} dt = \frac{k!}{s^{k+1}}. \end{aligned}$$

**7.B.18.** Use the definition of the Gamma function  $\Gamma(t)$  in Chapter 6 in order to prove

$$\mathcal{L}(t^\alpha)(s) = \Gamma(\alpha + 1) \frac{1}{s^{\alpha+1}}$$

for general  $\alpha > 0$ . Compare the result to the one of 7.B.17(g).  $\circ$

**7.B.19.** For  $s > -1$ , calculate the Laplace transform  $\mathcal{L}(g)(s)$  of the function

$$g(t) = t e^{-t}.$$

Further, for  $s > 1$ , calculate the Laplace transform  $\mathcal{L}(h)(s)$  of the function

$$h(t) = t \sinh t.$$

$$\begin{aligned} \hat{f}(k) &= \sum_{r=0}^{N-1} \left( \frac{1}{N} \sum_{s=0}^{N-1} f(s) e^{-i \frac{2\pi}{N} r s} \right) e^{i \frac{2\pi}{N} r k} \\ &= \frac{1}{N} \sum_{s=0}^{N-1} f(s) \left( \sum_{r=0}^{N-1} e^{i \frac{2\pi}{N} r (k-s)} \right) \\ &= \frac{1}{N} \sum_{s=0}^{N-1} f(s) \delta_{ks} N = f(k). \end{aligned}$$

□

The computations in the proof also verify that the Fourier image of a periodic complex valued function with a unique period among the chosen sampling periods is just its amplitude at this particular frequency. Thus, if the signal has been created as a superposition of periodic signals with the sampling frequencies only, we obtain the absolutely optimal result. However, if the transformed signal has a frequency not exactly available among the sampling frequencies, there are nonzero amplitudes at all the sampling frequencies in the Fourier image. This is called frequency leaking in the technical literature. There is a vast amount of literature devoted to fast implementation and exploitation of the discrete Fourier transform, as well as other similar discrete tools. This is an extremely active area of current research.

### 3. Metric spaces

At the end of the chapter, we will focus on the concepts of distance and convergence in a more abstract way. This also provides the conceptual background for some of the already derived properties of Fourier series and Fourier transform. We need these concepts in miscellaneous contexts later.

It is hoped that the subsequent pages are a useful (and hopefully manageable) trip into the world of mathematics for the competent or courageous!

**7.3.1. Metrics and norms.** When we discussed Fourier series, the distance between functions on a space of functions, was commonly referred to. Now we examine the concept of distance more thoroughly.

We are familiar with the distance of points  $x, y$  in the Euclidean space  $\mathbb{R}^n$  given by the size of the vector  $x - y$ .

A very different example of distance is the so called *discrete metric* defined on any set  $X$  as follows. Each element  $x \in X$  has got distance zero from itself and one from all other elements in  $X$ . Notice that the triangle inequality is strict here – making detours when walking from one element to another always increases the distance travelled.

Both of these distances are generalized in the following concept:

**7.B.20.** The basic Laplace transforms are enumerated in the following table:

$y(t)$	$\mathcal{L}(y)(s)$
$t^k$	$\frac{k!}{s^{k+1}}$
$e^{at}$	$\frac{1}{s-a}$
$t e^{at}$	$\frac{1}{(s-a)^2}$
$t^n e^{at}$	$\frac{n!}{(s-a)^{n+1}}$
$\sin \omega t$	$\frac{\omega}{s^2 + \omega^2}$
$\cos \omega t$	$\frac{s}{s^2 + \omega^2}$
$e^{at} \sin \omega t$	$\frac{\omega}{(s-a)^2 + \omega^2}$
$e^{at} (\cos \omega t + \frac{a}{\omega} \sin \omega t)$	$\frac{s}{(s-a)^2 + \omega^2}$
$t \sin \omega t$	$\frac{2\omega s}{(s^2 + \omega^2)^2}$
$\sin \omega t - \omega t \cos \omega t$	$\frac{2\omega^3}{(s^2 + \omega^2)^2}$

Establish the 5th and 6th rows of the table above using Euler's formula  $e^{i\omega t} = \cos \omega t + i \sin \omega t$ .

As expected, using the features of the Laplace transform allows us to find explicit solutions to some differential equations. By 7.D.18, it is straightforward to incorporate the initial conditions into the solution. We present just two such examples in the problems at the conclusion of this Chapter, see 7.D.21. We return to this topic in Chapter 8.

### C. Metric spaces

The concept of metric is an abstract version of what we understand as the distance in Euclidean geometry. It is always based on the triangle inequality. The axioms in Definition 7.3.1 follow the Euclidean experience, saying that our "distance" of two elements has to be strictly positive (except if the two elements coincide), should be symmetric in the arguments, and should satisfy the triangle inequality.

Other concepts available in the literature are more abstract and might lead to more general objects (the most important ones being pseudometrics, ultrametrics, and semi-metrics).<sup>3</sup>

**7.C.1.** The discrete metric space  $X$  is defined as the set  $X$  with the function  $d : X \times X \rightarrow \mathbb{R}$

$$d(x, y) = \begin{cases} 1 & x \neq y \\ 0 & x = y. \end{cases}$$

Show that this is a metric space according to Definition 7.3.1.

Show how to introduce a metric on Cartesian products of metric spaces, so that product of two discrete metric spaces is again discrete.

<sup>3</sup>The first axiomatic definition of a "traditional" metric was given by Maurice Fréchet in 1906. However, the name of the metric comes from Felix Hausdorff, who used this word in his work from 1914.

### AXIOMS OF A METRIC AND A NORM

A set  $X$  together with a mapping  $d : X \times X \rightarrow \mathbb{R}$  such that for all  $x, y, z \in X$ , the following conditions are satisfied

- (1)  $d(x, y) \geq 0$ ; and  $d(x, y) = 0$  if and only if  $x = y$ ,
- (2)  $d(x, y) = d(y, x)$ ,
- (3)  $d(x, z) \leq d(x, y) + d(y, z)$ ,

is called a *metric space*. The mapping  $d$  is a *metric* on  $X$ .

If  $X$  is a vector space over  $\mathbb{R}$  and  $\| \cdot \| : X \rightarrow \mathbb{R}$  is a function satisfying

- (4)  $\|x\| \geq 0$ ; and  $\|x\| = 0$  if and only if  $x = 0$ ,
- (5)  $\|\lambda x\| = |\lambda| \|x\|$ , for all scalars  $\lambda$ ,
- (6)  $\|x + y\| \leq \|x\| + \|y\|$ ,

then the function  $\| \cdot \|$  is called a *norm* on  $X$ , and the space  $X$  is then a *normed vector space*. Every norm defines a metric by setting  $d(x, y) = \|x - y\|$ .

The Euclidean distance in the vector spaces  $\mathbb{R}^n$  satisfies the above three requirements and it is given by a norm.

The  $L_1$  norm  $\| \cdot \|_1$  and the  $L_2$  norm  $\| \cdot \|_2$  on functions, satisfy the norm properties and thus define a metric on the relevant spaces of functions.

Of course, not every metric can be defined by a norm in this way. The discrete metric mentioned above is an example.

Metrics given by a norm have very specific properties since their behaviour on the whole space  $X$  can be derived from the properties in an arbitrarily small neighbourhood of the zero element  $x = 0 \in X$ .

**7.3.2. Convergence.** The concepts of (close) neighbourhoods of particular elements, convergence of sequences of elements and the corresponding "topological" concepts can be defined on abstract metric spaces in much the same way as in the case of the real and complex numbers and their sequences. See the beginning of the fifth chapter, 5.2.3–5.2.8. We can almost copy these paragraphs; although the proof of the theorem 5.2.8 is much harder. We begin with the concept of convergent sequences in a metric space  $X$  with metric  $d$ :

#### CAUCHY SEQUENCES

Consider an arbitrary sequence of elements  $x_0, x_1, \dots$  in  $X$ . Suppose that for any fixed positive real number  $\varepsilon$ ,

$$d(x_i, x_j) < \varepsilon$$

for all but finitely many pairs of terms  $x_i, x_j$  of the sequence.

In other words, for any given  $\varepsilon > 0$ , there is an index  $N$  such that the above inequality holds for all  $i, j > N$ . Loosely put, the elements of the sequence are eventually arbitrarily close to each other.

Such a sequence is called a *Cauchy sequence*.

Just as in the case of the real or complex numbers, we would like every Cauchy sequence of terms  $x_i \in X$  to converge to some  $x$  in the following sense:

**Solution.** All three axioms of a metric from 7.3.1 are obviously satisfied in our definition of the discrete metric space.

Consider two metric spaces  $X$  and  $Y$  with metrics  $d_X$  and  $d_Y$ . The first obvious idea seems to add the distances of the components, i.e.

$$d((x_1, y_1), (x_2, y_2)) = d_X(x_1, x_2) + d_Y(y_1, y_2).$$

Clearly this is a metric (verify in detail!), but if the metric spaces  $X$  and  $Y$  are discrete, then considering points  $u = (x_1, y_1)$  and  $w = (x_2, y_2)$  such that  $x_1 \neq x_2, y_1 \neq y_2$  we arrive at  $d(u, w) = 2$ . Thus, this is not a discrete metric space.

But there is another simple possibility of introducing a metric on  $X \times Y$  using the maximum of the distances:

$$d((x_1, y_1), (x_2, y_2)) = \max\{d_X(x_1, x_2), d_Y(y_1, y_2)\}.$$

We call this the *product of the metric spaces  $X$  and  $Y$* . The triangle inequality as well as the other axioms are obvious (write down the explicit arguments!). Moreover, if both  $X$  and  $Y$  are discrete, then  $d$  is also a discrete metric.  $\square$

**7.C.2.** Decide whether or not the following sets and mappings form a metric space:

- i)  $\mathbb{N}, d(m, n) = \gcd(m, n)$
- ii)  $\mathbb{N}, d(m, n) = \frac{\max(m, n)}{\gcd(m, n)} - 1$
- iii) World population,  $d(P_1, P_2) = n$ ,  
 $P_1 = X_0, X_1, \dots, X_{n+1} = P_2$  is the shortest sequence of people, such that  $X_i$  knows  $X_{i+1}$  for  $i = 0, \dots, n$ .

**Solution.**

- i) No. The "distance"  $d$  does not satisfy that  $d(m, m) = 0$ .
- ii) No. The first and second conditions in the definition 7.3.1 are fulfilled, but the triangle inequality (property (3)) is not. The distance of 8 and 9 is 8, the distance of 8 and 6 is 3 and the distance of 6 and 9 is 2, thus  $d(8, 9) > d(8, 6) + d(6, 9)$ .
- iii) No. The "distance" is not symmetric. It would be a metric space, if the definition the word "knows" is changed to mean "know each other".  $\square$

**7.C.3.** Consider the set of binary words of the length  $n$ . Define the distance between two words as the number of bits in which they differ. This is called the Hamming distance, see 12.5.2). Show that it defines a metric.

**Solution.** The first two axioms of a metric are satisfied. For the third one let the words  $x$  and  $z$  differ in  $k$  bits. Let  $y$  be another word. Then consider just  $k$  bits, in which  $x$  and  $z$  differ. Clearly  $y$  differs in each of these bits exactly from one each of  $x$  and  $z$ . Thus considering only the parts of words  $x_p, y_p, z_p$  in the  $k$  bits, we have  $d(x_p, y_p) + d(y_p, z_p) = d(x_p, z_p)$ . In the other bits, the words  $x$  and  $z$  are the same, while  $x$  and  $y$  or  $y$  and  $z$  may differ. Thus  $d(x, y) + d(y, z) \geq d(x, z)$  and the third axiom is satisfied also.  $\square$

CONVERGENT SEQUENCES

Let  $x_0, x_1, \dots$  be a sequence in a metric space  $X$  and let  $x$  be an element of  $X$ . We say that the sequence  $\{x_i\}$  *converges* to the element  $x$ , if, for every positive real number  $\varepsilon$ , there is an integer  $N > 0$ , so that  $i > N$  implies  $d(x_i, x) < \varepsilon$ .

By the triangle inequality, it follows that for each pair of terms  $x_i, x_j$  from a convergent sequence with sufficiently large indices,

$$d(x_i, x_j) \leq d(x_i, x) + d(x, x_j) < 2\varepsilon.$$

Therefore, every convergent sequence is a Cauchy sequence. Conversely however, not every Cauchy sequence is convergent. Metric spaces where every Cauchy sequence is convergent are called *complete metric spaces*.

**7.3.3. Topology, convergence, and continuity.** Just as in the case of the real numbers, we can formulate the convergence in terms of "open neighbourhoods".

OPEN AND CLOSED SETS

**Definition** The *open  $\varepsilon$ -neighbourhood* of an element  $x$  in a metric space  $X$  (or just  $\varepsilon$ -neighbourhood for short) is the set

$$\mathcal{O}_\varepsilon(x) = \{y \in X; d(x, y) < \varepsilon\}.$$

A subset  $U \subset X$  is *open* if and only if for all  $x \in U$ ,  $U$  contains some  $\varepsilon$ -neighbourhood of  $x$ .

We define a subset  $W \subset X$  to be *closed* if and only if its complement  $X \setminus W$  is an open set.

Instead of an  $\varepsilon$ -neighbourhood, we also talk about (open)  $\varepsilon$ -ball centered at  $x$ . In the case of a normed space, we can consider  $\varepsilon$ -balls centered at zero: along with  $x$ ,  $\varepsilon$ -balls determine an  $\varepsilon$ -neighbourhood.

The *limit points of a subset  $A \subset X$*  are defined as those elements  $x \in X$  such that there is a sequence of points in  $A$  other than  $x$  converging to  $x$ .

**Lemma.** A subset in a metric space is closed if and only if it contains all of its limit points

**PROOF.** Suppose  $A$  is closed and  $x$  is a limit point of  $A$  but not belonging to  $A$ . Then  $x \in X \setminus A$  which is open, so there is an  $\varepsilon$ -neighbourhood of  $x$  not intersecting with  $A$ . But in every  $\varepsilon$ -neighbourhood of  $x$ , there are infinitely many points of the set  $A$ , since  $x$  is a limit point. This is a contradiction.

Conversely, suppose  $A$  contains all of its limit points and suppose  $x \in X \setminus A$ . If in every  $\varepsilon$ -neighbourhood of the point  $x$ , there is a point  $x_\varepsilon \in A$ , then the choices  $\varepsilon = 1/n$  provide a sequence of points  $x_n \in A$  converging to  $x$ . But then, the point  $x$  would have to be a limit point, thus lying in  $A$ , which again leads to a contradiction.  $\square$

For every subset  $A$  in a metric space  $X$ , we define its *interior* as the set of those points  $x$  in  $A$  for which a neighbourhood of  $x$  also belongs to  $A$ . We define the closure  $\bar{A}$  of

**7.C.4.** Consider any connected subset  $S \subset \mathbb{R}^n$  (any two points in  $S$  can be connected with a path lying in  $S$ ). Define the distance between two points as the length of the shortest path between the points. Is it a metric on  $S$ ?

**Solution.** It is a metric. All the axioms of the metric are trivially satisfied. But this metric has a special significance. The principle of "shortest way" is often met in reality. Recall for example Fermat's principle (see 5.E.123) of the least time, where we measure the length of a path by the time it is traveled by light. Generally, shortest paths in a metric space are called *geodesics*.  $\square$

**7.C.5.** Consider a space of integrable function on the interval  $[a, b]$ . Define the ( $L_1$ ) distance of the functions  $f, g$  as

$$\|f, g\| = \int_a^b |f(x) - g(x)| dx$$

. Why it is not a metric space?

**Solution.** The first axiom of the metric space in 7.3.1 is not satisfied. Any function of zero measure has distance 0 from the null function.

But if we consider an equivalence where two functions are equivalent, if they differ by a function of measure zero, then we get the space  $S^0(a, b)$ . The given distance considered on the equivalence classes of this equivalence is the  $L_1$  metric.  $\square$

**7.C.6.** Let  $r$  be a rational number and  $p$  a prime number. Then  $r$  can be uniquely written in the form  $r = p^k \frac{u}{v}$ , where  $u \in \mathbb{Z}$  and  $v \in \mathbb{N}$  are coprime and  $p$  does not divide both, the numerator  $u$  and the denominator  $v$ . Consider the map  $\|\cdot\|_p : \mathbb{Q} \rightarrow \mathbb{R}, \|r\| \mapsto p^{-k}$ . Show that it is a norm on  $\mathbb{Q}$  as a vector space over  $\mathbb{Q}$ . It is called the *p-adic norm*.  $\circ$

**Solution.** It is an exercise in elementary number theory.  $\square$

**7.C.7.** Consider the power set (the set of all subsets) of a given finite set. Determine whether the functions  $d_1$  and  $d_2$ , defined for all subsets  $X, Y$  by

(a)  $d_1(X, Y) := |(X \cup Y) \setminus (X \cap Y)|$ ,

(b)  $d_2(X, Y) := \frac{|(X \cup Y) \setminus (X \cap Y)|}{|X \cup Y|}$ , for  $X \cup Y \neq \emptyset$ ,  
 $d_2(\emptyset, \emptyset) := 0$

are metrics. ( $|X|$  is meant the number of elements of a set  $X$ , thus the metric  $d_1$  measures the size of the symmetric difference of the sets, while  $d_2$  measures the relative symmetric difference.)

**Solution.** We omit verifications of the first and second conditions from the definition of a metric in exercises on deciding whether a particular mapping is a metric. We analyze the triangle inequality only.

The case (a). For any sets  $X, Y, Z$ ,

$$(1) \quad (X \cup Z) \setminus (X \cap Z) \subseteq ((X \cup Y) \setminus (X \cap Y)) \cup ((Y \cup Z) \setminus (Y \cap Z))$$

To show this, suppose first that  $x$  is an element satisfying  $x \in X$  and  $x \notin Z$ . Then either  $x \in Y$  in which case  $x \in (Y \cup Z) \setminus (Y \cap Z)$ , or  $x \notin Y$  in which case  $x \in (X \cup Y) \setminus (X \cap Y)$ .

a set  $A$  as the union of the original set  $A$  with the set of all limit points of  $A$ .

As easily as in the case of the real numbers, we can verify that the intersection of any system of closed sets as well as the union of any finite system of closed sets is also closed.

On the other hand, any union of open sets is again an open set. A finite intersection of open sets is again an open set. Prove these propositions by yourselves in detail!

We also advise the reader to verify that the interior of a set  $A$  equals the union of all open sets contained in  $A$ , (alternatively put, the interior of  $A$  is the largest open subset of  $A$ ). The closure of  $A$  is the intersection of all closed sets which contain  $A$ , (alternatively put, the closure of  $A$  is the smallest closed superset of  $A$ ).

The closed and open sets are the essential concepts of the mathematical discipline called *topology*. Without pursuing these ideas further, we have just familiarised ourselves with the *topology of the metric spaces*.

The concept of convergence can be reformulated now as follows. A sequence of elements  $x_i, i = 0, 1, \dots$ , in a metric space  $X$  converges to  $x \in X$  if and only if for every open set  $U$  containing  $x$ , all but finitely many points of our sequence lie in  $U$ .

Just as in the case of the real numbers, we can define *continuous mappings* between metric spaces:

CONTINUOUS MAPPINGS

Let  $W$  and  $Z$  be metric spaces. A mapping  $f : W \rightarrow Z$  is continuous if and only if the inverse image  $f^{-1}(V)$  of every open set  $V \subset Z$  is an open set in  $W$ . This is equivalent to the statement that  $f$  is continuous if and only if for every  $z = f(x) \in Z$  and positive real number  $\varepsilon$ , there is a positive real number  $\delta$  such that for all elements  $y \in W$  with distance  $d_W(x, y) < \delta, d_Z(z, f(y)) < \varepsilon$ .

Again, as in the case of real-valued functions, a mapping  $f$  from one metric space to another is continuous if and only if it preserves the convergence of sequences (check this yourselves!).

**7.3.4.  $L_p$ -norms.** Now we have the general tools with which we can look at examples of metric spaces created by finite-dimensional vectors or functions at our disposal. We restrict ourselves to an extraordinarily useful class of norms.

We begin with the real or complex finite-dimensional vector spaces  $\mathbb{R}^n$  and  $\mathbb{C}^n$ , and for a fixed real number  $p \geq 1$  and any vector  $z = (z_1, \dots, z_n)$ , we define

$$\|z\|_p = \left( \sum_{i=1}^n |z_i|^p \right)^{1/p}.$$

We prove that this indeed defines a norm. The first two properties from the definition are clear. It remains to prove the triangle inequality. For that purpose, we use *Hölder's inequality*:

It follows that  $x$  belongs to the union, that is, the right side of 1. By symmetry, the same result holds if  $x$  is an element satisfying  $x \notin X$  and  $x \in Z$ . Since then all possibilities when  $x$  belongs to the left side of 1 are accounted for, the inclusion 1 is established.

But then,

$$\begin{aligned} d_1(X, Z) &= |(X \cup Z) \setminus (X \cap Z)| \\ &\leq |((X \cup Y) \setminus (X \cap Y)) \cup ((Y \cup Z) \setminus (Y \cap Z))| \\ &\leq |(X \cup Y) \setminus (X \cap Y)| + |(Y \cup Z) \setminus (Y \cap Z)| \\ &= d_1(X, Y) + d_1(Y, Z). \end{aligned}$$

The case (b). Proceed similarly to the case of  $d_1$ . Denote by  $X'$  the complement of a set  $X$ . The equalities

$$\begin{aligned} (X \cup Y) \setminus (X \cap Y) &= \\ (X \cap Y' \cap Z) \cup (X \cap Y' \cap Z') \cup (X' \cap Y \cap Z) \cup (X' \cap Y \cap Z'), \\ (Y \cup Z) \setminus (Y \cap Z) &= \\ (X \cap Y \cap Z') \cup (X \cap Y' \cap Z) \cup (X' \cap Y \cap Z') \cup (X' \cap Y' \cap Z), \\ ((X \cup Z) \setminus (X \cap Z)) \cup (Y \setminus (X \cup Z)) &= (X \cap Y \cap Z') \cup \\ (X \cap Y' \cap Z') \cup (X' \cap Y \cap Z) \cup (X' \cap Y' \cap Z) \cup (X' \cap Y \cap Z'), \end{aligned}$$

which, again, can be proved by listing several possibilities, imply a stronger form of (1), namely

$$\begin{aligned} ((X \cup Z) \setminus (X \cap Z)) \cup (Y \setminus (X \cup Z)) &\subseteq \\ ((X \cup Y) \setminus (X \cap Y)) \cup ((Y \cup Z) \setminus (Y \cap Z)). \end{aligned}$$

Further, we invoke the inequality

$$\frac{|(X \cup Z) \setminus (X \cap Z)|}{|X \cup Z|} \leq \frac{|((X \cup Z) \setminus (X \cap Z)) \cup (Y \setminus (X \cup Z))|}{|X \cup Z \cup (Y \setminus (X \cup Z))|}, \quad X \cup Z \neq \emptyset.$$

This is based on calculations with non-negative numbers only since in general

$$\frac{x}{z} \leq \frac{x+y}{z+y}, \quad y \geq 0, z > 0, x \in [0, z].$$

Since

$$X \cup Z \cup (Y \setminus (X \cup Z)) = X \cup Y \cup Z,$$

we obtain

$$\begin{aligned} d_2(X, Z) &= \frac{|(X \cup Z) \setminus (X \cap Z)|}{|X \cup Z|} \\ &\leq \frac{|((X \cup Z) \setminus (X \cap Z)) \cup (Y \setminus (X \cup Z))|}{|X \cup Z \cup (Y \setminus (X \cup Z))|} \\ &\leq \frac{|((X \cup Y) \setminus (X \cap Y)) \cup ((Y \cup Z) \setminus (Y \cap Z))|}{|X \cup Y \cup Z|} \leq \\ &\frac{|(X \cup Y) \setminus (X \cap Y)| + |(Y \cup Z) \setminus (Y \cap Z)|}{|X \cup Y \cup Z|} \\ &\leq \frac{|(X \cup Y) \setminus (X \cap Y)|}{|X \cup Y|} + \frac{|(Y \cup Z) \setminus (Y \cap Z)|}{|Y \cup Z|} = \\ &d_2(X, Y) + d_2(Y, Z), \end{aligned}$$

if  $X \cup Z \neq \emptyset$  and  $Y \neq \emptyset$ . However, for  $X = Z = \emptyset$  or  $Y = \emptyset$ , the triangle inequality clearly still holds.

Therefore, both mappings are metrics. The metric  $d_1$  is quite elementary, but the other metric, the metric  $d_2$  has wider applications. In the literature, it is also known as *Jaccard's metric*.<sup>4</sup>  $\square$

<sup>4</sup>It is named after the biologist Paul Jaccard, who described the measure of similarity in insects populations using the function  $1 - d_2$  in 1908.

HÖLDER INEQUALITY

**Lemma.** For a fixed real number  $p > 1$  and every pair of  $n$ -tuples of non-negative real numbers  $x_i$  and  $y_i$ ,

$$\sum_{i=1}^n x_i y_i \leq \left( \sum_{i=1}^n x_i^p \right)^{1/p} \cdot \left( \sum_{i=1}^n y_i^q \right)^{1/q},$$

where  $1/q = 1 - 1/p$ .

**PROOF.** Denote by  $X$  and  $Y$  the expressions in the product on the right-hand side of the inequality to be proved. If all of the numbers  $x_i$  or all of the numbers  $y_i$  are zero, then the statement is clearly true. Therefore, we can assume that  $X \neq 0$  and  $Y \neq 0$ .

We need to use the fact that the exponential function is a convex function. This can be stated: the graph of the exponential function lies below any of its chords, and indeed, the second derivative is again the exponential function, thus it is always positive. Hence, for any  $a$  and  $b$ , with  $p, q$  as above,

$$e^{(1/p)a + (1/q)b} \leq (1/p)e^a + (1/q)e^b$$

(in fact, this is the trivial case of the Jensen inequality, see 6.D.18).

Now, for those  $k$  with  $x_k y_k \neq 0$  we define the numbers  $v_k$  and  $w_k$  so that

$$x_k = X e^{v_k/p}, \quad y_k = Y e^{w_k/q}.$$

Then

$$e^{v_k/p + w_k/q} \leq \frac{1}{p} e^{v_k} + \frac{1}{q} e^{w_k}.$$

By substitution, it follows immediately that

$$x_k y_k \leq XY \left( \frac{1}{p} \left( \frac{x_k}{X} \right)^p + \frac{1}{q} \left( \frac{y_k}{Y} \right)^q \right).$$

Summing over  $k = 1, \dots, n$ , gives (notice that adding the terms with  $x_k y_k = 0$  does not spoil the inequality)

$$\begin{aligned} \frac{1}{XY} \sum_{i=1}^n x_i y_i &\leq \frac{1}{pX^p} \sum_{i=1}^n x_i^p + \frac{1}{qY^q} \sum_{i=1}^n y_i^q \\ &= \frac{1}{pX^p} X^p + \frac{1}{qY^q} Y^q = \frac{1}{p} + \frac{1}{q} = 1. \end{aligned}$$

Multiplying this inequality by  $XY$  finishes the proof.  $\square$

Now we can prove that  $\| \cdot \|_p$  is indeed a norm:

MINKOWSKI INEQUALITY

For every  $p > 1$  and all  $n$ -tuples of non-negative real numbers  $(x_1, \dots, x_n)$  and  $(y_1, \dots, y_n)$ ,

$$\left( \sum_{i=1}^n (x_i + y_i)^p \right)^{1/p} \leq \left( \sum_{i=1}^n x_i^p \right)^{1/p} + \left( \sum_{i=1}^n y_i^p \right)^{1/p}.$$

7.C.8. Let

$$d(x, y) := \frac{|x - y|}{1 + |x - y|}, \quad x, y \in \mathbb{R}.$$

Prove that  $d$  is a metric on  $\mathbb{R}$ .

**Solution.** We prove the triangle inequality only (the rest is clear). Introduce an auxiliary function

$$(1) \quad f(t) := \frac{t}{1+t}, \quad t \geq 0.$$

Note that  $f(s) - f(r) = \frac{s}{1+s} - \frac{r}{1+r} = \frac{s-r}{(1+s)(1+r)} > 0$ , whenever  $s > r \geq 0$ .

It follows that  $f$  is increasing, a fact which can also be verified by examining the first derivative. Therefore,

$$\begin{aligned} d(x, z) &= \frac{|x - z|}{1 + |x - z|} = \frac{|x - y + y - z|}{1 + |x - y + y - z|} \\ &\leq \frac{|x - y| + |y - z|}{1 + |x - y| + |y - z|} \\ &= \frac{|x - y|}{1 + |x - y| + |y - z|} + \frac{|y - z|}{1 + |x - y| + |y - z|} \\ &\leq \frac{|x - y|}{1 + |x - y|} + \frac{|y - z|}{1 + |y - z|} \\ &= d(x, y) + d(y, z), \quad x, y, z \in \mathbb{R}. \end{aligned}$$

□

The metrics in the next problems are defined by norms on vector spaces of functions. See the definitions and discussion in 7.3.1.

7.C.9. Determine the distance between the functions

$f(x) = x$ ,  $g(x) = -\frac{x}{\sqrt{1+x^2}}$ ,  $x \in [1, 2]$  as elements of the normed vector space  $\mathcal{S}^0[1, 2]$  of (piecewise) continuous functions on the interval  $[1, 2]$  with norm

- (a)  $\|f\|_1 = \int_1^2 |f(x)| \, dx$ ;  
 (b)  $\|f\|_\infty = \max\{|f(x)|; x \in [1, 2]\}$ .

**Solution.** The case (a). We need only compute the norm of the difference of the functions

$$\begin{aligned} \int_1^2 |f(x) - g(x)| \, dx &= \int_1^2 x + \frac{x}{\sqrt{1+x^2}} \, dx \\ &= \left(\frac{x^2}{2} + \sqrt{1+x^2}\right)\Big|_1^2 = \frac{3}{2} + \sqrt{5} - \sqrt{2}. \end{aligned}$$

The case (b). It is necessary to compute

$$\max_{x \in [1, 2]} |f(x) - g(x)| = \max_{x \in [1, 2]} \left(x + \frac{x}{\sqrt{1+x^2}}\right).$$

Since

$$\left(x + \frac{x}{\sqrt{1+x^2}}\right)' = 1 + \frac{1}{(\sqrt{1+x^2})^3} > 0, \quad x \in [1, 2],$$

it follows that  $f - g$  is increasing, and so attains its maximum at the right end point of the interval when  $x = 2$ . So

$$\max_{x \in [1, 2]} \left(x + \frac{x}{\sqrt{1+x^2}}\right) = 2 + \frac{2}{\sqrt{1+2^2}} = 2 + \frac{2}{\sqrt{5}}.$$

□

To verify this inequality, we can use the following observation.

$$\sum_{i=1}^n (x_i + y_i)^p = \sum_{i=1}^n x_i(x_i + y_i)^{p-1} + \sum_{i=1}^n y_i(x_i + y_i)^{p-1}$$

and by Hölder's inequality (recall  $p > 1$ ),

$$\begin{aligned} \sum_{i=1}^n x_i(x_i + y_i)^{p-1} &\leq \left(\sum_{i=1}^n x_i^p\right)^{1/p} \left(\sum_{i=1}^n (x_i + y_i)^{(p-1)q}\right)^{1/q} \\ \sum_{i=1}^n y_i(x_i + y_i)^{p-1} &\leq \left(\sum_{i=1}^n y_i^p\right)^{1/p} \left(\sum_{i=1}^n (x_i + y_i)^{(p-1)q}\right)^{1/q}. \end{aligned}$$

Adding the last two inequalities, and taking into account that  $p + q = pq$ , and so  $(p - 1)q = pq - q = p$ , we arrive at

$$\frac{\sum_{i=1}^n (x_i + y_i)^p}{\left(\sum_{i=1}^n (x_i + y_i)^p\right)^{1/q}} \leq \left(\sum_{i=1}^n x_i^p\right)^{1/p} + \left(\sum_{i=1}^n y_i^p\right)^{1/p}.$$

that is

$$\left(\sum_{i=1}^n (x_i + y_i)^p\right)^{1-1/q} \leq \left(\sum_{i=1}^n x_i^p\right)^{1/p} + \left(\sum_{i=1}^n y_i^p\right)^{1/p},$$

or

$$\left(\sum_{i=1}^n (x_i + y_i)^p\right)^{1/p} \leq \left(\sum_{i=1}^n x_i^p\right)^{1/p} + \left(\sum_{i=1}^n y_i^p\right)^{1/p},$$

since  $1 - 1/q = 1/p$ . This is the *Minkowski inequality* which we wanted to prove.

Thus we have verified that on every finite-dimensional real or complex vector space, there is a class of norms  $\|\cdot\|_p$  for all  $p > 1$ . The case  $p = 1$  was considered earlier. We can also consider  $p = \infty$  by setting

$$\|z\|_\infty = \max\{|z_i|, i = 1, \dots, n\}.$$

This is obviously a norm.

We notice that Hölder's inequality can, in the context of these norms, be written for all  $x = (x_1, \dots, x_n)$ ,  $y = (y_1, \dots, y_n)$  as

$$\sum_{i=1}^n |x_i| \cdot |y_i| \leq \|x\|_p \cdot \|y\|_q$$

for all  $p \geq 1$  and  $q$  satisfying  $1/p + 1/q = 1$ . For  $p = 1$ , we set  $q = \infty$ .

**7.3.5.  $L_p$ -norms for sequences and functions.** Now we can easily define the  $L_p$ -norms on suitable infinite-dimensional vector spaces as well. We begin with sequences.

The vector space  $\ell_p$ ,  $p \geq 1$ , is the set of all sequences of real or complex numbers  $x_0, x_1, \dots$  such that

$$\sum_{i=0}^{\infty} |x_i|^p < \infty.$$

If  $x = (x_1, x_2, \dots) \in \ell_p$ ,  $p \geq 1$ , then the norm is given by

$$\|x\|_p = \left(\sum_{i=0}^{\infty} |x_i|^p\right)^{1/p}$$

The  $L_1$  or  $L_2$  distances, discussed in the beginning of this chapter (cf. 7.1.2), reflect the basic intuition about the distance between graphs of the functions. However, in practice we need to understand more subtle concepts of distances. The most obvious way is to include the derivatives in a way similar to the values of the functions.

**7.C.10.** Consider the space  $\mathcal{S}^1[a, b]$  of piecewise differentiable (real or complex) functions on the interval  $[a, b]$  and show that the formula

$$\|f\| = \left( \int_a^b |f(x)|^2 + \alpha^2 |f'(x)|^2 dx \right)^{1/2}$$

with any real  $\alpha \geq 0$  is a norm on this vector space (up to the identification of functions differing only in the points of discontinuity).

Compute the distance between functions  $f(x) = \sin(x) + 0.1[\sin(6x)]^2 - 0.03 \sin(60x)$  and  $g(x) = \sin(x)$  on the interval  $[-\pi, \pi]$  in this norm and explain its dependence on  $\alpha$ .

**Solution.** The formula

$$\langle f, g \rangle \mapsto \int_a^b f(x)\overline{g(x)} + \alpha^2 f'(x)\overline{g'(x)} dx$$

defines a scalar product on  $\mathcal{S}^1[a, b]$ . The mapping is linear in the first argument  $f$ , provides complex conjugate value if the arguments are exchanged and clearly is positive if  $f = g$  is non-zero on any interval (Ignore the values in the points of discontinuity, cf. the the discussion in 7.1.2). Thus the corresponding quadratic form defines a norm on the complex vector space  $\mathcal{S}^1[a, b]$ .

The distance in this norm is easily computed to obtain

$$\sqrt{0.02639 + 11.3097\alpha^2}.$$

Its dependence on  $\alpha$  can be seen in the illustration — the values of the function  $f(x)$  are nearly equal to  $\sin x$ , but the very wiggly difference is well apparent in the derivatives.

If  $\alpha = 0$ , the distance 0.162 is the usual  $L_2$  distance. If  $\alpha = 1$  the distance is 3.367.<sup>5</sup>  $\square$

<sup>5</sup>Here is an illustration of the very important concept of *Sobolev spaces*, where any number of derivatives can be involved. Moreover, we can use  $L_p$ ,  $p \geq 1$  in the definition of the norm instead of  $p = 2$ . There is much literature on this subject.

That  $\|x\|_p$  is a norm follows immediately from the Minkowski inequality by letting  $n \rightarrow \infty$ .

The vector space  $\ell_\infty$ , is the set of all bounded sequences of real or complex numbers  $x_0, x_1, \dots$

If  $x = (x_0, x_1, \dots) \in \ell_\infty$ , then its norm is given by

$$\|x\|_\infty = \sup\{|x_i|, i = 0, 1, 2, 3 \dots\}$$

It is easily checked that this is indeed a norm.

Eventually, we return to the space of functions  $\mathcal{S}^0[a, b]$  on a finite interval  $[a, b]$  or  $\mathcal{S}_c^0[a, b]$  on an unbounded interval. We have already met the  $L_1$  norm  $\|\cdot\|_1$ . However, for every  $p > 1$  and for all functions in such a space of functions, the Riemann integrals

$$\int_a^b |f(x)|^p dx$$

surely exist, so we can define

$$\|f\|_p = \left( \int_a^b |f(x)|^p dx \right)^{1/p}.$$

The Riemann integral was defined in terms of limits, using the Riemann sums which correspond to splittings  $\Xi$  with representatives  $\xi_i$ . In our case, those are the finite sums

$$S_{\Xi, \xi} = \sum_{i=1}^n |f(\xi_i)|^p (x_i - x_{i-1}).$$

Hölder's inequality applied to the Riemann sums of a product  $|f(x)g(x)|$  of two functions  $f(x)$  and  $g(x)$  gives

$$\begin{aligned} & \sum_{i=1}^n |f(\xi_i)||g(\xi_i)|(x_i - x_{i-1}) = \\ & = \sum_{i=1}^n |f(\xi_i)|(x_i - x_{i-1})^{1/p} |g(\xi_i)|(x_i - x_{i-1})^{1/q} \\ & \leq \left( \sum_{i=1}^n |f(\xi_i)|^p (x_i - x_{i-1}) \right)^{1/p} \left( \sum_{i=1}^n |g(\xi_i)|^q (x_i - x_{i-1}) \right)^{1/q}. \end{aligned}$$

where on the right-hand side, there is the product of the Riemann sums for the integrals  $\|f\|_p$  and  $\|g\|_q$ .

Moving to limits, we thus verify *Hölder's inequality for integrals*:

$$\int_a^b f(x)g(x) dx \leq \left( \int_a^b f(x)^p dx \right)^{1/p} \left( \int_a^b g(x)^q dx \right)^{1/q}$$

which is valid for all non-negative real-valued functions  $f$  and  $g$  in our space of piecewise continuous functions with compact support.

In just the same way as in the previous paragraph, we can derive the integral form of the Minkowski inequality from Hölder's inequality:

$$\|f + g\|_p \leq \|f\|_p + \|g\|_p.$$

Thus  $\|\cdot\|_p$  is indeed a norm on the vector space of all continuous functions having a compact support for all  $p > 1$  (we verified this for  $p = 1$  long ago).

Now we move to more theoretical considerations. Though these exercises may not look particularly practical, they should be of help in understanding the basic concepts of metric spaces, the convergence as well as their links to the topological concepts.

**7.C.11.** Show that the definition of a metric as a function  $d$  defined on  $X \times X$  for a non-empty set  $X$  and satisfying

- (1)  $d(x, y) = 0$ , if and only if  $x = y$ ,  $x, y \in X$ ,
- (2)  $d(x, z) \leq d(y, x) + d(y, z)$ ,  $x, y, z \in X$ ,

is equivalent to the definition given in the theoretical part, in paragraph 7.3.1.

**Solution.** At first glance, it seems that this definition demands fewer requirements on the metric than the definition from the theoretical part. The two definitions are equivalent if and only if the two conditions of non-degeneracy and triangle inequality imply

- (3)  $d(x, y) \geq 0$ ,  $x, y \in X$ ,
- (4)  $d(x, y) = d(y, x)$ ,  $x, y \in X$ .

However, if we set  $x = z$  in (2), we get the non-negativity of the metric from (1). Similarly, the choice  $y = z$  in (2) together with (1) implies that  $d(x, y) \leq d(y, x)$  for all points  $x, y \in X$ . Interchanging the variables  $x$  and  $y$  then gives  $d(y, x) \leq d(x, y)$ , i.e. (4). Thus, it is proved that the definitions are equivalent.  $\square$

**7.C.12.** Describe all sequences in a discrete metric space  $X$ , which are convergent or Cauchy.

**Solution.** Since the distance between two points  $x, y$  in  $X$  is either 1 or zero, the sequence  $x_1, x_2, \dots$  is Cauchy if and only if all  $x_i$  are equal, except for a finite number of them. But then, the sequence is convergent.  $\square$

This problem shows a behaviour quite different from the convergence of sequences in the metric spaces  $X = \mathbb{R}$  or  $X = \mathbb{C}$ . But sequences of integers would behave in a very similar way. On the other hand, we deal mostly with metrics on spaces of functions, where intuition gained in the real line  $\mathbb{R}$  may be useful.

**7.C.13.** Determine whether or not the sequence  $\{x_n\}_{n \in \mathbb{N}}$  where

$$x_1 = 1, \quad x_n = 1 + \frac{1}{2} + \dots + \frac{1}{n}, \quad n \in \mathbb{N} \setminus \{1\},$$

is a Cauchy sequence in  $\mathbb{R}$  using the standard metric.

**Solution.** Recall that

$$(1) \quad \sum_{k=1}^{\infty} \frac{1}{k} = \infty, \quad \text{i.e.} \quad \sum_{k=m}^{\infty} \frac{1}{k} = \infty, \quad m \in \mathbb{N}.$$

Therefore,

$$\lim_{n \rightarrow \infty} |x_n - x_m| = \sum_{k=m+1}^{\infty} \frac{1}{k} = \infty, \quad m \in \mathbb{N}.$$

We use the word “norm” for the entire space  $\mathcal{S}^0[a, b]$  of piecewise continuous functions in this context; however, we should bear in mind that we have to identify those functions which differ only by their values at points of discontinuity.

Among these norms, the case of  $p = 2$  is special because of the existence of the inner product. In this case, we could have derived the triangle inequality much more easily using the Schwarz inequality.

For the functions from  $\mathcal{S}^0[a, b]$ , we can define an analogy of the  $L_\infty$ -norm on  $n$ -dimensional vectors. Since our functions are piecewise continuous, they always have suprema of absolute values on a finite closed interval, so we can set

$$\|f\|_\infty = \sup\{f(x), x \in [a, b]\}$$

for such a function  $f$ . If we considered both the one-sided limits (which always exist by our definition) and the value of the function itself to be the value  $f(x)$  at points of discontinuity, we can work with maxima instead of suprema. It is apparent again that it is a norm (except for the problems with values at discontinuity points).

**7.3.6. Completion of metric spaces.** Both the real numbers

$\mathbb{R}$  and the complex numbers  $\mathbb{C}$  are (with the metric given by the absolute value) a complete metric space. This is contained in the axiom of the existence of suprema. Recall that the real numbers were created as a “completion” of the space of rational numbers which is not complete. It is evident that the closure of the set  $\mathbb{Q} \subset \mathbb{R}$  is  $\mathbb{R}$ .

#### DENSE AND NOWHERE-DENSE SUBSETS

We say that a subset  $A \subset X$  in a metric space  $X$  is *dense* if and only if the closure of  $A$  is the whole space  $X$ .

A set  $A$  is said to be *nowhere dense* in  $X$  if and only if the set  $X \setminus \bar{A}$  is dense.

Evidently,  $A$  is dense in  $X$  if every open set in the whole space  $X$  has a non-empty intersection with  $A$ .

In all cases of norms on functions from the previous paragraph, the metric spaces defined in this way are not complete since it can happen that the limit of a Cauchy sequence of functions from our vector space  $\mathcal{S}^0[a, b]$  should be a function which does not belong to this space any more. Consider the interval  $[0, 1]$  as the domain of functions  $f_n$  which take zero on  $[0, 1/n]$  and are equal to  $\sin(1/x)$  on  $[1/n, 1]$ . They converge to the function  $\sin(1/x)$  in all  $L_p$  norms, but this function does not lie in the space.

#### COMPLETION OF A METRIC SPACE

Let  $X$  be a metric space with metric  $d$  which is not complete. A metric space  $\tilde{X}$  with metric  $\tilde{d}$  such that  $X \subset \tilde{X}$ ,  $d$  is the restriction of  $\tilde{d}$  to the subset  $X$ , and the closure  $\bar{X}$  in  $\tilde{X}$  is the whole space  $\tilde{X}$  is called a *completion of the metric space*  $X$ .

Hence the sequence  $\{x_n\}$  is not a Cauchy sequence.

Alternatively,  $\{x_n\}$  is not a Cauchy sequence, since if it is, then it is convergent in the complete metric space  $\mathbb{R}$ , which contradicts the divergence shown in (1).  $\square$

**7.C.14.** Repeat the question from the previous problem with the metric  $d$  given by (cf. 7.C.8)

$$d(x, y) := \frac{|x - y|}{1 + |x - y|}, \quad x, y \in \mathbb{R}.$$

**Solution.** Instead of repeating the arguments, we point out the difference between the given metric from the standard one. The difference is expressed by the function  $f$  introduced in (1). This is a continuous function and, moreover a bijection between the sets  $[0, \infty)$  and  $[0, 1)$ , having the property that  $f(0) = 0$ . Further, the property of a sequence being Cauchy or convergent in a metric space is defined by being Cauchy or convergent for the real numbers describing the distances between the elements in the sequence. But the continuous mappings preserve convergence or the property being Cauchy, and hence the solution for the new metric is the same as with the standard one.  $\square$

**7.C.15.** Determine whether or not the metric space  $\mathcal{C}[-1, 1]$  of continuous functions on the interval  $[-1, 1]$  with metric given by the norm

- (a)  $\|f\|_p = \left( \int_{-1}^1 |f(x)|^p dx \right)^{1/p}$  for  $p \geq 1$ ;  
 (b)  $\|f\|_\infty = \max\{|f(x)|; x \in [-1, 1]\}$

is complete.

**Solution.** The case (a). For every  $n \in \mathbb{N}$ , define a function

$$f_n(x) = 0, \quad x \in [-1, 0), \quad f_n(x) = 1, \quad x \in \left(\frac{1}{n}, 1\right], \\ f_n(x) = nx, \quad x \in \left[0, \frac{1}{n}\right].$$

For every  $m \geq n, m, n \in \mathbb{N}$ , we compute the inequality

$$\left( \int_{-1}^1 |f_m(x) - f_n(x)|^p dx \right)^{1/p} < \left( \int_0^{1/n} 1 dx \right)^{1/p} = \left(\frac{1}{n}\right)^{1/p}.$$

It follows that the sequence  $\{f_n\}_{n \in \mathbb{N}} \subset \mathcal{C}[-1, 1]$  is a Cauchy sequence of functions.

Suppose the sequence  $\{f_n\}$  has a  $\|\cdot\|_p$  limit  $f$  in  $\mathcal{C}[-1, 1]$ . We show that this limit cannot be continuous in  $x = 0$ . For every  $\varepsilon \in (0, 1)$ , there exists an  $n(\varepsilon) \in \mathbb{N}$  such that

$$f_n(x) = 0, \quad x \in [-1, 0], \quad f_n(x) = 1, \quad x \in [\varepsilon, 1]$$

for all  $n \geq n(\varepsilon)$ . Imagine,  $f(y) \neq 1$  at some  $y \geq \varepsilon$ . Then  $\|f - f_n\| \geq \delta > 0$  for all  $n \geq n(\varepsilon)$  and some  $\delta$ , since  $f$  is continuous. Thus  $f \neq 1$  on some bounded interval containing  $y$ . Therefore  $f$  must satisfy

$$f(x) = 0, \quad x \in [-1, 0], \quad f(x) = 1, \quad x \in [\varepsilon, 1]$$

for an arbitrarily small  $\varepsilon > 0$ . Thus, necessarily,

$$f(x) = 0, \quad x \in [-1, 0], \quad f(x) = 1, \quad x \in (0, 1].$$

The following theorem says that the completion of an arbitrary (incomplete) metric space  $X$  can be found in essentially the same way as the real numbers were created from the rationals. (Actually, the reader might read the detailed proof below first having this completion of rationals in mind, which verifies that this construction leads to  $\mathbb{R}$  with the standard complete metric, thus satisfying the axioms of the reals.)

**7.3.7. Theorem.** Let  $X$  be a metric space with metric  $d$  which is not complete. Then there exists a completion  $\tilde{X}$  of  $X$ .

**PROOF.** The idea of the construction is identical to the one used when building the real numbers. Two Cauchy sequences  $x_i$  and  $y_i$  of points belonging to  $X$  are considered equivalent if and only if  $d(x_i, y_i)$  converges to zero for  $i$  approaching infinity. This is a convergence of real numbers, thus the definition is correct.

From the properties of convergence on the real numbers, it is clear that the relation defined above is an equivalence relation. The reader is advised to verify this in detail. For instance, the transitivity follows from the fact that the sum of two sequences converging to zero converges to zero as well.

We define  $\tilde{X}$  as the set of the classes of this equivalence of Cauchy sequences. The original points  $x \in X$  can be identified with the class of sequences equivalent to the constant sequence  $x_i = x, i = 0, 1, \dots$

It is now easy to define the metric  $\tilde{d}$ . We put

$$\tilde{d}(\tilde{x}, \tilde{y}) = \lim_{i \rightarrow \infty} d(x_i, y_i)$$

for sequences  $\tilde{x} = \{x_0, x_1, \dots\}$  and  $\tilde{y} = \{y_0, y_1, \dots\}$ .

First, we have to verify that this limit exists at all and is finite. Notice the consequence of the triangle inequality for differences. Taking  $x, y$ , and  $z \in X$ ,  $d(x, y) \leq d(x, z) + d(y, z)$  and thus,  $d(x, y) - d(x, z) \leq d(y, z)$ . Swapping  $y$  and  $z$ , we obtain  $d(x, z) - d(x, y) \leq d(y, z)$ . Thus,

$$(1) \quad |d(x, y) - d(x, z)| \leq d(y, z)$$

(draw a picture!). Now, the fact that both the sequences  $\tilde{x}$  and  $\tilde{y}$  are Cauchy sequences implies that the considered sequence is also a Cauchy sequence of real numbers:

$$|d(x_i, y_i) - d(x_j, y_j)| \leq |d(x_i, y_i) - d(x_i, y_j)| \\ + |d(x_i, y_j) - d(x_j, y_j)| \\ \leq d(y_i, y_j) + d(x_i, x_j).$$

Thus, the limit of  $d(x_i, y_i)$  exists.

If we select different representatives  $\tilde{x} = \{x'_0, x'_1, \dots\}$  and  $\tilde{y} = \{y'_0, y'_1, \dots\}$ , then by similar argument as above

$$|d(x'_i, y'_i) - d(x_i, y_i)| \leq |d(x'_i, y'_i) - d(x'_i, y_i)| \\ + |d(x'_i, y_i) - d(x_i, y_i)| \\ \leq d(x_i, x'_i) + d(y_i, y'_i).$$

Therefore, the definition is indeed independent of the choice of representatives.

We verify that  $\tilde{d}$  is a metric on  $\tilde{X}$ . The first and second properties are clear, so it remains to prove the triangle inequality. For that purpose, choose three Cauchy representatives of

But this function is not continuous on  $[-1, 1]$ , so it does not belong to the considered metric space. Therefore, the sequence  $\{f_n\}$  does not have a limit in  $\mathcal{C}[-1, 1]$ , so this space is not complete.

The case (b). Let an arbitrary Cauchy sequence  $\{f_n\}_{n \in \mathbb{N}} \subset \mathcal{C}[-1, 1]$  be given. The terms of this sequence are continuous functions  $f_n$  on  $[-1, 1]$  having the property that for  $\varepsilon > 0$  (or for every  $\varepsilon/2$  if you want) there is an  $n(\varepsilon) \in \mathbb{N}$  such that

$$(1) \quad \max_{x \in [-1, 1]} |f_m(x) - f_n(x)| < \frac{\varepsilon}{2}, \quad m, n \geq n(\varepsilon).$$

In particular, for every  $x \in [-1, 1]$ , we get a Cauchy sequence  $\{f_n(x)\}_{n \in \mathbb{N}} \subset \mathbb{R}$  of numbers. Since the metric space  $\mathbb{R}$  with the usual metric is complete, every (for  $x \in [-1, 1]$ ) sequence  $\{f_n(x)\}$  is convergent. Set

$$f(x) := \lim_{n \rightarrow \infty} f_n(x), \quad x \in [-1, 1].$$

Letting  $m \rightarrow \infty$  in (1), we obtain

$$\max_{x \in [-1, 1]} |f(x) - f_n(x)| \leq \frac{\varepsilon}{2} < \varepsilon, \quad n \geq n(\varepsilon).$$

It follows that the sequence  $\{f_n\}_{n \in \mathbb{N}}$  converges uniformly (that is, with respect to the given norm), to the function  $f$  on  $[-1, 1]$ . Since the uniform limit of continuous functions is continuous, so is  $f$ , so  $f \in \mathcal{C}[-1, 1]$ , see 6.3.4. Therefore, the metric space is complete.  $\square$

The same reasoning as above, and hence the same results, apply to the more general metric space  $\mathcal{C}[a, b]$  of continuous functions on any closed bounded interval  $[a, b]$  or on the space  $\mathcal{C}_c$  of continuous functions with compact support.

**7.C.16.** Prove that the metric space  $\ell_2$  is complete.

**Solution.** Recall that  $\ell_2$  is the space of sequences of real numbers with the  $L_2$ -norm, see 7.3.5.

Consider an arbitrary Cauchy sequence  $\{x_n\}_{n \in \mathbb{N}}$  in the space  $\ell_2$ . Every term of this sequence is again a sequence, i.e.,  $x_n = \{x_n^k\}_{k \in \mathbb{N}}$ ,  $n \in \mathbb{N}$ . Of course, the range of indices does not matter – there is no difference whether  $n, k \in \mathbb{N}$  or  $n, k \in \mathbb{N} \cup \{0\}$ . Introduce auxiliary sequences  $y_k$  for  $k \in \mathbb{N}$  so that

$$y_k = \{y_k^n\}_{n \in \mathbb{N}} = \{x_n^k\}_{n \in \mathbb{N}}.$$

If  $\{x_n\}$  is a Cauchy sequence in  $\ell_2$ , then each of the sequences  $y_k$  is a Cauchy sequence in  $\mathbb{R}$  (the sequences  $y_k$  are sequences of real numbers). It follows from the completeness of  $\mathbb{R}$  (with respect to the usual metric) that all of the sequences  $y_k$  are convergent. Denote their limits by  $z_k$ ,  $k \in \mathbb{N}$ .

It suffices to prove that  $z = \{z_k\}_{k \in \mathbb{N}} \in \ell_2$  and that the sequence  $\{x_n\}$  converges for  $n \rightarrow \infty$  in  $\ell_2$  just to the sequence  $z$ . The sequence  $\{x_n\}_{n \in \mathbb{N}} \subset \ell_2$  is a Cauchy sequence; therefore, for every  $\varepsilon > 0$ , there is an  $n(\varepsilon) \in \mathbb{N}$  with the property that

$$\sum_{k=1}^{\infty} (x_m^k - x_n^k)^2 < \varepsilon, \quad m, n \geq n(\varepsilon), \quad m, n \in \mathbb{N}.$$

In particular,

$$\sum_{k=1}^l (x_m^k - x_n^k)^2 < \varepsilon, \quad m, n \geq n(\varepsilon), \quad m, n, l \in \mathbb{N},$$

the elements  $\tilde{x}, \tilde{y}, \tilde{z}$ , and we obtain

$$\begin{aligned} \tilde{d}(\tilde{x}, \tilde{z}) &= \lim_{i \rightarrow \infty} d(x_i, z_i) \\ &\leq \lim_{i \rightarrow \infty} d(x_i, y_i) + \lim_{i \rightarrow \infty} d(y_i, z_i) \\ &= \tilde{d}(\tilde{x}, \tilde{y}) + \tilde{d}(\tilde{y}, \tilde{z}). \end{aligned}$$

The restriction of the metric  $\tilde{d}$  just defined to the original space  $X$  is identical to the original metric because the original points are represented by constant sequences.

It is required to prove that  $X$  is dense in  $\tilde{X}$ . Let  $\tilde{x} = \{x_i\}$  be a fixed Cauchy sequence, and let  $\varepsilon > 0$  be given. Since the sequence  $x_i$  is a Cauchy sequence, all pairs of its terms  $x_n, x_m$  for sufficiently large indices  $m$  and  $n$  become closer to each other than  $\varepsilon$ . Then the choice  $y = x_n$  for one of those indices necessarily implies that the elements  $y$  and  $x_m$  are closer together than  $\varepsilon$ , and so,  $\tilde{d}(\tilde{y}, \tilde{x}) \leq \varepsilon$ . Hence there is an element  $y$  of the original space such that the distance of the sequences of  $y$ 's from the chosen sequence  $x_i$  does not exceed  $\varepsilon$ . This establishes the denseness of  $X$ .

It remains to prove that the constructed metric space is complete. That is, that Cauchy sequences of points of the extended space  $\tilde{X}$  with respect to the metric  $\tilde{d}$  are necessarily convergent to a point in  $\tilde{X}$ . This can be done by approximating the points of a Cauchy sequence  $\tilde{x}_k$  by points  $y_k$  from the original space  $X$  so that the resulting sequence  $\tilde{y} = \{y_i\}$  would be the limit of the original sequence with respect to the metric  $\tilde{d}$ .

Since  $X$  is a dense subset in  $\tilde{X}$ , we can choose, for every element  $\tilde{x}_k$  of our fixed sequence, an element  $z_k \in X$  so that the constant sequence  $\tilde{z}_k$  would satisfy  $\tilde{d}(\tilde{x}_k, \tilde{z}_k) < 1/k$ . Now consider the sequence  $\tilde{z} = \{z_0, z_1, \dots\}$ . The original sequence  $\tilde{x}$  is Cauchy. So for a fixed real number  $\varepsilon > 0$ , there is an index  $n(\varepsilon)$  such that  $\tilde{d}(\tilde{x}_n, \tilde{x}_m) < \varepsilon/2$  whenever both  $m$  and  $n$  are greater than  $n(\varepsilon)$ . Without loss of generality, the index  $n(\varepsilon)$  is greater than or equal to  $4/\varepsilon$ . Now, for  $m$  and  $n$  greater than  $n(\varepsilon)$ , we get:

$$\begin{aligned} d(z_m, z_n) &= \tilde{d}(\tilde{z}_m, \tilde{z}_n) \\ &\leq \tilde{d}(\tilde{z}_m, \tilde{x}_m) + \tilde{d}(\tilde{x}_m, \tilde{x}_n) + \tilde{d}(\tilde{x}_n, \tilde{z}_n) \\ &\leq 1/m + \varepsilon/2 + 1/n \leq 2\frac{\varepsilon}{4} + \frac{\varepsilon}{2} = \varepsilon. \end{aligned}$$

Hence it is a Cauchy sequence  $z_i$  of elements in  $X$ , and so  $\tilde{z} \in \tilde{X}$ . From the triangle inequality,

$$\tilde{d}(\tilde{z}, \tilde{x}_n) \leq \tilde{d}(\tilde{z}, \tilde{z}_n) + \tilde{d}(\tilde{z}_n, \tilde{x}_n).$$

From the previous bounds, both terms on the right-hand side converge to zero. Hence the distances  $\tilde{d}(\tilde{x}_n, \tilde{z})$  approach zero, thereby finishing the proof.  $\square$

**7.3.8. Uniqueness.** We consider now the uniqueness of the completion of metric spaces.

whence, letting  $m \rightarrow \infty$ ,

$$\sum_{k=1}^l (z_k - x_n^k)^2 \leq \varepsilon, \quad n \geq n(\varepsilon), \quad n, l \in \mathbb{N},$$

i.e. (this time  $l \rightarrow \infty$ )

$$(1) \quad \sum_{k=1}^{\infty} (z_k - x_n^k)^2 \leq \varepsilon, \quad n \geq n(\varepsilon), \quad n \in \mathbb{N}.$$

Especially,

$$\sum_{k=1}^{\infty} (z_k - x_n^k)^2 < \infty, \quad n \geq n(\varepsilon), \quad n \in \mathbb{N}$$

and, at the same time,

$$\sum_{k=1}^{\infty} (x_n^k)^2 < \infty, \quad n \in \mathbb{N},$$

which follows straight from  $\{x_n\}_{n \in \mathbb{N}} \subset \ell_2$ .

Since (cf. the special case of Hölder's inequality for  $p = 2$  in 7.3.4)

$$\sum_{k=1}^{\infty} (z_k x_n^k) \leq \sqrt{\sum_{k=1}^{\infty} z_k^2} \cdot \sqrt{\sum_{k=1}^{\infty} (x_n^k)^2}, \quad n \in \mathbb{N}$$

and

$$\sum_{k=1}^{\infty} (z_k - x_n^k)^2 = \sum_{k=1}^{\infty} (z_k^2 - 2z_k x_n^k + (x_n^k)^2), \quad n \in \mathbb{N}.$$

Hence

$$\sum_{k=1}^{\infty} z_k^2 < \infty.$$

It is proved that  $z \in \ell_2$ . The fact that  $\{x_n\}$  converges for  $n \rightarrow \infty$  to  $z$  in  $\ell_2$  follows from (1).  $\square$

The next problem addresses the question of the power of different metrics on the same space of functions in terms of convergence. We deal with the space  $\mathcal{S}_c$  of piecewise continuous functions with compact support, equipped with the  $L_p$  metrics. We write briefly  $\mathcal{L}_p$  for these metric spaces. In particular, we show that convergence in  $\mathcal{L}_p$  for some positive  $p$  does not always imply convergence in  $\mathcal{L}_q$  for another positive  $q \neq p$ .

**7.C.17.** Let  $0 < p < \infty$ . For each positive integer  $n$ , define the sequence of functions

$$f_n(x) = \begin{cases} n^{1/p} & -1/n \leq x \leq 1/n \\ 0 & \text{otherwise.} \end{cases}$$

Decide for which  $q$  the sequence  $f_n$  converges in  $\mathcal{L}_q$ .

**Solution.** Let  $q$  be any positive real number. Then

$$\int_{-\infty}^{\infty} |f_n(x)|^q dx = \int_{-1/n}^{1/n} n^{q/p} dx = (2/n)n^{q/p} = 2n^{(q/p)-1}.$$

If  $0 < q < p$  and if  $n \rightarrow \infty$ , then

$$\int_{-\infty}^{\infty} |f_n(x)|^q dx \rightarrow 0.$$

So  $\|f_n\|_q \rightarrow 0$ , and the sequence converges to the zero function. Similarly if  $0 < p < q$  and if  $n \rightarrow \infty$ , then

$$\int_{-\infty}^{\infty} |f_n(x)|^q dx \rightarrow \infty.$$

## ISOMETRIES

A mapping  $\varphi : X_1 \rightarrow X_2$  between metric spaces with metrics  $d_1$  and  $d_2$ , respectively, is called an *isometry* if and only if all elements  $x, y \in X$  satisfy  $d_2(\varphi(x), \varphi(y)) = d_1(x, y)$ .

Of course, every isometry is a bijection onto its image (this follows from the property that the distance between distinct elements is non-zero) and the corresponding inverse mapping is an isometry as well.

Now, consider two inclusions of a dense subset,  $\iota_1 : X \rightarrow \tilde{X}_1$  and  $\iota_2 : X \rightarrow \tilde{X}_2$ , into two completions of the space  $X$ , and denote the corresponding metrics by  $d, d_1$ , and  $d_2$ , respectively. The mapping

$$\varphi : \iota_1(X) \xrightarrow{\iota_1^{-1}} X \xrightarrow{\iota_2} \tilde{X}_2$$

is well-defined on the dense subset  $\iota_1(X) \subset \tilde{X}_1$ . Its image is the dense subset  $\iota_2(X) \subset \tilde{X}_2$  and, moreover, this mapping is clearly an isometry. The dual mapping  $\iota_1 \circ \iota_2^{-1}$  works in the same way.

Every isometric mapping maps, of course, Cauchy sequences to Cauchy sequences. At the same time, such Cauchy sequences converge to the same element in the completion if and only if this holds for their images under the isometry  $\varphi$ . Thus if such a mapping  $\varphi$  is defined on a dense subset  $X$  of a metric space  $\tilde{X}_1$ , then it has a unique extension to the whole  $\tilde{X}_1$  with values lying in the closure of the image  $\varphi(X)$ , i. e.  $\tilde{X}_2$ .

By using the previous ideas, there is a unique extension of  $\varphi$  to the mapping  $\tilde{\varphi} : \tilde{X}_1 \rightarrow \tilde{X}_2$  which is both a bijection and an isometry. Thus, the completions  $\tilde{X}_1$  and  $\tilde{X}_2$  are indeed identical in this sense.

Thus it is proved:

**Theorem.** Let  $X$  be a metric space with metric  $d$  which is not complete. Then the completion  $\tilde{X}$  of  $X$  with metric  $\tilde{d}$  is unique up to bijective isometries.

In the following three paragraphs, we introduce three theorems about complete metric spaces. They are highly applicable in both mathematical analysis and verifying convergence of numerical methods.

**7.3.9. Banach's contraction principle.** A mapping  $F : X \rightarrow X$  on a metric space  $X$  with metric  $d$  is called a *contraction mapping* if and only if there is a real constant  $0 \leq C < 1$  such that for all elements  $x, y$  in  $X$ ,

$$d(F(x), F(y)) \leq C d(x, y).$$

**Theorem.** If  $F$  is a contraction mapping on a complete metric space  $X$ , then it has a fixed point, i. e., there is a  $z \in X$  such that  $F(z) = z$ .

**PROOF.** The proof naturally follows the intuitive idea that iterative application of a contraction mapping starting from an initial value  $z_0 \in X$  should "accumulate" to some point.

So  $\|f_n\|_q$  diverges, and in particular,  $f_n$  cannot converge to any limit.

Finally, for  $q = p$  we have  $\int |f_n(x)|^p dx = 2$  for all positive integers  $n$ , and so as  $n \rightarrow \infty$  we get  $\|f_n\|_p \rightarrow 2^{1/p}$ . At the same time, for any  $g \in \mathcal{S}_c$ , if  $g(x) \neq 0$  at some  $x \neq 0$  where  $g$  is continuous, its distance from  $f_n$  cannot converge to zero.

It follows that  $f_n$  converges to 0 in  $\mathcal{L}_q$ ,  $0 < q < p$ , but it does not converge in  $\mathcal{L}_q$  with  $q \geq p$ .  $\square$

The next problem deals with the extremely useful Banach fixed point theorem, showing the necessity of all the requirements in Theorem 7.3.9.

**7.C.18.** Show that the mapping  $f : \langle 0, \infty \rangle \rightarrow \langle 0, \infty \rangle$  given by

$$f(x) = x + e^{-x}$$

satisfies, for all  $x \neq y$ , the condition

$$|f(x) - f(y)| < |x - y|,$$

but it does not have any fixed point, i.e.  $f(x) \neq x$  for any  $x$ . (Thus the condition  $|f(x) - f(y)| \leq C|x - y|$ , with constant  $C < 1$ , in the Banach fixed point Theorem 7.3.9 is essential.)

**Solution.** Clearly the function  $f$  is strictly increasing on the entire domain. Assume  $y < x$ . Then  $e^{-x} < e^{-y}$  and

$$|f(x) - f(y)| = |x - y + e^{-x} - e^{-y}| < |x - y|.$$

Finally,  $f(x) = x$  implies  $e^{-x} = 0$  which is impossible.  $\square$

Dealing with convergence of real numbers, we observe

that the topological concepts of open neighbourhoods and the compactness are most useful. This is of course even more true for metric spaces, where we can work with open balls of radius  $r$  etc. The definitions remain essentially the same.

**7.C.19.** We have already seen the discrete metric space  $X \neq \emptyset$  with the metric  $d : X \times X \rightarrow \mathbb{R}$  defined by the formula

$$d(x, y) := 1, \quad x \neq y, \quad d(x, y) := 0, \quad x = y.$$

- Decide whether  $(X, d)$  is complete.
- Describe all open, closed, and bounded sets in  $(X, d)$ .
- Describe the interior, boundary, limit, and isolated points of an arbitrary set in  $(X, d)$ .
- Describe all compact sets in  $(X, d)$ .

**Solution.** The case (a) was essentially dealt with in 7.C.12. For an arbitrary sequence  $\{x_n\}_{n \in \mathbb{N}}$  to be a Cauchy sequence, it is necessary in this space that there is an index  $n \in \mathbb{N}$  such that  $x_n = x_{n+m}$  for all  $m \in \mathbb{N}$ . Any sequence with this property then necessarily converges to the common value  $x_n = x_{n+1} = \dots$  (we talk about almost stationary sequences). So the metric space  $(X, d)$  is complete.

The case (b). The open 1-neighbourhood of any element contains this element only. Therefore, every singleton set is open. Since the union of any number of open sets is an open set, every set is open in  $(X, d)$ . By complements,

The metric space  $X$ , of course, needs to be complete; otherwise it could happen that the limit point does not exist in it.

Choose an arbitrary  $z_0 \in X$  and consider the sequence  $z_i, i = 0, 1, \dots$

$$z_1 = F(z_0), \quad z_2 = F(z_1), \dots, \quad z_{i+1} = F(z_i), \dots$$

From the assumptions, we have

$$\begin{aligned} d(z_{i+1}, z_i) &= d(F(z_i), F(z_{i-1})) \\ &\leq C d(z_i, z_{i-1}) \leq \dots \leq C^i d(z_1, z_0). \end{aligned}$$

The triangle inequality then implies that for all natural numbers  $j$ ,

$$\begin{aligned} d(z_{i+j}, z_i) &\leq \sum_{k=1}^j d(z_{i+k}, z_{i+k-1}) \\ &\leq \sum_{k=1}^j C^{i+k-1} d(z_1, z_0) = C^i d(z_1, z_0) \sum_{k=1}^j C^{k-1} \\ &\leq C^i d(z_1, z_0) \sum_{k=1}^{\infty} C^{k-1} = \frac{C^i}{1-C} d(z_1, z_0). \end{aligned}$$

Now, since  $0 \leq C < 1$ ,  $\lim_{n \rightarrow \infty} C^n = 0$ , so for every positive (no matter how small)  $\varepsilon$ , the right-hand expression is surely less than  $\varepsilon$  for sufficiently large indices  $i$ , that is,

$$d(z_i, z_{i+j}) \leq \frac{C^i}{1-C} d(z_1, z_0) \leq \varepsilon.$$

However, this ensures that the sequence  $z_i$  is a Cauchy sequence. Since  $X$  is complete, the sequence has a limit  $z$ , and all that remains to be proved is  $F(z) = z$ .

Every contraction mapping is continuous. Therefore,

$$F(z) = F\left(\lim_{n \rightarrow \infty} z_n\right) = \lim_{n \rightarrow \infty} F(z_n) = z.$$

This finishes the proof.  $\square$

The next two theorems extend the intuitive understanding of “density” of closed intervals  $[a, b] \subset \mathbb{R}$ , not allowing for any “holes” there. They are essential for the understanding of compactness of metric spaces. In fact, they are both special cases of more general theorems on topological spaces.

**7.3.10. Cantor intersection theorem.** For any set  $A$  in a metric space  $X$  with metric  $d$ , the real number

$$\text{diam } A = \sup_{x, y \in A} d(x, y)$$

is called the *diameter of the set A*. The set  $A$  is said to be *bounded* if and only if  $\text{diam } A < \infty$ .

**Theorem.** If  $A_1 \supset A_2 \supset \dots \supset A_i \supset \dots$  is a non-increasing sequence of non-empty closed subsets in a complete metric space  $X$  and if  $\text{diam } A_i \rightarrow 0$ , then there is exactly one point  $x \in X$  belonging to the intersection of all the sets  $A_i$ .<sup>2</sup>

<sup>2</sup>Georg Cantor is considered as the founder of the set theory which he introduced and developed in the last quarter of 19th century. At this time,

this also means that every set is closed. The fact that the 2-neighbourhood of any element coincides with the whole space implies that every set is bounded in  $(X, d)$ .

The case (c). Once again, we use the fact that the open 1-neighbourhood of any element contains this element only. It follows that every point of any set is both its interior and its isolated point and that the sets have neither boundary nor limit points.

The case (d). Every finite set in an arbitrary metric space is compact (it defines a compact metric space by restricting the domain of  $d$ ). It follows from the classification of convergent sequences (see (a)), that no infinite sequence can be compact in  $(X, d)$ .  $\square$

**7.C.20.** In the metric space  $\mathcal{S}[-1, 1]$  with metric given by the norm  $\|\cdot\|_\infty$ , consider the sets

$$A = \{f \in \mathcal{S}[-1, 1]; f(0) \in (0, 2)\},$$

$$B = \{f \in \mathcal{S}[-1, 1]; \int_{-1}^1 f(x) \, dx = 0\}.$$

Are these sets open? Are these sets closed?

**Solution.** The interior of a set  $M$  is the set of all interior points of  $M$  and it is usually denoted by  $M^0$ . A set  $M$  is then open if and only if  $M = M^0$ . Similarly, we define the closure of a set  $M$  as the set of all points having zero distance from  $M$ ; it is denoted by  $\overline{M}$ . A set  $M$  is closed if and only if  $M = \overline{M}$ . Since

$$A^0 = A, \quad \overline{A} = \{f \in \mathcal{S}[-1, 1]; f(0) \in [0, 2]\}, \quad B^0 = \emptyset, \quad \overline{B} = B$$

(especially,  $\overline{A}$  contains functions  $f$  for which  $f(0)$  can attain values from the whole closed interval  $[0, 2]$ ), the set  $A$  is open and not closed, and, the other way around, the set  $B$  is closed and not open.  $\square$

One of the most important concepts related to complete metric spaces is given by the principle of nested balls (cf. the theorem 7.3.10). Under some additional conditions, it says that a metric space  $(X, d)$  is complete if and only if every sequence  $\{A_n\}_{n \in \mathbb{N}}$  of nested (i.e.,  $A_{n+1} \subseteq A_n, n \in \mathbb{N}$ ) non-empty closed sets  $A_n$  has non-empty intersection. That is,

$$(1) \quad \bigcap_{n \in \mathbb{N}} A_n \neq \emptyset.$$

**7.C.21.** Verify that the additional condition in the theorem

$$(1) \quad \lim_{n \rightarrow \infty} \sup \{d(x, y); x, y \in A_n\} = 0.$$

cannot be omitted.

**Solution.** That the requirement (1) cannot be omitted is probably contrarily to many readers' expectations. For a counterexample, consider the set  $X = \mathbb{N}$  with metric

$$d(m, n) = 1 + \frac{1}{m+n}, \quad m \neq n, \quad d(m, n) = 0, \quad m = n.$$

It is indeed a metric. The first and second properties are clearly satisfied. To prove the triangle inequality, it suffices to observe that  $d(m, n) \in (1, 4/3]$  if  $m \neq n$ . Hence the only

**PROOF.** Select one point  $x_i$  for each set  $A_i$ . Since  $\text{diam } A_i \rightarrow 0$ , for every positive real number  $\varepsilon$ , we can find an index  $n(\varepsilon)$  such that for all  $A_i$  with indices  $i \geq n(\varepsilon)$ , their diameters are less than  $\varepsilon$ . For sufficiently large indices  $i, j$ ,  $d(x_i, x_j) \leq \varepsilon$ , and thus our sequence is a Cauchy sequence. Therefore, it has a limit point  $x \in X$ .  $x$  must be a limit point of all the sets  $A_i$ , thus it belongs to all of them (since they are all closed). So  $x$  belongs to their intersection. This proves the existence of  $x$ .

Assume there are two points  $x$  and  $y$ , both belonging to the intersection of all the sets  $A_i$ . Then  $d(x, y)$  must be less than the diameter of the sets  $A_i$ . But  $\text{diam } A_i \rightarrow 0$ , so  $d(x, y) = 0$ , hence  $x = y$ . This proves the uniqueness of  $x$ .  $\square$

**7.3.11. Theorem (Baire theorem).** *If  $X$  is a complete metric space, then the intersection of every countable system of open dense sets  $A_i$  is a dense set in the metric space  $X$ .*<sup>3</sup>

**PROOF.** Suppose  $X$  contains a system of dense open sets  $A_i, i = 1, 2, \dots$ . It is required to show that the set  $A = \bigcap_{i=1}^\infty A_i$  has a non-empty intersection with any open set  $U \subset X$ . Proceed inductively, invoking the previous theorem.

Since  $A_1$  is dense, there is a  $z_1 \in A_1 \cap U$ , but since the set  $A_1$  is open, the closure of an  $\varepsilon_1$ -neighbourhood  $U_1$  (for sufficiently small  $\varepsilon_1$ ) of the point  $z_1$  is contained in  $A_1$  as well. Denote the closure of this  $\varepsilon_1$ -ball  $U_1$  by  $B_1$ .

Further, suppose that the points  $z_i$  and their open  $\varepsilon_i$ -neighbourhoods  $U_i$  are already chosen for  $i = 1, \dots, n$ , so that

$$z_k \in B_k = \overline{U}_k, \quad z_k \in \bigcap_{i=1}^k B_i \subset \bigcap_{i=1}^k A_i \cap U.$$

Since the set  $A_{n+1}$  is open and dense in  $X$ , there is a point  $z_{n+1} \in A_{n+1} \cap U_n$ ; however, since  $A_{n+1} \cap U_n$  is open, the point  $z_{n+1}$  belongs to it together with a sufficiently small  $\varepsilon_{n+1}$ -neighbourhood  $U_{n+1}$ .

Then, the closures surely satisfy  $B_{n+1} = \overline{U}_{n+1} \subset \overline{U}_n$ , and so the closed set  $B_{n+1}$  is contained in  $A_{n+1} \cap \overline{U}_n$ . Moreover, we can assume that all  $\varepsilon_n \leq 1/n$ .

If we proceed in this inductive way from the original point  $z_1$  and the set  $B_1$ , we obtain a non-increasing sequence of non-empty closed sets  $B_n$  whose diameter approaches zero. Therefore, there is a point  $z$  common to all of these sets. That is,

$$z \in \bigcap_{i=1}^\infty \overline{U}_i = \bigcap_{i=1}^\infty B_i \subset \bigcap_{i=1}^\infty A_i \cap U,$$

which is the statement to be proved.  $\square$

the new abstract approach to fundamentals of Mathematics caused fierce objections. It also led to the severe internal crises of Mathematics in the beginning of the 20th century. This part of the history of Mathematics is fascinating.

<sup>3</sup>This theorem is a part of considerations by René-Louis Baire in his 1899 doctoral thesis. More generally, a topological space satisfying the property as in the theorem is called a *Baire space* and the theorem simply says that every complete metric space is a Baire space.

Cauchy sequences are those which are constant from some index on. These sequences are constant except for finitely many terms, sometimes called almost stationary sequences. Thus, every Cauchy sequence is convergent, so the metric space is complete. Define

$$A_n := \left\{ m \in \mathbb{N}; d(m, n) \leq 1 + \frac{1}{2n} \right\}, \quad n \in \mathbb{N}.$$

As the inequality in their definition is not strict, it is guaranteed that they are closed sets. Since  $A_n = \{n, n + 1, \dots\}$ , it follows that  $\{A_n\}$  are nested, but with empty intersection (contrary to (1)). If the requirement (1) is omitted, then the metric space is not complete, contradicting the data. Of course, in this case the condition (1) is not met, as

$$\begin{aligned} & \limsup_{n \rightarrow \infty} \{d(x, y); x, y \in A_n\} \\ &= \lim_{n \rightarrow \infty} \left( 1 + \frac{1}{2n + 1} \right) = 1 \neq 0. \end{aligned}$$

□

**7.C.22.** Determine whether the set (known as the Hilbert cube)

$$A = \left\{ \{x_n\}_{n \in \mathbb{N}} \in \ell_2; |x_n| \leq \frac{1}{n}, n \in \mathbb{N} \right\}$$

is compact in  $\ell_2$ . Then determine the compactness of the set

$$B = \left\{ \{x_n\}_{n \in \mathbb{N}} \in \ell_\infty; |x_n| < \frac{1}{n}, n \in \mathbb{N} \right\}$$

in the space  $\ell_\infty$ .

**Solution.** The space  $\ell_2$  is complete (see 7.C.16). Every closed subset of a complete metric space defines a complete metric space. The set  $A$  is evidently closed in  $\ell_2$ , so it suffices to show that it is totally bounded, and from the theorem 7.3.13(3) it is compact. To do that, construct an  $\varepsilon$ -net of  $A$  for any given  $\varepsilon > 0$ : Begin with the well-known series

$$\sum_{k=1}^{\infty} \frac{1}{k^2} = \frac{\pi^2}{6}$$

(see (1)).

For every  $\varepsilon > 0$ , there is an  $n(\varepsilon) \in \mathbb{N}$  satisfying

$$\sqrt{\sum_{k=n(\varepsilon)+1}^{\infty} \frac{1}{k^2}} < \frac{\varepsilon}{2}.$$

From each of the intervals  $[-1/n, 1/n]$  for  $n \in \{1, \dots, n(\varepsilon)\}$ , choose finitely many points  $x_1^n, \dots, x_{m(n)}^n$  so that for any  $x \in [-1/n, 1/n]$  that

$$\min_{j \in \{1, \dots, m(n)\}} |x - x_j^n| < \frac{\varepsilon}{\sqrt{5^n}}.$$

Consider such sequences  $\{y_n\}_{n \in \mathbb{N}}$  from  $\ell_2$  whose terms with indices  $n > n(\varepsilon)$  are zero, and at the same time,

$$y_1 \in \left\{ x_1^1, \dots, x_{m(1)}^1 \right\}, \dots, y_{n(\varepsilon)} \in \left\{ x_1^{n(\varepsilon)}, \dots, x_{m(n(\varepsilon))}^{n(\varepsilon)} \right\}.$$

There are only finitely many such sequences and they create the desired  $\varepsilon$ -net for  $A$ : let  $x_n \in \ell_2$  is arbitrary. According to our choice of the sequences  $y_n$ , there is  $y_n$  such that

**7.3.12. Bounded and compact sets.** The following concepts facilitated our discussions when dealing with the real and complex numbers. They can be reformulated for general metric spaces with almost no change:

An *interior point* of a subset  $A$  in a metric space is such an element of  $A$  which belongs to it together with some of its  $\varepsilon$ -neighbourhoods.

A *boundary point* of a set  $A$  is an element  $x \in X$  such that each its neighbourhood has a non-empty intersection with both  $A$  and the complement  $X \setminus A$ . A boundary point may or may not belong to the set  $A$  itself.

A *limit point* of a set  $A$  is an element  $x$  equal to the limit of a sequence  $x_i \in A$ , such that  $x_i \neq x$  for all  $i$ . Clearly a limit point may or may not belong to the set  $A$ .

An *isolated point* of a set  $A$  is an element  $a \in A$  such that one of its  $\varepsilon$ -neighbourhoods in  $X$  has the singleton intersection  $\{a\}$  with  $A$ .

An *open cover* of a set  $A$  is a system of open sets  $U_i \subset X$ ,  $i \in I$ , such that their union contains  $A$ .

COMPACT SETS

A metric space  $X$  is called *compact* if every sequence of points  $x_i \in X$  has a subsequence converging to some point  $x \in X$ .

Any subset  $A \subset X$  in a metric space is called *compact* if it is compact as the metric space with the restricted metric.

Clearly, the compact subsets in discrete metric spaces  $X$  are exactly the finite subsets of  $X$ .

In the case of the real numbers  $\mathbb{R}$  and complex numbers  $\mathbb{C}$ , our definition reveals the compact subsets discussed there and we would also like to come to useful properties as we did for real and complex numbers in the paragraphs 5.2.7–5.2.8.

Just as an appetizer, notice that the continuous functions between general metric spaces behave as the real functions:

**Theorem.** Let  $f : X \rightarrow Y$  be a continuous mapping between metric spaces. Then the images of compact sets are compact.

**PROOF.** Recall that any convergent sequence of points  $x_i \rightarrow x$  in  $X$  is mapped onto the convergent sequence  $f(x_i) \rightarrow f(x)$  in  $Y$ . Thus, the statement follows immediately from our definition of the compactness via convergent subsequences. □

In particular we obtain the most useful consequence on the minima and maxima of continuous real valued functions on compact subsets:

**Corollary.** Let  $f : X \rightarrow \mathbb{R}$  be a real function defined on a compact metric space. Then there are the points  $x_0$  and  $y_0$  in  $X$  such that

$$f(x_0) = \max_{x \in X} \{f(x)\}, \quad f(y_0) = \min_{x \in X} \{f(x)\}.$$

**PROOF.** The image  $f(X)$  must be a compact subset in  $\mathbb{R}$ , thus it must achieve both maximum and minimum (which are

$$\begin{aligned}
 d(x_n, y_n) &= \sqrt{\sum_{k=1}^{\infty} (x_k - y_k)^2} \\
 &\leq \sqrt{\sum_{k=1}^{n(\varepsilon)} (x_k - y_k)^2} + \sqrt{\sum_{k=n(\varepsilon)+1}^{\infty} x_k^2} \\
 &\leq \sqrt{\frac{\varepsilon^2}{5} + \frac{\varepsilon^2}{5^2} + \cdots + \frac{\varepsilon^2}{5^{n(\varepsilon)}}} + \frac{\varepsilon}{2} \\
 &< \varepsilon \cdot \sqrt{\frac{1}{1 - \frac{1}{5}} - 1} + \frac{\varepsilon}{2} = \varepsilon.
 \end{aligned}$$

Since  $\varepsilon > 0$  is arbitrary, the set  $A$  is totally bounded, which implies compactness.

The closure of the set  $B$  is

$$\bar{B} = \left\{ \{x_n\}_{n \in \mathbb{N}} \in l_{\infty}; |x_n| \leq \frac{1}{n}, n \in \mathbb{N} \right\}.$$

Hence  $B$  is not closed, and so it is not compact. The set  $\bar{B}$  is compact. The proof of this fact is much simpler than for the set  $A$ , thus we leave it as an exercise for the reader.  $\square$

**7.C.23.** Prove that on each metric space  $X$ , the given metric  $d$  is a continuous function  $X \times X \rightarrow \mathbb{R}$ .  $\circ$

**7.C.24.** Show that if  $F$  is a continuous mapping on a compact metric space  $X$ , then the inequality

$$d(F(x), F(y)) < d(x, y),$$

for all  $x \neq y$ , implies the existence of a fixed point.

**Solution.** The infimum  $\alpha$  of the values of the continuous function  $d(x, F(x))$  must be achieved in a point  $x_0 \in X$  (see 7.3.12 for the concepts and main results and use the previous result 7.C.23). Since distances are non-negative,  $\alpha \geq 0$ . If  $\alpha \neq 0$ , then

$$d(F(x_0), F(F(x_0))) < d(x_0, F(x_0)) = \alpha$$

which is a contradiction.  $\square$

the supremum and the infimum of the bounded and closed image).  $\square$

The concept of boundedness is a little more complicated in the case of general metric spaces. For any point  $x$  and subset  $B \subset X$  in a metric space  $X$  with metric  $d$ , we define their *distance*<sup>4</sup>

$$\text{dist}(x, B) = \inf_{y \in B} \{d(x, y)\}.$$

We say that a metric space  $X$  is *totally bounded* if for every positive real number  $\varepsilon$ , there is a finite set  $A$  such that

$$\text{dist}(x, A) < \varepsilon$$

for all points  $x \in X$ . We call such an  $A$  an  $\varepsilon$ -net of  $X$ .

Note that a metric space is *bounded* if  $X$  has a finite diameter. We can immediately see that a totally bounded space is always bounded. Indeed, the diameter of a finite set is finite, and if  $A$  is the set corresponding to  $\varepsilon$  from the definition of total boundedness, then the distance  $d(x, y)$  of two points can always be bounded by the sum of  $\text{dist}(x, A)$ ,  $\text{dist}(y, A)$ , and  $\text{diam } A$ , which is a finite number.

In the case of a metric on a subset of a finite-dimensional Euclidean space, these concepts coincide since the boundedness of a set guarantees the boundedness of all coordinates in a fixed orthonormal basis, and this implies total boundedness. (Verify this in detail by yourselves!)

The next theorem provides the promised very useful alternative characterisations of compactness:

**7.3.13. Theorem.** *The following statements about a metric space  $X$  are equivalent:*

- (1)  $X$  is compact;
- (2) every open covering of  $X$ ,  $X = \cup_{i \in I} U_i$ , contains a finite covering  $X = \cup_{k=1}^n U_{j_k}$ , where all  $j_k \in I$ ;
- (3)  $X$  is complete and totally bounded.

**PROOF.** We show consecutively the implications (1)  $\implies$  (3)  $\implies$  (2)  $\implies$  (1).

Thus, start assuming  $X$  is compact. Then for each Cauchy sequence of points  $x_i$ , there is a sub-sequence  $x_{i_n}$  converging to a point  $x \in X$ . We just have to verify that the initial sequence also converges to the same limit,  $x_i \rightarrow x$ . This is easy and we leave it to the reader. So  $X$  is complete.

Suppose  $X$  is not totally bounded. Then there is  $\varepsilon > 0$  such that no finite  $\varepsilon$ -net exists in  $X$ . Then there is a sequence of points  $x_i$  such that  $d(x_i, x_j) \geq \varepsilon$  for all  $i \neq j$ . (Verify this almost obvious claim – look at the definition of  $\varepsilon$ -nets!) Then this is a sequence of points, where no sub-sequence can be a Cauchy sequence, so  $X$  is not compact. This contradicts (1), so we conclude that  $X$  is totally bounded.

<sup>4</sup>Notice, that the distance between two subsets  $A, B \subset X$  should express how “different” they are. Thus we define the (Hausdorff) distance as follows  $\text{dist}(A, B) = \max\{\sup\{\text{dist}(x, B), x \in A\}, \sup\{\text{dist}(y, A), y \in B\}\}$ . This difference is finite for bounded sets and it is easy to see that it vanishes if and only if the closures of  $A$  and  $B$  coincide. This means, the distances of the point  $x$  and one-point set  $\{x\}$  are very much different,  $\text{dist}(x, A) \neq \text{dist}(\{x\}, A)$ , in general.

The next implication, namely (3)  $\implies$  (2) is more demanding. So assume  $X$  is complete and totally bounded, but  $X$  does not satisfy (2).

Then there is an open covering  $U_\alpha$ ,  $\alpha \in I$ , of  $X$ , which does not contain any finite covering. Choose a sequence of positive real numbers  $\varepsilon_k \rightarrow 0$  and consider the finite  $\varepsilon_k$ -nets from the definition of total boundedness. Further, for each  $k$ , consider the system  $\mathcal{A}_k$  of closed balls with centres in the points of the  $\varepsilon_k$ -net and diameters  $2\varepsilon_k$ . Clearly each such system  $\mathcal{A}_k$  covers the entire space  $X$ . Altogether, there must be at least one closed ball  $C$  in the system  $\mathcal{A}_1$  which is not covered by a finite number of the sets  $U_\alpha$ . Call it  $C_1$  and notice that  $\text{diam } C_1 = 2\varepsilon_1$ .

Next, consider the sets  $C_1 \cap C$ , with balls  $C \in \mathcal{A}_2$  which cover the entire set  $C_1$ . Again, at least one of them cannot be covered by a finite number of  $U_\alpha$ , we call it  $C_2$ . This way, we inductively construct a sequence of sets  $C_k$  satisfying  $C_{k+1} \subset C_k$ ,  $\text{diam } C_k \leq 2\varepsilon_k$ ,  $\varepsilon_k \rightarrow 0$ , and none of them can be covered by a finite number of the open sets  $U_\alpha$ .

Finally we choose one point  $x_k \in C_k$  in each of these sets. By construction, this must be a Cauchy-sequence. Consequently, this sequence of points has a limit  $x$  since  $X$  is complete. Thus there is  $U_{\alpha_0}$  containing  $x$  and containing also some  $\delta$ -neighbourhood  $B_\delta(x)$ . But now, if  $\text{diam } C_k \leq 2\varepsilon_k < \delta$ , then  $C_k \subset B_\delta(x) \subset U_{\alpha_0}$ , which is a contradiction.

The remaining step is to show the implication (2)  $\implies$  (1). Assume (2) and considering any sequence of points  $x_i \in X$ , we set  $C_n = \{x_k; k \geq n\}$ . The intersection of these sets must be non-empty by the following general lemma:

**Lemma.** *Let  $X$  be a metric space such that property (2) in the Theorem holds. Consider a system of closed sets  $D_\alpha$ ,  $\alpha \in I$ , such that each its finite subsystem  $D_{\alpha_1}, \dots, D_{\alpha_k}$  has non-empty intersection. Then also*

$$\bigcap_{\alpha \in I} D_\alpha \neq \emptyset.$$

This simple lemma is proved by contradiction, again. If the latter intersection is empty, then

$$X = X \setminus (\bigcap_{\alpha \in I} D_\alpha) = \bigcup_{\alpha \in I} (X \setminus D_\alpha) = \bigcup_{\alpha \in I} V_\alpha,$$

where  $V_\alpha = X \setminus D_\alpha$  are open sets. Thus, there must be a finite number of them,  $\{V_{\alpha_1}, \dots, V_{\alpha_n}\}$ , covering  $X$  too. Thus, we obtain

$$X = \bigcup_{i=1}^n V_{\alpha_i} = \bigcup_{i=1}^n (X \setminus D_{\alpha_i}) = X \setminus (\bigcap_{i=1}^n D_{\alpha_i}).$$

This is a contradiction with our assumptions on  $D_\alpha$  and the lemma is proved.

Now, let  $x \in \bigcap_{n=1}^\infty C_n$ . By construction, there is a subsequence  $x_{n_k}$  in our sequence of points  $x_n \in X$ , so that  $d(x_{n_k}, x) < 1/k$ . This is a converging subsequence, and so the proof is complete.  $\square$

As an immediate corollary of the latter theorem, each closed subset in a compact metric space is again compact. For subsets of a totally bounded set are totally bounded, and closed subsets of a complete metric space are also complete.

Another consequence is an alternative proof that a subset  $K \subset \mathbb{R}^n$  is compact, if and only if it is closed and bounded.

Notice also that while the conditions (1) and (3) are given in terms of the metric, the equivalent condition (2) is purely topological.

**7.3.14. Continuous functions.** We revisit the questions related to continuity of mappings between metric spaces. In fact, many ideas understood for the functions of one real variable generalize naturally.

In particular, as we already showed, every continuous function  $f : X \rightarrow \mathbb{R}$  on a compact set  $X$  is bounded and achieves its maximum and minimum. Here is another argument for this using the purely topological concept of compactness:

Consider the open intervals  $U_n = (n - 1, n + 1) \subset \mathbb{R}$ ,  $n \in \mathbb{Z}$  covering  $\mathbb{R}$ . Then their preimages  $f^{-1}(U_i)$  cover  $X$ , so that there is a finite number of them, covering  $X$  as well. Thus  $f$  is bounded and the supremum and infimum of its values exist. Consider sequences  $f(x_n)$  and  $f(y_n)$  converging to the supremum and infimum, respectively. Then there must be convergent subsequences of the points  $x_n$  and  $y_n$  in  $X$  and their limits  $x$  and  $y$  are in  $X$  too. But then  $f(x)$  and  $f(y)$  are the supremum and infimum of the values of  $f$  since  $f$  is continuous and thus respects convergence.

We should also enjoy to see the differences between the “purely topological” concepts, as the continuity (possibly defined merely by means of open sets), and the next stronger concepts, which are “metric” properties.

UNIFORMLY CONTINUOUS MAPPINGS

A mapping  $f : X \rightarrow Y$  between metric space is called *uniformly continuous*, if for each  $\varepsilon > 0$  there is a  $\delta > 0$ , such that  $d_Y(f(x), f(y)) < \varepsilon$  for all  $x, y \in X$  with  $d_X(x, y) < \delta$ .

Notice the following simple lemma:

**Lemma.** *A mapping  $f : X \rightarrow Y$  between metric spaces is uniformly continuous if and only if for each pair of sequences  $x_k$  and  $y_k$  in  $X$ ,  $d_X(x_k, y_k) \rightarrow 0$  implies  $d_Y(f(x_k), f(y_k)) \rightarrow 0$ .*

**PROOF.** If  $f$  is uniformly continuous, then the the claim on the sequences is obvious.

Now, assume the property of sequences holds true, but  $f$  is not uniformly continuous. Then, employing the negation of the defining property, there is an  $\varepsilon > 0$  such that for all  $\delta = 1/n$ , there are  $x_n, y_n$  with  $d_X(x_n, y_n) < 1/n$  and  $d_Y(f(x_n), f(y_n)) \geq \varepsilon$ . But this violates the assumed condition. □

This observation leads to the following generalization of the behavior of real functions:

**Theorem.** *Each continuous mapping  $f : X \rightarrow Y$  on a compact metric space  $X$  is uniformly continuous.*

PROOF. Assume  $f$  is a continuous function. Consider any two sequences  $x_k$  and  $y_k$  with  $d_X(x_k, y_k) \rightarrow 0$  and assume their images do not satisfy  $d_Y(f(x_k), f(y_k)) \rightarrow 0$ . Then, for some  $\varepsilon > 0$ , there must be a subsequence  $(x_{k_n}, y_{k_n})$  for which  $d_Y(f(x_{k_n}), f(y_{k_n})) > \varepsilon$ .

Since  $X$  is compact, there is a further subsequence of  $x_{k_n}$  converging to some point  $x \in X$ . Without loss of generality, we may assume that the original sequence  $(x_k, y_k)$  has got all these properties (we are aiming at a conflict with our assumption that  $f$  is not uniform continuous). Of course,  $d_X(x, y_k) \leq d_X(x, x_k) + d_X(x_k, y_k) \rightarrow 0$  and so  $\lim_{k \rightarrow \infty} y_k = x$ , too.

Next, notice that the metric  $d_Y : Y \times Y \rightarrow \mathbb{R}$  is always a continuous function. Indeed, remind the definition of the product metric on  $X \times X$  by the maximum of the distances of the components, see 7.C.1. With this definition, the continuity of  $d$  is obvious from the estimate

$$|d(x, y) - d(x', y')| \leq d(x, x') + d(y, y'),$$

cf. 7.3.8(1).

Now, the continuity of  $f$  ensures

$$\lim_{k \rightarrow \infty} d_Y(f(x_k), f(y_k)) = d_Y(f(x), f(x)) = 0.$$

But this violates our assumption on the sequences and the proof is complete.  $\square$

A very useful variation on the theme of continuity is the following definition.

#### LIPSCHITZ CONTINUITY

A function  $f : X \rightarrow Y$  between metric spaces is called *Lipchitz continuous* if there is a constant  $C > 0$  such that for all points  $x, y \in X$

$$d_Y(f(x), f(y)) \leq C d_X(x, y).$$

Every Lipschitz continuous function is uniformly continuous.

**7.3.15. Arzelà-Ascoli Theorem.** To conclude, we consider some spaces of functions. These provide examples of how much they may differ from the usual Euclidean spaces. First, we introduce some terminology. Basically we want to deal with functions, which are all uniformly continuous in the very same way:

#### EQUICONTINUOUS FUNCTIONS

Consider a space  $M$  of mappings  $f : X \rightarrow Y$  between metric spaces. We say that the functions in  $M$  are *equicontinuous*, if for each  $\varepsilon > 0$  there is a  $\delta > 0$ , such that  $d_Y(f(x), f(y)) < \varepsilon$  for all  $x, y \in X$  with  $d_X(x, y) < \delta$ , for all functions  $f \in M$ .

Consider the metric space  $\mathcal{C}(X)$  of all continuous (real or complex) functions on a compact metric space  $X$ , with its  $\|\cdot\|_\infty$  norm. This means that the distance between two functions  $f, g$  is the maximum of the distance between their values  $f(x)$  and  $g(x)$  for  $x \in X$ .

We say that a set  $M \subset \mathcal{C}(X)$  of real functions is *uniformly bounded*, if there is a constant  $K \in \mathbb{R}$  such that  $|f(x)| \leq K$  for all functions  $f \in M$  and points  $x \in X$ . Of course, bounded sets  $M$  of functions in  $\mathcal{C}(X)$  are always uniformly bounded, by the definition of the norm.

**Theorem.** Consider a compact metric space  $X$ . A set  $M \subset \mathcal{C}(X)$  in the space of continuous functions with the supremum norm  $\|\cdot\|_\infty$  is compact if and only if it is bounded, closed, and equicontinuous.<sup>5</sup>

**PROOF.** Suppose  $M$  is compact. Then  $M$  is totally bounded (and thus also uniformly bounded as noticed above). Since every compact subset is closed, it remains to verify the equicontinuity.

Given  $\varepsilon > 0$ , consider the corresponding  $\varepsilon$ -net  $(f_1, f_2, \dots, f_k) \subset M$  from the definition of the total boundedness of  $M$ . Recall that all the functions  $f_i$  are uniformly continuous (as continuous functions on a compact set). Thus there is a  $\delta_i$  for each  $f_i$ , such that  $d_X(x, y) < \delta_i$  implies  $|f_i(x) - f_i(y)| < \varepsilon$ .

Of course, we take  $\delta$  to be the minimum of the finite many  $\delta_i$ ,  $i = 1, \dots, k$ . Then the same equality holds for all  $f_i$  in the  $\varepsilon$ -net. But now, considering an arbitrary function  $f \in M$ , there is a function  $f_j$  in our  $\varepsilon$ -net with  $\|f - f_j\|$  and so  $d_X(x, y) < \delta$  implies that  $|f(x) - f(y)|$  is at most

$$|f(x) - f_j(x)| + |f_j(x) - f_j(y)| + |f_j(y) - f(y)| \leq 3\varepsilon,$$

and the equicontinuity has been proved.

Conversely, suppose that  $M$  is a bounded, closed, and equicontinuous subset of  $\mathcal{C}(X)$ , with  $X$  as a compact metric space.

First we show that  $M$  is complete. Obviously, a Cauchy sequence in the  $\|\cdot\|_\infty$  norm is also pointwise Cauchy sequence of real or complex numbers. Thus the sequence of functions converges pointwise. Next, the pointwise limit must be bounded and the equicontinuity property implies that this limit will be continuous as well.

Thus, we need to find a Cauchy (sub)sequence within any sequence of functions  $f_n \in M$ .

The compact space  $X$  itself is totally bounded and therefore it contains a countably dense set  $A \subset X$  (we may take the points in all  $1/k$ -nets for  $k \in \mathbb{N}$ ). Write  $A = \{a_1, a_2, \dots\}$  as a sequence.

Choose a subsequence of functions  $f_{1j}$ ,  $j = 1, 2, \dots$  within the functions  $f_n$ , so that the sequence of values  $f_{1j}(a_1)$  converges. (This is possible, since the set  $M$  is bounded in the  $\|\cdot\|_\infty$  norm). Similarly, the subsequence  $f_{2j}$  can be chosen from  $f_{1k}$ , so that  $f_{2j}(a_2)$  converges. In general, the  $m$ -th subsequence is chosen from  $f_{(m-1)k}$  and have the values  $f_{mj}(a_m)$  converging (and by our construction, it converges in all  $a_i$ ,  $i < m$  too).

<sup>5</sup>A weaker version providing a sufficient condition was first published by Ascoli in 1883, the complete exposition was given by Arzelà in 1895. Again, there are much more general versions of this theorem in the realm of topological spaces.

As a result, we can choose the sequence of function  $g_k = f_{kk}$  for all positive integers  $k$  with the hope that this is a Cauchy sequence. This is where the equicontinuity helps.

Start with any  $\varepsilon > 0$  and find  $\delta_\varepsilon > 0$ , such that  $|f(x) - f(y)| < \varepsilon$  whenever the arguments  $x$  and  $y$  are closer than  $\delta_\varepsilon$ . Let  $A_\varepsilon \subset A$  be subset forming a  $\delta_\varepsilon$ -net. This is a finite set and so there must be an  $n \in \mathbb{N}$  such that for all  $i, j \geq n$  and all  $a \in A_\varepsilon$ , we know  $|g_i(a) - g_j(a)| < \varepsilon$ . But then, for every  $x \in X$ , there is some  $a \in A_\varepsilon$  with  $d_X(x, a) < \delta_\varepsilon$  and so  $|g_i(x) - g_j(x)|$  can be at most

$$|g_i(x) - g_i(a)| + |g_i(a) - g_j(a)| + |g_j(a) - g_j(x)| \leq 3\varepsilon.$$

Thus, the sequence  $g_k$  is a Cauchy sequence in  $C(X)$ , and so  $M$  is compact.  $\square$

**D. Additional exercises to the whole chapter**

Let us begin this section with problems similar to those described in the introduction of Chapter 7. (cf. 7.A.1, 7.A.2).

**7.D.1.** Let  $\mathcal{S}^0[0, 1]$  be the space of  $\mathbb{F}$ -valued piecewise continuous functions defined on  $[0, 1]$ , where  $\mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$ , endowed with the  $L_2$ -inner product

$$\langle f, g \rangle := \int_0^1 f(x)\overline{g(x)} dx.$$

With respect to the induced norm  $\|\cdot\|_2$  compute:

- (a)  $\|f\|_2$ , where  $f(x) = x + b$ , with  $b$  being some constant;
- (b) the distance  $\|f - g\|_2$  between  $f(x) = \cos(2\pi x)$  and  $g(x) = \sin(2\pi x)$ .

**Solution.** (a) By definition,  $\|f\|_2 = \sqrt{\langle f, f \rangle} = \sqrt{\int_0^1 (x + b)^2 dx}$ , and we easily compute that

$$\int_0^1 (x + b)^2 dx = \left[ \frac{x^3}{3} \right]_0^1 + 2 \left[ \frac{bx^2}{2} \right]_0^1 + [b^2x]_0^1 = \frac{1}{3} + b + b^2.$$

Thus  $\|f\|_2 = \sqrt{\frac{1}{3} + b + b^2}$ .

For (b) and the distance between the given  $f, g$ , we compute

$$\begin{aligned} \langle f - g, f - g \rangle &= \int_0^1 (\cos(2\pi x) - \sin(2\pi x))^2 dx = \int_0^1 (1 - 2\cos(2\pi x)\sin(2\pi x)) dx = \int_0^1 (1 - \sin(4\pi x)) dx \\ &= \left[ x - \frac{\cos(4\pi x)}{4\pi} \right]_0^1 = 1, \end{aligned}$$

where the third equality relies on the identity  $\sin(2t) = 2\sin(t)\cos(t)$ . Thus  $\|f - g\|_2 = \sqrt{1} = 1$ . □

**7.D.2.** Compute the  $L_2$ -norm of the function  $f(x) = e^{ix}$ , defined on the interval  $[-\pi, \pi]$ .

**Solution.** We can express  $f$  as  $f(x) = e^{ix} = \cos(x) + i\sin(x)$ , for all  $x \in [-\pi, \pi]$ . Then, with respect to  $L_2$ -product we see that

$$\langle f, f \rangle = \int_{-\pi}^{\pi} (\cos(x) + i\sin(x))(\cos(x) - i\sin(x)) dx = \int_{-\pi}^{\pi} (\cos^2(x) + \sin^2(x)) dx = \int_{-\pi}^{\pi} dx = 2\pi.$$

Thus  $\|f\|_2 = \sqrt{2\pi}$ . □

**7.D.3.** Consider the vector space  $\mathbb{R}_3[x]$  of polynomials of one variable of degree at most 3 with real coefficients, endowed with the  $L_2$ -inner product (i.e., the same inner product  $\langle \cdot, \cdot \rangle$  as the one in Problem 7.D.1). Let  $W$  be the subspace of  $\mathbb{R}_3[x]$  having as basis the set  $B = \{x, x^2\}$ . Find an orthonormal basis of  $W$  with respect to  $\langle \cdot, \cdot \rangle$ .

**Solution.** Set  $E_1 = x$  and  $E_2 = x^2$ . The Gram-Schmidt procedure states that an orthogonal basis of  $W$  is given by

$$\left\{ w_1 = E_1, \quad w_2 = E_2 - \frac{\langle E_2, w_1 \rangle}{\|w_1\|_2^2} w_1 \right\}.$$

We compute

$$\langle E_2, w_1 \rangle = \int_0^1 x^3 dx = \frac{x^4}{4} \Big|_0^1 = \frac{1}{4}, \quad \text{and} \quad \langle w_1, w_1 \rangle = \int_0^1 x^2 dx = \frac{x^3}{3} \Big|_0^1 = \frac{1}{3}.$$

Thus  $w_2 = E_2 - \frac{3}{4}E_1 = x^2 - \frac{3}{4}x$ . As a verification, observe that

$$\langle w_1, w_2 \rangle = \langle x, x^2 - \frac{3}{4}x \rangle = \frac{1}{4} - \frac{3}{4} \cdot \frac{1}{3} = 0.$$

Consequently, an orthonormal basis of  $W$  is given by the “vectors”  $\{\hat{w}_1 = \frac{w_1}{\|w_1\|_2}, \hat{w}_2 = \frac{w_2}{\|w_2\|_2}\}$ , where  $\|w_1\|_2 = \frac{1}{\sqrt{3}}$  and

$$\|w_2\|_2 = \sqrt{\int_0^1 \left(x^2 - \frac{3}{4}x\right)^2 dx} = \frac{1}{\sqrt{80}},$$

respectively. □

**7.D.4.** Consider the inner vector space  $(\mathbb{R}_3[x], \langle \cdot, \cdot \rangle)$  of the previous task 7.D.3, and let  $W$  be the subspace of  $\mathbb{R}_3[x]$  spanned by the basis  $\{1, x^2\}$ . Find a basis of the orthogonal complement  $W^\perp$  of  $W$  with respect to  $\langle \cdot, \cdot \rangle$ .

**Solution.** By assumption  $W$  is spanned by the set  $\{1, x^2\}$ . Thus, a vector  $f(x) = a_3x^3 + a_2x^2 + a_1x + a_0 \in W^\perp$  in  $W^\perp$  must satisfy

$$\langle f(x), 1 \rangle = 0, \quad \text{and} \quad \langle f(x), x^2 \rangle = 0.$$

This gives the following system of equations

$$\left\{ \frac{a_3}{4} + \frac{a_2}{3} + \frac{a_1}{2} + a_0 = 0, \quad \frac{a_3}{6} + \frac{a_2}{5} + \frac{a_1}{4} + \frac{a_0}{3} = 0 \right\}.$$

We can solve this in Sage via the cell

```
var("a3", "a2", "a1", "a0")
solve([(1/4)*a3+(1/3)*a2+(1/2)*a1+a0==0, (1/6)*a3+(1/5)*a2+(1/4)*a1+(1/3)*a0==0], a3, a2, a1, a0)
```

Sage returns the solution

```
[a3 == 16*r1 + 3*r2, a2 == -15*r1 - 15/4*r2, a1 == r2, a0 == r1]
```

which means that  $a_3 = 16a + 3b$  and  $a_2 = -15(a + \frac{b}{4})$  with  $a_1 = b \in \mathbb{R}$  and  $a_0 = a \in \mathbb{R}$  being the free variables. Thus

$$f(x) = b(3x^3 - \frac{15}{4}x^2 + x) + a(16x^3 - 15x^2 + 1),$$

and this implies that  $W^\perp = \text{span}\{f_1(x), f_2(x)\}$ , where  $f_1(x) = 3x^3 - \frac{15}{4}x^2 + x$  and  $f_2(x) = 16x^3 - 15x^2 + 1$ , respectively. It remains to prove that  $f_1(x), f_2(x)$  are linearly independent which one can easily check (for instance one may compute the Wronskian as in the Problem 6.D.16). Thus  $\{f_1, f_2\}$  is a basis of  $W^\perp$ .  $\square$

**7.D.5.** Given the vector subspace  $\langle \sin(x), x \rangle$  of the space of continuous real-valued functions defined on the interval  $[0, \pi]$ , complete the function  $x$  to an orthogonal basis of the subspace and determine the orthogonal projection of the function  $\frac{1}{2} \sin(x)$  onto it.  $\circ$

**7.D.6.** Given the vector subspace  $\langle \cos(x), x \rangle$  of the space of continuous real-valued functions defined on the interval  $[0, \pi]$ , complete the function  $\cos(x)$  to an orthogonal basis of the subspace and determine the orthogonal projection of the function  $\sin(x)$  onto it.  $\circ$

**7.D.7.** Show that the system of functions  $1, \sin(x), \cos(x), \dots, \sin(nx), \cos(nx), \dots$  is orthogonal with respect to the  $L_2$  inner product on the interval  $I = [-\pi, \pi]$ .  $\circ$

*Next we will focus on tasks about Fourier series of periodic functions, and their convergence.*

**7.D.8.** Let  $f : (-\pi, \pi) \rightarrow \mathbb{R}$  be the piecewise function defined by

$$f(x) = \begin{cases} -1, & \text{if } -\pi < x < -\pi/3, \\ 0, & \text{if } -\pi/3 \leq x \leq \pi/3, \\ 1, & \text{if } \pi/3 < x < \pi. \end{cases}$$

- (1) Find the  $2\pi$ -periodic extension of  $f$  and sketch its graph via Sage for  $x \in (-3\pi, 3\pi)$ ;
- (2) Prove that the Fourier series  $F$  of the  $2\pi$ -periodic extension of  $f$  is a sine series. Next determine explicitly  $F$ ;
- (3) Use Sage to verify your computations in (2);
- (4) Present the 5th partial sum of the approximation. Next confirm your result via Sage and plot  $F_5, F_{10}, F_{20}$  and  $F_{100}$  together with  $f$ , for  $x \in (-\pi, \pi)$ .
- (5) Use Sage to specify the 5th, 10th, and 100th coefficient of the Fourier series  $F$  corresponding to  $f$ .

**Solution.** (1) The  $2\pi$ -periodic extension of  $f$  is defined by  $\hat{f}(x) = f(x)$  for all  $-\pi < x < \pi$  with  $\hat{f}(x) = \hat{f}(x + 2\pi)$  for all  $x \in \mathbb{R}$ . In Sage to plot this periodic extension for  $x \in (-3\pi, 3\pi)$  we can use appropriately the `piecewise` function. In particular, the block

```
f1(x)=-1; f2(x)=0; f3(x)=1
f=piecewise([( (-3*pi, -7*pi/3), f1), [(-7*pi/3, -5*pi/3), f2], [(-5*pi/3, -pi), f3], [(-pi, -pi/3), f1],
[(-pi/3, pi/3), f2], [(pi/3, pi), f3], [(pi, 5*pi/3), f1], [(5*pi/3, 7*pi/3), f2], [(7*pi/3, 3*pi), f3]])
a = f.plot(x, -3*pi, 3*pi, thickness=2, color="red",
exclude=[-7*pi/3, -5*pi/3, -pi, -pi/3, pi/3, pi, 5*pi/3, 7*pi/3])
a.show(ticks=pi/3, tick_formatter=pi)
```

produces the following figure:

Here one may avoid to use the `exclude` option (to exclude the jump discontinuities) and in this case Sage will produce the figure given in the r.h.s, where the vertical lines should not be considered as part of the required graph.

(2) It is easy to see that  $f(x)$  (and hence  $\hat{f}$ ) is an odd function, thus  $a_n = 0$  for all  $n \in \mathbb{N}$ . Consequently the Fourier series of  $f$  is a sine series. As for  $b_n$ , first notice that the function  $g(x) := f(x) \sin(nx)$  satisfies

$$g(x) = \begin{cases} -\sin(nx), & \text{if } -\pi < x < -\pi/3, \\ 0, & \text{if } -\pi/3 \leq x \leq \pi/3, \\ \sin(nx) & \text{if } \pi/3 < x < \pi, \end{cases} \quad \text{and} \quad g(-x) = \begin{cases} \sin(nx), & \text{if } \pi/3 < x < \pi, \\ 0, & \text{if } -\pi/3 \leq x \leq \pi/3, \\ -\sin(nx), & \text{if } -\pi < x < -\pi/3. \end{cases}$$

Thus  $g(-x) = g(x)$  for all  $x \in (-\pi, \pi)$ , that is,  $g$  is an even function. Therefore,

$$\begin{aligned} b_n &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin(nx) dx = \frac{2}{\pi} \int_0^{\pi} f(x) \sin(nx) dx = \frac{2}{\pi} \left[ \int_0^{\pi/3} f(x) \sin(nx) dx + \int_{\pi/3}^{\pi} f(x) \sin(nx) dx \right] \\ &= \frac{2}{\pi} \int_{\pi/3}^{\pi} 1 \cdot \sin(nx) dx = \frac{2}{\pi} \left[ -\frac{\cos(nx)}{n} \right]_{\pi/3}^{\pi} = \frac{2}{n\pi} \left( -\cos(n\pi) + \cos\left(\frac{n\pi}{3}\right) \right) = \frac{2}{n\pi} \left( -(-1)^n + \cos\left(\frac{n\pi}{3}\right) \right) \\ &= \frac{2}{n\pi} \left( (-1)^{n+1} + \cos\left(\frac{n\pi}{3}\right) \right). \end{aligned}$$

Consequently, the Fourier series of the function at hand has the form  $F(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + \cos(\frac{n\pi}{3})}{n} \sin(nx)$ .

(3) To confirm the previous expression in Sage it suffices to confirm the expressions of the Fourier coefficients, which can be done via the method presented in 7.A.10, that is,

```
f1(x)=-1; f2(x)=0; f3(x)=1
g=piecewise([[(-pi, -pi/3), f1], [(-pi/3, pi/3), f2], [(pi/3, pi), f3]]); L=pi; n=var("n")
an=(1/L)*integral(f1(x)*cos(n*pi*x/L), x, -pi, -pi/3)+(1/L)*integral(f2(x)*cos(n*pi*x/L), x, -pi/3, pi/3)\
+(1/L)*integral(f3(x)*cos(n*pi*x/L), x, pi/3, pi); show("a_n=", an.expand())
bn=(1/L)*integral(f1(x)*sin(n*pi*x/L), x, -pi, -pi/3)+(1/L)*integral(f2(x)*sin(n*pi*x/L), x, -pi/3, pi/3)\
+(1/L)*integral(f3(x)*sin(n*pi*x/L), x, pi/3, pi); show("b_n=", bn.expand())
```

Executing this block, we obtained the desired result:

$$a_n=0, \quad b_n = -\frac{2 \cos(\pi n)}{\pi n} + \frac{2 \cos\left(\frac{1}{3} \pi n\right)}{\pi n}.$$

(4) An application of the given formula in (2) gives

$$F_5(x) = \frac{3 \sin(x)}{\pi} - \frac{3 \sin(2x)}{2\pi} - \frac{3 \sin(4x)}{4\pi} + \frac{3 \sin(5x)}{5\pi}.$$

To confirm this expression in Sage, simply add the following cell to the block above:

```
pS5 = f.fourier_series_partial_sum(5,pi); show("5th partial sum = ",pS5)
```

To generate the required graphs, include the following syntax in the initial block in (3):

```
pS5 = f.fourier_series_partial_sum(5,pi); pS10 = f.fourier_series_partial_sum(10,pi)
pS20 = f.fourier_series_partial_sum(20,pi); pS100 = f.fourier_series_partial_sum(100,pi)
a = f.plot(x, -pi, pi, thickness=2, color="red", legend_label=r"$f$", exclude=[-pi/3, pi/3])
```

```
s1 = plot(pS5, x, -pi, pi, linestyle="--", color="midnightblue", legend_label=r"$F_5$")
s2 = plot(pS10, x, -pi, pi, linestyle="--", color="midnightblue", legend_label=r"$F_{10}$")
s3 = plot(pS20, x, -pi, pi, linestyle="--", color="midnightblue", legend_label=r"$F_{15}$")
s4 = plot(pS100, x, -pi, pi, linestyle="--", color="midnightblue", legend_label=r"$F_{100}$")
(a+s1).show(); (a+s2).show(); (a+s3).show(); (a+s4).show()
```

Running the code all together, we obtain the following figures:

(5) By the result in (4) we already know the 5th coefficient which is given by  $\frac{3}{5\pi}$ . For a Sage description of the 10th and 100th coefficient of  $F$ , one can proceed as described in 7.A.14. In fact, the Fourier series is a sine series, hence we need the function `f.fourier_series_sine_coefficient(k)`, and the implementation of the method is as follows:

```
f1(x)=-1; f2(x)=0; f3(x)=1
f=piecewise([[(-pi, -pi/3), f1], [[-pi/3, pi/3], f2],[[pi/3, pi), f3]])
Fc5=f.fourier_series_sine_coefficient(5)
show("5th coefficient = ",Fc5)
Fc10=f.fourier_series_sine_coefficient(10)
show("10th coefficient = ",Fc10)
Fc100=f.fourier_series_sine_coefficient(100)
show("100th coefficient = ",Fc100)
```

This confirms the value of the 5th coefficient and additionally provides the values of the other two coefficients in question, namely:

$$10\text{th coefficient} = -\frac{3}{10\pi}, \quad 100\text{th coefficient} = -\frac{3}{100\pi}.$$

Can you guess which coefficient is the 1000th? □

**7.D.9. (Reverse) sawtooth function.** Consider the function defined by

$$f(x) = \begin{cases} \frac{\pi - x}{2}, & \text{if } 0 < x \leq 2\pi, \\ f(x + 2\pi), & \text{otherwise.} \end{cases}$$

- (1) Describe the given function  $f$  for  $x \in (-2\pi, 4\pi]$ , and next use Sage to plot its graph over this interval.
- (2) Find the Fourier series of  $f$  and next use Sage to confirm the result.

(3) Use Sage to plot the partial sums  $F_5$ ,  $F_8$ ,  $F_{15}$  and  $F_{50}$ , in one single figure.

(4) Examine the convergence of the Fourier series and show that

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots$$

**Solution.** (1) The given function  $f$  provides the  $2\pi$ -periodic extension of the function  $(\pi - x)/2$ , the latter defined on  $(0, 2\pi]$ .

Hence, it should be  $f(x) = f(x + 2\pi) = \frac{\pi - x - 2\pi}{2} = \frac{-\pi - x}{2}$ , for all  $x \in (-2\pi, 0]$  and  $f(x) = f(x - 2\pi) = \frac{\pi - x + 2\pi}{2} = \frac{3\pi - x}{2}$ , for all  $x \in (2\pi, 4\pi]$ , that is,

$$f(x) = \begin{cases} \frac{-\pi - x}{2}, & \text{if } -2\pi < x \leq 0, \\ \frac{\pi - x}{2}, & \text{if } 0 < x \leq 2\pi, \\ \frac{3\pi - x}{2}, & \text{if } 2\pi < x \leq 4\pi. \end{cases}$$

To sketch the graph of this piecewise function use the `piecewise` command, as before. For clarity, you may also mark the endpoints where  $f$  is defined (e.g., with black dots). This can be done using the command `point`, as follows:

```
f1(x)= (pi-x)/2;f2(x)= (-pi-x)/2;f3(x)= (3*pi-x)/2
f = piecewise([[(-2*pi, 0),f2], [(0, 2*pi),f1], [(2*pi, 4*pi), f3]])
p=f.plot(x, -2*pi, 4*pi, exclude=[0, 2*pi], legend_label=r"$f$")
p0=point([0, -pi/2], size=30, color="black")
p1=point([2*pi, -pi/2], size=30, color="black")
p2=point([4*pi, -pi/2], size=30, color="black")
show(p+p0+p1+p2)
```

Below one can see the produced plot:

(2) By assumption the period is  $2\pi$ , so the Fourier series has the form  $F(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos(nx) + b_n \sin(nx))$ , where

$$a_0 = \frac{1}{\pi} \int_0^{2\pi} f(x) dx, \quad a_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \cos(nx) dx, \quad b_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \sin(nx) dx.$$

First we will prove that  $a_n = 0$  for all  $n \in \mathbb{N}$ . It is very easy to see that  $a_0 = 0$ . Next, based on integration by parts, we get

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_0^{2\pi} f(x) \cos(nx) dx = \frac{1}{2\pi} \int_0^{2\pi} (\pi - x) \cos(nx) dx = \frac{1}{2} \int_0^{2\pi} \cos(nx) dx - \frac{1}{2\pi} \int_0^{2\pi} x \cos(nx) dx \\ &= \frac{1}{2} \left[ \frac{\sin(nx)}{n} \right]_0^{2\pi} - \frac{1}{2\pi} \int_0^{2\pi} x \cdot \left( \frac{\sin(nx)}{n} \right)' dx \\ &= \frac{1}{2n} (\sin(2n\pi) - \sin(0)) - \frac{1}{2\pi} \left( \left[ x \frac{\sin(nx)}{n} \right]_0^{2\pi} - \frac{1}{n} \int_0^{2\pi} \sin(nx) dx \right) \\ &= 0 - \frac{1}{2n\pi} (2\pi \sin(2n\pi) - 0) + \frac{1}{2n\pi} \left[ -\frac{\cos(nx)}{n} \right]_0^{2\pi} = 0 - 0 - \frac{1}{2n^2\pi} (\cos(2n\pi) - \cos(0)) = 0, \end{aligned}$$

for all positive integers  $n$ . In a similar way, for  $b_n$  we compute

$$\begin{aligned}
 b_n &= \frac{1}{\pi} \int_0^{2\pi} f(x) \sin(nx) dx = \frac{1}{2\pi} \int_0^{2\pi} (\pi - x) \sin(nx) dx = \frac{1}{2} \int_0^{2\pi} \sin(nx) dx - \frac{1}{2\pi} \int_0^{2\pi} x \sin(nx) dx \\
 &= -\frac{1}{2n} [\cos(nx)]_0^{2\pi} + \frac{1}{2\pi} \int_0^{2\pi} x \left( \frac{\cos(nx)}{n} \right)' dx \\
 &= -\frac{1}{2n} (\cos(2n\pi) - \cos(0)) + \frac{1}{2\pi} \left( \left[ x \frac{\cos(nx)}{n} \right]_0^{2\pi} - \frac{1}{n} \int_0^{2\pi} \cos(nx) dx \right) \\
 &= -\frac{1}{2n} (1 - 1) + \frac{1}{2n\pi} (2\pi \cos(2n\pi) - 0) - \frac{1}{2n\pi} \left[ \frac{\sin(nx)}{n} \right]_0^{2\pi} = \frac{2\pi}{2n\pi} - \frac{1}{2n^2\pi} (\sin(2n\pi) - \sin(0)) = \frac{1}{n}.
 \end{aligned}$$

Thus the Fourier series associated to  $f$  is given by  $F(x) = \sum_{n=1}^{\infty} \frac{\sin(nx)}{n}$ . To confirm this expression by Sage one can compute the Fourier coefficients, as usual, i.e.,

```

var("n"); f(x)=(pi-x)/2; f = piecewise([(0, 2*pi), f])
an=(1/pi)*integral(((pi-x)/2)*cos(n*x), x, 0, 2*pi)
bn=(1/pi)*integral(((pi-x)/2)*sin(n*x), x, 0, 2*pi)
show("a_n=", an.expand()); show("b_n=", bn.expand())
    
```

(3) Recall that for the partial sums Sage provides the built-in function `fourier_series_partial_sum`. For our case the implementation can be done by continue typing in the previous block the following:

```

partS5=f.fourier_series_partial_sum(5,pi); show("5th partial sum = ",partS5)
partS8=f.fourier_series_partial_sum(8,pi); show("8th partial sum = ",partS8)
partS15=f.fourier_series_partial_sum(15,pi); show("15th partial sum = ",partS15)
partS50=f.fourier_series_partial_sum(50,pi); show("50th partial sum = ",partS50)
    
```

Run the whole syntax yourselves to obtain the corresponding expressions of the partial sums  $F_5, F_8, F_{15}$  and  $F_{50}$ . To plot them, execute the block given below (notice that this is independent of the previous cells).

```

f1(x)= (pi-x)/2; f2(x)= (-pi-x)/2; f3(x)= (3*pi-x)/2
f = piecewise([(-2*pi, 0),f2], [(0, 2*pi),f1], [(2*pi, 4*pi), f3])
partS5=f.fourier_series_partial_sum(5,pi);partS8=f.fourier_series_partial_sum(8,pi)
partS15=f.fourier_series_partial_sum(15,pi);partS50=f.fourier_series_partial_sum(50,pi)
p=f.plot(x, -2*pi, 4*pi, exclude=[0, 2*pi], legend_label=r"$f$")
s5=plot(partS5, x, -2*pi, 4*pi, linestyle="--", color="midnightblue", legend_label=r"$F_5$")
s8=plot(partS8, x, -2*pi, 4*pi, linestyle="--", color="darkgreen", legend_label=r"$F_8$")
s15=plot(partS15, x, -2*pi, 4*pi, linestyle="--", color="darkorange", legend_label=r"$F_{15}$")
s50=plot(partS50, x, -2*pi, 4*pi, linestyle="--", color="crimson", legend_label=r"$F_{50}$")
(p+s5+s8+s15+s50).show(figsize=8, ticks=pi/2, tick_formatter=pi)
    
```

This generates the following figure:

We should mention that in this block  $f$  was introduced as in the first part (see (1)), with aim to display a larger portion of the graph of  $f$ . To verify the computations in part (2), however, it was adequate to use only the function  $(\pi - x)/2$  on its initial domain.

(4) By the figure above, it is clear that the Fourier series  $F(x)$  of  $f$  converges to  $f(x)$ , at each point  $x$  where  $f$  is continuous, which means that for any  $x \in (0, 2\pi)$  we have

$$\frac{\pi - x}{2} = F(x) = \sum_{n=1}^{\infty} \frac{\sin(nx)}{n} = \sin(x) + \frac{\sin(2x)}{2} + \frac{\sin(3x)}{3} + \frac{\sin(4x)}{4} + \frac{\sin(5x)}{5} + \dots$$

This applies to  $x = \pi/2$  and gives

$$\frac{\pi}{4} = \sin\left(\frac{\pi}{2}\right) + \frac{\sin(\pi)}{2} + \frac{\sin(3\pi/2)}{3} + \frac{\sin(2\pi)}{4} + \frac{\sin(5\pi/2)}{5} + \dots = 1 + 0 - \frac{1}{3} + 0 + \frac{1}{5} - \dots$$

On the other hand, the points of discontinuity of  $f$  appear at  $x = 2k\pi$ , for  $k \in \mathbb{Z}$ . The average value of our function at these points equals to 0, and hence the Fourier expansion of  $f$  converges to 0 at any jump discontinuity of  $f$ .  $\square$

**7.D.10.** Compute the complex version of the Fourier series of the  $2\pi$ -periodic extension of the following function (often referred to as the “pulse wave”)

$$g(x) = \begin{cases} 0, & \text{if } -\pi < x < 0, \\ 1, & \text{if } 0 < x < \pi. \end{cases}$$

$\circ$

**7.D.11.** Consider the exponential mapping  $f(x) = e^x$  with  $x \in [0, 1)$ . Use Sage to implement the following:

- (1) Determine and illustrate the 1-periodic extension of  $f$  for  $x \in [-1, 2)$  (with at least two different Sage methods);
- (2) Compute the Fourier series of  $f$  on the interval  $[0, 1)$ , and then illustrate its 5th, 15th and 25th partial sum (with at least two different Sage methods);
- (3) Determine the convergence of the Fourier series obtained above.

**Solution.** (1) The 1-periodic extension of  $f$  on the interval  $[-1, 2)$  is given by  $f(x + 1)$  for  $-1 \leq x < 0$ , by  $f(x)$  for  $0 \leq x < 1$  and  $f(x - 1)$  for  $1 \leq x < 2$ . In Sage one method utilizes the `piecewise` function while another one relies on the `def` procedure to define piecewise functions. The implementation goes as follows:

```
f=piecewise([[RealSet.closed_open(-1, 0), e^(x+1)], [(0, 1), e^x], [(1, 2), e^(x-1)]])
a=f.plot(x, -1, 2, thickness=1.5, color="grey", exclude=[0, 1])
p0=point([-1, 1], size=30, color="black")
p1=point([0, 1], size=30, color="black")
p2=point([1, 1], size=30, color="black")
show(a+p0+p1+p2)
```

```
var("t")
def g(t):
    if 0 <= t < 1:
        return e^t
    elif -1 <= t < 0:
        return e^(t+1)
    elif 1 <= t < 2:
        return e^(t-1)
b=plot(g, (-1, 2), exclude=[0, 1], thickness=1.5, color="grey")
p0=point([-1, 1], size=30, color="black")
p1=point([0, 1], size=30, color="black")
p2=point([1, 1], size=30, color="black")
show(b+p0+p1+p2)
```

They both produce the same figure, which is presented here:

Notice that as in 7.D.9, both blocks include code for marking with black dots the endpoints where the periodic extension is defined.

(2) As usual, it is sufficient to compute the Fourier coefficients. However, one should carefully apply the general formulas from 7.1.6 and here is a possible implementation:

```
f=piecewise([[ (0, 1), e^x ]]); T=1; n=var("n"); Om=pi
an=(2/T)*integral((e^x)*cos(2*n*Om*x), x, 0, 1); show("a_n=", an.expand())
bn=(2/T)*integral((e^x)*sin(2*n*Om*x), x, 0, 1); show("b_n=", bn.expand())
```

Sage's answer has the form

$$a_n = \frac{4\pi n e \sin(2\pi n)}{4\pi^2 n^2 + 1} + \frac{2 \cos(2\pi n) e}{4\pi^2 n^2 + 1} - \frac{2}{4\pi^2 n^2 + 1}, \quad b_n = -\frac{4\pi n \cos(2\pi n) e}{4\pi^2 n^2 + 1} + \frac{4\pi n}{4\pi^2 n^2 + 1} + \frac{2 e \sin(2\pi n)}{4\pi^2 n^2 + 1}.$$

Recalling that  $\sin(2n\pi) = 0$  and  $\cos(2n\pi) = 1$  for all  $n$ , this means that

$$a_n = \frac{2(e-1)}{1+4n^2\pi^2}, \quad (n \in \mathbb{N}), \quad \text{and} \quad b_n = \frac{4n\pi(1-e)}{1+4n^2\pi^2}, \quad (n \in \mathbb{Z}_+),$$

respectively. It follows that the Fourier series of the function at hand has the form

$$F(x) = e - 1 + 2(e-1) \sum_{n=1}^{\infty} \frac{\cos(2n\pi x)}{1+4n^2\pi^2} + 4\pi(1-e) \sum_{n=1}^{\infty} \frac{n \sin(2n\pi x)}{1+4n^2\pi^2}. \quad (b)$$

Now, to plot the required partial sums, we can proceed as in the previous tasks (cf. 7.D.9), i.e.,

```
f=piecewise([[ (0, 1), e^x ]])
partS5 = f.fourier_series_partial_sum(5, 1/2)
partS15 = f.fourier_series_partial_sum(15, 1/2)
partS25 = f.fourier_series_partial_sum(25, 1/2)
a = f.plot(x, 0, 1, thickness=1.5, color="black")
s5=plot(partS5, x, -1, 1, linestyle="--", color="grey")
s15=plot(partS15, x, -1, 1, linestyle="--", color="grey")
s25=plot(partS25, x, -1, 1, linestyle="--", color="grey")
show(a+s5); show(a+s15); show(a+s25)
```

Notice in the first line of this block we could replace the open set  $(0, 1)$  with the correct set that  $f$  is defined, i.e., the set  $[0, 1)$ . This could be done by the command `RealSet.closed_open(0, 1)`, but it is *not* so essential in the sense that it does not effect the Fourier series, as previously mentioned in ???. This block produces the following three figures:

An alternative method to derive the partial sums utilizes a combination of certain built-in functions in Sage, namely `fourier_series_sine_coefficient` and `fourier_series_cosine_coefficient`. Below we present the case for the 5th partial sum and similarly are treated the rest cases.

```
f=piecewise([[0, 1), e**x]])
a5=[f.fourier_series_cosine_coefficient(n, 1/2) for n in range(6)]
b5=[f.fourier_series_sine_coefficient(n, 1/2) for n in range(6)]
fs5=(a5[0]/2)+(sum([a5[k]*cos(2*k*pi*x) for k in range(1, 6)]))
+(sum([b5[k]*sin(2*k*pi*x) for k in range(1, 6)]))
print(bool(fs5.expand()==f.fourier_series_partial_sum(5,1/2).expand()))
a=f.plot(x, 0, 1, thickness=1.5, color="black")
b=fs5.plot(x, 0, 1, linestyle="--")
(a+b).show(figsize=8)
```

In this block we programmed Sage to compare the expression of the 5th partial sum, denoted by `fs5` and defined manually, with the one that one derives via the usual method by the command `fourier_series_partial_sum`. This comparison is performed by the `bool` command, and Sage's answer is `True`. One could also obtain the explicit form of the partial sums in question, which we skipped to save some space.

As a side remark, we finally mention that for a formal verification of the Fourier coefficients  $a_n, b_n$  one can use the following formulas

$$\int e^x \cos(\alpha x) dx = \frac{e^x (\alpha \sin(\alpha x) + \cos(\alpha x))}{1 + \alpha^2} + C, \quad \int e^x \sin(\beta x) dx = \frac{e^x (\sin(\beta x) - \beta \cos(\beta x))}{1 + \beta^2} + C,$$

with  $\alpha, \beta \in \mathbb{R}$ . Both of them can be derived by integrations by parts (see 6.B.7 for the second one).

(3) The function  $f(x) = e^x$  is continuous at any  $x \in (0, 1)$ . It is also continuous at  $x = 0$  since  $\lim_{x \rightarrow 0^-} e^x = 1 = \lim_{x \rightarrow 0^+} f(x)$ . It also satisfies according to Dirichlet's theorem (see ??) we should have  $e^x = F(x)$  for all  $x \in [0, 1]$ , where  $F$  is given in (b).  $\square$

- 7.D.12.** (1) Derive a cosine Fourier series of  $f$  on the interval  $[0, 1]$  and illustrate some of its partial sums;  
 (2) Derive a sine Fourier series of  $f$  on the interval  $(0, 1]$  and illustrate some of its partial sums;

Note the differences between the three cases as shown in the diagrams. The approximation differs in relation to the continuity. The first diagram uses  $n = 5$ , the second uses  $n = 3$ , while the last diagram uses  $n = 10$ .

We use the formulae ( $\alpha, \beta \in \mathbb{R}$ )

$$(1) \int e^x \cos(\alpha x) dx = \frac{e^x (\alpha \sin(\alpha x) + \cos(\alpha x))}{1 + \alpha^2} + C,$$

$$(2) \int e^x \sin(\beta x) dx = \frac{e^x (\sin(\beta x) - \beta \cos(\beta x))}{1 + \beta^2} + C,$$

both of which can be obtained by two integrations by parts. Actually, the second one was computed in detail in ??(d). We obtain

$$\begin{aligned} (a) \quad a_n &= 2 \int_0^1 e^x \cos(2n\pi x) dx \\ &= 2 \left[ \frac{e^x (2n\pi \sin(2n\pi x) + \cos(2n\pi x))}{1 + 4n^2 \pi^2} \right]_0^1 \\ &= \frac{2(e-1)}{1 + 4n^2 \pi^2}, \quad n \in \mathbb{N} \cup \{0\}, \end{aligned}$$

$$\begin{aligned} b_n &= 2 \int_0^1 e^x \sin(2n\pi x) dx \\ &= 2 \left[ \frac{e^x (\sin(2n\pi x) - 2n\pi \cos(2n\pi x))}{1 + 4n^2 \pi^2} \right]_0^1 \\ &= \frac{4n\pi(1-e)}{1 + 4n^2 \pi^2}, \quad n \in \mathbb{N}; \end{aligned}$$

$$\begin{aligned} (b) \quad a_n &= 2 \int_0^1 e^x \cos(n\pi x) dx \\ &= 2 \left[ \frac{e^x (n\pi \sin(n\pi x) + \cos(n\pi x))}{1 + n^2 \pi^2} \right]_0^1 \\ &= \frac{2((-1)^n e - 1)}{1 + n^2 \pi^2}, \quad n \in \mathbb{N} \cup \{0\}; \end{aligned}$$

$$\begin{aligned} (c) \quad b_n &= 2 \int_0^1 e^x \sin(n\pi x) dx \\ &= 2 \left[ \frac{e^x (\sin(n\pi x) - n\pi \cos(n\pi x))}{1 + n^2 \pi^2} \right]_0^1 \\ &= \frac{2n\pi(1 + (-1)^{n+1} e)}{1 + n^2 \pi^2}, \quad n \in \mathbb{N}. \end{aligned}$$

Substitution then yields the corresponding Fourier series for  $g(x)$ :

$$\begin{aligned} (a) \quad & e - 1 + 2(e - 1) \sum_{n=1}^{\infty} \frac{\cos(2n\pi x)}{1 + 4n^2 \pi^2} \\ & + 4\pi(1 - e) \sum_{n=1}^{\infty} \frac{n \sin(2n\pi x)}{1 + 4n^2 \pi^2}; \end{aligned}$$

(b)  $e - 1 + 2 \sum_{n=1}^{\infty} \frac{((-1)^n e - 1) \cos(n\pi x)}{1 + n^2 \pi^2}$ ;  
 (c)  $2\pi \sum_{n=1}^{\infty} \frac{n(1 + (-1)^{n+1} e) \sin(n\pi x)}{1 + n^2 \pi^2}$ .

**7.D.13.** Determine the cosine Fourier series for a periodic extension of the function

$$g(x) = 1, \quad x \in [0, 1), \quad g(x) = 0, \quad x \in [1, 4).$$

Determine also the sine Fourier series for

$$f(x) = x - 1, \quad x \in (0, 2), \quad f(x) = 3 - x, \quad x \in [2, 4).$$

**Solution.** We have already encountered the construction of a cosine Fourier series in ??(b) and also 7.A.15(b). It is the case of the Fourier series of an even function. Therefore, the first thing we do is extend the definition of the function  $g$  to the interval  $(-4, 0)$  so that it is even. This means

$$g(x) := 1 \text{ for } x \in (-1, 0), \quad g(x) := 0 \text{ for } x \in (-4, -1].$$

Now we can consider its periodic extension onto the whole  $\mathbb{R}$  with period  $x_0 = -4, T = 8$  and  $\omega = \pi/4$ .

Necessarily  $b_n = 0$  for all  $n \in \mathbb{N}$  in a cosine Fourier series. We determine the Fourier coefficients  $a_n, n \in \mathbb{N}$

$$\begin{aligned} a_0 &= \frac{2}{T} \int_{x_0}^{x_0+T} g(x) \, dx = \frac{2}{8} \int_{-1}^1 1 \, dx = \frac{1}{2} \int_0^1 1 \, dx = \frac{1}{2}, \\ a_n &= \frac{2}{T} \int_{x_0}^{x_0+T} g(x) \cos(n\omega x) \, dx = \frac{1}{2} \int_0^1 \cos \frac{n\pi x}{4} \, dx \\ &= \frac{2}{n\pi} \sin \frac{n\pi}{4}. \end{aligned}$$

We use

$$(1) \quad \int_{-a}^a f(x) \, dx = 2 \int_0^a f(x) \, dx,$$

which is valid for every even function  $f$  integrable on the interval  $[0, a]$ .

The expression  $\sin(n\pi/4)$  is conveniently left as is, rather than the alternative of sorting out when it attains which of its five different values. Thus we write the cosine Fourier series in the form:

$$\frac{1}{4} + \sum_{n=1}^{\infty} \left( \frac{2}{n\pi} \sin \frac{n\pi}{4} \cos \frac{n\pi x}{4} \right).$$

The sine Fourier transform of the function can be determined analogously from the odd extension of the given segment. Again,  $T = 8$  and  $\omega = \pi/4$  for the function  $f$ . This time it is the coefficients  $a_n, n \in \mathbb{N} \cup \{0\}$ , which are zero. To find the remaining coefficients, use integration by parts and (1) (the product of two odd functions is an even function). For all  $n \in \mathbb{N}$

$$\begin{aligned} b_n &= \frac{2}{T} \int_{x_0}^{x_0+T} f(x) \sin(n\omega x) \, dx \\ &= \frac{1}{2} \left( \int_0^2 (x-1) \sin \frac{n\pi x}{4} \, dx - \int_2^4 (x-3) \sin \frac{n\pi x}{4} \, dx \right) \\ &= \left[ (1-x) \frac{2}{n\pi} \cos \frac{n\pi x}{4} \right]_0^2 + \left[ \frac{8}{n^2 \pi^2} \sin \frac{n\pi x}{4} \right]_0^2 \\ &\quad - \left[ (3-x) \frac{2}{n\pi} \cos \frac{n\pi x}{4} \right]_2^4 - \left[ \frac{8}{n^2 \pi^2} \sin \frac{n\pi x}{4} \right]_2^4 \\ &= \frac{2}{n\pi} ((-1)^n - 1) + \frac{16}{n^2 \pi^2} \sin \frac{n\pi}{2}. \end{aligned}$$

Immediately,  $b_n = 0$  when  $n$  is even. So the sine Fourier series can be written

$$\begin{aligned} &\sum_{n=1}^{\infty} \left( \left( \frac{2}{n\pi} ((-1)^n - 1) + \frac{16}{n^2 \pi^2} \sin \frac{n\pi}{2} \right) \sin \frac{n\pi x}{4} \right) \\ &= \sum_{n=1}^{\infty} \left( \left( \frac{-4}{(2n-1)\pi} + \frac{(-1)^{n-1} 16}{(2n-1)^2 \pi^2} \right) \sin \frac{(2n-1)\pi x}{4} \right). \end{aligned}$$

□

**7.D.14.** Write the Fourier series of the  $\pi$ -periodic function which equals cosine on the interval  $(-\pi/2, \pi/2)$ . Then write the cosine Fourier series of the  $2\pi$ -periodic function  $y = |\cos x|$ .

**Solution.** We are looking for one Fourier series only, since the second part of the problem is just a reformulation of the first part. Therefore, we construct the Fourier series for the function  $g(x) = \cos x, x \in [-\pi/2, \pi/2]$ . Since  $g$  is even,  $b_n = 0, n \in \mathbb{N}$ . We compute

$$\begin{aligned}
 a_n &= \frac{2}{\pi} \int_{-\pi/2}^{\pi/2} \cos x \cos(2nx) \, dx \\
 &= \frac{2}{\pi} \int_{-\pi/2}^{\pi/2} \frac{1}{2} (\cos((2n+1)x) + \cos((2n-1)x)) \, dx \\
 &= \frac{1}{\pi} \left[ \frac{\sin((2n+1)x)}{2n+1} + \frac{\sin((2n-1)x)}{2n-1} \right]_{-\pi/2}^{\pi/2} \\
 &= \frac{2}{\pi} \left( \frac{(-1)^n}{2n+1} + \frac{(-1)^{n+1}}{2n-1} \right) \\
 &= \frac{4}{\pi} \frac{(-1)^{n+1}}{4n^2-1}
 \end{aligned}$$

for every  $n \in \mathbb{N}$ . The calculation is also valid for  $n = 0$ , thus  $a_0 = 4/\pi$ . The desired Fourier series is

$$\frac{2}{\pi} + \frac{4}{\pi} \sum_{n=1}^{\infty} \left( \frac{(-1)^{n+1}}{4n^2-1} \cos(2nx) \right).$$

□

**7.D.15.** Sum the two series

$$\sum_{n=1}^{\infty} \frac{1}{n^4}, \quad \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^4}.$$

**Solution.** We hint at the procedure by which the series

$$\sum_{n=1}^{\infty} \frac{1}{n^{2k}}, \quad \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^{2k}}$$

for general  $k \in \mathbb{N}$  can be calculated. Use the identities

$$(1) \quad x = \pi - 2 \sum_{n=1}^{\infty} \frac{\sin(nx)}{n}, \quad x \in (0, 2\pi),$$

$$(2) \quad x^2 = \frac{4\pi^2}{3} + 4 \sum_{n=1}^{\infty} \frac{\cos(nx)}{n^2} - 4\pi \sum_{n=1}^{\infty} \frac{\sin(nx)}{n}, \quad x \in (0, 2\pi),$$

which follow from the constructions of the Fourier series for the functions  $g(x) = x$  and  $g(x) = x^2$ , respectively, on the interval  $[0, 2\pi)$ .

By (1),

$$\sum_{n=1}^{\infty} \frac{\sin(nx)}{n} = \frac{\pi-x}{2}, \quad x \in (0, 2\pi).$$

Substituting into (2) gives

$$\sum_{n=1}^{\infty} \frac{\cos(nx)}{n^2} = \frac{3x^2 - 6\pi x + 2\pi^2}{12}, \quad x \in (0, 2\pi).$$

Since the values of the series

$$\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}, \quad \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2} = \frac{\pi^2}{12}$$

have been already determined, substitution then proves the validity of this last equation at the marginal points  $x = 0$ ,  $x = 2\pi$ . The left-hand series is evidently bounded from above by  $\sum_{n=1}^{\infty} \frac{1}{n^2}$ , thus it converges absolutely and uniformly on  $[0, 2\pi]$ . Therefore, it can be integrated term by term:

$$\begin{aligned}
 \sum_{n=1}^{\infty} \frac{\sin(nx)}{n^3} &= \sum_{n=1}^{\infty} \left[ \frac{\sin(ny)}{n^3} \right]_0^x = \int_0^x \sum_{n=1}^{\infty} \frac{\cos(ny)}{n^2} \, dy \\
 &= \int_0^x \frac{3y^2 - 6\pi y + 2\pi^2}{12} \, dy = \frac{x^3 - 3\pi x^2 + 2\pi^2 x}{12}, \quad x \in [0, 2\pi].
 \end{aligned}$$

In fact, every Fourier series may be integrated term by term. Further integration gives

$$\begin{aligned}
 \sum_{n=1}^{\infty} \frac{1 - \cos(nx)}{n^4} &= \sum_{n=1}^{\infty} \left[ -\frac{\cos(ny)}{n^4} \right]_0^x = \int_0^x \sum_{n=1}^{\infty} \frac{\sin(ny)}{n^3} \, dy \\
 &= \int_0^x \frac{y^3 - 3\pi y^2 + 2\pi^2 y}{12} \, dy = \frac{x^4 - 4\pi x^3 + 4\pi^2 x^2}{48}, \quad x \in [0, 2\pi].
 \end{aligned}$$

Substituting  $x = \pi$  leads to

$$\sum_{n=1}^{\infty} \frac{1+(-1)^{n+1}}{n^4} = \sum_{n=1}^{\infty} \frac{1-\cos(n\pi)}{n^4} = \frac{\pi^4}{48}.$$

Since the numerator on the left-hand side is zero for even numbers  $n$  and is 2 for odd numbers  $n$ , the series can be written

$$(3) \quad \sum_{n=1}^{\infty} \frac{2}{(2n-1)^4} = \frac{\pi^4}{48}.$$

From the expression

$$\sum_{n=1}^{\infty} \frac{1}{n^4} = \sum_{n=1}^{\infty} \frac{1}{(2n)^4} + \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} = \frac{1}{16} \sum_{n=1}^{\infty} \frac{1}{n^4} + \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4},$$

it follows that

$$\sum_{n=1}^{\infty} \frac{1}{n^4} = \frac{16}{15} \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} = \frac{16}{15} \cdot \frac{1}{2} \cdot \frac{\pi^4}{48} = \frac{\pi^4}{90},$$

thereby having summed up the first series. As for the second one,

$$\begin{aligned} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^4} &= \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} - \sum_{n=1}^{\infty} \frac{1}{(2n)^4} = \sum_{n=1}^{\infty} \frac{1}{(2n-1)^4} - \frac{1}{16} \sum_{n=1}^{\infty} \frac{1}{n^4} \\ &= \frac{1}{2} \cdot \frac{\pi^4}{48} - \frac{1}{16} \cdot \frac{\pi^4}{90} = \frac{7\pi^4}{720}. \end{aligned}$$

One can proceed similarly to sum the series

$$\sum_{n=1}^{\infty} \frac{1}{n^{2k}}, \quad \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^{2k}}$$

for other  $k \in \mathbb{N}$ .

It is natural to ask for the value of the series  $\sum_{n=1}^{\infty} \frac{1}{n^3}$ . This problem has been tackled by mathematicians for centuries without success. The reader may justifiably be surprised by this since the procedure above is applicable to all the odd powers as well.

For instance, one can start with the identity

$$\sum_{n=1}^{\infty} \frac{\cos(nx)}{n} = -\ln \left( 2 \sin \frac{x}{2} \right), \quad x \in (0, 2\pi),$$

which, by the way, can be proved by expanding the right-hand function into a Fourier series. If, similarly to the above, integrate the left-hand series term by term twice and substituted  $x \rightarrow 0+$  in the limit, we get the series  $\sum_{n=1}^{\infty} \frac{1}{n^3}$ . Thus, it should suffice to integrate the right-hand function twice and calculate one limit. However, the integration of the right-hand side leads to a non-elementary integral. That is, the antiderivative cannot be expressed in terms of the elementary functions.<sup>6</sup>

□

**7.D.16.** Determine the function  $f$  whose Fourier transform is the function

$$\tilde{f}(\omega) = \frac{1}{\sqrt{2\pi}} \frac{\sin \omega}{\omega}, \quad \omega \neq 0.$$

**Solution.** We might have noticed that the sinc function appeared as the image of the characteristic function  $h_{\Omega}$  of the interval  $(-\Omega, \Omega)$  in one of the previous problems:

$$\tilde{h}_{\Omega}(\omega) = \frac{2\Omega}{\sqrt{2\pi}} \operatorname{sinc}(\omega\Omega).$$

In this case  $\Omega = 1$  and the function  $f$  is the half of  $h_1$ .

The result can be computed directly. The inverse Fourier transform is

$$\begin{aligned} f(t) &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{\sin \omega}{\omega} e^{i\omega t} d\omega \\ &= \frac{1}{2\pi} \left( \int_{-\infty}^0 \frac{\sin \omega}{\omega} e^{i\omega t} d\omega + \int_0^{\infty} \frac{\sin \omega}{\omega} e^{i\omega t} d\omega \right). \end{aligned}$$

Substitute  $-\omega$  for  $\omega$  in the first integral, to obtain

<sup>6</sup>The function  $\zeta(p) = \sum_{n=1}^{\infty} \frac{1}{n^p}$  is called the Riemann zeta function.  
EXPAND THE FOOTNOTE!

$$\begin{aligned} f(t) &= \frac{1}{2\pi} \left( \int_0^\infty \frac{\sin \omega}{\omega} e^{-i\omega t} d\omega + \int_0^\infty \frac{\sin \omega}{\omega} e^{i\omega t} d\omega \right) \\ &= \frac{1}{2\pi} \int_0^\infty \frac{\sin \omega}{\omega} 2(e^{-i\omega t} + e^{i\omega t}) d\omega = \frac{1}{\pi} \int_0^\infty \frac{\sin \omega}{\omega} \cos(\omega t) d\omega. \end{aligned}$$

Continue via trigonometric identities to obtain

$$f(t) = \frac{1}{2\pi} \left( \int_0^\infty \frac{\sin(\omega(1+t))}{\omega} d\omega + \int_0^\infty \frac{\sin(\omega(1-t))}{\omega} d\omega \right).$$

The substitutions  $u = \omega(1+t)$ ,  $v = \omega(1-t)$  then give

$$\begin{aligned} f(t) &= \frac{1}{2\pi} \left( \int_0^\infty \frac{\sin u}{u} du - \int_0^\infty \frac{\sin v}{v} dv \right) = 0, \quad t > 1; \\ f(t) &= \frac{1}{2\pi} \left( \int_0^\infty \frac{\sin u}{u} du + \int_0^\infty \frac{\sin v}{v} dv \right) = \frac{1}{\pi} \int_0^\infty \frac{\sin u}{u} du, \quad t \in (-1, 1); \\ f(t) &= \frac{1}{2\pi} \left( -\int_0^\infty \frac{\sin u}{u} du + \int_0^\infty \frac{\sin v}{v} dv \right) = 0, \quad t < -1. \end{aligned}$$

Thus the function  $f$  is zero for  $|t| > 1$  and constant (necessarily non-zero) for  $|t| < 1$ . (Throughout, we assume that the inverse Fourier transform exists).

The constant is  $f(t) = 1/2$  for  $|t| < 1$ , from the standard result

$$\int_0^\infty \frac{\sin u}{u} du = \frac{\pi}{2}.$$

Alternatively, we can 'guess' that the constant is one, i.e.

$$g(t) = 1, \quad |t| < 1; \quad g(t) = 0, \quad |t| > 1$$

and compute

$$\mathcal{F}(g)(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-1}^1 e^{-i\omega t} dt = \frac{2}{\sqrt{2\pi}} \int_0^1 \cos(\omega t) dt = \frac{2}{\sqrt{2\pi}} \frac{\sin \omega}{\omega}.$$

So  $f(0) = g(0)/2 = 1/2$ , which also establishes

$$\int_0^\infty \frac{\sin u}{u} du = \frac{\pi}{2}.$$

□

#### 7.D.17. Using the relation

$$(1) \quad \mathcal{L}(f')(s) = s\mathcal{L}(f)(s) - \lim_{t \rightarrow 0^+} f(t),$$

derive the Laplace transforms of both the functions  $y = \cos t$  and  $y = \sin t$ .

**Solution.** Notice first that from (1), it follows that

$$\begin{aligned} \mathcal{L}(f'')(s) &= s\mathcal{L}(f')(s) - \lim_{t \rightarrow 0^+} f'(t) = s \left( s\mathcal{L}(f)(s) - \lim_{t \rightarrow 0^+} f(t) \right) - \lim_{t \rightarrow 0^+} f'(t) = \\ &= s^2\mathcal{L}(f)(s) - s \lim_{t \rightarrow 0^+} f(t) - \lim_{t \rightarrow 0^+} f'(t). \end{aligned}$$

Therefore,

$$-\mathcal{L}(\sin t)(s) = \mathcal{L}(-\sin t)(s) = \mathcal{L}((\sin t)'')(s) = s^2\mathcal{L}(\sin t)(s) - s \lim_{t \rightarrow 0^+} \sin t - \lim_{t \rightarrow 0^+} \cos t = s^2\mathcal{L}(\sin t)(s) - 1,$$

whence we get

$$-\mathcal{L}(\sin t)(s) = s^2\mathcal{L}(\sin t)(s) - 1, \quad \text{i. e.} \quad \mathcal{L}(\sin t)(s) = \frac{1}{s^2+1}.$$

Now, invoking (1), we determine

$$\mathcal{L}(\cos t)(s) = \mathcal{L}((\sin t)')(s) = s \frac{1}{s^2+1} - \lim_{t \rightarrow 0^+} \sin t = \frac{s}{s^2+1}.$$

□

**7.D.18.** Using the discussion from the previous problem, prove that for a continuous function  $y$  with enough sufficiently higher order derivatives

$$\mathcal{L}(y^{(n)})(s) = s^n \mathcal{L}(y)(s) - \sum_{i=1}^n s^{n-i} y^{(i-1)}(0).$$

**Solution.** Clearly

$$\begin{aligned}\mathcal{L}(y')(s) &= s\mathcal{L}(y)(s) - y(0) \\ \mathcal{L}(y'')(s) &= s^2\mathcal{L}(y)(s) - sy(0) - y'(0)\end{aligned}$$

and the claim is verified by induction. □

**7.D.19.** Find the Laplace transform of Heaviside's function  $H(t)$  and, for real  $a$ , the shifted Heaviside's function  $H_a(t) = H(t - a)$ :

$$H(t) = \begin{cases} 0 & \text{for } t < 0, \\ \frac{1}{2} & \text{for } t = 0, \\ 1 & \text{for } t > 0. \end{cases}$$

**Solution.**

$$\begin{aligned}\mathcal{L}(H(t))(s) &= \int_0^\infty H(t) e^{-st} dt = \int_0^\infty e^{-st} dt \\ &= \left[ -\frac{e^{-st}}{s} \right]_0^\infty = -\frac{1}{s}(0 - 1) = \frac{1}{s}, \\ \mathcal{L}(H_a(t))(s) &= \mathcal{L}(H(t - a))(s) \\ &= \int_0^\infty H(t - a) e^{-st} dt = \int_a^\infty e^{-st} dt \\ &= \int_0^\infty e^{-s(t+a)} dt = e^{-as} \mathcal{L}(H(t))(s) = \frac{e^{-as}}{s}.\end{aligned}$$

□

**7.D.20.** Show that for real  $a$ ,

$$(1) \quad \mathcal{L}(f(t) \cdot H_a(t))(s) = e^{-as} \mathcal{L}(f(t + a))(s)$$

**Solution.**

$$\begin{aligned}\mathcal{L}(f(t)H_a(t))(s) &= \int_0^\infty f(t)H(t - a)e^{-st} dt = \int_a^\infty f(t)e^{-st} dt \\ &= \int_0^\infty f(t + a)e^{-s(t+a)} dt = e^{-as} \int_0^\infty f(t + a)e^{-st} dt \\ &= e^{-as} \mathcal{L}(f(t + a))(s).\end{aligned}$$

□

**7.D.21.** Find a function  $y(t)$  satisfying the differential equation

$$y''(t) + 4y(t) = \sin 2t$$

and the initial conditions  $y(0) = 0$  and  $y'(0) = 0$ .

**Solution.** From the example 7.D.18:

$$s^2\mathcal{L}(y)(s) + 4\mathcal{L}(y)(s) = \mathcal{L}(\sin 2t)(s)$$

Now, by 7.B.17(d)

$$\mathcal{L}(\sin 2t)(s) = \frac{2}{s^2 + 4}.$$

It follows that

$$\mathcal{L}(y)(s) = \frac{2}{(s^2 + 4)^2}.$$

The inverse transform then gives

$$y(t) = \frac{1}{8} \sin 2t - \frac{1}{4}t \cos 2t.$$

□

**7.D.22.** Find a function  $y(t)$  satisfying the differential equation and the initial conditions:

$$y''(t) + 4y(t) = f(t), \quad y(0) = 0, \quad y'(0) = -1,$$

where  $f(t)$  is the piecewise continuous function

$$f(t) = \begin{cases} \cos(2t) & \text{for } 0 \leq t < \pi, \\ 0 & \text{for } t \geq \pi. \end{cases}$$

**Solution.** This problem is a model for the undamped oscillations of a spring (excluding friction and other phenomena like non-linearities in the toughness of the spring and so on). It is initiated by an exterior force during the initial period only and then ceases.

The function  $f(t)$  can be written as a linear combination of Heaviside's function  $H(t)$  and its shift. That is,

$$f(t) = \cos(2t)(H(t) - H_\pi(t))$$

up to the values  $t = 0, t = \pi, \dots$  Since

$$\mathcal{L}(y'')(s) = s^2 \mathcal{L}(y) - sy(0) - y'(0) = s^2 \mathcal{L}(y) + 1,$$

we get, making use of the previous example 7.D.20, the right-hand sides to the calculation of the Laplace transform

$$\begin{aligned} s^2 \mathcal{L}(y) + 1 + 4\mathcal{L}(y) &= \mathcal{L}(\cos(2t)(H(t) - H_\pi(t))) \\ &= \mathcal{L}(\cos(2t) \cdot H(t)) - \mathcal{L}(\cos(2t) \cdot H_\pi(t)) \\ &= \mathcal{L}(\cos(2t)) - e^{-\pi s} \mathcal{L}(\cos(2(t + \pi))) \\ &= (1 - e^{-\pi s}) \frac{s}{s^2 + 4}. \end{aligned}$$

Hence,

$$\mathcal{L}(y) = -\frac{1}{s^2 + 4} + (1 - e^{-\pi s}) \frac{s}{(s^2 + 4)^2}.$$

The inverse transform then yields the solution in the form

$$y(t) = -\frac{1}{2} \sin(2t) + \frac{1}{4}t \sin(2t) + \mathcal{L}^{-1} \left( e^{-\pi s} \frac{s}{(s^2 + 4)^2} \right).$$

According to (1),

$$\begin{aligned} \mathcal{L}^{-1} \left( e^{-\pi s} \frac{s}{(s^2 + 4)^2} \right) &= \frac{1}{4} \mathcal{L}^{-1} (e^{-\pi s} \mathcal{L}(t \sin(2t))) \\ &= (t - \pi) \sin(2(t - \pi)) \cdot H_\pi(t). \end{aligned}$$

Since the Heaviside function  $H_\pi(t)$  is zero for  $t < \pi$  and equals 1 for  $t > \pi$ , we get the solution in the form

$$y(t) = \begin{cases} \frac{t-2}{4} \sin(2t) & \text{for } 0 \leq t < \pi \\ \left( \frac{5t-2}{4} - \pi \right) \sin(2t) & \text{for } t \geq \pi. \end{cases}$$

□

More details!

Key to the exercises

**7.A.2.** Similarly to 7.A.1, one can use the Gram–Schmidt process with respect to the mentioned scalar product. This gives the functions

$$f_1(x) = \frac{1}{x}, \quad f_2(x) = \frac{1}{x^2} - \frac{3}{4x}, \quad f_3(x) = \frac{1}{x^3} - \frac{3}{2x^2} + \frac{13}{24x}.$$

and it is easy to check that the set  $\{f_1, f_2, f_3\}$  forms an orthonormal basis. We also see that:

- The projection of the function  $\frac{1}{x^4}$  has the form  $\frac{15}{32}f_1 + \frac{69}{40}f_2 + \frac{9}{4}f_3$ , while the distance is  $\frac{\sqrt{14}}{2240} = 0.00167$ .
- The projection of the function  $x$  has the form  $2f_1 + 96(-\frac{3}{4} + \ln(2))f_2 + 5760(-\frac{3}{2} \ln(2) + \frac{25}{24})f_3$ , while the distance is approximately 0.035.

Let us now illustrate the functions  $x$  and  $1/x^4$  and their approximations.

In this figure we see that the function  $\frac{1}{x^4}$ , which is the one whose shape is similar to that of one or more generators, is approximated much better by the projection.

**7.A.7.** We have just to check the orthogonality of the couples  $L_m(x), L_n(x)$  with respect to the inner product  $\langle f, g \rangle_\omega = \int_0^\infty f(t)g(t) e^{-t} dt$ . This can be done by integration by parts.

**7.A.8.** The claim follows from the fact that the powers  $x^k$  appear in the polynomials  $T_k$  or  $L_k$  the first time. Thus the linear hulls of the first  $k$  functions always coincide.

**7.A.9.** We mention that since  $f, g$  are both piecewise continuous functions defined on  $[-\pi, \pi]$ , the product  $f\bar{g}$  also belongs to  $\mathcal{S}^0([-\pi, \pi])$ . Thus, the function  $f\bar{g}$  is Riemann integrable and  $(f, g) := \int_{-\pi}^\pi f(x)\bar{g}(x)dx$  is well-defined. The rest details proving that  $(\cdot, \cdot)$  is an inner product on  $\mathcal{S}^0([-\pi, \pi])$  rely on elementary properties of integrals. Next, we see that

$$\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) = \frac{1}{\pi} \int_{-\pi}^\pi \frac{1}{2} dx = \frac{1}{\pi} \left[\frac{x}{2}\right]_{-\pi}^\pi = \frac{\pi}{\pi} = 1.$$

Moreover, for any positive integer  $n$  we have

$$\begin{aligned} \left(\frac{\sqrt{2}}{2}, \sin(nx)\right) &= \frac{\sqrt{2}}{2\pi} \int_{-\pi}^\pi \sin(nx) dx = -\frac{\sqrt{2}}{2\pi} \left[\frac{1}{n} \cos(nx)\right]_{-\pi}^\pi = -\frac{\sqrt{2}}{2n\pi} [\cos(n\pi) - \cos(-n\pi)] = 0, \\ \left(\frac{\sqrt{2}}{2}, \cos(nx)\right) &= \frac{\sqrt{2}}{2\pi} \int_{-\pi}^\pi \cos(nx) dx = 0, \\ (\sin(nx), \sin(nx)) &= \frac{1}{\pi} \int_{-\pi}^\pi \sin^2(nx) dx = \frac{1}{2\pi} \int_{-\pi}^\pi (1 - \cos(2nx)) dx = \frac{1}{2\pi}(\pi + \pi) - \frac{1}{2\pi} \left[\frac{1}{2n} \sin(2n)\right]_{-\pi}^\pi = 1, \\ (\cos(nx), \cos(nx)) &= \frac{1}{\pi} \int_{-\pi}^\pi \cos^2(nx) dx = \frac{1}{2\pi} \int_{-\pi}^\pi (1 + \cos(2nx)) dx = 1. \end{aligned}$$

Finally, using appropriate trigonometric identities it is not hard to prove that

$$(\cos(mx), \cos(nx)) = (\cos(mx), \sin(nx)) = (\sin(mx), \sin(nx)) = 0$$

for all positive integers  $m, n$  with  $m \neq n$ . Moreover, we have  $(\cos(mx), \sin(nx)) = 0$  also for  $m = n$ , and the claim follows.

**7.A.12.** A confirmation of the expression presented in 7.A.11 goes as follows:

```
f = piecewise([[(-pi, pi), abs(x)]]); L=pi; n=var("n")
an=(1/L)*integral(abs(x)*cos(n*pi*x/L), x, -pi, pi); show("a_n=", an.expand())
bn=(1/L)*integral(abs(x)*sin(n*pi*x/L), x, -pi, pi); show("b_n=", bn.expand())
```

For the approximation with  $k = 5$ , and its graph, add in the previous block the cell

```
Fs5 = f.fourier_series_partial_sum(5,pi); show("5th partial sum = ",Fs5)
s5 = plot(Fs5, x, -pi-0.5, pi+0.5, linestyle="--", tick_formatter=[2*pi, None])
a=plot(f, x, -pi, pi, color="black", thickness=1.5)
show(a+s5)
```

Execute this code to obtain the explicit form of  $F_5(x)$  and confirm graphically that it provides a pretty good approximation of the function at hand. The confirmation of the identity  $F_5(x) = F_6(x)$  can be easily done and we leave this for practice.

**7.A.13.** The sign function has discontinuities at  $x = 0$  and  $x = \pm\pi$ . Since  $\operatorname{sgn}(-x) = -\operatorname{sgn}(x)$  for all  $x$  we get  $a_n = 0$  for all  $n \in \mathbb{N}$ , and the Fourier series of  $\operatorname{sgn}(x)$  is a sine series,  $F(x) = \sum_{n=1}^{\infty} b_n \sin(nx)$ . The function  $g(x) = \operatorname{sgn}(x) \sin(nx)$  is even, as a product of two odd functions, thus

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} \operatorname{sgn}(x) \sin(nx) dx = \frac{2}{\pi} \int_0^{\pi} \sin(nx) dx = \frac{2}{\pi} \left[ -\frac{\cos(nx)}{n} \right]_0^{\pi} = \frac{2}{\pi} \left[ -\frac{\cos(n\pi)}{n} + \frac{1}{n} \right] = \frac{2(1 - (-1)^n)}{n\pi}.$$

We can simplify this by observing that

$$b_n = \begin{cases} 0, & \text{if } n = 2m, \text{ where } m \in \mathbb{Z}_+, \\ \frac{4}{n\pi}, & \text{if } n = 2m - 1, \text{ where } m \in \mathbb{Z}_+. \end{cases}$$

Therefore, the corresponding Fourier series has the form

$$F(x) = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{1 - (-1)^n}{n} \sin(nx) = \frac{4}{\pi} \sum_{m=1}^{\infty} \frac{1}{(2m-1)} \sin((2m-1)x).$$

**7.A.17.** Since  $f$  is neither even, nor odd, the complex Fourier coefficients will have both real and imaginary part. In particular, using the properties of the exponential map, we compute

$$c_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^x e^{-inx} dx = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{(1-in)x} dx = \frac{1}{2\pi} \left[ \frac{e^{(1-in)x}}{(1-in)} \right]_{-\pi}^{\pi} = \frac{1}{2\pi(1-in)} \left( e^{(1-in)\pi} - e^{-(1-in)\pi} \right).$$

Now it is easy to see that  $e^{(1-in)\pi} = e^{\pi} \cos(n\pi)$  and  $e^{-(1-in)\pi} = e^{-\pi} \cos(n\pi)$ . Thus, recalling the identity  $2 \sinh(x) = (e^x - e^{-x})$ , we have arrived at the following expression:

$$c_n = \frac{\cos(n\pi)}{2\pi(1-in)} (e^{\pi} - e^{-\pi}) = \frac{\sinh(\pi)}{\pi} \frac{(1+in)}{(1+n^2)} \cos(n\pi) = \frac{\sinh(\pi)}{\pi} \frac{(1+in)}{(1+n^2)} (-1)^n.$$

This also gives  $c_0 = \frac{\sinh(\pi)}{\pi} = \frac{e^{\pi} - e^{-\pi}}{2\pi}$ . As for  $c_{-n}$  we see that

$$c_{-n} = \frac{\sinh(\pi)}{\pi} \frac{(1-in)}{(1+(-n)^2)} \cos(-nx) = \frac{\sinh(\pi)}{\pi} \frac{(1-in)}{(1+n^2)} (-1)^n = \overline{c_n},$$

as it is required. Recalling now that  $e^{inx} + e^{-inx} = 2 \cos(nx)$  and  $e^{inx} - e^{-inx} = 2i \sin(nx)$ , we finally get

$$\begin{aligned} F(x) &= c_0 + \sum_{n=1}^{\infty} c_n e^{inx} + \sum_{n=1}^{\infty} c_{-n} e^{-inx} \\ &= \frac{\sinh(\pi)}{\pi} \left( 1 + \sum_{n=1}^{\infty} \frac{(1+in)}{(1+n^2)} (-1)^n e^{inx} + \sum_{n=1}^{\infty} \frac{(1-in)}{(1+n^2)} (-1)^n e^{-inx} \right) \\ &= \frac{\sinh(\pi)}{\pi} \left( 1 + \sum_{n=1}^{\infty} \frac{(-1)^n}{1+n^2} \left[ (1+in) e^{inx} + (1-in) e^{-inx} \right] \right) \\ &= \frac{\sinh(\pi)}{\pi} \left( 1 + \sum_{n=1}^{\infty} \frac{(-1)^n}{1+n^2} \left[ e^{inx} + e^{-inx} + in(e^{inx} - e^{-inx}) \right] \right) \\ &= \frac{\sinh(\pi)}{\pi} \left( 1 + 2 \sum_{n=1}^{\infty} \frac{(-1)^n}{1+n^2} \left[ \cos(nx) + i^2 n \sin(nx) \right] \right) \\ &= \frac{\sinh(\pi)}{\pi} \left( 1 + 2 \sum_{n=1}^{\infty} \frac{(-1)^n}{1+n^2} \left[ \cos(nx) - n \sin(nx) \right] \right). \end{aligned}$$

In order to plot  $f$  together with the 20th partial sum of the Fourier series, use the cell given here:

```
f=piecewise([[(-pi,pi), e**x]])
a=plot(f, x, -pi, pi, color="steelblue", thickness=1.5)
```

```

Fs20 = f.fourier_series_partial_sum(20,pi)
s20 = plot(Fs20, x, -4*pi, 4*pi,color="grey", linestyle="--")
(a+s20).show(ticks=pi, tick_formatter=pi, figsize=8)
    
```

Running this cell we obtain the following figure:

**7.A.18.** In this case the period is given by  $T = 2L = 1$ , i.e.,  $L = 1$ . Thus

$$F(x) = \sum_{n=-\infty}^{\infty} c_n e^{\frac{in\pi x}{L}} = \sum_{n=-\infty}^{\infty} c_n e^{in\pi x}, \quad c_n = \frac{1}{2L} \int_{-L}^L e^{-x} e^{-\frac{in\pi x}{L}} dx = \frac{1}{2} \int_{-1}^1 e^{-x} e^{-in\pi x} dx.$$

We compute

$$\begin{aligned} c_n &= \frac{1}{2} \int_{-1}^1 e^{-(1+in\pi)x} dx = \frac{1}{2} \left[ \frac{e^{-(1+in\pi)x}}{-(1+in\pi)} \right]_{-1}^1 = -\frac{1}{2(1+in\pi)} \left( e^{-(1+in\pi)} - e^{(1+in\pi)} \right) \\ &= -\frac{1}{2(1+in\pi)} \left( e^{-1} e^{-in\pi} - e^1 e^{in\pi} \right) = \frac{(-1)^n}{(1+in\pi)} \frac{e^1 - e^{-1}}{2} = \frac{(-1)^n}{(1+in\pi)} \sinh(1). \end{aligned}$$

Here we used the identities  $e^{in\pi} = e^{-in\pi} = \cos(n\pi) = (-1)^n$ . Hence, the Fourier series of  $f$  has the form

$$F(x) = \sum_{n=-\infty}^{\infty} \left[ \frac{(-1)^n}{(1+in\pi)} \sinh(1) \right] e^{in\pi x} = \sinh(1) \sum_{n=-\infty}^{\infty} \frac{(-1)^n (1-in\pi)}{1+n^2\pi^2} e^{in\pi x}.$$

**7.A.24.** We need the even extension of  $f$  on  $(-\pi, \pi)$ , which reads by

$$f_{\text{ev}}(x) = \begin{cases} f(x), & \text{if } 0 \leq x < \pi, \\ f(-x), & \text{if } -\pi < x < 0 \end{cases} = \begin{cases} \sin(x), & \text{if } 0 \leq x < \pi, \\ -\sin(x), & \text{if } -\pi < x < 0. \end{cases}$$

We may extend  $f_{\text{ev}}$  periodically all over  $\mathbb{R}$  by setting  $f_{\text{ev}}(x + 2\pi) = f_{\text{ev}}(x)$  for all the other  $x$ . Notice the values of this  $2\pi$ -periodic extension at  $\pm\pi$  coincide with  $f(\pi) = \sin(\pi) = 0$  (and similarly for  $\pm N\pi$ ,  $N \in \mathbb{N}$ ). Let us use Sage to illustrate this extension on  $(-\pi, \pi)$ :

```

f1(x)=sin(x); f2(x)=-sin(x)
f = piecewise([[(-pi, 0), f2], [RealSet.closed_open(0, pi), f1]])
p=f.plot(x, -pi, pi, exclude=[0], color="black")
p.show(figsize=8, ticks=pi/2, tick_formatter=pi)
    
```

Running this block we obtain the figure given here:

Now, for the cosine extension we have  $b_n = 0$  while the coefficients  $a_n$  are given by  $a_n = \frac{2}{\pi} \int_0^\pi \sin(x) \cos(nx) dx$ . Using the identity  $2 \sin(\theta) \cos(\varphi) = \sin(\theta + \varphi) + \sin(\theta - \varphi)$  we obtain

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_0^\pi \left( \sin((1+n)x) + \sin((1-n)x) \right) dx = \frac{1}{\pi} \left[ -\frac{\cos((1+n)x)}{n+1} - \frac{\cos((1-n)x)}{1-n} \right]_0^\pi \\ &= \frac{1}{\pi} \left( \frac{1 - \cos((n+1)\pi)}{n+1} + \frac{\cos((1-n)\pi) - 1}{n-1} \right) = \frac{1}{\pi} \left( \frac{1 - (-1)^{n+1}}{n+1} + \frac{(-1)^{n+1} - 1}{n-1} \right) \\ &= \frac{1}{\pi} \left( \frac{1 + (-1)^n}{n+1} - \frac{(-1)^n + 1}{n-1} \right) = \frac{(1 + (-1)^n)}{\pi} \left( \frac{1}{n+1} - \frac{1}{n-1} \right) = -\frac{2(1 + (-1)^n)}{\pi(n^2 - 1)}, \end{aligned}$$

which makes sense for all integers  $n > 1$ . To verify this expression in Sage one may add in the block presented above the following cell:

```
L=pi; n=var("n"); an=(2/L)*integral(sin(x)*cos(n*pi*x/L), x, 0, pi);
show("a_n=", an.expand())
```

Moreover, it is easy to see that

$$a_1 = \frac{2}{\pi} \int_0^\pi \sin(x) \cos(x) dx = 0, \quad a_0 = \frac{2}{\pi} \int_0^\pi \sin(x) dx = \frac{4}{\pi}.$$

All together, we have proved that

$$a_n = \begin{cases} \pi/4, & \text{if } n = 0, \\ 0, & \text{if } n \geq 1, n = 2k + 1 \text{ odd}, \\ -\frac{4}{(n^2-1)\pi}, & \text{if } n > 1, n = 2k \text{ even}. \end{cases}$$

Therefore for all  $x \in (-\pi, \pi)$  by Dirichlet's condition we have that

$$\sin(x) = \frac{2}{\pi} - \frac{4}{\pi} \sum_{k=1}^{\infty} \frac{\cos(2kx)}{4k^2 - 1} = \frac{2}{\pi} - \frac{4}{\pi} \left( \frac{\cos(2x)}{3} + \frac{\cos(4x)}{15} + \frac{\cos(6x)}{35} + \dots \right).$$

We may use Sage to illustrate the 3rd and 5th partial sums of the approximation, with brown and blue color respectively, together with the graph of  $f_{ev}$  for  $x \in (-\pi, \pi)$ . It suffices to add to the initial block the following one:

```
Fs3 = f.fourier_series_partial_sum(3, pi)
Fs5 = f.fourier_series_partial_sum(5, pi)
s3 = plot(Fs3, x, -pi, pi, color="brown", linestyle="--")
s5 = plot(Fs5, x, -pi, pi, linestyle="--", color="steelblue")
(p+s3+s5).show(ticks=pi/2, tick_formatter=pi, figsize=8)
```

Let us pose the figure that one obtains after executing the whole syntax together:

**7.A.25.** Here we need the odd extension of  $f$ , which is given by

$$f_{\text{odd}}(x) = \begin{cases} f(x), & \text{if } 0 < x < \pi, \\ -f(-x), & \text{if } -\pi < x < 0 \end{cases} = \begin{cases} \cos(x), & \text{if } 0 < x < \pi, \\ -\cos(x), & \text{if } -\pi < x < 0. \end{cases}$$

We may extend  $f_{\text{odd}}$  over the whole real line by setting  $f_{\text{odd}}(x + 2\pi) = f_{\text{odd}}(x)$  for  $x$  outside  $(-\pi, \pi)$ . At  $x = \pm\pi$  the values of this extension will coincide with the values  $f(\pm\pi) = \mp 1$ . Let us illustrate the extension for  $x \in (-\pi, \pi)$  by Sage, via the same method as above:

```
f1(x)=cos(x); f2(x)=-cos(x)
f = piecewise([(-pi, 0), f2], [(0, pi), f1])
p=f.plot(x, -pi, pi, exclude=[0])
p.show(figsize=8, ticks=pi/2, tick_formatter=pi)
```

Running this block we obtain the figure given here:

Now, since we are interesting in the sine expansion, we have necessarily  $a_n = 0$  for all  $n \in \mathbb{N}$ . Moreover, since  $L = \pi$  we see that  $b_n = \frac{2}{\pi} \int_0^\pi \cos(x) \sin(nx) dx$ . To compute this integral use the identity  $2 \sin(nx) \cos(x) = \sin((1+n)x) + \sin((n-1)x)$ , which gives

$$b_n = \frac{1}{\pi} \int_0^\pi (\sin((1+n)x) + \sin((n-1)x)) dx = -\frac{1}{\pi} \left[ \frac{\cos((n+1)x)}{n+1} + \frac{\cos((n-1)x)}{n-1} \right]_0^\pi = \frac{2n((-1)^n + 1)}{(n^2 - 1)\pi}.$$

This holds for all  $n > 1$  and can be verified in Sage by adding in the previous block the syntax given here:

```
L=pi; n=var("n")
bn=(2/L)*integral(cos(x)*sin(n*pi*x/L), x, 0, pi)
show("b_n=", bn.expand())
```

On the other hand, for  $n = 1$  we get

$$b_1 = \frac{2}{\pi} \int_0^\pi \cos(x) \sin(x) dx = \frac{1}{\pi} \int_0^\pi \sin(2x) dx = 0,$$

thus we have proved that

$$b_n = \begin{cases} 0, & \text{if } n = 1, \\ 0, & \text{if } n > 1, n = 2k + 1 \text{ odd}, \\ \frac{4n}{(n^2-1)\pi}, & \text{if } n > 1, n = 2k \text{ even}. \end{cases}$$

Therefore, one deduces that

$$\cos(x) = \sum_{k=1}^{\infty} \frac{8k}{(4k^2-1)\pi} \sin(2kx) = \frac{8}{3\pi} \sin(2x) + \frac{16}{15\pi} \sin(4x) + \frac{24}{35\pi} \sin(6x) + \dots$$

for all  $x \in (0, \pi)$ . Below are presented the approximations obtained for  $n = 10$  and  $n = 30$ , respectively, on the interval  $(-\pi, \pi)$ .

#### 7.B.4.

$$f_1 * f_2(t) = \begin{cases} t - \frac{t^2}{2} + 4 & \text{for } t \in [-2, -1] \\ 1 - t + \frac{1}{2} & \text{for } t \in [-1, 1] \\ \frac{t^2}{2} - 2t + 2 & \text{for } t \in [1, 2] \\ 0 & \text{otherwise.} \end{cases}$$

**7.B.14.** It is a good exercise on derivation and integration by parts. We may differentiate with respect to  $t$  inside the integral and  $\frac{d}{dt}f(t-x)$  can be interpreted as  $-\frac{d}{dx}f(t-x)$ .

**7.B.16.** Another good exercise on derivation and integration by parts. We may differentiate twice with respect to  $t$  inside the integral and  $f''(t-x)$  can be interpreted either as a derivative with respect to  $t$  or  $x$ .

**7.B.18.** The definition of  $\Gamma(t)$  reveals

$$\mathcal{L}(t^\alpha) = \int_0^\infty e^{-st} t^\alpha dt = \frac{1}{s^{\alpha+1}} \int_0^\infty e^{-x} x^\alpha dx = \frac{\Gamma(\alpha+1)}{s^{\alpha+1}}.$$

**7.B.19.** Integrate by parts to obtain

$$\mathcal{L}(g)(s) = \int_0^\infty t e^{-t} e^{-st} dt = \int_0^\infty t e^{-(s+1)t} dt = \lim_{t \rightarrow \infty} \left( \frac{t e^{-(s+1)t}}{-(s+1)} \right) - 0 - \int_0^\infty \frac{e^{-(s+1)t}}{-(s+1)} dt = - \left( \lim_{t \rightarrow \infty} \frac{e^{-(s+1)t}}{(s+1)^2} - \frac{e^0}{(s+1)^2} \right) = \frac{1}{(s+1)^2}.$$

Differentiating the Laplace transform of a general function  $-f$  (i. e., an improper integral) with respect to the parameter  $s$  gives

$$\left( \int_0^\infty -f(t) e^{-st} dt \right)' = \int_0^\infty -f(t) (e^{-st})' dt = \int_0^\infty t f(t) e^{-st} dt.$$

This means that the derivative of the Laplace transform  $\mathcal{L}(-f)(s)$  is the Laplace transform of the function  $tf(t)$ . The Laplace transform of the function  $y = \sinh t$  has already been determined as the function  $y = \frac{1}{s^2-1}$ . Therefore,

$$\mathcal{L}(h)(s) = \left( -\frac{1}{s^2-1} \right)' = \frac{2s}{(s^2-1)^2}.$$

We could also have determined  $\mathcal{L}(g)(s)$  this way.

**7.B.20.**

$$\begin{aligned} & \mathcal{L}(\cos \omega t)(s) + i\mathcal{L}(\sin \omega t)(s) = \mathcal{L}(e^{i\omega t})(s) \\ &= \int_0^\infty e^{i\omega t} e^{-st} dt = \int_0^\infty e^{(i\omega-s)t} dt \\ &= -\frac{1}{s-i\omega} \left[ e^{(i\omega-s)t} \right]_0^\infty \\ &= -\frac{1}{s-i\omega} \left( \lim_{t \rightarrow \infty} \frac{e^{i\omega t}}{e^{st}} - 1 \right) = \frac{1}{s-i\omega} = \frac{s+i\omega}{(s-i\omega)(s+i\omega)} \\ &= \frac{s}{s^2+\omega^2} + i\frac{\omega}{s^2+\omega^2} \end{aligned}$$

**7.C.23.** Recall the definition of the product metric of the Cartesian product  $X \times X$  where the distance is given as the maximum of the distance of the components. The claim follows directly from the triangle inequality and the topological definition of the continuity.

**7.D.5.** The orthogonal basis has the form  $\{x, -\frac{3}{\pi^2}x + \sin(x)\}$ , while the projection does not change the function  $\frac{1}{2}\sin(x)$  since it already lies in the space.

**7.D.6.** The orthogonal basis has the form  $\{\cos(x), \frac{4}{\pi}\cos(x) + x\}$ . Moreover, the required projection is given by  $3\pi/(\pi^4 - 24)(4\cos(x) + \pi x)$ . Notice that this is a very bad approximation.

**7.D.7.** We have already checked the orthogonality of the cosine terms in the solution to the example 7.A.4. The sine terms are obtained the same way since they are just shifts of cosines by  $\pi/2$  in the argument. The mixed couples provide an odd function to be integrated on a symmetric interval around the origin and so the integral also vanishes.

**7.D.10.** For  $n \neq 0$  we have

$$c_n = \frac{1}{2\pi} \int_0^\pi e^{-inx} dx = \frac{1}{2\pi} \left[ \frac{e^{-inx}}{-in} \right]_0^\pi = \frac{1}{2\pi} \frac{(1 - (-1)^n)}{in}.$$

Moreover,  $c_0 = \frac{1}{2\pi} \int_0^\pi dx = \frac{1}{2}$ . Thus

$$F(x) = \frac{1}{2} + \sum_{n=1}^\infty c_n e^{inx} + \sum_{n=-\infty}^{-1} c_n e^{inx} = \frac{1}{2} + \sum_{n=1}^\infty \frac{1}{2\pi} \frac{(1 - (-1)^n)}{in} e^{inx} + \sum_{n=-\infty}^{-1} \frac{1}{2\pi} \frac{(1 - (-1)^n)}{in} e^{inx}.$$

Next, in the second of the sums, replace  $n$  with  $-n$ . This gives

$$\begin{aligned} F(x) &= \frac{1}{2} + \frac{1}{2\pi} \sum_{n=1}^\infty \frac{(1 - (-1)^n)}{in} (e^{inx} - e^{-inx}) = \frac{1}{2} + \frac{1}{2\pi} \sum_{n=1}^\infty \frac{(1 - (-1)^n)}{in} 2i \sin(nx) \\ &= \frac{1}{2} + \frac{1}{\pi} \sum_{n=1}^\infty \frac{(1 - (-1)^n)}{n} \sin(nx). \end{aligned}$$

It is easy to see that when  $n$  is even, the terms are all 0. For  $n$  odd, put  $n = 2m - 1$  to obtain

$$F(x) = \frac{1}{2} + \frac{2}{\pi} \sum_{m=1}^\infty \left( \frac{1}{2m-1} \right) \sin(2m-1)x = \frac{1}{2} + \frac{2}{\pi} \left( \sin(x) + \frac{\sin(3x)}{3} + \frac{\sin(5x)}{5} + \dots \right).$$

Notice that this expression is similar to the problem described in 7.1.9. In particular, we could use the result from 7.1.9 to derive our claim after an easy transformation.

**7.D.15.** Determine the convolution of the functions  $f_1$  and  $f_2$ , where

$$f_1 * f_2(t) = \begin{cases} \frac{(t+1)^2}{2} & \text{for } t \in [-1, 0] \\ \frac{1-t^2}{2} & \text{for } t \in [0, 1] \\ 0 & \text{otherwise.} \end{cases}$$

## Calculus with more variables

*one variable is not enough?  
– never mind, just recall vectors!*

### A. Multivariate functions

We start this chapter with a couple of easy examples to "grasp" a little multivariate functions.

**8.A.1.** Solve the system of inequalities. Mark the resulting area in the plane.

- a)  $x^2 + y^2 \leq 4$   
 $y \geq \frac{1}{x}$
- b)  $y \leq \arctan x$   
 $y \leq \frac{1}{x^2}$
- c)  $x^2 + (y - 1)^2 \geq 4$   
 $y + x^2 - 2x \geq 0$   
 $y \geq 0$

**Solution.** Whenever you have to solve an inequality of the form  $f(x, y) \geq 0$  ( $f : \mathbb{R}^2 \rightarrow \mathbb{R}$  is a function of two variables, but the same method is valid for inequalities with more variables), you just consider the border curve  $f(x, y) = 0$ . This curve divides the plane into some areas. Then all points in any of the areas either satisfy the inequality or the whole area does not satisfy it. If we have a system of inequalities, we

At the beginning of our journey through the mathematical landscape, we saw that vectors can be manipulated nearly as easily as scalars. Now, we return to situations where the relations between objects are expressed with the help of more (yet still finitely many) parameters. This is really necessary when modeling processes or objects in practice, where functions  $\mathbb{R} \rightarrow \mathbb{R}$  of one variable are seldom adequate. At least, functions dependent on finitely many parameters are necessary, and the dependence of the change of the results on the parameters is often more important than the result itself. There is little need for brand new ideas. Many problems we encounter can be reduced to ones we can solve already. We return to the discussion of situations when the values of functions are described in terms of instantaneous changes. That is, we consider ordinary differential equations. In the next chapter, we consider partial differential equations and provide a gentle introduction to variational problems.

### 1. Functions and mappings on $\mathbb{R}^n$

**8.1.1. The world of functions.** In the sequel, the main objects are mappings between Euclidean spaces,  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$ . We have seen many such examples already. The complex valued real functions correspond to  $n = 1, m = 2$ , while the power series converge inside of a circle in the complex plane, providing examples of  $f : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ . We have also dealt with vector valued real functions, representing parametrized curves  $c : \mathbb{R} \rightarrow \mathbb{R}^n$  (see e.g. the paragraphs on curvatures and Frenet frames in 6.1.16 on page 526).

In linear algebra and geometry, we saw the linear and affine maps  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  defined with the help of matrices  $A \in \text{Mat}_{m,n}(\mathbb{R})$  and constant vectors  $y \in \mathbb{R}^m$ :

$$\mathbb{R}^n \ni x \mapsto y + Ax \in \mathbb{R}^m.$$

In coordinates, the value is given by the expression  $\sum_j a_{ij}x_j + y_i$ , where  $A = (a_{ij})$  and  $y = (y_i)$ .

Finally, the quadratic forms were mappings  $\mathbb{R}^n \rightarrow \mathbb{R}$  given by symmetric matrices  $S = (s_{ij})$  and the formula

$$\mathbb{R}^n \ni x \mapsto x^T S x \in \mathbb{R}.$$

In coordinates, the value is  $\sum_{i,j} s_{ij}x_i x_j$ .

solve each inequality separately and then intersect the result. In our cases we get

**8.A.2.** Determine the domain of the function  $\mathbb{R}^2 \rightarrow \mathbb{R}$ :

a)

$$\frac{xy}{y(x^3 + x^2 + x + 1)},$$

b)

$$\ln(x^2 - y^2),$$

c)

$$\ln(-x^2 - y^2),$$

d)

$$\arcsin(2\chi_{\mathbb{Q}}(x)),$$

where  $\chi_{\mathbb{Q}}$  denotes the indicator function of the rational numbers,

e)

$$f(x, y, z) = \sqrt{\ln x \cdot \arcsin(y^2 z)}.$$

**Solution.** a) The formula correctly expresses a value iff the denominator of the fraction is non-zero. Therefore, the formula defines a function on the set  $\mathbb{R}^2 \setminus \{([x, 0], [-1, y]), x, y \in \mathbb{R}\}$ .

b) The formula is correct iff the argument of the logarithm is positive, i. e.,  $|x| > |y|$ . Therefore, the domain of this function is  $\{(x, y) \in \mathbb{R}^2, |x| > |y|\}$ . You can see the graph of this function in the picture.

c) This formula is again a composition of a logarithm and a polynomial of two variables. However, the polynomial  $-x^2 -$

In general, all such mappings  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  are composed of  $m$  components of functions  $f_i : \mathbb{R}^n \rightarrow \mathbb{R}$ . So we start with this case.

**8.1.2. Multivariate functions.** We can stress the dependence on the variables  $x_1, \dots, x_n$  by writing the functions as

$$f(x_1, x_2, \dots, x_n) : \mathbb{R}^n \rightarrow \mathbb{R}.$$

The goal is to extend methods for monitoring the values of functions and their changes for this situation.

We speak about *functions of more variables* or, more compactly, *multivariate functions*.

We often work with the cases  $n = 2$  or  $n = 3$  so that the concepts being introduced are easier to understand. In these cases, letters like  $x, y, z$  are used instead of numbered variables. This means that a function  $f$  defined in the “plane”  $\mathbb{R}^2$  is denoted

$$\mathbb{R}^2 \ni (x, y) \mapsto f(x, y) \in \mathbb{R},$$

and, similarly, in the “space”  $\mathbb{R}^3$

$$\mathbb{R}^3 \ni (x, y, z) \mapsto f(x, y, z) \in \mathbb{R}.$$

Just as in the case of univariate functions, the domain  $A \subset \mathbb{R}^n$  on which the function in question is defined needs to be considered. When examining a function given by a concrete formula, the first task is often to find the largest domain on which the formula makes sense.

It is also useful to consider the *graph* of a multivariate function, i. e., the subset  $G_f \subset \mathbb{R}^n \times \mathbb{R} = \mathbb{R}^{n+1}$ , defined by

$$G_f = \{(x_1, \dots, x_n, f(x_1, \dots, x_n)); (x_1, \dots, x_n) \in A\},$$

where  $A$  is the domain of  $f$ . For instance, the graph of the function defined in the plane by the formula

$$f(x, y) = \frac{x + y}{x^2 + y^2}$$

is quite a smooth surface, see the illustration below. The maximal domain of this function consists of all the points of the plane except for the origin  $(0, 0)$ .

When defining the function, and especially when drawing its graph, fixed *coordinates* are used in the plane. Fixing the value of either of the coordinates, implies only one variable remains. Fixing the value of  $x$ , for example, gives the mapping

$$\mathbb{R} \rightarrow \mathbb{R}^3, y \mapsto (x, y, f(x, y)),$$

i.e., a *curve* in the space  $\mathbb{R}^3$ . Curves are vector functions of one variable, already worked with in chapter six (see 6.1.14). The images of the curves for some fixed values of the coordinates  $x$  and  $y$  are depicted by lines in the illustration.

add the “coordinate lines” in the picture

$y^2$  takes on only non-positive real values, where the logarithm is undefined (as a function  $\mathbb{R} \rightarrow \mathbb{R}$ ).

d) This formula correctly defines a value iff the argument of the arc sine lies in the interval  $[-1, 1]$ , which is broken by exactly those pairs  $(= [x, y] \in \mathbb{R}^2$  whose first component is rational. The formula thus defines a function on the set  $\{[x, y], x \in \mathbb{R} \setminus \mathbb{Q}\}$ .

e) The argument of the square root must be non-negative, that is either the image of the logarithm is positive and the image of arcsine as well, or both images are negative. Thus we get that the domain is the set

$$\{[x, y, z] \in \mathbb{R}^3; (x \geq 1 \wedge y \neq 0 \wedge 0 \leq z \leq \frac{1}{y^2}) \vee (x \in (0, 1) \wedge y \neq 0 \wedge -\frac{1}{y^2} \leq z \leq 0) \vee (x > 0 \wedge y = 0)\}.$$

□

In the following examples  $k([x, y]; r)$  means a circle with the center  $[x, y]$  and the radius  $r$ .

**8.A.3.** Determine the domain of the function  $f$  and mark the resulting area in the plane:

- i)  $f(x, y) = \sqrt{(x^2 + y^2 - 1)(4 - x^2 - y^2)}$ ,
- ii)  $f(x, y) = \sqrt{1 - x^2} + \sqrt{1 - y^2}$ ,
- iii)  $f(x, y) = \sqrt{\frac{x^2 + y^2 - x}{2x - x^2 - y^2}}$ ,
- iv)  $f(x, y) = \arcsin \frac{x}{y} - \frac{1}{|y| - |x|}$ ,
- v)  $f(x, y) = \sqrt{1 - x^2 - 4y^2}$ ,
- vi)  $f(x, y, z) = \sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2}}$ .

**Solution.** a) It has to hold  $(x^2 + y^2 - 1 \geq 0, 4 - x^2 - y^2 \geq 0)$  or  $(x^2 + y^2 - 1 \leq 0, 4 - x^2 - y^2 \leq 0)$ , that is  $(x^2 + y^2 \geq 1, x^2 + y^2 \leq 4)$  or  $(x^2 + y^2 \leq 1, x^2 + y^2 \geq 4)$ , which is an annulus between the circles  $k([0, 0]; 1)$  and  $k([0, 0]; 2)$ .

b) It is a circle with the center  $[0, 0]$  and vertices  $[\pm 1, \pm 1]$

c) The area between circles  $k([\frac{1}{2}, 0]; \frac{1}{2})$  and  $k([1, 0]; 1)$ , the smaller circle belongs to the area, the bigger one does not.

d) The area between the lines  $y = x$  and  $y = -x$  (without these lines).

e) The ellipse (together with the inner space) with the center  $[0, 0]$ , with the major axis lying on the  $x$ -axis with the major radius  $a = 1$ , and the minor axis on the  $y$ -axis with the minor radius  $b = \frac{1}{2}$ .

f) The ellipsoid (with the inner space) with the center  $[0, 0, 0]$  a semiaxes lying on the  $x, y, z$  axis respectively, with radii  $a, b$ , and  $c$ . □

### B. The topology of $E_n$

In the previous chapter, we have defined general metric spaces and we have studied especially metric spaces consisting of the set of functions. As we have already seen in the previous chapter, many metrics can be defined on the space  $\mathbb{R}^n$  (or on its subsets). For instance, considering a map of a

### 8.1.3. Euclidean spaces.

In the case of functions of one variable, the entire differential and integral calculus is based on the concepts of convergence, open neighbourhoods, continuity, and so on. In the last part of chapter seven, these concepts were generalized for the metric spaces, rather than only for the Euclidean spaces  $\mathbb{R}^n$ . Before proceeding it is appropriate to revise these ideas, and do further reading if necessary. We present a brief summary:

The Euclidean space  $E_n$  is perceived as a set of points in  $\mathbb{R}^n$  without any choice of coordinates, and its modelling vector space  $\mathbb{R}^n$  is considered to be the vector space of all increments that can be added to the points of the space  $E_n$  (the modelling vector space).

Moreover, the standard scalar product

$$u \cdot v = \sum_{i=1}^n x_i y_i,$$

is selected on  $\mathbb{R}^n$ , where  $u = (x_1, \dots, x_n)$  and  $v = (y_1, \dots, y_n)$  are arbitrary vectors. This gives a *metric* on  $E_n$ , i.e. a function describing the distance  $\|P - Q\|$  between pairs of points  $P, Q$  by the formula

$$\|P - Q\|^2 = \|u\|^2 = \sum_{i=1}^n x_i^2,$$

where  $u$  is the vector which yields the point  $P$  when added to the point  $Q$ . In the plane  $E_2$ , for instance, the distance between the points  $P_1 = (x_1, y_1)$  and  $P_2 = (x_2, y_2)$  is given by

$$\|P_1 - P_2\|^2 = (x_1 - x_2)^2 + (y_1 - y_2)^2.$$

The metric defined in this manner satisfies the triangle inequality for every triple of points  $P, Q, R$ :

$$\|P - R\| = \|(P - Q) + (Q - R)\| \leq \|P - Q\| + \|Q - R\|.$$

state as a subset of  $\mathbb{R}^2$ , the distance of two points may be defined as the time necessary to get from one of the points to the other by public transport or on foot. In France, for example, the shortest paths between most pairs of points in this metric are far from line segments. In this chapter we will focus on the space  $E_n$ , that is  $\mathbb{R}^n$  with the usual metric (distance) known to the mankind for a long time. The property, that the shortest path between any two points of this space is the line segment connecting them could be seen as the defining property (for example the above example does not satisfy it). Let us examine the space  $E_n$  in more detail.

**8.B.1.** Show that every non-empty proper subset of  $E_n$  has a boundary point (which need not lie in it).

**Solution.** Let  $U \subset E_n$  be a non-empty subset with no boundary point. Consider a point  $X \in U$ , a point  $Y \in U' := E_n \setminus U$ , and the line segment  $XY \subset E_n$ . Intuitively, going from  $X$  to  $Y$  along this segment, we must once get from  $U$  to  $U'$ , and this can happen only at a boundary point (everyone who has ever been to a foreign country is surely well acquainted with this fact). Formally, let  $A$  be the point of  $XY$  for which  $|XA| = \sup\{|XZ|, XZ \in U\}$  (apparently, there is exactly one such point on the segment  $XY$ ). This point is a boundary point of  $U$ : it follows from the definition of  $A$  that any line segment  $XB$  (with  $B \in XA$ ) is contained in  $U$ ; in particular,  $B \in U$ . However, if there were a neighborhood of  $A$  contained in  $U$ , then there would exist a part of the line segment  $XY$  longer than  $XA$  which would be contained in  $U$ , which contradicts the definition of the point  $A$ . Therefore, any neighborhood of the point  $A$  contains a point from  $U$  as well as a point from  $E_n \setminus U$ .  $\square$

**8.B.2.** Prove that the only non-empty clopen (both closed and open) subset of  $E_n$  is  $E_n$  itself.

**Solution.** It follows from the above exercise 8.B.1 that every non-empty proper subset  $U$  of  $E_n$  has a boundary point. If  $U$  is closed, then it is equal to its closure; therefore, it contains all of its boundary points. However, an open set (by definition) cannot contain a boundary point.  $\square$

**8.B.3.** Show that the space  $E_n$  cannot be written as the union of (at least two) disjoint non-empty open sets.

**Solution.** Suppose that  $E_n$  can be expressed thus, i. e.,  $E_n = \cup_{i \in I} U_i$ , where  $I$  is an index set. Let us fix a set  $U$  from this union. Then, we can write  $E_n = U \cup \bar{U}$ , where both  $U$  and  $\bar{U}$  (being a union of open sets) are open. However, they are also complements of open sets; therefore, they are closed as well. This contradicts the result of the previous exercise 8.B.2.  $\square$

**8.B.4.** Prove or disprove: a union of (even infinitely many) closed subsets of  $E^n$  is a closed subset of  $E^n$ .

**Solution.** The proposition does not hold. As a counterexample, consider the union

$$\bigcup_{i=3}^{\infty} \left[ \frac{1}{i}, 1 - \frac{1}{i} \right]$$

See 3.4.3(1) in geometry, or the axioms of metrics in 7.3.1, or the same inequality 5.2.2(2) for complex scalars. The concepts defined for real and complex scalars and discussed for metric spaces in detail can be carried over (extended) with no problem for the points  $P_i$  of any Euclidean space:

TOPOLOGY AND METRIC IN EUCLIDEAN SPACES

- (1) *a Cauchy sequence*: a sequence of points  $P_i$  such that for every fixed  $\varepsilon > 0$ ,  $\|P_i - P_j\| < \varepsilon$  holds for all indices but for finitely many exceptional points  $P_k$ ;
- (2) *a convergent sequence*: a sequence of points  $P_i$  converges to a point  $P$  if and only if for every fixed  $\varepsilon > 0$ ,  $\|P_i - P\| < \varepsilon$  holds for all but finitely many indices  $i$ ; the point  $P$  is then called the *limit* of the sequence  $P_i$ ;
- (3) *a limit point  $P$  of a set  $A \subset E_n$* : there exists a sequence of points in  $A$  converging to  $P$  and different from  $P$ ;
- (4) *a closed set*: contains all of its limit points;
- (5) *an open set*: its complement is closed;
- (6) *an open  $\delta$ -neighbourhood of a point  $P$* : the set  $\mathcal{O}_\delta(P) = \{Q \in E_n; \|P - Q\| < \delta\}$ ,  $\delta \in \mathbb{R}$ ,  $\delta > 0$ ;
- (7) *a boundary point  $P$  of a set  $A$* : every  $\delta$ -neighbourhood of  $P$  has non-empty intersection with both  $A$  and the complement  $E_n \setminus A$ ;
- (8) *an interior point  $P$  of a set  $A$* : there exists a  $\delta$ -neighbourhood of  $P$  which lies inside  $A$ ;
- (9) *a bounded set*: lies inside some  $\delta$ -neighbourhood of one of its points (for a sufficiently large  $\delta$ );
- (10) *a compact set*: both closed and bounded.
- (11) *limit of a mapping*:  $a \in \mathbb{R}^m$  is the limit of function  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  in a limit point  $x_0$  of its domain  $A$ , if for each  $\varepsilon > 0$ , there is a  $\delta$ -neighbourhood  $U$  of  $x_0$ , such that  $\|f(x) - a\| < \varepsilon$  for all  $x \in U$ ; this happens if and only if for each sequence  $x_n \in A$  converging to  $x_0$ , the values  $f(x_n)$  converge to  $a$ .
- (12) *continuity*: mapping  $f : A \subset \mathbb{R}^n \rightarrow \mathbb{R}^m$  is continuous in  $x_0 \in A$  if the limit  $\lim_{x \rightarrow x_0} f(x)$  exists and equals to  $f(x_0)$ ; the mapping  $f$  is continuous on  $A$ , if it is continuous in all points in  $A$ .

Both the first and second items deal with norms of differences of points approaching zero. Since the square of the norm is the sum of squares of the individual components, it is clear that this happens if and only if the individual components approach zero. In particular, the sequences of points  $P_i$  are Cauchy or convergent if and only if these properties are possessed by the real sequences obtained from the particular coordinates of the points  $P_i$  in every Cartesian coordinate system. Therefore, it also follows from Lemma 5.2.3 that every Cauchy sequence of points in  $E_n$  is convergent. Especially,  $E_n$  is a complete metric space.

Similarly, the mappings from the item (11) are  $m$ -tuples of the component functions and the limits are given as the  $m$ -tuples of limits of these components.

Recall some further results already discussed at the more general level of the metric spaces in chapter seven:

hodil by se obrazek na ilustraci pojmu, napr. obr. 1

of closed subsets of  $\mathbb{R}$ , which is equal to the open interval  $(0, 1)$ .  $\square$

**8.B.5.** Prove or disprove: an intersection of (even infinitely many) open subsets of  $E^n$  is an open subset of  $E^n$ .

**Solution.** The proposition does not hold in general. As a counterexample, consider the intersection

$$\bigcap_{i=2}^{\infty} \left(1 - \frac{1}{i}, 1 + \frac{1}{i}\right)$$

of open subsets of  $\mathbb{R}$ , which is equal to the closed singleton  $\{1\}$ .  $\square$

**8.B.6.** Consider the graph of a continuous function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$  as a subset of  $E_3$ . Determine whether this subset is open, closed, and compact, respectively.

**Solution.** The subset is not open since any neighborhood of a point  $[x_0, y_0, f(x_0, y_0)]$  contains a segment of the line  $x = x_0, y = y_0$ . However, there is a unique point of the graph of the function on this segment, and that is the point  $[x_0, y_0, f(x_0, y_0)]$ .

The continuity of  $f$  implies that the subset is closed – we will show that every convergent sequence of points of the graph of  $f$  converges to a point which also lies in the graph: If such a sequence is convergent in  $E_3$ , then it must converge in every component, so the sequence  $\{[x_n, y_n]\}_{n=1}^{\infty}$  is convergent in  $\mathbb{R}^2$ . Let us denote this limit by  $[a, b]$ . Then, it follows from the definition of continuity that its function values at the points  $[x_n, y_n]$  must converge to the value  $f(a, b)$ . However, this means that the sequence  $\{[x_n, y_n, f(x_n, y_n)]\}_{n=1}^{\infty}$  converges to the point  $[a, b, f(a, b)]$ , which belongs to the graph of the function  $f$ . Therefore, the graph is a closed set.

The subset is closed, yet it is not compact since it is not bounded (its orthogonal projection onto the coordinate plane  $xy$  is the whole  $\mathbb{R}^2$ ). (A subset of  $E_n$  is compact iff it is both closed and bounded.)  $\square$

And now let us study the limits of functions (a limit is defined thanks to the topology of  $E_n$ , see 8.1.3)

### C. Limits and continuity of multivariate functions

If we approach limits of multivariate functions, there is one fact we have to deal with:

Let us emphasize that there is no analogy of L'Hospital rule for multivariate functions. Counting limits  $\frac{0}{0}$  or  $\frac{\infty}{\infty}$ , we have to be "clever".

In one dimension we can approach a point either from right or left (and the limit in the point exists, if both one-sided limits exist and are equal to each other). In more dimensions we can approach a point from infinitely many directions, and the limit in the point exists, iff limits of the function narrowed to any path leading to the point exist and must be equal to each other.

The easiest way to obtain a limit is (as with the functions of one variable) to plug in the given point to the function prescription and if we get a meaningful expression, we are done.

A mapping is continuous if and only if its preimages of open sets are open (check this carefully!). Further, each continuous function on a compact set  $A$  is uniformly continuous, bounded and attains its maximum and minimum, cf. the paragraph 7.3.14 on the page 682.

The reader should make an appropriate effort to read the paragraphs 3.4.3, 5.2.5–5.2.8, 7.3.3–7.3.5, and 7.3.12 as well as try to think out/recall the definitions and connections of all these concepts.

**8.1.4. Compact sets.** Working with general open, closed, or compact sets could seem useless in the case of the real line  $E_1$  since intervals are almost always used.

In the case of metric spaces in the last part of chapter seven, the ideas are complicated at first sight. However, the same approach is easy in the case of Euclidean spaces  $\mathbb{R}^n$ . It is also very useful and important (and it is, of course, a special case of general metric spaces).

Just as in the case of  $E_1$  or  $E_2$ , we deal with the open covers of sets (i.e., systems of open sets containing the given sets), and Theorem 5.2.8 is again true (with mere reformulations):

**Theorem.** Subsets  $A \subset E_n$  of Euclidean spaces satisfy:

- (1)  $A$  is open if and only if it is a union of a countable (or finite) system of  $\delta$ -neighbourhoods,
- (2) every point  $a \in A$  is either interior or boundary,
- (3) every boundary point of  $A$  is either an isolated or a limit point of  $A$ ,
- (4)  $A$  is compact if and only if every infinite sequence contained in it has a subsequence converging to a point in  $A$ ,
- (5)  $A$  is compact if and only if each of its open covers contains a finite subcover.

**PROOF.** The proof from 5.2.8 can be reused without changes in the case of claims (1)–(3), yet now the concepts have to be perceived in a different way, and the "open intervals" are substituted with multidimensional  $\delta$ -neighbourhoods of appropriate points.

However, the proof of the fourth and fifth claims has to be adjusted properly. Actually, we proved the claims there for  $\mathbb{R}$  and  $\mathbb{C}$ , thus in dimensions one and two. Thus the reader may either extend the two-dimensional reasoning, or to rewrite the proof of the corresponding propositions for general metric spaces in 7.3.12, while noticing the parts which can be simplified for Euclidean spaces.  $\square$

**8.1.5. Curves in  $E_n$ .** Almost all the discussion about limits, derivatives, and integrals of functions in chapters 5 and 6 concerned functions of a real variable and real or complex values since only the triangle inequality valid for the magnitudes of the real and complex numbers is used. This argument can be carried over to any function of a real variable with values in a Euclidean

Otherwise we can get "undeterminate" expression. There are some tricks, we can use to count such a limit:

- (1) factorize the numerator or the denominator according to some known formula and then reduce,
- (2) expand the numerator and the denominator with an appropriate term and then shorten,
- (3)  $\frac{\text{bounded expression}}{\infty} = 0, 0 \cdot (\text{bounded expression}) = 0;$
- (4) use an appropriate substitution to get a limit of a function of one variable
- (5) try polar coordinates

$$\begin{aligned} x &= r \cos \varphi, \\ y &= r \sin \varphi \end{aligned}$$

(it usually works with the expression  $x^2 + y^2$ , we have  $x^2 + y^2 = r^2 \cos^2 \varphi + r^2 \sin^2 \varphi = r^2(\cos^2 \varphi + \sin^2 \varphi) = r^2$ , which is independent of  $\varphi$ );

- (6) try  $y = kx$  or  $y = kx^2$  or generally  $x = f(k)$  a  $y = g(k)$  (to prove the non-existence of the limit: if the limit after the substitution depends on  $k$ , the original limit does not exist)

8.C.1.  $\lim_{(x,y) \rightarrow (e^2,1)} \frac{\ln x}{y}$

8.C.2.  $\lim_{(x,y) \rightarrow (4,4)} \frac{\sqrt{x}-\sqrt{y}}{x-y}$

8.C.3.  $\lim_{(x,y) \rightarrow (1,\infty)} \frac{\cos y}{x+y}$

8.C.4.  $\lim_{(x,y) \rightarrow (0,2)} \frac{e^{xy}-1}{x}$

8.C.5.  $\lim_{(x,y) \rightarrow (\infty,\infty)} \frac{x^2+y^2}{x^4+y^4}$

8.C.6.  $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2+y^2}{x+y}$

8.C.7.  $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2-y^2}{x^2+y^2}$

8.C.8.  $\lim_{(x,y) \rightarrow (\infty,\infty)} \left(\frac{2xy}{x^2+y^2}\right)^{x^2}$

8.C.9.  $\lim_{(x,y) \rightarrow (1,1)} \frac{x+y}{\sqrt{x^2+y^2}}$

8.C.10.  $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2+y^2}{\sqrt{x^2+y^2+1}-1}$

8.C.11.  $\lim_{(x,y) \rightarrow (0,0)} xy^2 \cos \frac{1}{xy^2}$

8.C.12.  $\lim_{(x,y) \rightarrow (0,0)} \frac{\sin xy}{x}$

8.C.13.  $\lim_{(x,y) \rightarrow (0,0)} \frac{x^3+y^3}{x^2+y^2}$

8.C.14.  $\lim_{(x,y) \rightarrow (\infty,\infty)} (x^2 + y^2)e^{-(x+y)}$

8.C.15.  $\lim_{(x,y) \rightarrow (\infty,1)} \left(1 + \frac{1}{x}\right)^{\frac{x^2}{x+y}}$

8.C.16.  $\lim_{(x,y) \rightarrow (0,0)} \frac{xy}{x^2+y^2}$

8.C.17.  $\lim_{(x,y) \rightarrow (0,0)} \frac{1-\cos(x^2+y^2)}{(x^2+y^2)xy}$

8.C.18. Prove that  $\lim_{(x,y) \rightarrow (0,0)} \frac{-y}{x^2-y}$  does not exist.

8.C.19. Prove that

$$\lim_{(x,y) \rightarrow (1,-2)} \frac{2x + xy - y - 2}{x^2 + y^2 - 2x + 4y + 5}$$

does not exist.

space  $\mathbb{R}^n$ . Several tools for the work with curves are introduced in paragraphs 6.1.14–6.1.12.

For every (parametrized) curve<sup>1</sup>, that is, a mapping  $c = (c_1(t), \dots, c_n(t)) : \mathbb{R} \rightarrow \mathbb{R}^n$  in an  $n$ -dimensional space, the concepts simply extend the ideas from the univariate functions with some extra thoughts:

First note that both the limit and the derivative of curves make sense in an affine space even without selecting the coordinates (where the limit is again a point in the original space, while the derivative is a vector in the modeling vector space!).

In the case of an integral, curves are considered in the vector space  $\mathbb{R}^n$ . The reason for this can be seen even in the case of one dimension, where the origin is needed to be able to see the “area under the graph of a function”.

It is apparent that limits, derivatives, and integrals have to be considered via the  $n$  individual coordinate components in  $\mathbb{R}^n$ . In particular, their existence is determined in the same way:

BASIC CONCEPTS FOR CURVES

(1) *limit*:

$$\lim_{t \rightarrow t_0} c(t) = \left( \lim_{t \rightarrow t_0} c_1(t), \dots, \lim_{t \rightarrow t_0} c_n(t) \right) \in \mathbb{R}^n$$

(2) *derivative*:

$$\begin{aligned} c'(t_0) &= \lim_{t \rightarrow t_0} \frac{1}{|t - t_0|} \cdot (c(t) - c(t_0)) \\ &= (c'_1(t_0), \dots, c'_n(t_0)) \in \mathbb{R}^n \end{aligned}$$

(3) *integral*:

$$\int_a^b c(t) dt = \left( \int_a^b c_1(t) dt, \dots, \int_a^b c_n(t) dt \right) \in \mathbb{R}^n.$$

We can directly formulate the analogy of the connection between the Riemann integral and the antiderivative for curves in  $\mathbb{R}^n$  (see 6.2.9):

**Proposition.** *Let  $c$  be a curve in  $\mathbb{R}^n$ , continuous on an interval  $[a, b]$ . Then its Riemann integral  $\int_a^b c(t) dt$  exists. Moreover, the curve*

$$C(t) = \int_a^t c(s) ds \in \mathbb{R}^n$$

*is well-defined, differentiable, and  $C'(t) = c(t)$  for all values  $t \in [a, b]$ .*

It is not simple to extend the mean value theorem and, in general, the Taylor’s expansion with remainder, see 5.3.9 and 6.1.3. They can be applied in a selected coordinate system to the particular coordinate functions of a differentiable function  $c(t) = (c_1(t), \dots, c_n(t))$  on a finite interval  $[a, b]$ . In the case of the mean value theorem, for instance, there are numbers  $t_i$  such that

$$c_i(b) - c_i(a) = (b - a) \cdot c'_i(t_i), \quad i = 1, \dots, n.$$

<sup>1</sup>In geometry, one often makes a distinction between a curve as a subset of  $E_n$  and its parametrization  $\mathbb{R} \rightarrow \mathbb{R}^n$ . The word “curve”, means exclusively the parametrized curve here.

**Solution.** The lines through  $[1, -2]$  have the equation  $y = kx - k - 2$ . As we approach  $[1, -2]$  along one of these lines, we get the limit  $\frac{k}{1+k^2}$ , which is different for different  $k$ , thus the limit does not exist.  $\square$

Let us recall, that a function is continuous in points, where the limit exists and is equal to the function value.

**8.C.20.** Find the discontinuity points of  $f(x, y) = \frac{2x-5y}{x^2+y^2-1}$ .  $\circ$

**8.C.21.** Find the discontinuity points of  $f(x, y) = \frac{\sin(x^2y+xy^2)}{\cos(x-y)}$ .  $\circ$

**8.C.22.** Find the discontinuity points of

$$f(x, y) = \begin{cases} \frac{x^3+y^3}{x^2+y^2} & \text{pro } [x, y] \neq [0, 0], \\ 0 & \text{pro } [x, y] = [0, 0]. \end{cases}$$

$\circ$

**D. Tangent lines, tangent planes, graphs of multivariate functions**

**8.D.1.** A car is moving at velocity given by the vector  $(0, 1, 1)$ . At the initial time  $t = 0$ , it is situated at the point  $[1, 0, 0]$ . The acceleration of the car in time  $t$  is given by the vector  $(-\cos t, -\sin t, 0)$ . Describe the dependency of the position of the car upon the time  $t$ .

**Solution.** As we have already discussed in paragraph 8.1.5, we got acquainted with the means of solving this type of problem as early as in chapter 6. Notice that the “integral curve”  $C(t)$  from the theorem of paragraph 8.1.5 starts at the point  $(0, 0, 0)$  (in other words,  $C(0) = (0, 0, 0)$ ). In the affine space  $\mathbb{R}^n$ , we can move it so that it starts at an arbitrary point, and this does not change its derivative (this is performed by adding a constant to every component in the parametric equation of the curve). Therefore, up to the movement, this integral curve is determined uniquely (nothing else than constants can be added to the components without changing the derivative). When we integrate the curve of acceleration, we get the curve of velocity  $(-\sin t, \cos t - 1, 0)$ . Considering the initial velocity as well, we obtain the velocity curve of the car:  $(-\sin t, \cos t, 1)$  (we shifted the curve of the vector  $(0, 1, 1)$ , i. e., so that now the velocity curve at time  $t = 0$  agrees with the given initial velocity). Further integration leads to the curve  $(\cos t - 1, \sin t, t)$ . Shifting this of the vector  $(1, 0, 0)$  then fits with the initial position of the car. Therefore, the car moves along the curve  $[\cos t, \sin t, t]$  (this curve is called a helix).  $\square$

**8.D.2.** Determine both the parametric and implicit equations of the tangent line to the curve  $c : \mathbb{R} \rightarrow \mathbb{R}^3$ ,  $c(t) = (c_1(t), c_2(t), c_3(t)) = (t, t^2, t^3)$  at the point which corresponds to the parameter’s value  $t = 1$ .

**Solution.** The value  $t = 1$  corresponds to the point  $c(1) = [1, 1, 1]$ . The derivatives of the particular components are  $c'_1(t) = 1$ ,  $c'_2(t) = 2t$ ,  $c_3(t) = 3t^2$ . The values of

These numbers  $t_i$  are distinct in general, so the difference vector of the boundary points  $c(b) - c(a)$  cannot be expressed as a multiple of the derivative of the curve at a single point, in general.

For example, for a differentiable curve  $c(t)$  in the plane  $E_2$ ,  $c(t) = (x(t), y(t))$

$$\begin{aligned} c(b) - c(a) &= (x'(\xi)(b-a), y'(\eta)(b-a)) \\ &= (b-a) \cdot (x'(\xi), y'(\eta)) \end{aligned}$$

for two (in general different) values  $\xi, \eta \in [a, b]$ . However, this reasoning is still sufficient for the following estimate:

**Lemma.** If  $c$  is a curve in  $E_n$  with continuous derivative on a compact interval  $[a, b]$ , then for all  $a \leq s \leq t \leq b$

$$\|c(t) - c(s)\| \leq \sqrt{n}(\max_{r \in [a,b]} \|c'(r)\|) |t - s|.$$

**PROOF.** Direct application of the mean value theorem gives for appropriate points  $r_i$  inside the interval  $[s, t]$  the following:

$$\begin{aligned} \|c(t) - c(s)\|^2 &= \sum_{i=1}^n (c_i(t) - c_i(s))^2 \leq \sum_{i=1}^n (c'_i(r_i)(t-s))^2 \\ &\leq (t-s)^2 \sum_{i=1}^n \max_{r \in [s,t]} c'_i(r)^2 \\ &\leq n(\max_{r \in [s,t], i=1, \dots, n} |c'_i(r)|)^2 (t-s)^2 \\ &\leq n \max_{r \in [s,t]} \|c'(r)\|^2 (t-s)^2. \end{aligned}$$

$\square$

Another important concept is the *tangent vector* to a curve  $c : \mathbb{R} \rightarrow E_n$  at a point  $c(t_0) \in E_n$ . It is defined as the vector in the modelling vector space  $\mathbb{R}^n$  given by the derivative  $c'(t_0) \in \mathbb{R}^n$ .

Consider  $c$  to be the path of an object moving in the space in time. Then the tangent vector at a point  $t_0$  can be perceived physically as the instantaneous velocity at this point. maybe also a pict. The straight line  $T$  given parametrically as

$$T : c(t_0) + (t - t_0) \cdot c'(t_0)$$

is called the *tangent line to the curve  $c$*  at the point  $t_0$ . Unlike the tangent vector, the (unparametrized) tangent line  $T$  is independent of the parametrization of the curve  $c$ . The chain rule ensures that changing the parametrization leads to the same tangent vector, up to multiple.

**8.1.6. Partial derivatives.** If we look at the multivariate function  $f(x_1, \dots, x_n) : \mathbb{R}^n \rightarrow \mathbb{R}$  as at the function of one real variable  $x_i$  while the other variables are assumed constant, we can consider the derivative of this function. This is called the *partial derivative of the function  $f$*  with respect to  $x_i$ , and it is denoted as  $\frac{\partial f}{\partial x_i}$ ,  $i = 1, \dots, n$ , or (without referring to the particular function) as the operator  $\frac{\partial}{\partial x_i}$  on the functions.

More generally, for every function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  and an arbitrary curve  $c : \mathbb{R} \rightarrow \mathbb{R}^n$ , their composition  $(f \circ c)(t) : \mathbb{R} \rightarrow \mathbb{R}$  can be considered. This composite function  $F = f \circ c$  expresses the behaviour of the function  $f$  along the curve

the derivatives at the point  $t = 1$  are 1, 2, 3. Therefore, the parametric equations of the tangent line are:

$$\begin{aligned} x &= c'_1(1)s + c_1(1) = t + 1, \\ y &= c'_2(1)s + c_2(1) = 2t + 1, \\ z &= c'_3(1)s + c_3(1) = 3t + 1. \end{aligned}$$

In order to get the implicit equations (which are not given canonically), we eliminate the parameter  $t$ , thereby obtaining:

$$\begin{aligned} 2x - y &= 1, \\ 3x - z &= 2. \end{aligned} \quad \square$$

**8.D.3.** Determine the tangent line  $p$  to the curve  $c(t) = (\ln t, \arctan t, e^{\sin(\pi t)})$  at the point  $t_0 = 1$ .

**8.D.4.** Find a point on the curve  $c(t) = (t^2 - 1, -2t^2 + 5t, t - 5)$  such that the tangent line passing through it is parallel to the plane  $\rho: 3x + y - z + 7 = 0$ .

**Solution.** The direction  $c'(t_0)$  of the curve  $c(t)$  in  $t_0$  has to be perpendicular to the normal of  $\rho$ , that is the scalar multiple of these two vectors is 0. The tangent vector in the point  $c(t)$  is  $(2t, -4t + 5, 1)$ , the normal vector of the plane  $\rho$  is  $(3, 1, -1)$  (just read off the coefficients by  $x, y$  and  $z$  in the equation of  $\rho$ . That is  $3 \cdot 2t + 1 \cdot (-4t + 5) + 1 \cdot 1 = 0$ , which gives  $[3, -18, -7]$ .  $\square$

**8.D.5.** Find the parametric equation of the tangent line of the curve given as the intersection of surfaces  $x^2 + y^2 + z^2 = 4$  and  $x^2 + y^2 - 2x = 0$  in the point  $[1, 1, \sqrt{2}]$ .

**Solution.**  $p = \{[1 - \sqrt{2}s, 1, \sqrt{2} + s]; s \in \mathbb{R}\}$ .  $\square$

**8.D.6. The set of differentiable functions.** We can notice that multivariate polynomials are differentiable on the whole of their domain. Similarly, the composition of a differentiable univariate function and a differentiable multivariate function leads to a differentiable multivariate function. For instance, the function  $\sin(x + y)$  is differentiable on the whole  $\mathbb{R}^2$ ;  $\ln(x + y)$  is a differentiable function on the set of points with  $x > y$  (an open half-plane, i. e., without the boundary line). The proofs of these propositions are left as an exercise on limit compositions.

**Remark.** Notation of partial derivatives. The partial derivative of a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  in variables  $x_1, \dots, x_n$  with respect to the variable  $x_1$  will be denoted by both  $\frac{\partial f}{\partial x_1}$  and the shorter expression  $f_{x_1}$ . In the exercise part of the book, we will rather keep to the latter notation. On the other hand, the notation  $\frac{\partial f}{\partial x_1}$  better catches the fact that this is a derivative of  $f$  in the direction of the vector field  $\frac{\partial}{\partial x_1}$  (you will learn what a vector field is in paragraph 9.1.1).

**8.D.7.** Determine the domain of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2 \sqrt{y}$ . Calculate the partial derivatives where they are defined on this domain.

*c.* The simplest case is using parametrized straight lines  $c$  and choosing the lines  $c_i(t) = (x_1, \dots, x_i + t, \dots, x_n)$ , the derivative of  $f \circ c_i$  yields just the partial derivatives  $\frac{\partial f}{\partial x_i}$ . More generally, derivatives can be defined in any direction:

DIRECTIONAL AND PARTIAL DERIVATIVES

**Definition.**  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  has derivative in the direction of a vector  $v \in \mathbb{R}^n$  at a point  $x \in E_n$  if and only if the derivative  $d_v f(x)$  of the composite mapping

$$t \mapsto f(x + tv)$$

exists at the point  $t = 0$ , i.e.

$$d_v f(x) = \lim_{t \rightarrow 0} \frac{1}{t} (f(x + tv) - f(x)).$$

The partial derivatives are the values  $\frac{\partial f}{\partial x_i} = d_{e_i} f$  where  $e_i$  are the elements of the standard basis of  $\mathbb{R}^n$ .

In other words, the directional derivative expresses the infinitesimal increment of the function  $f$  in the direction  $v$ .

For functions in the plane,

$$\frac{\partial}{\partial x} f(x, y) = \lim_{t \rightarrow 0} \frac{1}{t} (f(x + t, y) - f(x, y))$$

$$\frac{\partial}{\partial y} f(x, y) = \lim_{t \rightarrow 0} \frac{1}{t} (f(x, y + t) - f(x, y)).$$

Especially, the partial differentiation with respect to a given variable is just the casual one-variable differentiation while considering the other variables to be constants.

**8.1.7. The differential of a function.** Partial or directional derivatives are not always good enough to obtain a fair approximation of the behaviour of a function by linear expressions. There are three concerns for a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  there. First, the directional derivatives at a point  $x \in \mathbb{R}^n$  may not exist in all directions, although the partial derivatives are well defined. Second, the dependence of the directional derivatives  $d_v f(x)$  on the direction  $v$  need not be linear. Third, even if  $d_v f(x)$  is a linear mapping in the argument  $v$ , the function still may be not 'well behaved' around the point  $x$ .

As an example, consider the functions in the plane with coordinates  $(x, y)$  given by the formulae

$$g(x, y) = \begin{cases} 1 & \text{if } xy = 0 \\ 0 & \text{otherwise} \end{cases}$$

$$h(x, y) = \begin{cases} x & \text{if } y = 0 \\ y & \text{if } x = 0 \\ 0 & \text{otherwise} \end{cases}$$

$$k(x, y) = \begin{cases} x & \text{if } y = x^2 \neq 0 \\ 0 & \text{otherwise.} \end{cases}$$

Both partial derivatives of  $g$  at  $(0, 0)$  exist and no other directional derivatives do, and  $g$  is even not continuous at the origin. The functions  $h$  and  $k$  are continuous at  $(0, 0)$  and  $h$  has all its directional derivatives at the origin equal zero,

**Solution.** The domain of the function in question in  $\mathbb{R}^2$  is the half-plane  $\{(x, y), y \geq 0\}$ . In order to determine the partial derivative with respect to a given variable, we consider the other variables to be constants in the formula that defines the function. Then, we simply differentiate the expression as a univariate function. We thus get:

$$f_x = 2xy \text{ a } f_y = \frac{1}{2} \frac{x^2}{\sqrt{y}}.$$

The partial derivatives exist at all points of the domain except for the boundary line  $y = 0$ .  $\square$

**8.D.8.** Determine the derivative of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^2yz$  at the point  $[1, -1, 2]$  in the direction  $v = (3, 2, -1)$ .

**Solution.** The directional derivative can be calculated in two ways. The first one is to derive it directly from the definition (see paragraph 8.1.6). The second one is to use the differential of the function; see 8.1.7 and theorem 8.1.8. Since the given function is a polynomial, it is differentiable on the whole  $\mathbb{R}^3$ .

Let us follow the definition:

$$\begin{aligned} f_v(x, y, z) &= \lim_{t \rightarrow 0} \frac{1}{t} [f(x + 3t, y + 2t, z - t) - f(x, y, z)] \\ &= \lim_{t \rightarrow 0} \frac{1}{t} [(x + 3t)^2(y + 2t)(z - t) - x^2yz] \\ &= \lim_{t \rightarrow 0} \frac{1}{t} [t(6xyz + 2x^2z - x^2y) + t^2(\dots)] \\ &= 6xyz + 2x^2z - x^2y. \end{aligned}$$

We have thus derived the derivative in the direction of the vector  $(3, 2, -1)$  as a function of three real variables which determine the point at which we are interested in the value of the derivative. Evaluating this for the desired point thus leads to  $f_v(1, -1, 2) = -7$ .

In order to compute the directional derivative from the differential of the function, we first have to determine the partial derivatives of the function:

$$f_x = 2xyz, \quad f_y = x^2z, \quad f_z = x^2y.$$

It follows from the note beyond theorem 8.1.8 that we can express

$$\begin{aligned} f_v(1, -1, 2) &= 3f_x(1, -1, 2) + 2f_y(1, -1, 2) + \\ &\quad + (-1)f_z(1, -1, 2) = \\ &= 3 \cdot (-4) + 2 \cdot 2 + (-1) \cdot (-1) = -7. \quad \square \end{aligned}$$

**8.D.9.** Determine the derivative of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = \frac{\cos(x^2y)}{z}$  at the point  $[0, 0, 2]$  in the direction of the vector  $(1, 2, 3)$ .

**Solution.** The domain of this function is  $\mathbb{R}^3$  except for the plane  $z = 0$ . The following calculations will be considered only on this domain. The function in question is differentiable at the point  $[0, 0, 2]$  (this follows from the note 8.D.6). We can determine the value of the examined directional derivative by 8.1.7, using partial derivatives.

First, we determine the partial derivatives of the given function (as we have already mentioned in exercise 8.D.7, in

except for the partial derivatives, which are equal to 1. In particular,  $d_v h(0, 0)$  is not a linear mapping in the argument  $v$ . More generally, consider a function  $f$  which, along the lines  $(r \cos \theta, r \sin \theta)$  with a fixed angle  $\theta$ , takes the values  $\alpha(\theta)r$ , where  $\alpha(\theta)$  is a periodic odd function of the angle  $\theta$ , with period  $2\pi$ . All of its directional derivatives  $d_v f$  at  $(0, 0)$  exist, yet these are not linear expressions depending on the directions  $v$  for general functions  $\alpha(\theta)$ . The graph of  $f$  can be visualized as a “deformed cone” and we can hardly hope for a good linear approximation at its vertex.

Finally,  $k$  has all directional derivatives zero, i.e.  $d_v h(0) = 0$  for all directions  $v$ , which is a linear dependence on  $v \in \mathbb{R}^2$ . But still, the zero mapping is a very bad approximation of  $k$  along the parabola  $y = x^2$ . Check all these claims in detail yourselves!

Therefore, we imitate the case of univariate functions as thoroughly as possible, and avoid such a pathological behaviour of functions directly by defining and using the concept of differential:

DIFFERENTIAL OF A FUNCTION

**Definition.** A function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  has got the *differential* at a point  $x$  if and only if all of the following three conditions hold:

- (1) the directional derivatives  $d_v f(x)$  at the point  $x$  exist for all vectors  $v \in \mathbb{R}^n$ ,
- (2)  $d_v f(x)$  is linearly dependent on the argument  $v$ ,
- (3)  $\lim_{v \rightarrow 0} \frac{1}{\|v\|} (f(x + v) - f(x) - d_v f(x)) = 0$ .

The linear expression  $d_v f$  (in a vector variable  $v$ ) is then called the *differential  $df$  of the function  $f$*  evaluated at the increase  $v$ .

In words, it is required that the behaviour of the function  $f$  at the point  $x$  is well approximated by linear functions of increments of the variable quantities.

It follows directly from the definition of directional derivatives that the differential can be defined solely by the property (3). If there is a linear form  $df(x)$  such that the increments  $v$  at the point  $x$  satisfy the property (3) with  $d_v f(x) = df(x)(v)$ , then  $df(x)(v)$  is apparently just the directional derivative of the function  $f$  at the point  $x$ , so the properties (1) and (2) are automatically satisfied.

Notice, that in dimension one, the only linear functions are multiplications by constant numbers, and if such a number satisfying (3) exists, we call it the derivative  $f'(x)$  in the point  $x$ . Then the first two properties automatically hold true and thus we did not have to distinguish the derivative and the differential there.

**8.1.8.** Examine what can be said about the differential of a function  $f(x, y)$  in the plane, supposing both partial derivatives  $\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}$  exist and are continuous in a neighbourhood of a point  $(x_0, y_0)$ . To this purpose, consider any smooth curve  $t \mapsto (x(t), y(t))$  with  $x_0 = x(0), y_0 = y(0)$ .

order to determine the partial derivative with respect to  $x$ , we differentiate it as a univariate function (in  $x$ ) and use the chain rule; similarly for other partial derivatives):

$$f_x = -\frac{2xy \sin(x^2y)}{z}, \quad f_y = -\frac{x^2 \sin(x^2y)}{z},$$

$$f_z = -\frac{\cos(x^2y)}{z^2}.$$

Evaluating the expression gives

$$f_x(0, 0, 2) + 2 \cdot f_y(0, 0, 2) + 3 \cdot f_z(0, 0, 2)$$

$$= 1 \cdot 0 + 2 \cdot 0 + 3 \cdot \left(-\frac{1}{4}\right) = -\frac{3}{4}. \quad \square$$

**8.D.10.** Having a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  with differential  $df(x)$  and a point  $x \in \mathbb{R}^n$ , determine a unit direction  $v \in \mathbb{R}^n$  in which the directional derivative  $d_v(x)$  is maximal.

**Solution.** According to the note beyond theorem 8.1.5, we are maximizing the function  $f_v(x) = v_1 f_{x_1}(x) + v_2 f_{x_2}(x) + \dots + v_n f_{x_n}(x)$  in dependence on the variables  $v_1, \dots, v_n$  which are bound by the condition  $v_1^2 + \dots + v_n^2 = 1$ . We have already solved this type of problem in chapter 3, when we talked about linear optimization (viz 3.A.5). The value  $f_v(x)$  can be interpreted as the scalar product of the vectors  $(f_{x_1}, \dots, f_{x_n})$  and  $(v_1, \dots, v_n)$ . And this product is maximal if the vectors are of the same direction. The vector  $v$  can thus be obtained by normalizing the vector  $(f_{x_1}, \dots, f_{x_n})$ . In general, we say the the function grows maximally in the direction  $(f_{x_1}, \dots, f_{x_n})$ . Then, this vector is called the gradient of the function  $f$ . In paragraph 8.1.26, we will recall this idea and go into further details.  $\square$

Counting the differential of a function is technicly very easy, just plug into the definition.

**8.D.11.** Find the differential of a function  $f$  in a point  $P$ :

- i)  $f(x, y) = \arctan \frac{x+y}{1-xy}, P = [\sqrt{3}, 1]$
- ii)  $f(x, y) = \arcsin \frac{x}{\sqrt{x^2+y^2}}, P = [1, \sqrt{3}]$ .
- iii)  $f(x, y) = xy + \frac{x}{y}, P = [1, 1]$ .

**Solution.**

- i)  $df(\sqrt{3}, 1) = \frac{1}{4}dx + \frac{1}{2}dy,$
- ii)  $df(1, \sqrt{3}) = \frac{\sqrt{3}}{4}dx - \frac{1}{4}dy,$
- iii)  $df(1, 1) = 2dx.$

$\square$

Let us realize, that differential of a function is a linear map:

**8.D.12.** Count the differential of the function  $f(x, y, z) = 2^x \sin y \arctan z$  in the point  $[-4, \frac{\pi}{2}, 0]$  evaluated on  $dx = 0.05, dy = 0.06,$  and  $dz = 0.08.$

**Solution.**  $df(-4, \frac{\pi}{2}, 0) = 0dx + 0dy + \frac{1}{16}dz = 0.005.$   $\square$

The differential thus can be used to approximate the values of a function.

The idea is to use the mean value theorem for univariate functions for differences of function values, where only one of the variables changes:  $f(x, y) - f(x_0, y) = \frac{\partial f}{\partial x}(x_1, y)(x - x_0)$  for suitable  $x_1$  between  $x_0$  and  $x$ .

Apply this in both summands of the following expression separately, to obtain

$$\frac{1}{t}(f(x(t), y(t)) - f(x_0, y_0)) =$$

$$\frac{1}{t}(f(x(t), y(t)) - f(x_0, y(t))) + \frac{1}{t}(f(x_0, y(t)) - f(x_0, y_0))$$

$$= \frac{1}{t}(x(t) - x_0) \frac{\partial f}{\partial x}(x(\xi), y(t)) + \frac{1}{t}(y(t) - y_0) \frac{\partial f}{\partial y}(x_0, y(\eta))$$

for suitable numbers  $\xi$  and  $\eta$  between 0 and  $t$ . Indeed, by exploiting that the curve  $(x(t), y(t))$  is differentiable, there must be such values  $\xi$  and  $\eta$ .

Especially, for every sequence of numbers  $t_n$  converging to zero, the corresponding sequences of numbers  $\xi_n$  and  $\eta_n$  also converge to zero (by the squeeze theorem for three limits) and they all satisfy the above equality.

If  $t$  converges to 0, the continuity of the partial derivatives, together with the test for convergence of functions using subsequences of the input values (cf. 5.2.15), as well as the properties of the limits of sums and products of functions (cf. Theorem 5.2.13) imply

$$\frac{d}{dt} f(x(t), y(t))|_{t=0} = x'(0) \frac{\partial f}{\partial x}(x_0, y_0) + y'(0) \frac{\partial f}{\partial y}(x_0, y_0),$$

which is a pleasant extension of the theorem on differentiation of composite functions of one variable for the case  $f \circ c$ .

Of course, with the special choice of parametrized straight lines with direction vector  $v = (\xi, \eta)$ ,

$$(x(t), y(t)) = (x_0 + t\xi, y_0 + t\eta),$$

the calculation leads to the derivative in the direction  $v = (\xi, \eta)$  and the equality

$$d_v f(x_0, y_0) = \frac{\partial f}{\partial x}(x_0, y_0)\xi + \frac{\partial f}{\partial y}(x_0, y_0)\eta.$$

This formula can be expressed in a neat way to describe coordinate expressions of linear functions on vector spaces:

$$df = \frac{\partial f}{\partial x}dx + \frac{\partial f}{\partial y}dy,$$

where  $dx$  stands for the differential of the function  $(x, y) \mapsto x$ , i.e.  $dx(v) = \xi$ , and similarly for  $dy$ . In other words, the directional derivative  $d_v f$  is a linear function  $\mathbb{R}^n \rightarrow \mathbb{R}$  on the increments, with coordinates given by the partial derivatives.

Now we could similarly prove that the assumption of continuous partial derivatives at a given point guarantees the approximation property of the differential as well. In particular, note that the computation for  $f \circ c$  above excluded phenomena like the function  $k(x, y)$  above (there  $d_v k(0, 0) = 0$ , but the derivative along the curve  $(t, t^2)$  was one). We shall better do this for the general multivariate functions straightaway.

**8.D.13.** Approximate  $\sqrt{2.98^2 + 4.05^2}$  with the use of differential (and not with a calculator).

**Solution.** We use the differential of the function  $f(x, y) = \sqrt{x^2 + y^2}$  in  $[3, 4]$ . Then  $f'_x = \frac{x}{\sqrt{x^2 + y^2}}$ ,  $f'_y = \frac{y}{\sqrt{x^2 + y^2}}$ , thus

$$\begin{aligned} \sqrt{2.98^2 + 4.05^2} &\doteq f(3^2, 4^2) + df(2.98 - 3, 4.05 - 4) \\ &= \sqrt{3^2 + 4^2} + \frac{3}{\sqrt{3^2 + 4^2}}(-0.02) + \frac{4}{\sqrt{3^2 + 4^2}}(0.05) \\ &= 5 - \frac{0,06}{5} + \frac{0,2}{5} = 5,028. \quad \square \end{aligned}$$

**8.D.14.** With the help of a differential calculate

- i)  $\arctan \frac{1,02}{0,95}$ ,
- ii)  $\ln(0,97^2 + 0,05^2)$ ,
- iii)  $\arcsin \frac{0,48}{1,05}$
- iv)  $1,04^{2,02}$ .

**8.D.15.** What is approximately the change (in  $cm^3$ ) in the volume of the cone with a base radius  $r = 10$  cm and height  $h = 10$  cm, if we increase the radius by 5 mm and we decrease the height by 5 mm?

**Solution.** The volume is (as a function of the radius  $r$  and a height  $h$ )  $V(r, h) = \frac{1}{3}\pi r^2 h$ . The change is approximately given by the differential of  $V$  in  $[10, 10]$  evaluated on  $dr = 10.5 - 10 = 0.5$  and  $dh = 9.5 - 10 = -0.5$ . We get  $\frac{50}{3}\pi cm^3$ .  $\square$

**8.D.16.** Find the tangent plane to the graph of a function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$  in a point  $P = [x_0, y_0, f(x_0, y_0)]$ :

- i)  $f(x, y) = \sqrt{1 - x^2 - y^2}$ ,  $P = [x_0, y_0, z_0] = [\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, ?]$ .
- ii)  $f(x, y) = e^{x^2 + y^2}$ ,  $P = [x_0, y_0, z_0] = [0, 0, ?]$ ,
- iii)  $f(x, y) = x^2 + xy + 2y^2$ ,  $P = [x_0, y_0, z_0] = [1, 1, ?]$ ,
- iv)  $f(x, y) = \arctan \frac{y}{x}$ ,  $P = [x_0, y_0, z_0] = [1, -1, ?]$ .

**Solution.**

i)  $f(x_0, y_0) = \sqrt{1 - \frac{1}{3} - \frac{1}{3}} = \frac{1}{\sqrt{3}}$ , thus  $z_0 = \frac{1}{\sqrt{3}}$ . Further  $f'_x = -\frac{x}{\sqrt{1 - x^2 - y^2}}$ ,  $f'_y = -\frac{y}{\sqrt{1 - x^2 - y^2}}$ , thus  $f'_x(x_0, y_0) = -\frac{1/\sqrt{3}}{1/\sqrt{3}} = -1$ ,  $f'_y(x_0, y_0) = -\frac{1/\sqrt{3}}{1/\sqrt{3}} = -1$ . The equation of a tangent plane in  $[\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}]$  is

$$z = \frac{1}{\sqrt{3}} - (x - \frac{1}{\sqrt{3}}) - (y - \frac{1}{\sqrt{3}}), \text{ or } x + y + z = \sqrt{3},$$

- ii)  $z_0 = 1, z = 1$ ,
- iii)  $z_0 = 4, 3x + 5y - z = 4$ ,
- iv)  $z_0 = -\frac{\pi}{4}, x + y - 2z = \frac{\pi}{2}$ .

$\square$

**8.1.9.** The following theorem provides a crucial and very useful observation.

CONTINUITY OF PARTIAL DERIVATIVES

**Theorem.** Let  $f : E_n \rightarrow \mathbb{R}$  be a function of  $n$  variables with continuous partial derivatives in a neighbourhood of the point  $x \in E_n$ . Then its differential  $df$  at the point  $x$  exists and its coordinate expression is given by the formula

$$df = \frac{\partial f}{\partial x_1} dx_1 + \frac{\partial f}{\partial x_2} dx_2 + \dots + \frac{\partial f}{\partial x_n} dx_n.$$

**PROOF.** This theorem can be derived analogously to the procedure described above, for the case  $n = 2$ . Care is needed in details to finish the reasoning about the approximation property. As above, consider a curve

$c(t) = (c_1(t), \dots, c_n(t))$ ,  $c(0) = (0, \dots, 0)$  and a point  $x \in \mathbb{R}^n$ , and express the difference  $f(x + c(t)) - f(x)$  for the composite function  $f(c(t))$  as follows:

$$\begin{aligned} &f(x_1 + c_1(t), \dots, x_n + c_n(t)) - f(x_1, x_2 + c_2(t), \dots) \\ &+ f(x_1, x_2 + c_2(t), \dots) - f(x_1, x_2, \dots, x_n + c_n(t)) \\ &\vdots \\ &+ f(x_1, x_2, \dots, x_n + c_n(t)) - f(x_1, x_2, \dots, x_n). \end{aligned}$$

Now, apply the mean value theorem to all of the  $n$  summands, obtaining (similarly to the case of two variables)

$$\begin{aligned} &(c_1(t) - c_1(0)) \frac{\partial f}{\partial x_1}(x_1 + c_1(\theta_1), \dots, x_n + c_n(t)) \\ &+ (c_2(t) - c_2(0)) \frac{\partial f}{\partial x_2}(x_1, x_2 + c_2(\theta_2), \dots, x_n + c_n(t)) \\ &\vdots \\ &+ (c_n(t) - c_n(0)) \frac{\partial f}{\partial x_n}(x_1, x_2, \dots, x_n + c_n(\theta_n)), \end{aligned}$$

for appropriate values  $\theta_i$ ,  $0 \leq \theta_i \leq t$ . This is a finite sum, so the same reasoning as in the case of two variables verifies that

$$\frac{d}{dt} f(x + c(t))|_{t=0} = c'_1(0) \frac{\partial f}{\partial x_1}(x) + \dots + c'_n(0) \frac{\partial f}{\partial x_n}(x).$$

The special choice of the curves  $c(t) = x + tv$  for a directional vector  $v$  verifies the statement about existence and linearity of the directional derivatives at  $x$ .

Finally, apply the mean value theorem in the same way to the difference

$$\begin{aligned} f(x + v) - f(x) &= d_v f(x + \theta v) \\ &= v_1 \frac{\partial f}{\partial x_1}(x + \theta v) + \dots + v_n \frac{\partial f}{\partial x_n}(x + \theta v) \end{aligned}$$

**8.D.17.** Find all points on the conic  $k : x^2 + 3y^2 - 2x + 6y - 8 = 0$  such that the normal of the conic is parallel to the  $y$  axis. For each point write the equation of the tangent in the point.

**Solution.** The normal to  $k$  in a point is parallel to the  $y$  axis iff the tangent line in the point is parallel to the  $x$  axis. The normal to  $k$  in  $[x_0, y_0] \in k$  is parallel to  $y$  axis iff one of the tangents to  $k$  in  $[x_0, y_0]$  is parallel to  $x$  axis, and this happens iff  $y'(x_0) = 0$ , where  $y$  is a function given implicitly by  $k$  in a neighborhood of  $[x_0, y_0]$ . Derivation of the equation of  $k$  gives  $2x + 6yy' - 2 + 6y' = 0$ , that is  $y' = \frac{1-x}{3(1+y)}$ . Thus  $y(x_0)' = 0$ , iff  $x_0 = 1$ . Substituting to the equation of  $k$  we get  $1 + 3y_0^2 - 2 + 6y_0 - 8 = 0$ , thus  $y_0 = 1$  or  $y_0 = -3$ . The sought points are  $[1, 1]$ , resp.  $[1, -3]$ , the equations of tangents in the points are  $y = 1$ , resp.  $y = -3$ .  $\square$

**8.D.18.** On the conic given by the equation  $3x^2 + 6y^2 - 3x + 3y - 2 = 0$  find all points where the normal to the conic is parallel with the line  $y = x$ . For each point give the equation of the tangent in the point.  $\circ$

**8.D.19.** On the conic given by the equation  $x^2 + xy + 2y^2 - x + 3y - 54 = 0$  find all points where the normal to the conic is parallel to the  $x$  axis. For each point give the equation of the tangent in the point.  $\circ$

**8.D.20.** On the graph of the function  $u(x, y, z) = x\sqrt{y^2 + z^2}$  find all points where the tangent plane is parallel to the plane  $x + y - z - u = 0$ .  $\circ$

**8.D.21.** Find the points on to the ellipsoid  $x^2 + 2y^2 + z^2 = 1$ , where the tangent planes are parallel to  $x - y + 2z = 0$ .

**Solution.** The equation of the tangent plane is determined by the partial derivatives of  $z = z(x, y)$  given implicitly by the equation  $x^2 + 2y^2 + z^2 = 1$  of the ellipsoid. The normal vector in  $[x_0, y_0, z_0]$  is  $(z'_x(x_0, y_0), z'_y(x_0, y_0), -1)$ . This vector has to be parallel to the normal  $(1, -1, 2)$  of the plane, thus  $(-2z'_x(x_0, y_0), -2z'_y(x_0, y_0), 2) = (1, -1, 2)$ . which yields  $2x_0 = z_0, 4y_0 = -z_0$  and after substituting to the ellipsoid's equation we get the sought points:  $[\frac{2}{\sqrt{22}}, -\frac{1}{\sqrt{22}}, \frac{4}{\sqrt{22}}]$  and  $[-\frac{2}{\sqrt{22}}, +\frac{1}{\sqrt{22}}, -\frac{4}{\sqrt{22}}]$ .

**Another solution.** It is useful to realize, that the normal vector in  $[x_0, y_0, z_0]$  of the surface given implicitly by  $F(x, y, z) = 0$  is the vector  $(F'_x(x_0, y_0, z_0), F'_y(x_0, y_0, z_0), F'_z(x_0, y_0, z_0))$ .  $\square$

**8.D.22.** Determine whether the tangent plane to the graph of the function  $f : \mathbb{R} \times \mathbb{R}^+ \rightarrow \mathbb{R}, f(x, y) = x \cdot \ln(y)$  at the point  $[1, \frac{1}{e}]$  goes through the point  $[1, 2, 3] \in \mathbb{R}^3$ .

**Solution.** First of all, we calculate the partial derivatives:  $f_x(x, y) = \ln(y), f_y(x, y) = \frac{x}{y}$ ; their values at the point  $[1, \frac{1}{e}]$  are  $-1, e$ ; further  $f(1, \frac{1}{e}) = -1$ . Therefore, the equation of the tangent plane is

$$z = f\left(1, \frac{1}{e}\right) + f_x\left(1, \frac{1}{e}\right)(x - 1) + f_y\left(1, \frac{1}{e}\right)\left(y - \frac{1}{e}\right) = -1 - x + ey.$$

with an appropriate  $\theta, 0 \leq \theta \leq 1$ , where the latter equality holds according to the formula for directional derivatives derived above, for sufficiently small  $v$ 's.

Since all the partial derivatives are continuous at the point  $x$ , for an arbitrarily small  $\varepsilon > 0$ , there is a  $\delta$ -neighbourhood  $U$  of the origin in  $\mathbb{R}^n$  such that for  $w \in U$ , all partial derivatives  $\frac{\partial f}{\partial x_i}(x + w)$  differ from  $\frac{\partial f}{\partial x_i}(x)$  by less than  $\varepsilon$ . Hence the estimate

$$\begin{aligned} \frac{1}{\|w\|} \|f(x + w) - f(x) - d_w f(x)\| &\leq \\ &\leq \frac{1}{\|w\|} \|f(x + w) - f(x) - d_w f(x + \theta w)\| + \\ &\quad \frac{1}{\|w\|} \|d_w f(x + \theta w) - d_w f(x)\| \\ &= \frac{1}{\|w\|} \|w_1 \left(\frac{\partial f}{\partial x_1}(x + \theta w) - \frac{\partial f}{\partial x_1}(x)\right) + \dots \\ &\quad + w_n \left(\frac{\partial f}{\partial x_n}(x + \theta w) - \frac{\partial f}{\partial x_n}(x)\right)\| \\ &\leq \frac{n}{\|w\|} \|w\| \varepsilon, \end{aligned}$$

where  $\theta$  is the parameter for which the expression on the second line vanishes. Thus, the approximation property of the differential is satisfied as well.  $\square$

The approximation property of the differential can be written as

$$f(x + v) = f(x) + df(x)(v) + \alpha(v),$$

where the function  $\alpha(v)$  satisfies  $\lim_{v \rightarrow 0} \frac{\alpha(v)}{\|v\|} = 0$ , i.e.  $\alpha(v) = o(\|v\|)$  in the asymptotic terminology introduced in 6.1.12 on the page 520.

**8.1.10. A plane tangent to the graph of a function.** The linear approximation of the function behaviour by its differential can be expressed in terms of its graph, similarly to the case of univariate functions. We work with hyperplanes instead of tangent lines.

In the case of a function on  $E_2$  and a fixed point  $(x_0, y_0) \in E_2$ , consider the plane in  $E_3$  given by the equation on the three coordinates  $(x, y, z)$ :

$$\begin{aligned} z &= f(x_0, y_0) + df(x_0, y_0)(x - x_0, y - y_0) \\ &= f(x_0, y_0) + \frac{\partial f}{\partial x}(x_0, y_0)(x - x_0) + \frac{\partial f}{\partial y}(x_0, y_0)(y - y_0). \end{aligned}$$

It is already seen that the increase of the function values of a differentiable function  $f : E_n \rightarrow \mathbb{R}$  at points  $x + tv$  and  $x$  is always expressed in terms of the directional derivative  $d_v f$  at a suitable point between them. Therefore, this is the only plane containing the point  $(x_0, y_0)$  with the property that all derivatives, and so the tangent lines of all curves

$$c(t) = (x(t), y(t), f(x(t), y(t)))$$

lie in this plane, too. It is called the *tangent plane* to the graph of the function  $f$ .

The given point does not satisfy this equation, so it does not lie in the tangent plane.  $\square$

**8.D.23.** Determine the parametric equation of the tangent line to the intersection of the graphs of the functions  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2 + xy - 6$ ;  $g : \mathbb{R} \times \mathbb{R}^+ \rightarrow \mathbb{R}$ ,  $g(x, y) = x \cdot \ln(y)$  at the point  $[2, 1]$ .

**Solution.** The tangent line to the intersection is the intersection of the tangent planes at the given point. The plane that is tangent to the graph of  $f$  and goes through the point  $[2, 1]$  is

$$z = f(2, 1) + f_x(2, 1)(x - x_0) + f_y(2, 1)(y - y_0) = 5x + 2y - 12.$$

The tangent plane to the graph of  $g$  is then

$$z = f(2, 1) + g_x(x, y)(2, 1)(x - x_0) + g(x, y)_y(2, 1)(y - y_0) = 2y - 2.$$

The intersection line of these two planes is given parametrically as  $[2, t, 2t - 2]$ ,  $t \in \mathbb{R}$ .

**Another solution.** The normal to the surface given by the equation  $f(x, y, z) = 0$  at the point  $b = [2, 1, 0]$  is  $(f_x(b), f_y(b), f_z(b)) = (5, 2, -1)$ ; the normal to the surface given by  $g(x, y, z) = 0$  at the same point is  $(0, 2, -1)$ . The tangent line is perpendicular to both normals; we can thus obtain a vector it is parallel to as the vector product of the normals, which is  $(0, 5, 10)$ . Since the tangent line goes through the point  $[2, 1, 0]$ , its parametric equation is  $[2, 1 + t, 2t]$ ,  $t \in \mathbb{R}$ .  $\square$

**8.D.24. V.** ypočtete všechny parciální derivace prvního a druhého řádu funkce  $f(x, y, z) = x^{\frac{y}{z}}$ .

**Solution.**  $f'_x = \frac{y}{z} x^{\frac{y}{z}-1}$ ,  $f'_y = x^{\frac{y}{z}} \ln x \cdot \frac{1}{z}$ ,  $f'_z = x^{\frac{y}{z}} \ln x \cdot \frac{-y}{z^2}$ ,  
 $f''_{xx} = \frac{y}{z} (\frac{y}{z} - 1) x^{\frac{y}{z}-2}$ ,  $f''_{yy} = x^{\frac{y}{z}} \ln^2 x \cdot \frac{1}{z^2}$ ,  
 $f''_{zz} = x^{\frac{y}{z}} \ln^2 x \cdot \frac{y^2}{z^4} + x^{\frac{y}{z}} \ln x \cdot \frac{2y}{z^3}$ ,  
 $f''_{xy} = \frac{1}{z} x^{\frac{y}{z}-1} + \frac{y}{z} x^{\frac{y}{z}-1} \ln x \cdot \frac{1}{z}$ ,  $f''_{xz} = \frac{-y}{z^2} x^{\frac{y}{z}-1} + \frac{y}{z} x^{\frac{y}{z}-1} \ln x \cdot \frac{-y}{z^2}$ ,  $f''_{yz} = x^{\frac{y}{z}} \ln^2 x \cdot \frac{-y}{z^3} + x^{\frac{y}{z}} \ln x \cdot \frac{-1}{z^2}$ .

**8.D.25.** Find all first and second order partial derivatives of  $z = f(x, y)$  in  $[1, \sqrt{2}, 2]$  defined in a neighborhood of the point by  $x^2 + y^2 + z^2 - xz - \sqrt{2}yz = 1$ .  $\circ$

**8.D.26.** Find all first and second order partial derivatives of  $z = f(x, y)$  in  $[-2, 0, 1]$  defined in a neighborhood of the point by  $2x^2 + 2y^2 + z^2 + 8xz - z + 8 = 0$ .  $\circ$

**8.D.27.** Determine all second partial derivatives of the function  $f$  given by  $f(x, y, z) = \sqrt{xy} \ln z$ .

**Solution.** First, we determine the domain of the given function: the argument of the square root must be non-negative, and the argument of the natural logarithm must be positive. Therefore,  $Df = \{(x, y, z) \in \mathbb{R}^3, (z \geq 1 \& (xy > 0)) \vee (0 < z < 1) \& (xy < 0)\}$ .

Two tangent planes to the graph of the function

$$f(x, y) = \sin(x) \cos(y)$$

are shown in the illustration. The diagonal line is the image of the curve  $c(t) = (t, t, f(t, t))$ .

For the case of functions of  $n$  variables, the tangent plane is defined as an analogy to the tangent plane to a surface in the three-dimensional space. Instead of being overwhelmed by many indices, it is useful to recall affine geometry, where hyperplanes can be used, see paragraph 4.1.3.

#### TANGENT (HYPER)PLANES

**Definition.** A *tangent hyperplane* to the graph of a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  at a point  $x \in \mathbb{R}^n$  is the hyperplane containing the point  $(x, f(x))$  with the modelling vector space which is the graph of the linear mapping  $df(x) : \mathbb{R}^n \rightarrow \mathbb{R}$ , i.e. the differential at the point  $x \in E_n$ .

The definition takes advantage of the fact that the directional derivative  $d_v f$  is given by the increment in the tangent (hyper)plane corresponding to the increment  $v$ .

Many analogies with the univariate functions follow from the latter fact. In particular, a differentiable function  $f$  on  $E_n$  has zero differential at a point  $x \in E_n$  if and only if its composition with any curve going through this point has a stationary point there, i.e., is neither increasing, nor decreasing in the linear approximation.

In other words, the tangent plane at such a point is parallel to the hyperplane of the variables (i.e., its modelling space is  $E_n \subset E_{n+1}$ , having added the last coordinate set to zero). Of course, this does not mean that  $f$  should have a local extremum at such a point. Just as in the case of univariate functions, this depends on the values of higher derivatives. But it is a necessary condition to the existence of extrema.

**8.1.11. Derivatives of higher orders.** The operation of differentiation can be iterated similarly to the case of univariate functions. This time, choose new directions for each iteration.

Fix an increment  $v \in \mathbb{R}^n$ . The enumeration of the differentials at this argument defines a (differential) operation on differentiable functions  $f : E_n \rightarrow \mathbb{R}$

$$f \mapsto d_v f = df(v),$$

and the result is again a function  $df(v) : E_n \rightarrow \mathbb{R}$ . If this function is differentiable as well, repeat this procedure with

Now, we calculate the first partial derivatives with respect to each of the three variables:

$$f_x = \frac{y \ln(z)}{2\sqrt{xy \ln(z)}}, f_y = \frac{x \ln(z)}{2\sqrt{xy \ln(z)}}, f_z = \frac{xy}{2z\sqrt{xy \ln(z)}}.$$

Each of these three partial derivatives is again a function of three variables, so we can consider (first) partial derivatives of these functions. Those are the second partial derivatives of the function  $f$ . We will write the variable with respect to which we differentiate as a subscript of the function  $f$ .

$$\begin{aligned} f_{xx} &= -\frac{y^2 \ln^2 z}{4(xy \ln z)^{\frac{3}{2}}}, \\ f_{xy} &= -\frac{xy \ln^2 z}{4(xy \ln z)^{\frac{3}{2}}} + \frac{\ln z}{2\sqrt{xy \ln z}}, \\ f_{xz} &= -\frac{xy^2 \ln z}{4z(xy \ln z)^{\frac{3}{2}}} + \frac{y}{2z\sqrt{xy \ln z}}, \\ f_{yy} &= -\frac{x^2 \ln^2 z}{4(xy \ln z)^{\frac{3}{2}}}, \\ f_{yz} &= -\frac{x^2 y \ln z}{4z(xy \ln z)^{\frac{3}{2}}} + \frac{x}{2z\sqrt{xy \ln z}}, \\ f_{zz} &= -\frac{x^2 y^2}{4z^2(xy \ln z)^{\frac{3}{2}}} - \frac{xy}{2z^2\sqrt{xy \ln z}}. \end{aligned}$$

By the theorem about interchangeability of partial derivatives (see 8.1.12), we know that  $f_{xy} = f_{yx}$ ,  $f_{xz} = f_{zx}$ ,  $f_{yz} = f_{zy}$ . Therefore, it suffices to compute the mixed partial derivatives (the word “mixed” means that we differentiate with respect to more than one variable) just for one order of differentiation.  $\square$

### E. Taylor polynomials

**8.E.1.** Write the second-order Taylor expansion of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = \ln(x^2 + y^2 + 1)$  at the point  $[1, 1]$ .

**Solution.** First, we compute the first partial derivatives:

$$f_x = \frac{2x}{x^2 + y^2 + 1}, f_y = \frac{2y}{x^2 + y^2 + 1},$$

then the Hessian:

$$Hf(x, y) = \begin{pmatrix} \frac{2y^2 - 2x^2 + 2}{(x^2 + y^2 + 1)^2} & -\frac{4xy}{(x^2 + y^2 + 1)^2} \\ -\frac{4xy}{(x^2 + y^2 + 1)^2} & \frac{2x^2 - 2y^2 + 2}{(x^2 + y^2 + 1)^2} \end{pmatrix}.$$

The value of the Hessian at the point  $[1, 1]$  is

$$\begin{pmatrix} \frac{2}{9} & -\frac{4}{9} \\ -\frac{4}{9} & \frac{2}{9} \end{pmatrix}.$$

another increment, and so on. In particular, work with iterations of partial derivatives. For *second-order partial derivatives*, write

$$\left( \frac{\partial}{\partial x_j} \circ \frac{\partial}{\partial x_i} \right) f = \frac{\partial^2}{\partial x_i \partial x_j} f = \frac{\partial^2 f}{\partial x_i \partial x_j}.$$

In the case of the repeated choice  $i = j$ , write

$$\left( \frac{\partial}{\partial x_i} \circ \frac{\partial}{\partial x_i} \right) f = \frac{\partial^2}{\partial x_i^2} f = \frac{\partial^2 f}{\partial x_i^2}.$$

Proceed in the same way with further iterations and talk about *partial derivatives of order  $k$*

$$\frac{\partial^k f}{\partial x_{i_1} \dots \partial x_{i_k}}.$$

More generally, one can iterate (assuming the function is sufficiently differentiable) any directional derivatives; for instance,  $d_v \circ d_w f$  for two fixed increments  $v, w \in \mathbb{R}^n$ .

#### $k$ -TIMES DIFFERENTIABLE FUNCTIONS

**Definition.** A function  $f : E_n \rightarrow \mathbb{R}$  is  *$k$ -times (continuously) differentiable* at a point  $x$  if and only if all its partial derivatives up to order  $k$  (inclusive) exist in a neighbourhood of the point  $x$  and are continuous at this point.

$f$  is  *$k$ -differentiable* if it is  $k$ -times (continuously) differentiable at all points of its domain.

From now on, the work is with continuously differentiable functions unless explicitly stated otherwise.

To show the basic features of the higher derivatives in the simplest form, work in the plane  $E_2$ . In the plane as well as in the space, iterated derivatives are often denoted by mere indices referring to the variable names, for example:

$$f_x = \frac{\partial f}{\partial x}, f_{xx} = \frac{\partial^2 f}{\partial x^2}, f_{xy} = \frac{\partial^2 f}{\partial x \partial y}, f_{yx} = \frac{\partial^2 f}{\partial y \partial x}.$$

Supposing the second-order partial derivatives are continuous at the point  $x$  (and exist in its neighborhood), we show that the partial derivatives commute. That is, the order in which differentiation is carried out does not matter.

By our assumption, the limits

$$\begin{aligned} f_{xy}(x, y) &= \lim_{t \rightarrow 0} \frac{1}{t} (f_x(x, y + t) - f_x(x, y)) \\ &= \lim_{t \rightarrow 0} \frac{1}{t} \left( \lim_{s \rightarrow 0} \frac{1}{s} (f(x + s, y + t) - f(x, y + t)) \right. \\ &\quad \left. - (f(x + s, y) - f(x, y)) \right) \end{aligned}$$

exist. However, since the limits can be expressed by any choice of values  $t_n \rightarrow 0$  and  $s_n \rightarrow 0$  and the limits of the corresponding sequences, the second derivative can be expressed

Altogether, we get that the second-order Taylor expansion at the point  $[1, 1]$  is

$$\begin{aligned} T_2(x, y) &= f(1, 1) + f_x(1, 1)(x - 1) + f_y(1, 1)(y - 1) \\ &\quad + \frac{1}{2}(x - 1, y - 1)Hf(1, 1)\begin{pmatrix} x - 1 \\ y - 1 \end{pmatrix} \\ &= \ln(3) + \frac{2}{3}(x - 1) + \frac{2}{3}(y - 1) + \frac{1}{9}(x - 1)^2 \\ &\quad - \frac{4}{9}(x - 1)(y - 1) + \frac{1}{9}(y - 1)^2 \\ &= \frac{1}{9}(x^2 + y^2 + 8x + 8y - 4xy - 14) + \ln(3). \end{aligned}$$

□

**Remark.** In particular, we can see that the second-order Taylor expansion of an arbitrary differentiable function at a given point is a second-order polynomial.

**8.E.2.** Determine the second-order Taylor polynomial of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ ,  $f(x, y) = xy \cos y$  at the point  $[\pi, \pi]$ . Decide whether the tangent plane to the graph of this function at the point  $[\pi, \pi, f(\pi, \pi)]$  goes through the point  $[0, \pi, 0]$ .

**Solution.** As in the above exercises, we find out that

$$T(x, y) = \frac{1}{2}\pi^2 y^2 - xy - \pi^3 y + \frac{1}{2}\pi^4.$$

The tangent plane to the graph of the given function at the point  $[\pi, \pi]$  is given by the first-order Taylor polynomial at the point  $[\pi, \pi]$ ; its general equation is thus

$$z = -\pi y - \pi x + \pi^2,$$

and this equation is satisfied by the given point  $[0, \pi, 0]$ . □

**8.E.3.** Determine the third-order Taylor polynomial of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^3 y + xz^2 + xy + 1$  at the point  $[0, 0, 0]$ . ○

**8.E.4.** Determine the second-order Taylor polynomial of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2 \sin y + y^2 \cos x$  at the point  $[0, 0]$ . Decide whether the tangent plane to the graph of this function at the point  $[0, 0, 0]$  goes through the point  $[\pi, \pi, \pi]$ . ○

**8.E.5.** Determine the second-order Taylor polynomial of the function  $\ln(x^2 y)$  at the point  $[1, 1]$ . ○

**8.E.6.** Determine the second-order Taylor polynomial of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,

$$f(x, y) = \tan(xy + y)$$

at the point  $[0, 0]$ . ○

### F. Extrema of multivariate functions

**8.F.1.** Determine the stationary points of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2 y + y^2 x - xy$  and decide which of these points are local extrema and of which type.

**Solution.** The first derivatives are  $f_x = 2xy + y^2 - y$ ,  $f_y = x^2 + 2xy - x$ . If we set both partial derivatives equal

$$f_{xy}(x, y) = \lim_{t \rightarrow 0} \frac{1}{t^2} \left( (f(x + t, y + t) - f(x, y + t)) - (f(x + t, y) - f(x, y)) \right),$$

if the limit on the right hand side exists (notice we cannot take this as granted without further arguments).

Consider the expression from which the last limit is taken as the function  $\varphi(x, y, t)$ , and try to express it in terms of partial derivatives. For a temporarily fixed  $t$ , denote

$$g(x, y) = f(x + t, y) - f(x, y).$$

Notice that the partial derivative  $g_y$  exists on a neighborhood of  $(x, y)$  and it is continuous in  $(x, y)$ . Thus, for small  $t$ , we may apply the mean value theorem viewing  $g$  as function of  $y$ . Therefore, the expression in the last large parentheses equals to

$$g(x, y + t) - g(x, y) = t \cdot g_y(x, y + t_0)$$

for a suitable  $t_0$  which lies between 0 and  $t$  (the value of  $t_0$  depends on  $t$ ). Next,  $g_y(x, y) = f_y(x + t, y) - f_y(x, y)$ , so we may rewrite  $\varphi$  as

$$\begin{aligned} \varphi(x, y, t) &= \frac{1}{t} g_y(x, y + t_0) \\ &= \frac{1}{t} (f_y(x + t, y + t_0) - f_y(x, y + t_0)). \end{aligned}$$

Another application of the mean value theorem yields

$$\varphi(x, y, t) = f_{yx}(x + t_1, y + t_0)$$

for a suitable  $t_1$  between 0 and  $t$ . Since it is assumed that the second order partial derivatives of  $f$  are continuous at the point  $(x, y)$ , the requested limit  $\lim_{t \rightarrow 0} \varphi(x, y, t)$  must exist and we have arrived at the desired equality  $f_{xy} = f_{yx}$ , too.

**8.1.12. Schwarz's Theorem.** The same procedure for functions of  $n$  variables proves the following fundamental result:<sup>2</sup>

#### COMMUTATIVITY OF PARTIAL DERIVATIVES

**Theorem.** Let  $f : E_n \rightarrow \mathbb{R}$  be a  $k$ -times differentiable function with continuous partial derivatives up to order  $k$  (inclusive) at the point  $x \in \mathbb{R}^n$ . Then all partial derivatives of the function  $f$  at the point  $x$  up to order  $k$  (inclusive) are independent of the order of differentiation.

**PROOF.** The proof for the second order is illustrated above in the special case when  $n = 2$ . In fact, it yields the general case as well. Indeed, notice that for every fixed choice of a pair of coordinates  $x_i$  and  $x_j$ , the discussion of their interchanging takes

<sup>2</sup>This is a great example of a result which was used widely for many decades before a complete proof was published in 1873 by Karl Hermann Amandus Schwarz (1843-1921). The result is also known as Clairaut's theorem – following the earlier version for functions requesting continuous partial derivatives on a neighborhood of  $x$ .

to zero simultaneously, the system has the following solution:  $\{x = y = 0\}$ ,  $\{x = 0, y = 1\}$ ,  $\{x = 1, y = 0\}$ ,  $\{x = 1/3, y = 1/3\}$ , which are four stationary points of the given function.

The Hessian of the function  $f$  is

$$\begin{pmatrix} 2y & 2x + 2y - 1 \\ 2x + 2y - 1 & 2x \end{pmatrix}.$$

Its values at the stationary points are, respectively,

$$\begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix}, \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \begin{pmatrix} 2/3 & 1 \\ 1 & 2/3 \end{pmatrix}.$$

Therefore, the first three Hessians are indefinite, and the last one is positive definite. The point  $[1/3, 1/3]$  is thus a local minimum.  $\square$

**8.F.2.** Determine the point in the plane  $x+y+3z = 5$  lying in  $\mathbb{R}^3$  which is closest to the origin of the coordinate system. First, do this by applying the methods of linear algebra; then, using the methods of differential calculus.

**Solution.** It is the intersection point of the perpendicular going through the point  $[0, 0, 0]$  to the plane. The normal to the plane is  $(t, t, 3t)$ ,  $t \in \mathbb{R}$ . Substituting into the equation of the plane, we get the intersection point  $[5/11, 5/11, 15/11]$ .

Alternatively, we can minimize the distance (or its square) of the plane's points from the origin, i. e., the function

$$(5 - y - 3z)^2 + y^2 + z^2.$$

Setting the partial derivatives equal to zero, we get the system

$$3y + 10z - 15 = 0$$

$$2y + 3z - 5 = 0,$$

whose solution is as above. Since we know that the minimum exists and is the only stationary point, we need not calculate the Hessian any more.  $\square$

**8.F.3.** Determine the local extrema of the function

$$f(x, y) = x^2 + \arctan^2 x + |y^3 + y|, \quad x, y \in \mathbb{R}.$$

**Solution.** The function  $f$  can be written as the sum  $f_1 + f_2$ , where  $f_1(x) = x^2 + \arctan^2 x$ ,  $f_2(y) = |y^3 + y|$ ,  $x, y \in \mathbb{R}$ .

If the function  $f$  has a local extremum at a point, then it does so with respect to an arbitrary subset of its domain. In other words, if the function has, for instance, a maximum at a point  $[a, b]$  and we set  $y = b$ , then the univariate function  $f(x, b)$  of  $x$  must have a maximum at the point  $x = a$ . Let us thus fix an arbitrary  $y \in \mathbb{R}$ . For this fixed value of  $y$ , we get a univariate function, which is a shift of the function  $f_1$ . This means that its maxima and minima are at the same points. However, it is easy to find the extrema of the function  $f_1$ . We can just realize that this function is even (it is the sum of two even functions, and the function  $y = \arctan^2 x$  is the product of two odd functions) and increasing for  $x \geq 0$  (the composition as well as the sum of increasing functions is again an increasing function). Therefore, it has a unique extremum, and that is a minimum at the point  $x = 0$ . Similarly, for any fixed value of  $x$ ,  $f$  is a shift of the function  $f_2$ , and  $f_2$  has a minimum at the point  $y = 0$ , which is its only extremum. We

place in a two-dimensional affine subspace, (all the other variables are considered to be constant and do not affect in the discussion). So neighbouring partial derivatives may be interchanged. This solves the problem in order two.

In the case of higher-order derivatives, the proof can be completed by induction on the order. Every order of the indices  $i_1, \dots, i_k$  can be obtained from a fixed one by several interchanges of adjacent pairs of indices.  $\square$

**8.1.13. Hessian.** The differential was introduced as the linear form  $df(x)$  which approximates the function  $f$  at a point  $x$  in the best possible way.

Similarly, a quadratic approximation of a function  $f : E_n \rightarrow \mathbb{R}$  is possible.

### HESSIAN

**Definition.** If  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  is a twice differentiable function, the symmetric matrix of functions

$$Hf(x) = \left( \frac{\partial^2 f}{\partial x_i \partial x_j} (x) \right) = \begin{pmatrix} \frac{\partial^2 f}{\partial x_1 \partial x_1} (x) & \dots & \frac{\partial^2 f}{\partial x_1 \partial x_n} (x) \\ \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_n \partial x_1} (x) & \dots & \frac{\partial^2 f}{\partial x_n \partial x_n} (x) \end{pmatrix}$$

is called the Hessian of the function  $f$ .

It is already seen from the previous reasonings that the vanishing of the differential at a point  $(x, y) \in E_2$  guarantees stationary behaviour along all curves going through this point. The Hessian

$$Hf(x, y) = \begin{pmatrix} f_{xx}(x, y) & f_{xy}(x, y) \\ f_{yx}(x, y) & f_{yy}(x, y) \end{pmatrix}$$

plays the role of the second derivative.

For every parametrized straight line

$$c(t) = (x(t), y(t)) = (x_0 + \xi t, y_0 + \eta t),$$

the derivative of the univariate function  $\alpha(t) = f(x(t), y(t))$  can be computed by means of the formula  $\frac{d}{dt} f(t) = f_x(x(t), y(t))x'(t) + f_y(x(t), y(t))y'(t)$  (derived in 8.1.8) and so the function

$$\begin{aligned} \beta(t) &= f(x_0, y_0) + t \frac{\partial f}{\partial x}(x_0, y_0)\xi + t \frac{\partial f}{\partial y}(x_0, y_0)\eta \\ &+ \frac{t^2}{2} \left( f_{xx}(x_0, y_0)\xi^2 + 2f_{xy}(x_0, y_0)\xi\eta + f_{yy}(x_0, y_0)\eta^2 \right) \end{aligned}$$

shares the same derivatives up to the second order (inclusive) at the point  $t = 0$  (calculate this on your own!). The function  $\beta$  can be written in terms of vectors as

$$\beta(t) = f(x_0, y_0) + df(x_0, y_0)(tv) + \frac{1}{2} Hf(x_0, y_0)(tv, tv),$$

where  $v = (\xi, \eta)$  is the increment given by the derivative of the curve  $c(t)$ , and the Hessian is used as a symmetric 2-form.

This is an expression which looks like Taylor's theorem for univariate functions, namely the quadratic approximation

have thus proved that  $f$  can have a local extremum only at the origin. Since

$$f(0, 0) = 0, \quad f(x, y) > 0, \quad [x, y] \in \mathbb{R}^2 \setminus \{[0, 0]\},$$

the function  $f$  has a strict local (even global) minimum at the point  $[0, 0]$ .  $\square$

**8.F.4.** Examine the local extrema of the function

$$f(x, y) = (x + y^2) e^{\frac{x}{2}}, \quad x, y \in \mathbb{R}.$$

**Solution.** This function has partial derivatives of all orders on the whole of its domain. Therefore, local extrema can occur only at stationary points, where both the partial derivatives  $f_x, f_y$  are zero. Then, it can be determined whether the local extremum occurs by computing the second derivatives.

We can easily determine that

$$\begin{aligned} f_x(x, y) &= e^{\frac{x}{2}} + \frac{1}{2}(x + y^2) e^{\frac{x}{2}}, \\ f_y(x, y) &= 2y e^{\frac{x}{2}}, \quad x, y \in \mathbb{R}. \end{aligned}$$

A stationary point  $[x, y]$  must satisfy

$$f_y(x, y) = 0, \quad \text{i. e.} \quad y = 0,$$

and, further,

$$f_x(x, y) = f_x(x, 0) = e^{\frac{x}{2}} \left(1 + \frac{1}{2}x\right) = 0, \quad \text{i. e.} \quad x = -2.$$

We can see that there is a unique stationary point, namely  $[-2, 0]$ .

Now, we calculate the Hessian  $Hf$  at this point. If this matrix (the corresponding quadratic form) is positive definite, the extremum is a strict local minimum. If it is negative definite, the extremum is a strict local maximum. Finally, if the matrix is indefinite, there will be no extremum at the point. We have

$$\begin{aligned} f_{xx}(x, y) &= \frac{1}{2} e^{\frac{x}{2}} \left(2 + \frac{1}{2}(x + y^2)\right), \quad f_{yy}(x, y) = 2 e^{\frac{x}{2}}, \\ f_{xy}(x, y) &= f_{yx}(x, y) = y e^{\frac{x}{2}}, \quad x, y \in \mathbb{R}. \end{aligned}$$

Therefore,

$$\begin{aligned} Hf(-2, 0) &= \begin{pmatrix} f_{xx}(-2, 0) & f_{xy}(-2, 0) \\ f_{yx}(-2, 0) & f_{yy}(-2, 0) \end{pmatrix} \\ &= \begin{pmatrix} 1/2e & 0 \\ 0 & 2/e \end{pmatrix}. \end{aligned}$$

We should recall that the eigenvalues of a diagonal matrix are exactly the values on the diagonal. Further, positive definiteness means that all the eigenvalues are positive. Hence it follows that there is a strict local minimum at the point  $[-2, 0]$ .  $\square$

**8.F.5.** Find the local extrema of the function

$$f(x, y, z) = x^3 + y^2 + \frac{z^2}{2} - 3xz - 2y + 2z, \quad x, y, z \in \mathbb{R}.$$

**Solution.** The function  $f$  is a polynomial; therefore, it has partial derivatives of all orders. It thus suffices to look for its stationary points (the extrema cannot be elsewhere). In order to find them, we differentiate  $f$  with respect to each of the three variables  $x, y, z$  and set the derivatives equal to zero. We thus obtain

$$3x^2 - 3z = 0, \quad \text{i. e.,} \quad z = x^2,$$

of a function by Taylor's polynomial of degree two. The following illustration shows both the tangent plane and this quadratic approximation for two distinct points and the function  $f(x, y) = \sin(x) \cos(y)$ .

popis obrázku

**8.1.14. Taylor's expansion.** The multidimensional version

of Taylor's theorem is an example of a mathematical statement where the most difficult part is finding the right formulation. The proof is then quite simple.

The discussion on the Hessians continues. Write  $D^k f$  for the  $k$ -th order approximations of the function  $f : E_n \rightarrow \mathbb{R}^n$ . It is always a  $k$ -linear expressions in the increments.

The differential  $D^1 f = df$  (the first order) and the Hessian  $D^2 f = Hf$  (the second order) are already discussed. For functions  $f : E_n \rightarrow \mathbb{R}$ , points  $x = (x_1, \dots, x_n) \in E_n$ , and increments  $v = (\xi_1, \dots, \xi_n)$ , set

$$D^k f(x)(v) = \sum_{1 \leq i_1, \dots, i_k \leq n} \frac{\partial^k f}{\partial x_{i_1} \cdots \partial x_{i_k}}(x_1, \dots, x_n) \xi_{i_1} \cdots \xi_{i_k}.$$

An illustrative example (making use of the symmetry of the partial derivatives) is, for  $E_2$ , the third-order expression

$$\begin{aligned} D^3 f(x, y)(\xi, \eta) &= \frac{\partial^3 f}{\partial x^3} \xi^3 + 3 \frac{\partial^3 f}{\partial x^2 \partial y} \xi^2 \eta \\ &\quad + 3 \frac{\partial^3 f}{\partial x \partial y^2} \xi \eta^2 + \frac{\partial^3 f}{\partial y^3} \eta^3, \end{aligned}$$

and, in general,

$$D^k f(x, y)(\xi, \eta) = \sum_{\ell=0}^k \binom{k}{\ell} \frac{\partial^k f}{\partial x^{k-\ell} \partial y^\ell} \xi^{k-\ell} \eta^\ell.$$

#### TAYLOR'S EXPANSION WITH REMAINDER

**Theorem.** Let  $f : E_n \rightarrow \mathbb{R}$  be a  $k$ -times differentiable function in a neighbourhood  $\mathcal{O}_\delta(x)$  of a point  $x \in E_n$ . For every increment  $v \in \mathbb{R}^n$  of size  $\|v\| < \delta$ , there exists a number  $\theta, 0 \leq \theta \leq 1$ , such that

$$\begin{aligned} f(x + v) &= f(x) + D^1 f(x)(v) + \frac{1}{2!} D^2 f(x)(v) + \\ &\quad \cdots + \frac{1}{(k-1)!} D^{k-1} f(x)(v) + \frac{1}{k!} D^k f(x + \theta \cdot v)(v). \end{aligned}$$

$$2y - 2 = 0, \quad \text{i. e., } y = 1,$$

and (utilizing the first equation)

$$z - 3x + 2 = 0, \quad \text{i. e., } x \in \{1, 2\}.$$

Therefore, there are two stationary points, namely  $[1, 1, 1]$  and  $[2, 1, 4]$ . Now, we compute all second-order partial derivatives:

$$\begin{aligned} f_{xx} &= 6x, & f_{xy} &= f_{yx} = 0, & f_{xz} &= f_{zx} = -3, \\ f_{yy} &= 2, & f_{yz} &= f_{zy} = 0, & f_{zz} &= 1. \end{aligned}$$

Having this, we are able to evaluate the Hessian at the stationary points:

$$\begin{aligned} Hf(1, 1, 1) &= \begin{pmatrix} 6 & 0 & -3 \\ 0 & 2 & 0 \\ -3 & 0 & 1 \end{pmatrix}, \\ Hf(2, 1, 4) &= \begin{pmatrix} 12 & 0 & -3 \\ 0 & 2 & 0 \\ -3 & 0 & 1 \end{pmatrix}. \end{aligned}$$

Now, we need to know whether these matrices are positive definite, negative definite, or indefinite in order to determine whether and which extrema occur at the corresponding points. Clearly, the former matrix (for the point  $[1, 1, 1]$ ) has eigenvalue  $\lambda = 2$ . Since its determinant equals  $-6$  and it is a symmetric matrix (all eigenvalues are real), the matrix must have a negative eigenvalue as well (because the determinant is the product of the eigenvalues). Therefore, the matrix  $Hf(1, 1, 1)$  is indefinite, and there is no extremum at the point  $[1, 1, 1]$ .

We will use the so-called Sylvester's criterion for the latter matrix  $Hf(2, 1, 4)$ . According to this criterion, a real-valued symmetric matrix

$$A = \begin{pmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{12} & a_{22} & a_{23} & \cdots & a_{2n} \\ a_{13} & a_{23} & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{1n} & a_{2n} & a_{3n} & \cdots & a_{nn} \end{pmatrix}$$

is positive definite if and only if all of its leading principal minors  $A$ , i. e. the determinants

$$d_1 = |a_{11}|, \quad d_2 = \begin{vmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{vmatrix}, \quad d_3 = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{12} & a_{22} & a_{23} \\ a_{13} & a_{23} & a_{33} \end{vmatrix}, \quad \dots$$

$$d_n = |A|,$$

are positive. Further, it is negative definite iff

$$d_1 < 0, \quad d_2 > 0, \quad d_3 < 0, \quad \dots, \quad (-1)^n d_n > 0.$$

The inequalities

$$|12| = 12 > 0, \quad \begin{vmatrix} 12 & 0 \\ 0 & 2 \end{vmatrix} = 24 > 0, \quad \begin{vmatrix} 12 & 0 & -3 \\ 0 & 2 & 0 \\ -3 & 0 & 1 \end{vmatrix} = 6 > 0,$$

imply that the matrix  $Hf(2, 1, 4)$  is positive definite – there is a strict local minimum at the point  $[2, 1, 4]$ .  $\square$

**8.F.6.** Find the local extrema of the function

$$z = (x^2 - 1)(1 - x^4 - y^2), \quad x, y \in \mathbb{R}.$$

**PROOF.** Given an increment  $v \in \mathbb{R}^n$ , consider the parametrized straight line  $c(t) = x + tv$  in  $E_n$ , and examine the function  $\varphi : \mathbb{R} \rightarrow \mathbb{R}$  defined by the composition  $\varphi(t) = f \circ c(t)$ . Taylor's theorem for univariate functions claims that (see Theorem 6.1.3)

$$\begin{aligned} \varphi(t) &= \varphi(0) + \varphi'(0)t + \dots \\ &\quad + \frac{1}{(k-1)!} \varphi^{(k-1)}(0)t^{k-1} + \frac{1}{k!} \varphi^{(k)}(\theta)t^k. \end{aligned}$$

It remains to verify that computing the derivatives  $\varphi^{(\ell)}$  yields the desired relation. This can be done quite easily by induction on the order  $k$ .

For  $k = 1$ , Taylor's theorem coincides with the corollary of the mean value theorem applied to the directional derivative, which is already used several times. When deriving it, the formula

$$\frac{d}{dt} \varphi(t) = \frac{\partial f}{\partial x_1}(x(t)) \cdot x'_1(t) + \dots + \frac{\partial f}{\partial x_n}(x(t)) \cdot x'_n(t)$$

is used. It holds for every continuously differentiable curve and function  $f$ , cf. 8.1.8 and 8.1.9. This means that

$$\varphi'(t) = D^1 f(c(t))(c'(t)) = D^1 f(c(t))(v)$$

for all  $t$  in a neighbourhood of zero. Proceed similarly for functions  $D^\ell f$ . Write  $c'(t)$  instead of the increment  $v$ , and recall that further differentiation of  $c(t)$  leads identically to zero everywhere, i.e.  $c''(t) = 0$  for all  $t$  (since it is a parametrized straight line). Suppose

$$\begin{aligned} \varphi^{(\ell)}(t) &= D^\ell f(x(t))(v) \\ &= \sum_{i_1, \dots, i_\ell} \left( \frac{\partial^\ell f}{\partial x_{i_1} \dots \partial x_{i_\ell}}(x_1(t), \dots, x_n(t)) x'_{i_1}(t) \cdots x'_{i_\ell}(t) \right) \end{aligned}$$

and calculate  $\varphi^{(\ell+1)}(t)$ . By the above formula for first-order differentiation in a given direction and the rule for the derivative of a product (see Theorem 5.3.4), the differentiation of the composite function gives

$$\begin{aligned} \varphi^{(\ell+1)}(t) &= \frac{d}{dt} D^\ell f(c(t))(c'(t)) \\ &= \frac{d}{dt} \sum_{i_1, \dots, i_\ell} \left( \frac{\partial^\ell f}{\partial x_{i_1} \dots \partial x_{i_\ell}}(x_1(t), \dots, x_n(t)) \right. \\ &\quad \left. \cdot x'_{i_1}(t) \cdots x'_{i_\ell}(t) \right) \\ &= \sum_{i_1, \dots, i_\ell} \left( \sum_{j=1}^n \frac{\partial^{\ell+1} f}{\partial x_{i_1} \dots \partial x_{i_\ell} \partial x_j}(x_1(t), \dots, x_n(t)) \right. \\ &\quad \left. \cdot x'_j(t) \cdot x'_{i_1}(t) \cdots x'_{i_\ell}(t) \right) + 0, \end{aligned}$$

which is the required formula for order  $\ell+1$ . Taylor's theorem now follows from substituting into the equality for  $\varphi$  at the beginning of this proof and the enumeration at the right values of  $t$ .  $\square$

**Solution.** Once again, we calculate the partial derivatives  $z_x$ ,  $z_y$  and set them equal to zero. This leads to the equations

$$-6x^5 + 4x^3 + 2x - 2xy^2 = 0, \quad (x^2 - 1)(-2y) = 0,$$

whose solutions  $[x, y] = [0, 0]$ ,  $[x, y] = [1, 0]$ ,  $[x, y] = [-1, 0]$ . (In order to find these solutions, it suffices to find the real roots  $1, -1$  of the polynomial  $-6x^4 + 4x^2 + 2$  using the substitution  $u = x^2$ . Now, we compute the second-order partial derivatives

$$\begin{aligned} z_{xx} &= -30x^4 + 12x^2 + 2 - 2y^2, \\ z_{xy} &= z_{yx} = -4xy, \\ z_{yy} &= -2(x^2 - 1) \end{aligned}$$

and evaluate the Hessian at the stationary points:

$$\begin{aligned} Hz(0, 0) &= \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}, \\ Hz(1, 0) &= Hz(-1, 0) = \begin{pmatrix} -16 & 0 \\ 0 & 0 \end{pmatrix}. \end{aligned}$$

We can see that the first matrix is positive definite, so the function has a strict local minimum at the origin.

However, the second and third matrices are negative semidefinite. Therefore, the knowledge of second partial derivatives is insufficient for deciding whether there is an extremum at the points  $[1, 0]$  and  $[-1, 0]$ . On the other hand, we can examine the function values near these points. We have  $z(1, 0) = z(-1, 0) = 0$ ,  $z(x, 0) < 0$  for  $x \in (-1, 1)$ . Further, consider  $y$  dependent on  $x \in (-1, 1)$  by the formula  $y = \sqrt{2(1 - x^4)}$ , so that  $y \rightarrow 0$  for  $x \rightarrow \pm 1$ . For this choice, we get  $z(x, \sqrt{2(1 - x^4)}) = (x^2 - 1)(x^4 - 1) > 0$ ,  $x \in (-1, 1)$ . We have thus shown that in arbitrarily small neighborhoods of the points  $[1, 0]$  and  $[-1, 0]$ , the function  $z$  takes on both higher and lower values than the function value at the corresponding point. Therefore, these are not extrema.  $\square$

**8.F.7.** Decide whether the polynomial

$$p(x, y) = x^6 + y^8 + y^4x^4 - x^6y^5$$

has a local extremum at the stationary point  $[0, 0]$ .

**Solution.** We can easily verify that the partial derivatives  $p_x$  and  $p_y$  are indeed zero at the origin. However, each of the partial derivatives  $p_{xx}$ ,  $p_{xy}$ ,  $p_{yy}$  is also equal to zero at the point  $[0, 0]$ . The Hessian  $Hp(0, 0)$  is thus both positive and negative semidefinite at the same time. However, a simple idea can lead us to the result: We can notice that  $p(0, 0) = 0$  and

$$p(x, y) = x^6(1 - y^5) + y^8 + y^4x^4 > 0$$

for  $[x, y] \in \mathbb{R} \times (-1, 1) \setminus \{[0, 0]\}$ . Therefore, the given polynomial has a local minimum at the origin.  $\square$

**8.F.8.** Determine local extrema of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^2y + y^2z + x - z$  on  $\mathbb{R}^3$ .  $\circ$

**8.F.9.**

**8.1.15. Formula with multi-indices.** To simplify the notation, let us introduce the multi-index notation for the polynomials with more variables.

MULTI-INDICES

A *multi-index*  $\alpha$  of length  $n$  is an  $n$ -tuple of non-negative integers  $(\alpha_1, \dots, \alpha_n)$ . The integer  $|\alpha| = \alpha_1 + \dots + \alpha_n$  is called the *size* of the multi-index  $\alpha$ .

Monomials are written shortly as  $x^\alpha$  instead of  $x_1^{\alpha_1}x_2^{\alpha_2}\dots x_n^{\alpha_n}$ . Real polynomials in  $n$  variables can be symbolically expressed in a similar way as univariate polynomials:

$$f = \sum_{|\alpha| \leq k} a_\alpha x^\alpha, \quad g = \sum_{|\beta| \leq \ell} b_\beta x^\beta \in \mathbb{R}[x_1, \dots, x_n].$$

$f$  is said to have total degree  $k$  if at least one coefficient with multi-indices  $\alpha$  of size  $k$  is non-zero, while all the coefficients with multi-indices of larger sizes vanish.

Nice formulae express addition and multiplication of multivariate polynomials of degrees  $k$  and  $\ell$  respectively:

$$\begin{aligned} f + g &= \sum_{|\alpha| \leq \max(k, \ell)} (a_\alpha + b_\alpha)x^\alpha, \\ fg &= \sum_{|\gamma|=0}^{k+\ell} \left( \sum_{\alpha+\beta=\gamma} a_\alpha b_\beta \right) x^\gamma, \end{aligned}$$

where the multi-indices are added componentwise, and the formally non-existing coefficients are assumed to be zero.

Moreover we write shortly

$$\partial_\alpha f = \frac{\partial^{|\alpha|} f}{\partial x_1^{\alpha_1} \dots \partial x_n^{\alpha_n}}$$

and  $\alpha! = \alpha_1! \dots \alpha_n!$ . In particular,  $\partial_\alpha f = f$  if  $|\alpha| = 0$ .

TAYLOR'S POLYNOMIALS VIA MULTI-INDICES

Taylor's expansion up to order  $r$  of a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$ , for an increment  $v \in \mathbb{R}^n$  is the polynomial

$$(1) \quad f(x + v) = f(x) + \sum_{1 \leq |\alpha| \leq k} \frac{1}{\alpha!} \partial_\alpha f(x) v^\alpha,$$

quite as the formula in dimension one.

**8.1.16. Real analytic functions.** If the multidimensional power series  $F(v) = \sum_{|\alpha| \geq 0} \frac{1}{\alpha!} \partial_\alpha f(x) v^\alpha$  converges at some neighborhood of  $v = 0$ , we call the function  $f$  (real) *analytic* on a neighborhood of  $x$ .

For instance, this happens if all the partial derivatives are uniformly bounded, i.e.,  $\partial_\alpha f(x) < C$  for all  $\alpha$ . Indeed, we may estimate

$$\left| \frac{1}{k!} \sum_{i_1, \dots, i_k} \frac{\partial^k f(x)}{\partial x_{i_1} \dots \partial x_{i_k}} v_{i_1} \dots v_{i_k} \right| \leq \frac{1}{k!} n^k C \|v\|^k$$

and thus the Taylor's series converges absolutely by the Weierstrass criterion for all  $v$ . Think about the details. Actually, our argument shows that the Taylor's series converges (on a small

Determine the local extrema of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^2y - y^2z + 4x + z$  on  $\mathbb{R}^3$ . ○

**8.F.10.** Determine the local extrema of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = xz^2 + y^2z - x + y$  on  $\mathbb{R}^3$ . ○

**8.F.11.** Determine the local extrema of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = y^2z - xz^2 + x + 4y$  on  $\mathbb{R}^3$ . ○

**8.F.12.** Determine the local extrema of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2y + x^2 + 2y^2 + y$  on  $\mathbb{R}^2$ . ○

**8.F.13.** Determine the local extrema of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2y + 2y^2 + 2y$  on  $\mathbb{R}^2$ . ○

**8.F.14.** Determine the local extrema of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2 + xy + 2y^2 + y$  on  $\mathbb{R}^2$ . ○

**8.F.15.** Determine the local extrema of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^2 + xy - 2y^2 + y$  on  $\mathbb{R}^2$ . ○

**G. Implicitly given functions and mappings**

**8.G.1.** Let  $F : \mathbb{R}^2 \rightarrow \mathbb{R}$  be a function,  $F(x, y) = xy \sin(\frac{\pi}{2}xy^2)$ . Show that the equality  $F(x, y) = 1$  implicitly defines a function  $f : U \rightarrow \mathbb{R}$  on a neighborhood  $U$  of the point  $[1, 1]$  so that  $F(x, f(x)) = 1$  for  $x \in U$ . Determine  $f'(1)$ .

**Solution.** The function is differentiable on the whole  $\mathbb{R}^2$ , so it is such on any neighborhood of the point  $[1, 1]$ . Let us evaluate  $F_y$  at  $[1, 1]$ :

$$F_y(x, y) = x \sin\left(\frac{\pi}{2}xy^2\right) + \pi x^2 y^2 \cos\left(\frac{\pi}{2}xy^2\right),$$

so  $F_y(1, 1) = 1 \neq 0$ . Therefore, it follows from theorem 8.1.25 that the equation  $F(x, y) = 1$  implicitly determines on a neighborhood of the point  $(1, 1)$  a function  $f : U \rightarrow \mathbb{R}$  defined on a neighborhood of the point (number) 1. Moreover, we have

$$F_x(x, y) = y \sin\left(\frac{\pi}{2}xy^2\right) + \frac{\pi}{2}xy^3 \cos\left(\frac{\pi}{2}xy^2\right),$$

so the derivative of the function  $f$  at the point 1 satisfies

$$f'(1) = -\frac{F_x(1, 1)}{F_y(1, 1)} = -\frac{1}{1} = -1. \quad \square$$

**Remark.** Notice that although we are unable to explicitly define the function  $f$  from the equation  $F(x, f(x)) = 1$ , we are able to determine its derivative at the point 1.

**8.G.2.** Considering the function  $F : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,

$$F(x, y) = e^x \sin(y) + y - \pi/2 - 1,$$

show that the equation  $F(x, y) = 0$  implicitly defines the variable  $y$  to be a function of  $x$ ,  $y = f(x)$ , on a neighborhood of the point  $[0, \pi/2]$ . Compute  $f'(0)$ .

**Solution.** The function is differentiable in a neighborhood of the point  $[0, \pi/2]$ ; moreover,  $F_y = e^x \cos y + 1$ ,  $F(0, \pi/2) = 1 \neq 0$ , so the equation indeed defines a function  $f : U \rightarrow \mathbb{R}$  on a neighborhood of the point  $[0, \pi/2]$ . Further, we have  $F_x = e^x \sin y$ ,  $F_x(0, \pi/2) = 1$ , and its derivative at the point

neighborhood of  $x$ ) if the partial derivatives grow with the order  $k$  slower than  $k!$ .

**8.1.17. Local extrema.** We examine the local maxima and minima of functions on  $E_n$  using the differential and the Hessian. Just as in the case of univariate functions, an interior point  $x_0 \in E_n$  of the domain of a function  $f$  is said to be a (local) *maximum* or *minimum* if and only if there is a neighbourhood  $U$  of  $x_0$  such that for all points  $x \in U$ , the function value satisfies  $f(x) \leq f(x_0)$  or  $f(x) \geq f(x_0)$ , respectively. If strict inequalities hold for all  $x \neq x_0$ , there is a *strict extremum*.

To simplify, suppose that  $f$  has continuous both first-order and second-order partial derivatives on its domain. A necessary condition for the existence of an extremum at a point  $x_0$  is that the differential be zero at this point, i.e.,  $df(x_0) = 0$ . If  $df(x_0) \neq 0$ , then there is a direction  $v$  in which  $d_v f(x_0) \neq 0$ . However, then the function value is increasing at one side of the point  $x_0$  along the line  $x_0 + tv$  and it is decreasing on the other side, see 5.3.2.

An interior point  $x \in E_n$  of the domain of a function  $f$  at which the differential  $df(x)$  is zero is called a *stationary point of the function*  $f$ .

To illustrate the concept on a simple function in  $E_2$ , consider  $f(x, y) = \sin(x) \cos(y)$ .

The shape of this function resembles the well-known egg plates, so it is evident that there are many extrema, and also many stationary points which are not extrema (“saddles” are visible in the picture).

Calculate the first derivatives, and then the necessary second-order ones:

$$f_x(x, y) = \cos(x) \cos(y), \quad f_y(x, y) = -\sin(x) \sin(y),$$

and both derivatives are zero for two sets of points

- (1)  $\cos(x) = 0, \sin(y) = 0$ , that is  $(x, y) = (\frac{2k+1}{2}\pi, \ell\pi)$ , for any  $k, \ell \in \mathbb{Z}$
- (2)  $\cos(y) = 0, \sin(x) = 0$ , that is  $(x, y) = (k\pi, \frac{2\ell+1}{2}\pi)$ , for any  $k, \ell \in \mathbb{Z}$ .

The second partial derivatives are

$$Hf(x, y) = \begin{pmatrix} f_{xx} & f_{xy} \\ f_{xy} & f_{yy} \end{pmatrix} (x, y) = \begin{pmatrix} -\sin(x) \cos(y) & -\cos(x) \sin(y) \\ -\cos(x) \sin(y) & -\sin(x) \cos(y) \end{pmatrix}.$$

So the following Hessians are obtained in two sets of stationary points:

0 satisfies:

$$f'(0) = -\frac{F_x(0, \pi/2)}{F_y(0, \pi/2)} = -\frac{1}{1} = -1. \quad \square$$

**8.G.3.** Let

$$F(x, y, z) = \sin(xy) + \sin(yz) + \sin(xz).$$

Show that the equation  $F(x, y, z) = 0$  implicitly defines a function  $z(x, y) : \mathbb{R}^2 \rightarrow \mathbb{R}$  on a neighborhood of the point  $[\pi, 1, 0] \in \mathbb{R}^3$  so that  $F(x, y, z(x, y)) = 0$ .

Determine  $z_x(\pi, 1)$  and  $z_y(\pi, 1)$ .

**Solution.** We will calculate  $F_z = y \cos(yz) + x \cos(xz)$ ,  $F_z(\pi, 1, 0) = \pi + 1 \neq 0$ , and the function  $z(x, y)$  is defined by the equation  $F(x, y, z(x, y)) = 0$  on a neighborhood of the point  $[\pi, 1, 0]$ . In order to find the values of the wanted partial derivatives, we first need to calculate the values of the remaining partial derivatives of the function  $F$  at the point  $[\pi, 1, 0]$ .

$$F_x(x, y, z) = y \cos(xy) + z \cos(xz) \quad F_x(\pi, 1, 0) = -1,$$

$$F_y(x, y, z) = x \cos(xy) + z \cos(yz) \quad F_y(\pi, 1, 0) = -\pi,$$

odkud

$$z_x(\pi, 1) = -\frac{F_x(\pi, 1, 0)}{F_z(\pi, 1, 0)} = -\frac{1}{\pi + 1},$$

$$z_y(\pi, 1) = -\frac{F_y(\pi, 1, 0)}{F_z(\pi, 1, 0)} = -\frac{\pi}{\pi + 1}. \quad \square$$

**8.G.4.** Having the mapping  $F : \mathbb{R}^3 \rightarrow \mathbb{R}^2$ ,  $F(x, y, z) = (f(x, y, z), g(x, y, z)) = (e^x \sin y, xyz)$ , show that the equation  $F(x, c_1(x), c_2(x)) = (0, 0)$  defines a curve  $c : \mathbb{R} \rightarrow \mathbb{R}^2$  on a neighborhood of the point  $[1, \pi, 1]$ . Determine the tangent vector to this curve at the point 1.

**Solution.** We will calculate the square matrix of the partial derivatives of the mapping  $F$  with respect to  $y$  and  $z$ :

$$H(x, y, z) = \begin{pmatrix} f_y & f_z \\ g_y & g_z \end{pmatrix} = \begin{pmatrix} x \cos y e^x \sin y & 0 \\ xz & xy \end{pmatrix}.$$

Hence,  $H(1, \pi, 1) = \begin{pmatrix} -1 & 0 \\ 1 & \pi \end{pmatrix}$  and  $\det H(1, \pi, 1) = -\pi \neq 0$ . Now, it follows from the implicit mapping theorem (see 8.1.25) that the equation  $F(x, c_1(x), c_2(x)) = (0, 0)$  on a neighborhood of the point  $[1, \pi, 1]$  determines a curve  $(c_1(x), c_2(x))$  defined on a neighborhood of the point  $[1, \pi]$ . In order to find its tangent vector at this point, we need to determine the (column) vector  $(f_x, g_x)$  at this point:

$$\begin{pmatrix} f_x \\ g_x \end{pmatrix} = \begin{pmatrix} \sin y e^x \sin y \\ yz \end{pmatrix}, \quad \begin{pmatrix} f_x(1, \pi, 1) \\ g_x(1, \pi, 1) \end{pmatrix} = \begin{pmatrix} 0 \\ \pi \end{pmatrix}.$$

The wanted tangent vector is thus

$$\begin{aligned} \begin{pmatrix} (c_1)_x(1) \\ (c_2)_x(1) \end{pmatrix} &= \begin{pmatrix} f_y(1, \pi, 1) & f_z(1, \pi, 1) \\ g_y(1, \pi, 1) & g_z(1, \pi, 1) \end{pmatrix}^{-1} \begin{pmatrix} f_x(1, \pi, 1) \\ g_x(1, \pi, 1) \end{pmatrix} = \\ &= \begin{pmatrix} -1 & 0 \\ 1 & \pi \end{pmatrix}^{-1} \begin{pmatrix} 0 \\ \pi \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ \frac{1}{\pi} & \frac{1}{\pi} \end{pmatrix} \begin{pmatrix} 0 \\ \pi \end{pmatrix}. \end{aligned}$$

(1)  $Hf(k\pi + \frac{\pi}{2}, \ell\pi) = \pm \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ , where the minus sign occurs when  $k$  and  $\ell$  have the same parity (remainder on division by two), and the sign  $+$  occurs in the other case;

(2)  $Hf(k\pi, \ell\pi + \frac{\pi}{2}) = \pm \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ , where again the minus sign occurs when  $k$  and  $\ell$  have the same parity, and the sign  $+$  occurs in the other case;

From the proposition of Taylor's theorem for order  $k = 2$ , there is, in a neighbourhood of one of the stationary points  $(x_0, y_0)$ ,

$$f(x, y) = f(x_0, y_0) + \frac{1}{2}Hf(x_0 + \theta(x - x_0), y_0 + \theta(y - y_0))(\xi, \eta).$$

Here,  $Hf$  is considered to be a quadratic form evaluated at the increment  $(x - x_0, y - y_0) = (\xi, \eta)$ . In the case (1),  $Hf(x_0, y_0)(\xi, \eta) = \pm(\xi^2 + \eta^2)$ , while in the case (2),  $Hf(x_0, y_0)(\xi, \eta) = \pm 2\xi\eta$ . While in the first case, the quadratic form is either always positive or always negative on all nonzero arguments, in the second case, there are always arguments with positive values and other arguments with negative values.

Since the Hessian of the function is continuous (i.e. all the partial derivatives up to order two are continuous), the Hessians in the nearby points are small perturbations of those in  $(x_0, y_0)$  and so these properties of the quadratic form  $Hf(x, y)$  remain true on some neighbourhood of  $(x_0, y_0)$ . This is obvious in cases (1) and (2), since a small perturbation of the matrices does clearly not change the latter properties of the quadratic forms in question. A general formal proof is presented below.

The local maximum occurs if and only if the point  $(x_0, y_0)$  belongs to the case (1) with  $k$  and  $\ell$  of the same parity. On the other hand, if the parities are different, then the point from the case (1) happens to be a point of a local minimum.

On the other hand, in the case (2) the entire function  $f$  behaves similarly to the Hessian and so the "saddle" points are not extrema.

**8.1.18. The decision rules.** In order to formulate the general statement about the Hessian and the local extrema at stationary points, it is necessary to remember the discussion about quadratic forms from the paragraphs 4.3.2–4.3.3 in the chapter on affine geometry. There are introduced the following types of quadratic forms  $h : E_n \rightarrow \mathbb{R}$ :

- *positive definite* if and only if  $h(u) > 0$  for all  $u \neq 0$
- *positive semidefinite* if and only if  $h(u) \geq 0$  for all  $u \in V$
- *negative definite* if and only if  $h(u) < 0$  for all  $u \neq 0$
- *negative semidefinite* if and only if  $h(u) \leq 0$  for all  $u \in V$
- *indefinite* if and only if  $h(u) > 0$  and  $h(v) < 0$  for appropriate  $u, v \in V$ .

- There are methods to allow determining whether or not a given form has any of these properties.

The Taylor expansion with remainder immediately yields the following rules:

LOCAL EXTREMA

**H. Constrained optimization**

We will begin with a somewhat atypical optimization problem.

**8.H.1.** A betting office accepts bets on the outcome of a tennis match. Let the odds laid against player  $A$  winning be  $a : 1$  (i. e., if a bettor bets  $x$  dollars on the event that player  $A$  wins and this really happens, then the bettor wins  $ax$  dollars) and, similarly, let the odds laid against player  $B$  winning be  $b : 1$  (fees are neglected). What is the necessary and sufficient condition for (positive real) numbers  $a$  and  $b$  so that a bettor cannot guarantee any profit regardless the actual outcome of the match? (For instance, if the odds were laid  $1.5 : 1$  against the win of  $A$  and  $5 : 1$  against the win of  $B$ , then the bettor could bet 3 dollars on  $B$  winning and 7 dollars on  $A$  winning and profit from this bet in either case).

**Solution.** Let the bettor have  $P$  dollars. The bet amount can be divided to  $kP$  and  $(1 - k)P$  dollars, where  $k \in (0, 1)$ . The profit is then  $akP$  dollars (if player  $A$  wins) or  $b(1 - k)P$  dollars (if  $B$  does). The bettor is always guaranteed to win the lesser of these two amounts; the total profit (or loss) is obtained by subtracting the bet  $P$ , then. Since each of  $a, b, P$  is a positive real number, the function  $akP$  is increasing, and the function  $b(1 - k)P$  is decreasing with respect to  $k$ . For  $k = 0$ ,  $b(1 - k)P$  is greater; for  $k = 1$ ,  $akP$  is. The minimum of the two numbers  $akP$  and  $b(1 - k)P$  is thus maximal for a  $k \in (0, 1)$ , namely for the value  $k_0$  which satisfies  $ak_0P = b(1 - k_0)P$ , whence  $k_0 = \frac{b}{a+b}$ . Therefore, the betting office must choose  $a, b$  so that  $ak_0P = b(1 - k_0)P < P$ , which is equivalent to  $ak_0 < 1$ , i. e.,  $ab < a + b$ . □

We managed to solve this constrained optimization problem even without using the differential calculus. However, we will not be able to do so in the following problems.

**8.H.2.** Find the extremal values of the function

$$h(x, y, z) = x^3 + y^3 + z^3$$

on the unit sphere  $S$  in  $\mathbb{R}^3$  given by the equation

$$F(x, y, z) = x^2 + y^2 + z^2 - 1$$

as well as on the circle which is the intersection of this sphere with the plane

$$G(x, y, z) = x + y + z.$$

**Solution.** First, we will look for stationary points of the function  $h$  on the sphere  $S$ . Computing the corresponding gradients (for instance,  $\text{grad } h(x, y, z) = (3x^2, 3y^2, 3z^2)$ ), we get the system

$$\begin{aligned} 0 &= 3x^2 - 2\lambda x, \\ 0 &= 3y^2 - 2\lambda y, \\ 0 &= 3z^2 - 2\lambda z, \\ 0 &= x^2 + y^2 + z^2 - 1 \end{aligned}$$

**Theorem.** Let  $f : E_n \rightarrow \mathbb{R}$  be a twice continuously differentiable function and  $x \in E_n$  be a stationary point of the function  $f$ . Then

- (1)  $f$  has a strict local minimum at  $x$  if  $Hf(x)$  is positive definite,
- (2)  $f$  has a strict local maximum at  $x$  if  $Hf(x)$  is negative definite,
- (3)  $f$  does not have an extremum at  $x$  if  $Hf(x)$  is indefinite.

**PROOF.** The Taylor second-order expansion with remainder applied to our function  $f(x_1, \dots, x_n)$ , an arbitrary point  $x = (x_1, \dots, x_n)$ , and any increment  $v = (v_1, \dots, v_n)$ , such that all points  $x + \theta v, \theta \in [0, 1]$ , lie in the domain of the function  $f$ , says that

$$f(x + v) = f(x) + df(x)(v) + \frac{1}{2}Hf(x + \theta \cdot v)(v)$$

for an appropriate real number  $\theta, 0 \leq \theta \leq 1$ . Since it is supposed that the differential is zero, we obtain

$$f(x + v) = f(x) + \frac{1}{2}Hf(x + \theta \cdot v)(v).$$

By assumption, the quadratic form  $Hf(x)$  is continuously dependent on the point  $x$ , and the definiteness or indefiniteness of quadratic forms can be determined by the sign of the major subdeterminants of the matrix  $Hf$ , see Sylvester's criterion in paragraph 4.3.3. However, the determinant itself is a polynomial expression in the coefficients of the matrix, hence a continuous function. Therefore, the non-vanishing and signs of the examined determinants are the same in a sufficiently small neighbourhood of the point  $x$  as at the point  $x$  itself.

In particular, for a positive definite  $Hf(x)$ , it is guaranteed that at a stationary point  $x, f(x + v) > f(x)$  for sufficiently small  $v$ . So this is a sharp minimum of the function  $f$  at the point  $x$ . The case of negative definiteness is analogous. If  $Hf(x)$  is indefinite, then there are directions  $v, w$  in which  $f(x + v) > f(x)$  and  $f(x + w) < f(x)$ , so there is no extremum at the stationary point in question. □

The theorem yields no result if the Hessian of the function is degenerate, yet not indefinite at the point in question. The reason is the same as in the case of univariate functions. In these cases, there are directions in which both the first and second derivatives vanish, so at this level of approximation, it cannot be determined whether the function behaves like  $t^3$  or  $\pm t^4$  until higher-order derivatives in the necessary directions are calculated.

At the same time, even at those points where the differential is non-zero, the definiteness of the Hessian  $Hf(x)$  has

consisting of four equations in four variables. Before trying to solve this system, we can estimate how many local constrained extrema we should anticipate the function to have. Surely,  $h(P)$  is in absolute value equal to at most 1, and this happens at all intersection points of the coordinate axes with  $S$ . Therefore, we are likely to get 6 local extrema. Further, inside every eighth of the sphere given by the coordinate planes, there may or may not be another extremum. The particular quadrants can be easily parametrized, and the function  $h$  (considered a function of two parameters) can be analyzed by standard means (or we can have it drawn in Maple, for example).

Actually, solving the system (no matter whether algebraically or in Maple again) leads to a great deal of stationary points. Besides the six points we have already talked about (two of the coordinates equal to zero and the other to  $\pm 1$ ) and which have  $\lambda = \pm \frac{3}{2}$ , there are also the points

$$P_{\pm} = \pm \left( \frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3} \right),$$

for example, where a local extremum indeed occurs.

If we restrict our interest to the points of the circle  $K$ , we must give another function  $G$  another free parameter  $\eta$  representing the gradient coefficient. This leads to the bigger system

$$\begin{aligned} 0 &= 3x^2 - 2\lambda x - \eta, \\ 0 &= 3y^2 - 2\lambda y - \eta, \\ 0 &= 3z^2 - 2\lambda z - \eta, \\ 0 &= x^2 + y^2 + z^2 - 1, \\ 0 &= x + y + z. \end{aligned}$$

However, since a circle is also a compact set,  $h$  must have both a global minimum and maximum on it. Further analysis is left to the reader.  $\square$

**8.H.3.** Determine whether the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^2y$  has any extrema on the surface  $2x^2 + 2y^2 + z^2 = 1$ . If so, find these extrema and determine their types.

**Solution.** Since we are interested in extrema of a continuous function on a compact set (ellipsoid) – it is both closed and bounded in  $\mathbb{R}^3$  – the given function must have both a minimum and maximum on it. Moreover, since the constraint is given by a continuously differentiable function and the examined function is differentiable, the extrema must occur at stationary points of the function in question on the given set. We can build the following system for the stationary points:

$$\begin{aligned} 2xy &= 4kx, \\ x^2 &= 4ky, \\ 0 &= 2kz. \end{aligned}$$

This system is satisfied by the points  $[\pm \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{6}}, 0]$  and  $[\pm \frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{6}}, 0]$ . The function takes on only two values at these four stationary points. It follows from the above that the first and second stationary points are maxima of

similar consequences as the non-vanishing of the second derivative of a univariate function. For a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$ , the expression  $z(x + v) = f(x) + df(x)(v)$  defines the tangent hyperplane to the graph of the function  $f$  in the space  $\mathbb{R}^{n+1}$ . Taylor's theorem of order two with remainder, as used in the proof above, provides the expression  $f(x + v) = z(x + v) + \frac{1}{2}Hf(x + \theta v)(v)$ .

If the Hessian is positive definite, all the values of the function  $f$  lie above the values of the tangent hyperplane for arguments in a sufficiently small neighbourhood of the point  $x$ , i.e. the whole graph is above the tangent hyperplane in a sufficiently small neighbourhood. In the case of negative definiteness, it is the other way round.

Finally, when the Hessian is indefinite, the graph of the function has values on both sides of the hyperplane. This happens, in general, along objects of lower dimensions in the tangent hyperplane, so there is no straightforward generalization of inflection points.

**8.1.19. The differential of mappings.** The concepts of derivative and differential can be easily extended to mappings  $F : E_n \rightarrow E_m$ . Having selected the Cartesian coordinate system on both sides, this mapping is an ordinary  $m$ -tuple

$$F(x_1, \dots, x_n) = (f_1(x_1, \dots, x_n), \dots, f_m(x_1, \dots, x_n))$$

of functions  $f_i : E_n \rightarrow \mathbb{R}$ .  $F$  is defined to be a *differentiable* or  *$k$ -times differentiable mapping* if and only if the corresponding property is shared by all the functions  $f_1, \dots, f_m$ .

The differentials  $df_i(x)$  of the particular functions  $f_i$  give a linear approximation of the increments of their values for the mapping  $F$ . Therefore, we can expect that they also give a coordinate expression of the linear mapping  $D^1F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$  between the modelling spaces which linearly approximates the increments of the mapping  $F$ .

DIFFERENTIAL AND JACOBI MATRIX

Consider a differentiable mapping  $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$  with components  $(f_1(x_1, \dots, x_n), \dots, f_m(x_1, \dots, x_n))$  and  $x$  in its domain. The matrix

$$D^1F(x) = \begin{pmatrix} df_1(x) \\ df_2(x) \\ \vdots \\ df_m(x) \end{pmatrix} = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} & \cdots & \frac{\partial f_1}{\partial x_n} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} & \cdots & \frac{\partial f_2}{\partial x_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_1} & \frac{\partial f_m}{\partial x_2} & \cdots & \frac{\partial f_m}{\partial x_n} \end{pmatrix} (x)$$

is called the *Jacobi matrix of the mapping  $F$*  at the point  $x$ .

The linear mapping  $D^1F(x)$  defined on the increments  $v = (v_1, \dots, v_n)$  by the Jacobi matrix is called the *differential of the mapping  $F$*  at a point  $x$  in the domain if and only if

$$\lim_{v \rightarrow 0} \frac{1}{\|v\|} \left( F(x + v) - F(x) - D^1F(x)(v) \right) = 0.$$

Recall that the definition of Euclidean distance guarantees that the limits of values in  $E_n$  exist if and only if the

the function on the given ellipsoid, while the other two are minima.  $\square$

**Remark.** Note that we have used the variable  $k$  instead of  $\lambda$  from the theorem 8.1.29.

**8.H.4.** Decide whether the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = z - xy^2$  has any minima and maxima on the sphere

$$x^2 + y^2 + z^2 = 1.$$

If so, determine them.

**Solution.** We are looking for solutions of the system

$$\begin{aligned} kx &= -y^2, \\ ky &= -2xy, \\ kz &= 1. \end{aligned}$$

The second equation implies that either  $y = 0$  or  $x = -\frac{k}{2}$ . The first possibility leads to the points  $[0, 0, 1], [0, 0, -1]$ . The second one cannot be satisfied. Note that because of the third equation  $k \neq 0$  and substituting into the equation of the sphere, we get the equation

$$\frac{k^2}{4} + \frac{k^2}{2} + \frac{1}{k^2} = 1,$$

which has no solution in real numbers (it is a quadratic equation in  $k^2$  with the negative discriminant). The function has a maximum and minimum, respectively, at the two computed points on the given sphere.  $\square$

**8.H.5.** Determine whether the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = xyz$ , has any extrema on the ellipsoid given by the equation

$$g(x, y, z) = kx^2 + ly^2 + z^2 = 1, \quad k, l \in \mathbb{R}^+.$$

If so, calculate them.

**Solution.** First, we build the equations which must be satisfied by the stationary points of the given function on the ellipsoid:

$$\begin{aligned} \frac{\partial g}{\partial x} &= \lambda \frac{\partial f}{\partial x} : yz = 2\lambda kx, \\ \frac{\partial g}{\partial y} &= \lambda \frac{\partial f}{\partial y} : xz = 2\lambda ly, \\ \frac{\partial g}{\partial z} &= \lambda \frac{\partial f}{\partial z} : xy = 2\lambda z. \end{aligned}$$

We can easily see that the equation can only be satisfied by a triple of non-zero numbers. Dividing pairs of equations and substituting into the ellipse's equation, we get eight solutions, namely the stationary points  $x = \pm \frac{1}{\sqrt{3k}}, y = \pm \frac{1}{\sqrt{3l}}, z = \pm \frac{1}{\sqrt{3}}$ . However, the function  $f$  takes on only two distinct values at these eight points. Since it is continuous and the given ellipsoid is compact,  $f$  must have both a maximum and minimum on it. Moreover, since both  $f$  and  $g$  are continuously differentiable, these extrema must occur at stationary points. Therefore, it must be that four of the computed stationary points are local maxima of the function (of value  $\frac{1}{3\sqrt{3kl}}$ ) and the other four are minima (of value  $-\frac{1}{3\sqrt{3kl}}$ ).  $\square$

limits of the particular coordinate components do. Direct application of Theorem 8.1.6 about the existence of the differential for functions of  $n$  variables to the particular coordinate functions of the mapping  $F$  thus leads to the following generalization (prove this in detail by yourselves!):

EXISTENCE OF THE DIFFERENTIAL

**Corollary.** Let  $F : E_n \rightarrow E_m$  be a mapping such that all of its coordinate functions have continuous partial derivatives in a neighbourhood of a point  $x \in E_n$ . Then the differential  $D^1F(x)$  exists, and it is given by the Jacobi matrix  $D^1F(x)$ .

**8.1.20. Lipschitz continuity.** Continuous differentiability of mappings allows good control on their variability in the following sense. Assume the estimates of the difference  $F(y) - F(x)$  for all  $x$  and  $y$  from a convex compact subset  $K$  in the domain of  $F$  are of interest. Applying the Taylor's theorem with remainder in order one on each of the components of  $F = (f_1, \dots, f_n)$  separately gives the estimate (write  $v = y - x$ )

$$\begin{aligned} \|F(y) - F(x)\|^2 &= \sum_{i=1}^m |f_i(y) - f_i(x)|^2 \\ &= \sum_{i=1}^m |D^1f_i(x + \theta_i v)(v)|^2 \\ &= \sum_{i=1}^m \sum_{j=1}^n \left| \frac{\partial f_i}{\partial x_j}(x + \theta_i v) v_j \right|^2 \\ &\leq \left( \max_{z \in K, i, j} \left| \frac{\partial f_i}{\partial x_j}(z) \right|^2 \right) nm \|v\|^2 = C^2 \|v\|^2 \end{aligned}$$

for an appropriate constant  $C \geq 0$ . The fact that continuous functions are bounded over each compact set is used.

This is the property of *Lipschitz continuity* of  $F$  on the compact set  $K$ :

$$\|F(y) - F(x)\| \leq C \|y - x\|, \quad \text{for all } x, y \in K$$

which was considered in 7.3.14 in the end of chapter 7.

**Proposition.** Each continuously differentiable mapping  $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is Lipschitz continuous over convex compact sets.

**8.1.21. Differential of composite mappings.** The following theorem formulates a very useful generalization of the *chain rule* for univariate functions. Except for the concept of the differential itself, which is mildly complicated, it is actually the same as the one already seen in the case of one variable.

The Jacobi matrix for univariate functions is a single number, namely the derivative of the function at a given point, so the multiplication of Jacobi matrices is simply the multiplication of the derivatives of the outer and inner components of the function. There is, of course, another special case: the formula derived and used several times for the derivative of a composition of multivariate functions with curves. There, the differential is the linear form expressed via the partial derivatives of the outer components, evaluated on the vector of the

**8.H.6.** Determine the global extrema of the function

$$f(x, y) = x^2 - 2y^2 + 4xy - 6x - 1$$

on the set of points  $[x, y]$  that satisfy the inequalities

$$(1) \quad x \geq 0, \quad y \geq 0, \quad y \leq -x + 3.$$

**Solution.** We are given a polynomial with continuous partial derivatives on a compact (i. e. closed and bounded) set. Such a function necessarily has both a minimum and a maximum on this set, and this can happen only at stationary points or on the boundary. Therefore, it suffices to find stationary points inside the set and the ones on a finite number of open (or singleton) parts of the boundary, then evaluate  $f$  at these points and choose the least and the greatest values. Notice that the set of points determined by the inequalities (1) is clearly a triangle with vertices at  $[0, 0]$ ,  $[3, 0]$ ,  $[0, 3]$ .

Let us determine the stationary points inside this triangle as the solution of the equations  $f_x = 0$ ,  $f_y = 0$ . Since

$$f_x(x, y) = 2x + 4y - 6, \quad f_y(x, y) = 4x - 4y,$$

these equations are satisfied only by the point  $[1, 1]$ . The boundary suggests itself to be expressed as the union of three line segments given by the choice of pairs of vertices. First, we consider  $x = 0$ ,  $y \in [0, 3]$ , when  $f(x, y) = -2y^2 - 1$ . However, we know the graph of this (univariate) function on the interval  $[0, 3]$  It is thus not difficult to find the points at which global extrema occur. They are the marginal points  $[0, 0]$ ,  $[0, 3]$ . Similarly, we can consider  $y = 0$ ,  $x \in [0, 3]$ , also obtaining the marginal points  $[0, 0]$ ,  $[3, 0]$ . Finally, we get to the line segment  $y = -x + 3$ ,  $x \in [0, 3]$ . Making some rearrangements, we get

$$f(x, y) = f(x, -x + 3) = -5x^2 + 18x - 19, \quad x \in [0, 3].$$

We thus need to find the stationary points of the polynomial  $p(x) = -5x^2 + 18x - 19$  from the interval  $[0, 3]$ . The equation  $p'(x) = 0$ , i. e.,  $-10x + 18 = 0$ , is satisfied by  $x = 9/5$ . This means that in the last case, we obtained one more point (besides the marginal points), namely  $[9/5, 6/5]$ , where a global extremum may occur. Altogether, we have these points as “suspects”:

$$[1, 1], \quad [0, 0], \quad [0, 3], \quad [3, 0], \quad \left[\frac{9}{5}, \frac{6}{5}\right]$$

with function values

$$-4, \quad -1, \quad -19, \quad -10, \quad -\frac{14}{5},$$

respectively. We can see that the function  $f$  takes on the greatest value  $-1$  at the point  $[0, 0]$  and the least value  $-19$  at the point  $[0, 3]$ .  $\square$

**8.H.7.** Determine whether the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = y^2z$  has any extrema on the line segment given by the equations  $2x + y + z = 1$ ,  $x - y + 2z = 0$  and the constraint  $x \in [-1, 2]$ . If so, find these extrema and determine their types. Justify all of your decisions.

**Solution.** We are looking for the extrema of a continuous function on a compact set. Therefore, the function must have both a minimum and a maximum on this set, and this will happen either at the marginal points of the segment or at those

derivative of the inner component, again given by the product of the one line (the form) and one column (the vector).

THE CHAIN RULE

**Theorem.** Let  $F : E_n \rightarrow E_m$  and  $G : E_m \rightarrow E_r$  be two differentiable mappings, where the domain of  $G$  contains the whole image of  $F$ . Then, the composite mapping  $G \circ F$  is also differentiable, and its differential at any point  $x$  in the domain of  $F$  is given by the composition of differentials

$$D^1(G \circ F)(x) = D^1G(F(x)) \circ D^1F(x).$$

The Jacobi matrix on the left hand side is the product of the corresponding Jacobi matrices on the right hand side.

**PROOF.** In paragraph 8.1.6 and in the proof of Taylor’s theorem, it was derived how the differentiation of mappings composed of functions and curves behaves. This proved the theorem in the special case of  $n = r = 1$ . The general case can be proved analogously, one just has to work with more vectors.

Fix an arbitrary increment  $v$  and calculate the directional derivative for the composition  $G \circ F$  at a point  $x \in E_n$ . This means to determine the differentials for the particular coordinate functions of the mapping  $G$  composed with  $F$ . To simplify, write  $g \circ F$  for any one of them.

$$d_v(g \circ F)(x) = \lim_{t \rightarrow 0} \frac{1}{t} (g(F(x + tv)) - g(F(x))).$$

The expression in parentheses can, from the definition of the differential of  $g$ , be expressed as

$$g(F(x + tv)) - g(F(x)) = dg(F(x))(F(x + tv) - F(x)) + \alpha(F(x + tv) - F(x)),$$

where  $\alpha$  is a function defined on a neighbourhood of the point  $F(x)$  which is continuous and  $\lim_{v \rightarrow 0} \frac{1}{\|v\|} \alpha(v) = 0$ . Substitution into the equality for the directional derivative yields

$$\begin{aligned} d_v(g \circ F)(x) &= \lim_{t \rightarrow 0} \frac{1}{t} \left( dg(F(x))(F(x + tv) - F(x)) \right. \\ &\quad \left. + \alpha(F(x + tv) - F(x)) \right) \\ &= dg(F(x)) \left( \lim_{t \rightarrow 0} \frac{1}{t} (F(x + tv) - F(x)) \right) \\ &\quad + \lim_{t \rightarrow 0} \frac{1}{t} \left( \alpha(F(x + tv) - F(x)) \right) \\ &= dg(F(x)) \circ D^1F(x)(v) + 0. \end{aligned}$$

The fact that linear mappings between finite-dimensional spaces are always continuous was used. In the last step the Lipschitz continuity of  $F$ , i.e.  $\|F(x+tv) - F(x)\| \leq C\|v\||t|$  was exploited, and the properties of the function  $\alpha$ .

So the theorem for the particular functions  $g_1, \dots, g_r$  of the mapping  $G$  is proved. The theorem in general now follows from the definition of matrix multiplication and its links to linear mappings. Think about all details!  $\square$

where the gradient of the examined function is a linear combination of the gradients of the functions that give the constraints. First, let us look for the points which satisfy the gradient condition:

$$\begin{aligned} 0 &= 2k + l, \\ 2yz &= k - l, \\ y^2 &= k + 2l, \\ 2x + y + z &= 1, \\ x - y + 2z &= 0. \end{aligned}$$

The solution of the system is  $[x, y, z] = [\frac{2}{3}, 0, -\frac{1}{3}]$  and  $[x, y, z] = [\frac{4}{9}, \frac{2}{9}, -\frac{1}{9}]$  (of course, the variables  $k$  and  $l$  can also be computed, but we are not interested in them). The marginal points of the given line segment are  $[-1, \frac{5}{3}, \frac{4}{3}]$  and  $[2, -\frac{4}{3}, -\frac{5}{3}]$ . Considering these four points, the function takes on the greatest value at the first marginal point ( $f(x, y, z) = \frac{100}{27}$ ), which is its maximum on the given segment, and it takes the least value at the second marginal point ( $f(x, y, z) = -\frac{80}{27}$ ), which is thus its minimum there.  $\square$

**8.H.8.** Find the maximal and minimal values of the polynomial

$$p(x, y) = 4x^3 - 3x - 4y^3 + 9y$$

on the set

$$M = \{[x, y] \in \mathbb{R}^2; x^2 + y^2 \leq 1\}.$$

**Solution.** This is again the case of a polynomial on a compact set; therefore, we can restrict our attention to stationary points inside or on the boundary of  $M$  and the “marginal” points on the boundary of  $M$ . However, the only solutions of the equations

$$p_x(x, y) = 12x^2 - 3 = 0, \quad p_y(x, y) = -12y^2 + 9 = 0$$

are the points

$$\left[\frac{1}{2}, \frac{\sqrt{3}}{2}\right], \quad \left[\frac{1}{2}, -\frac{\sqrt{3}}{2}\right], \quad \left[-\frac{1}{2}, \frac{\sqrt{3}}{2}\right], \quad \left[-\frac{1}{2}, -\frac{\sqrt{3}}{2}\right],$$

which are all on the boundary of  $M$ . This means that  $p$  has no extremum inside  $M$ . Now, it suffices to find the maximum and minimum of  $p$  on the unit circle  $k : x^2 + y^2 = 1$ . The circle  $k$  can be expressed parametrically as

$$x = \cos t, \quad y = \sin t, \quad t \in [-\pi, \pi].$$

Thus, instead of looking for the extrema of  $p$  on  $M$ , we are now seeking the extrema of the function

$$f(t) := p(\cos t, \sin t) = 4 \cos^3 t - 3 \cos t - 4 \sin^3 t + 9 \sin t$$

on the interval  $[-\pi, \pi]$ . For  $t \in [-\pi, \pi]$ , we have

$$f'(t) = -12 \cos^2 t \sin t + 3 \sin t - 12 \sin^2 t \cos t + 9 \cos t,$$

In order to determine the stationary points, we must express the function  $f'$  in a form from which we will be able to calculate the intersection of its graph with the  $x$ -axis. To this purpose, we will use the identity

$$\frac{1}{\cos^2 t} = 1 + \tan^2 t,$$

**8.1.22. Transformation of coordinates.** A mapping  $F : E_n \rightarrow E_n$  which has an inverse mapping  $G : E_n \rightarrow E_n$  defined on the entire image of  $F$  is called a *transformation*. Such a mapping can be perceived as a change of coordinates. It is usually required that both  $F$  and  $G$  be (continuously) differentiable mappings.

Just as in the case of vector spaces, the choice of “point of view”, i.e. the choice of coordinates, can simplify or deteriorate comprehension of the examined object. The change of coordinates is now being discussed in a much more general form than in the case of affine mappings in the fourth chapter. Sometimes, the term “curvilinear coordinates” is used in this general sense. An illustrative example is the change of the most usual coordinates in the plane to polar coordinates. That is, the position of a point  $P$  is given by its distance  $r = \sqrt{x^2 + y^2}$  from the origin and the angle  $\varphi = \arctan(y/x)$  between the ray from the origin to it and the  $x$ -axis (if  $x \neq 0$ ). Notice, this is just the transformation between the algebraic and geometric form of a complex number.

The illustration shows the the “line”  $r = \varphi$  drawn in the Cartesian coordinates.

The change from the polar coordinates to the standard ones is

$$P_{\text{polar}} = (r, \varphi) \mapsto (r \cos \varphi, r \sin \varphi) = P_{\text{Cartesian}}$$

It is apparent that it is necessary to limit the polar coordinates to an appropriate subset of points  $(r, \varphi)$  in the plane so that the inverse mapping would exist. The Cartesian image of lines in polar coordinates with constant coordinates  $r$  or  $\varphi$  is also shown in the illustration above.

Let us discuss an example how to deal with the concept of transformation and the theorem about differentiation of composite mappings. The inverse to the above is the transformation  $F : \mathbb{R}^2 \rightarrow \mathbb{R}^2$  (for instance, on the domain of all points in the first quadrant except for the points having  $x = 0$ ):

$$r = \sqrt{x^2 + y^2}, \quad \varphi = \arctan \frac{y}{x}.$$

Consider now the function  $g_t : E_2 \rightarrow \mathbb{R}$ , with free parameter  $t \in \mathbb{R}$ ,

$$g(r, \varphi, t) = \sin(r - t)$$

which is valid provided both sides are well-defined. We get

$$f'(t) = \cos^3 t [-12 \operatorname{tg} t + 3 (\operatorname{tg} t + \operatorname{tg}^3 t) - 12 \operatorname{tg}^2 t + 9 (1 + \operatorname{tg}^2 t)]$$

for  $t \in [-\pi, \pi]$  with  $\cos t \neq 0$ . However, this condition does not exclude any stationary points since  $\sin t \neq 0$  if  $\cos t = 0$ . Therefore, the stationary points of  $f$  are those points  $t \in [-\pi, \pi]$  for which

$$-4 \operatorname{tg} t + \operatorname{tg} t + \operatorname{tg}^3 t - 4 \operatorname{tg}^2 t + 3 + 3 \operatorname{tg}^2 t = 0.$$

The substitution  $s = \operatorname{tg} t$  leads to

$$s^3 - s^2 - 3s + 3 = 0, \quad \text{i. e.} \quad (s - 1)(s - \sqrt{3})(s + \sqrt{3}) = 0.$$

Then, the values

$$s = 1, \quad s = \sqrt{3}, \quad s = -\sqrt{3}$$

respectively correspond to

$$t \in \{-\frac{3}{4}\pi, \frac{1}{4}\pi\}, \quad t \in \{-\frac{2}{3}\pi, \frac{1}{3}\pi\}, \quad t \in \{-\frac{1}{3}\pi, \frac{2}{3}\pi\}.$$

Now, we evaluate the function  $f$  at each of these points as well as at the marginal points  $t = -\pi, t = \pi$ . Sorting them, we get

$$\begin{aligned} f(-\frac{1}{3}\pi) &= -1 - 3\sqrt{3} < f(-\frac{3}{4}\pi) = -3\sqrt{2} < \\ & f(-\frac{2}{3}\pi) = 1 - 3\sqrt{3} < -1, \\ & f(-\pi) = f(\pi) = -1 < 0, \\ f(\frac{2}{3}\pi) &= 1 + 3\sqrt{3} > f(\frac{1}{4}\pi) = 3\sqrt{2} > f(\frac{1}{3}\pi) = \\ & -1 + 3\sqrt{3} > 0. \end{aligned}$$

Therefore, the global minimum of the function  $f$  is at the point  $t = -\pi/3$ , while the global maximum is at  $t = 2\pi/3$ .

Now, let us get back to the original function  $p$ . Since we know the values  $\cos(-\frac{1}{3}\pi) = \frac{1}{2}, \sin(-\frac{1}{3}\pi) = -\frac{\sqrt{3}}{2}, \cos(\frac{2}{3}\pi) = -\frac{1}{2}, \sin(\frac{2}{3}\pi) = \frac{\sqrt{3}}{2}$ , we can deduce that the polynomial  $p$  takes on the minimal value  $-1 - 3\sqrt{3}$  (the same as  $f$ , of course) at the point  $[1/2, -\sqrt{3}/2]$  and the maximal value  $1 + 3\sqrt{3}$  at  $[-1/2, \sqrt{3}/2]$ .  $\square$

**8.H.9.** At which points does the function

$$f(x, y) = x^2 - 4x + y^2$$

take on global extrema on the set  $M : |x| + |y| \leq 1$ ?

**Solution.** Expressing  $f$  in the form

$$f(x, y) = (x - 2)^2 - 4 + y^2,$$

we can see that the global maximum and minimum occur at the same points as for the function

$$g(x, y) := \sqrt{(x - 2)^2 + y^2}, \quad [x, y] \in M,$$

since neither shifting the function nor applying the increasing function  $v = \sqrt{u}$  for  $u \geq 0$  changes the points of extrema (of course, they can change their values). However, we know that the function  $g$  gives the distance of a point  $[x, y]$  from the point  $[2, 0]$ . Since the set  $M$  is clearly a square with vertices  $[1, 0], [0, 1], [-1, 0], [0, -1]$ , the point of  $M$  that is closest to  $[2, 0]$  is the vertex  $[1, 0]$ , while the most distant one is  $[-1, 0]$ . Altogether, we have obtained that the minimal value of  $f$  occurs at the point  $[1, 0]$  and the maximal one at  $[-1, 0]$ .  $\square$

in polar coordinates. Such a function can approximate the waves on a water surface after a point impulse in the origin at the time  $t$ , see the illustration (there,  $t = -\pi/2$ ). While it was easy to define the function in polar coordinates, it would have been much harder to guess with Cartesian coordinates.

Compute the derivative of this function in Cartesian coordinates. Using the theorem,

$$\begin{aligned} \frac{\partial g}{\partial x}(x, y, t) &= \frac{\partial g}{\partial r}(r, \varphi) \frac{\partial r}{\partial x}(x, y) + \frac{\partial g}{\partial \varphi}(r, \varphi) \frac{\partial \varphi}{\partial x}(x, y) \\ &= \cos(\sqrt{x^2 + y^2} - t) \frac{x}{\sqrt{x^2 + y^2}} + 0 \end{aligned}$$

and, similarly,

$$\begin{aligned} \frac{\partial g}{\partial y}(x, y, t) &= \frac{\partial g}{\partial r}(r, \varphi) \frac{\partial r}{\partial y}(x, y) + \frac{\partial g}{\partial \varphi}(r, \varphi) \frac{\partial \varphi}{\partial y}(x, y) \\ &= \cos(\sqrt{x^2 + y^2} - t) \frac{y}{\sqrt{x^2 + y^2}}. \end{aligned}$$

**8.1.23. The inverse mapping theorem.** If the first derivative of a differentiable univariate function is non-zero, its sign determines whether the function is increasing or decreasing. Then, the function has this property in a neighbourhood of the point in question, and so an inverse function exists in the selected neighbourhood. The derivative of the inverse function  $f^{-1}$  is then the reciprocal value of the derivative of the function  $f$  (i.e. the inverse with respect to multiplication of real numbers). For higher dimensions there is the analogous result:

#### THE INVERSE MAPPING THEOREM

**Theorem.** Let  $F : E_n \rightarrow E_n$  be a differentiable mapping on a neighbourhood of a point  $x_0 \in E_n$ , and let the Jacobi matrix  $D^1 F(x_0)$  be invertible.

Then in some neighbourhood of  $y_0 = F(x_0)$ , the inverse mapping  $F^{-1}$  exists, it is differentiable, and its differential at the point  $F(x_0)$  is the inverse mapping to the differential  $D^1 F(x_0)$ .

Hence,  $D^1(F^{-1})(F(x_0))$  is given by the inverse matrix to the Jacobi matrix of the mapping  $F$  at the point  $x_0$ .

Interpreting this situation for a mapping  $E_1 \rightarrow E_1$  and linear mappings  $\mathbb{R} \rightarrow \mathbb{R}$  as their differentials, the nonvanishing is a necessary and sufficient condition for the differential

**8.H.10.** Compute the local extrema of the function  $y = f(x)$  given implicitly by the equation

$$3x^2 + 2xy + x = y^2 + 3y + \frac{5}{4}, \quad [x, y] \in \mathbb{R}^2 \setminus \left\{ \left[ x, x - \frac{3}{2} \right]; x \in \mathbb{R} \right\}.$$

**Solution.** In accordance with the theoretical part (see 8.1.25), let us denote

$$F(x, y) = 3x^2 + 2xy + x - y^2 - 3y - \frac{5}{4}, \quad [x, y] \in \mathbb{R}^2 \setminus \left\{ \left[ x, x - \frac{3}{2} \right]; x \in \mathbb{R} \right\}$$

and calculate the derivative

$$y' = f'(x) = -\frac{F_x(x, y)}{F_y(x, y)} = -\frac{6x+2y+1}{2x-2y-3}.$$

We can see that this derivative is continuous on the whole set in question. In particular, the function  $f$  is defined implicitly on this set (the denominator is non-zero).

A local extremum may occur only for those  $x, y$  which satisfy  $y' = 0$ , i. e.,  $6x + 2y + 1 = 0$ . Substituting  $y = -3x - 1/2$  into the equation  $F(x, y) = 0$ , we obtain  $-12x^2 + 6x = 0$ , which leads to

$$[x, y] = \left[ 0, -\frac{1}{2} \right], \quad [x, y] = \left[ \frac{1}{2}, -2 \right].$$

We can also easily compute that

$$y'' = (y')' = -\frac{(6+2y')(2x-2y-3) - (6x+2y+1)(2-2y')}{(2x-2y-3)^2}.$$

Substituting  $x = 0, y = -1/2, y' = 0$  and  $x = 1/2, y = -2, y' = 0$ , we obtain

$$y'' = -\frac{6(-2)-0}{4} > 0 \quad \text{for } [x, y] = \left[ 0, -\frac{1}{2} \right]$$

and

$$y'' = -\frac{6(+2)-0}{4} < 0 \quad \text{for } [x, y] = \left[ \frac{1}{2}, -2 \right].$$

We have thus proved that the implicitly given function has a strict local minimum at the point  $x = 0$  and a strict local maximum at  $x = 1/2$ .  $\square$

**8.H.11.** Find the local extrema of the function  $z = f(x, y)$  given on the maximum possible set by the equation

$$(1) \quad x^2 + y^2 + z^2 - xz - yz + 2x + 2y + 2z - 2 = 0.$$

**Solution.** Differentiating (1) with respect to  $x$  and  $y$  gives

$$2x + 2zz_x - z - xz_x - yz_x + 2 + 2z_x = 0,$$

$$2y + 2zz_y - xz_y - z - yz_y + 2 + 2z_y = 0.$$

Hence we get that

$$(2) \quad \begin{aligned} z_x = f_x(x, y) &= \frac{z - 2x - 2}{2z - x - y + 2}, \\ z_y = f_y(x, y) &= \frac{z - 2y - 2}{2z - x - y + 2}. \end{aligned}$$

We can notice that the partial derivatives are continuous at all points where the function  $f$  is defined. This implies that the local extrema can occur only at stationary points. These points satisfy

$$z_x = 0, \quad \text{i. e.} \quad z - 2x - 2 = 0,$$

$$z_y = 0, \quad \text{i. e.} \quad z - 2y - 2 = 0.$$

We have thus two equations, which allow us to express the dependency of  $x$  and  $y$  on  $z$ . Substituting into (1), we obtain the points

$$[x, y, z] = \left[ -3 + \sqrt{6}, -3 + \sqrt{6}, -4 + 2\sqrt{6} \right],$$

to be invertible as a linear mapping. In general finite dimensions, the non-generacy of the differential is the adequate concept.

**PROOF.** First, verify that the theorem makes sense and is as expected. If it is supposed that the inverse mapping exists and is differentiable at  $F(x_0)$ , then differentiating the composite mapping  $F^{-1} \circ F$  enforces the formula

$$\text{id}_{\mathbb{R}^n} = D^1(F^{-1} \circ F)(x_0) = D^1(F^{-1}) \circ D^1F(x_0),$$

which verifies the formula at the conclusion of the theorem. Therefore, it is known at the beginning which differential for  $F^{-1}$  to find.

Next, suppose that the inverse mapping  $F^{-1}$  exists in a neighbourhood of the point  $F(x_0)$  and that it is continuous. Since  $F$  is differentiable in a neighbourhood of  $x_0$ , it follows that

$$(1) \quad F(x) - F(x_0) - D^1F(x_0)(x - x_0) = \alpha(x - x_0)$$

with function  $\alpha : \mathbb{R}^n \rightarrow 0$  satisfying  $\lim_{v \rightarrow 0} \frac{1}{\|v\|} \alpha(v) = 0$ . To verify the approximation properties of the linear mapping  $(D^1F(x_0))^{-1}$ , it suffices to calculate the following limit for  $y = F(x)$  approaching  $y_0 = F(x_0)$ :

$$\lim_{y \rightarrow y_0} \frac{1}{\|y - y_0\|} (F^{-1}(y) - F^{-1}(y_0) - (D^1F(x_0))^{-1}(y - y_0)).$$

Substituting (1) for  $y - y_0$  into the latter equality yields

$$\begin{aligned} & \lim_{y \rightarrow y_0} \frac{1}{\|y - y_0\|} \left( x - x_0 \right. \\ & \quad \left. - (D^1F(x_0))^{-1}(D^1F(x_0)(x - x_0) + \alpha(x - x_0)) \right) \\ &= \lim_{y \rightarrow y_0} \frac{-1}{\|y - y_0\|} (D^1F(x_0))^{-1}(\alpha(x - x_0)) \\ &= (D^1F(x_0))^{-1} \lim_{y \rightarrow y_0} \frac{(-1)}{\|y - y_0\|} (\alpha(x - x_0)), \end{aligned}$$

where the last equality follows from the fact that linear mappings between finite-dimensional spaces are always continuous. Hence performing this linear mapping commutes with the limit process.

The proof is almost finished. The limit at the end of the expression is, using the properties of  $\alpha$ , zero if the values  $\|F(x) - F(x_0)\|$  are greater than  $C\|x - x_0\|$  for some constant  $C > 0$ . This can be translated in terms of the inverse as  $C\|F^{-1}(y) - F^{-1}(y_0)\| \leq \|y - y_0\|$ , i.e.

$$\|F^{-1}(y) - F^{-1}(y_0)\| \leq D\|y - y_0\|$$

for the constant  $D = C^{-1} > 0$ . This is Lipschitz continuity, which is a stronger property than  $F^{-1}$  being continuous. So, now it remains “merely” to prove the existence of a Lipschitz-continuous inverse mapping to the mapping  $F$ .

$$[x, y, z] = [-3 - \sqrt{6}, -3 - \sqrt{6}, -4 - 2\sqrt{6}].$$

Now, we need the second derivatives in order to decide whether the local extrema really occur at the corresponding points. Differentiating  $z_x$  in (2), we obtain

$$z_{xx} = f_{xx}(x, y) = \frac{(z_x - 2)(2z - x - y + 2) - (z - 2x - 2)(2z_x - 1)}{(2z - x - y + 2)^2},$$

with respect to  $x$ , and

$$z_{xy} = f_{xy}(x, y) = \frac{z_y(2z - x - y + 2) - (z - 2x - 2)(2z_y - 1)}{(2z - x - y + 2)^2},$$

with respect to  $y$ . We need not calculate  $z_{yy}$  since the variables  $x$  and  $y$  are interchangeable in (1) (if we swap  $x$  and  $y$ , the equation is left unchanged). Moreover, the  $x$ - and  $y$ -coordinates of the considered points are the same; hence  $z_{xx} = z_{yy}$ . Now, we evaluate that at the stationary points:

$$f_{xx}(-3 + \sqrt{6}, -3 + \sqrt{6}) = f_{yy}(-3 + \sqrt{6}, -3 + \sqrt{6}) = -\frac{1}{\sqrt{6}},$$

$$f_{xy}(-3 + \sqrt{6}, -3 + \sqrt{6}) = f_{yx}(-3 + \sqrt{6}, -3 + \sqrt{6}) = 0,$$

$$f_{xx}(-3 - \sqrt{6}, -3 - \sqrt{6}) = f_{yy}(-3 - \sqrt{6}, -3 - \sqrt{6}) = \frac{1}{\sqrt{6}},$$

$$f_{xy}(-3 - \sqrt{6}, -3 - \sqrt{6}) = f_{yx}(-3 - \sqrt{6}, -3 - \sqrt{6}) = 0.$$

As for the Hessian, we have

$$Hf(-3 + \sqrt{6}, -3 + \sqrt{6}) = \begin{pmatrix} -\frac{1}{\sqrt{6}} & 0 \\ 0 & -\frac{1}{\sqrt{6}} \end{pmatrix},$$

$$Hf(-3 - \sqrt{6}, -3 - \sqrt{6}) = \begin{pmatrix} \frac{1}{\sqrt{6}} & 0 \\ 0 & \frac{1}{\sqrt{6}} \end{pmatrix}.$$

Apparently, the first Hessian is negative definite, while the second one is positive definite. This means that there is a strict local maximum of the function  $f$  at the point  $[-3 + \sqrt{6}, -3 + \sqrt{6}]$ , and there is a strict local minimum at the point  $[-3 - \sqrt{6}, -3 - \sqrt{6}]$ .  $\square$

**8.H.12.** Determine the strict local extrema of the function

$$f(x, y) = \frac{1}{x} + \frac{1}{y}, \quad x \neq 0, \quad y \neq 0$$

on the set of points that satisfy the equation  $\frac{1}{x^2} + \frac{1}{y^2} = 4$ .

**Solution.** Since both the function  $f$  and the function given implicitly by the equation  $\frac{1}{x^2} + \frac{1}{y^2} - 4 = 0$  have continuous partial derivatives of all orders on the set  $\mathbb{R}^2 \setminus \{[0, 0]\}$ , we should look for stationary points, i. e., for the solution of the equations  $L_x = 0, L_y = 0$  for

$$L(x, y, \lambda) = \frac{1}{x} + \frac{1}{y} - \lambda \left( \frac{1}{x^2} + \frac{1}{y^2} - 4 \right), \quad x \neq 0, \quad y \neq 0.$$

We thus get the equations

$$-\frac{1}{x^2} + \frac{2\lambda}{x^3} = 0, \quad -\frac{1}{y^2} + \frac{2\lambda}{y^3} = 0,$$

which lead to  $x = 2\lambda, y = 2\lambda$ . Considering the set of points in question, the constraint  $x = y$  gives the stationary points

$$(1) \quad \left[ \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right], \quad \left[ -\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2} \right].$$

Now, let us examine the second differential of the function  $L$ . We can easily compute that

To simplify, reduce the general case slightly. Especially, without loss of generality, apply shifts of the coordinates by constant vectors. In particular, it can be assumed that  $x_0 = 0 \in \mathbb{R}^n, y_0 = F(x_0) = 0 \in \mathbb{R}^n$ . So assume this property of the mapping  $F$ .

Further, composing the mapping  $F$  with any linear mapping  $G$  yields a differentiable mapping again, and it is known how the differential changes. The choice  $G(y) = (D^1F(0))^{-1}(y)$  gives  $D^1(G \circ F)(0) = \text{id}_{\mathbb{R}^n}$  and thus we may assume that

$$D^1F(0) = \text{id}_{\mathbb{R}^n}.$$

With these assumptions, consider the mapping  $K(x) = F(x) - x$ . This mapping is also differentiable, and its differential at 0 is zero.

It is already known that each continuously differentiable mapping is Lipschitz continuous over every  $\delta$ -neighbourhood  $U_\delta$  of the origin (in its domain),

$$\|K(x) - K(y)\| \leq C\|x - y\|,$$

where  $C$  is bounded by the maximum of all absolute values of the partial derivatives in the Jacobi matrix of the mapping  $K$  in the neighbourhood  $U_\delta$ , cf. 8.1.20.

Since the differential of the mapping  $K$  at the point  $x_0 = 0$  is zero, one can, by selecting a sufficiently small neighbourhood  $U$  of the origin, achieve the bound

$$\|K(x) - K(y)\| \leq \frac{1}{2}\|x - y\|.$$

It follows by the triangle inequality that

$$\begin{aligned} \|x - y\| &= \|(F(x) - K(x)) - (F(y) - K(y))\| \\ &\leq \|F(x) - F(y)\| + \|K(x) - K(y)\| \\ &\leq \|F(x) - F(y)\| + \frac{1}{2}\|x - y\| \end{aligned}$$

and hence

$$\frac{1}{2}\|x - y\| \leq \|F(x) - F(y)\|.$$

With this estimate, if  $x \neq y$  are both in the neighbourhood  $U = U_\delta$ , then also  $F(x) \neq F(y)$ . Therefore, the mapping is bijective onto its image  $V = F(U)$ . Write  $F^{-1}$  for its inverse defined on  $V$ . For this mapping, the latter estimate says

$$\|F^{-1}(x) - F^{-1}(y)\| \leq 2\|x - y\|,$$

so this mapping is not only continuous (as we assumed in our first step in the proof), but also Lipschitz-continuous, as requested in the end of the previous part of the proof.

It could seem that the proof is complete, but this is not so.

To finish, it is necessary to show that the mapping  $F$  restricted to a sufficiently small neighbourhood  $U_\delta$  is not only bijective onto its image, but also that it maps open neighbourhoods of zero onto open neighbourhoods of zero.<sup>3</sup>

<sup>3</sup>In the literature, there are examples of mappings which continuously and bijectively map a line segment onto a square. So this is not an obvious requirement.

$$L_{xx} = \frac{2}{x^3} - \frac{6\lambda}{x^4}, \quad L_{xy} = 0, \quad L_{yy} = \frac{2}{y^3} - \frac{6\lambda}{y^4}, \quad x \neq 0, y \neq 0,$$

whence it follows that

$$d^2L(x, y) = \left(\frac{2}{x^3} - \frac{6\lambda}{x^4}\right) dx^2 + \left(\frac{2}{y^3} - \frac{6\lambda}{y^4}\right) dy^2.$$

Differentiating the constraint  $\frac{1}{x^2} + \frac{1}{y^2} = 4$ , we get

$$-\frac{2}{x^3} dx - \frac{2}{y^3} dy = 0, \quad \text{i. e.} \quad dy^2 = \frac{y^6}{x^6} dx^2.$$

Therefore,

$$d^2L(x, y) = \left[\frac{2}{x^3} - \frac{6\lambda}{x^4} + \left(\frac{2}{y^3} - \frac{6\lambda}{y^4}\right) \frac{y^6}{x^6}\right] dx^2.$$

In fact, we are considering a one-dimensional quadratic form whose positive (negative) definiteness at a stationary point means that there is a minimum (maximum) at that point. Realizing that the stationary points had  $x = 2\lambda$ ,  $y = 2\lambda$ , mere substitution yields

$$d^2L\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) = -4\sqrt{2} dx^2, \quad d^2L\left(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right) = 4\sqrt{2} dx^2,$$

which means that there is a strict local maximum of the function  $f$  at the point  $[\sqrt{2}/2, \sqrt{2}/2]$ , while at the point  $[-\sqrt{2}/2, -\sqrt{2}/2]$ , there is a strict local minimum. The corresponding values are:

$$(2) \quad f\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) = 2\sqrt{2}, \quad f\left(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right) = -2\sqrt{2}.$$

Now, we will demonstrate a quicker way how to obtain the result. We know (or we can easily calculate) the second partial derivatives of the function  $L$ , i. e., the Hessian with respect to the variables  $x$  and  $y$ :

$$HL(x, y) = \begin{pmatrix} \frac{2}{x^3} - \frac{6\lambda}{x^4} & 0 \\ 0 & \frac{2}{y^3} - \frac{6\lambda}{y^4} \end{pmatrix}.$$

The evaluation

$$HL\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) = \begin{pmatrix} -2\sqrt{2} & 0 \\ 0 & -2\sqrt{2} \end{pmatrix},$$

$$HL\left(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right) = \begin{pmatrix} 2\sqrt{2} & 0 \\ 0 & 2\sqrt{2} \end{pmatrix}$$

then tells us that the quadratic form is negative definite for the former stationary point (there is a strict local maximum) and positive definite for the latter one (there is a strict local minimum).

We should be aware of a potential trap in this “quicker” method in the case we obtain an indefinite form (matrix). Then, we cannot conclude that there is not an extremum at that point since as we have not included the constraint (which we did when computing  $d^2L$ ), we are considering a more general situation. The graph of the function  $f$  on the given set is a curve which can be defined as a univariate function. This must correspond to a one-dimensional quadratic form.  $\square$

Decrease the latter neighbourhood  $U = U_\delta$  so that the above estimates are true for the boundary of  $U$  as well and at the same time the Jacobi matrix of the mapping is invertible on all of  $U$ . This can be done since the determinant is a continuous mapping. Let  $B$  denote the boundary of the set  $U$ , that is, the corresponding sphere. Since  $B$  is compact and  $F$  is continuous, the function

$$\rho(x) = \|F(x)\|$$

achieves both the maximum and the minimum on  $B$ . Denote  $a = \frac{1}{2} \min_{x \in B} \rho(x)$  and consider any  $y \in \mathcal{O}_a(0)$  fixed. Of course,  $a > 0$  because  $x = 0$  is the only point with  $F(x) = 0$  within  $U_\delta$ . It is necessary to show that there is at least one  $x \in U$  such that  $y = F(x)$ , which completes the proof of the inverse mapping theorem.

For this purpose, consider the function ( $y$  is a fixed point)

$$h(x) = \|F(x) - y\|^2.$$

Again, the image  $h(U) \cup h(B)$  must have a minimum. This minimum cannot occur for  $x \in B$ .

Notice that  $F(0) = 0$ , hence  $h(0) = \|y\| < a$ . At the same time, the distance of  $y$  from  $F(x)$  for  $x \in B$  is at least  $a$  for all  $y \in \mathcal{O}_a(0)$  (since  $a$  is selected to be half the minimum of the magnitude of  $F(x)$  on the boundary). Therefore, the minimum occurs inside  $U$ , and it is a stationary point  $z$  of the function  $h$ . Fixing such  $z$ , means that for all  $j = 1, \dots, n$ ,

$$\frac{\partial h}{\partial x^j}(z) = \sum_{i=1}^n 2(f_i(z) - y_i) \frac{\partial f_i}{\partial x^j}(z) = 0.$$

This is a system of linear equations with variables  $\xi_i = f_i(z) - y_i$  and coefficients given by twice the Jacobi matrix  $D^1F(z)$ . In particular, for  $z \in U$ , such a system has a unique solution, and this is zero since the Jacobi matrix is invertible.

In this way the desired point  $x = z \in U$  is found, satisfying, for all  $i = 1, \dots, n$ , the equality  $f_i(z) = y_i$ , i.e.,  $F(z) = y$ .  $\square$

**8.1.24. The implicit functions.** The next goal is to employ the inverse mapping theorem for clarifying the properties of implicitly defined functions. To start, consider a differentiable function  $F(x, y)$  defined in the plane  $E_2$ , and look for those points  $(x, y)$  where  $F(x, y) = 0$ .

An example of this can be the usual (implicit) definition of straight lines and circles:

$$F(x, y) = ax + by + c = 0, \quad a, b, c \in \mathbb{R}$$

$$F(x, y) = (x - s)^2 + (y - t)^2 - r^2 = 0, \quad r > 0.$$

While in the first case, the relation between the quantities  $x$  and  $y$  can be expressed as the function (for  $b \neq 0$ )

$$y = f(x) = -\frac{a}{b}x - \frac{c}{b}$$

for all  $x$ ; in the other case, for any point  $(x_0, y_0)$  satisfying the equation of the circle and such that  $y_0 \neq t$  (these are the

**8.H.13.** Find the global extrema of the function

$$f(x, y) = \frac{1}{x} + \frac{1}{y}, \quad x \neq 0, y \neq 0$$

on the set of points that satisfy the equation  $\frac{1}{x^2} + \frac{1}{y^2} = 4$ .

**Solution.** This exercise is to illustrate that looking for global extrema may be much easier than for local ones (cf. the above exercise) even in the case when the function values are considered on an unbounded set. First, we would determine the stationary points (1) and the values (2) the same way as above. Let us emphasize that we are looking for the function's extrema on a set that is *not* compact, so we will not do with evaluating the function at the stationary points. The reason is that the function  $f$  may not have an extremum on the considered set – its range might be an open interval. However, we will show that this is not the case here.

Let us thus consider  $|x| \geq 10$ . We can realize that the equation  $\frac{1}{x^2} + \frac{1}{y^2} = 4$  can be satisfied only by those values  $y$  for which  $|y| \geq 1/2$ . We have thus obtained the bounds

$$-2\sqrt{2} < -\frac{1}{10} - 2 \leq f(x, y) \leq \frac{1}{10} + 2 < 2\sqrt{2}, \quad \text{if } |x| \geq 10.$$

At the same time, we have (interchanging  $x$  and  $y$  leads to the same task)

$$-2\sqrt{2} < -\frac{1}{10} - 2 \leq f(x, y) \leq \frac{1}{10} + 2 < 2\sqrt{2}, \quad \text{if } |y| \geq 10.$$

Hence we can see that the function  $f$  must have global extrema on the considered set, and this must happen inside the square  $ABCD$  with vertices  $A = [-10, -10]$ ,  $B = [10, -10]$ ,  $C = [10, 10]$ ,  $D = [-10, 10]$ .

The intersection of the “hundred times reduced” square with vertices at  $\tilde{A} = [-1/10, -1/10]$ ,  $\tilde{B} = [1/10, -1/10]$ ,  $\tilde{C} = [1/10, 1/10]$ ,  $\tilde{D} = [-1/10, 1/10]$  and the given set is clearly the empty set. Therefore, the global extrema are at points inside the compact set bounded by these two squares. Since  $f$  is continuously differentiable on this set, the global extrema can occur only at stationary points. We thus must have

$$f_{\max} = f\left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}\right) = 2\sqrt{2}, \quad f_{\min} = f\left(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right) = -2\sqrt{2}.$$

□

**8.H.14.** Determine the maximal and minimal values of the function  $f(x, y, z) = xyz$  on the set  $M$  given by the conditions

$$x^2 + y^2 + z^2 = 1, \quad x + y + z = 0.$$

**Solution.** It is not hard to realize that  $M$  is a circle. However, for our problem, it is sufficient to know that  $M$  is compact, i. e. bounded (the first condition of the equation of the unit sphere) and closed (the set of solutions of the given equations is closed since if the equations are satisfied by all terms of a converging sequence, then it is satisfied by its limit as well). The function  $f$  as well as the constraint functions  $F(x, y, z) = x^2 + y^2 + z^2 - 1$ ,  $G(x, y, z) = x + y + z$

marginal points of the circle in the direction of the coordinate  $x$ ). There is a neighbourhood of the point  $x_0$  in which either

$$y = f(x) = t + \sqrt{(x-s)^2 - r},$$

or

$$y = f(x) = t - \sqrt{(x-s)^2 - r},$$

according to whether  $(x_0, y_0)$  belongs to the upper or lower semicircle.

If a diagram of the situation is drawn, the reason is clear: describing both the semicircles simultaneously by a single function  $y = f(x)$  is not possible. The boundary points of the interval  $[s-r, s+r]$  are even more interesting. They also satisfy the equation of the circle with  $y = t$ , yet  $F_y(s \pm r, t) = 0$ , which describes the position of the tangent line to the circle at these points, parallel to the  $y$ -axis. There are no neighbourhoods of these points in which the circle could be described as a function  $y = f(x)$ .

Moreover, the derivatives of the function  $y = f(x) = t + \sqrt{(x-s)^2 - r^2}$  can be easily expressed in terms of partial derivatives of the function  $F$ :

$$f'(x) = \frac{1}{2} \frac{2(x-s)}{\sqrt{r^2 - (x-s)^2}} = \frac{x-s}{y-t} = -\frac{F_x}{F_y}.$$

If the roles of the variables  $x$  and  $y$  are interchanged and a relation  $x = f(y)$  such that  $F(f(y), y) = 0$  is sought, then neighbourhoods of the points  $(s \pm r, t)$  are obtained with no problem. Notice that the partial derivative  $F_x$  is non-zero at these points.

So it is observed (though for only two examples): for a function  $F(x, y)$  and a point  $(a, b) \in E_2$  such that  $F(a, b) = 0$ , there is the unique function  $y = f(x)$  satisfying  $F(x, f(x)) = 0$  on some neighbourhood of  $x$  if  $F_y(a, b) \neq 0$ . In this case,  $f'(a) = -F_x(a, b)/F_y(a, b)$  can even be computed. We prove that in fact, this proposition is always true.

The last statement about derivatives can be remembered (and is quite comprehensible if things are properly understood) from the expression for the differential of the (constant) function  $g(x) = F(x, y(x))$  and the differential  $dy = f'(x)dx$

$$0 = dg = F_x dx + F_y dy = (F_x + F_y f'(x)) dx.$$

One can work analogously with the implicit expressions  $F(x, y, z) = 0$ , to look for a function  $g(x, y)$  such that  $F(x, y, g(x, y)) = 0$ . As an example, consider the function  $f(x, y) = x^2 + y^2$ , whose graph is the rotational paraboloid centered at the point  $(0, 0)$ . This can be defined implicitly by the equation

$$0 = F(x, y, z) = z - x^2 - y^2.$$

Before formulating the result for the general situation, notice which dimensions could/should appear in the problem. If it is desired to find, for this function  $F$ , a curve  $c(x) = (c_1(x), c_2(x))$  in the plane such that

$$F(x, c(x)) = F(x, c_1(x), c_2(x)) = 0,$$

have continuous partial derivatives of all orders (since they are polynomials). The Jacobi constraint matrix is

$$\begin{pmatrix} F_x(x, y, z) & F_y(x, y, z) & F_z(x, y, z) \\ G_x(x, y, z) & G_y(x, y, z) & G_z(x, y, z) \end{pmatrix} = \begin{pmatrix} 2x & 2y & 2z \\ 1 & 1 & 1 \end{pmatrix}.$$

Its rank is reduced (less than 2) if and only if the vector  $(2x, 2y, 2z)$  is a multiple of the vector  $(1, 1, 1)$ , which gives  $x = y = z$ , and thus  $x = y = z = 0$  (by the second constraint). However, the set  $M$  does contain the origin. Therefore, we may look for stationary points using the method of Lagrange multipliers. For

$$L(x, y, z, \lambda_1, \lambda_2) = xyz - \lambda_1(x^2 + y^2 + z^2 - 1) - \lambda_2(x + y + z),$$

the equations  $L_x = 0, L_y = 0, L_z = 0$  give

$$yz - 2\lambda_1 x - \lambda_2 = 0,$$

$$xz - 2\lambda_1 y - \lambda_2 = 0,$$

$$xy - 2\lambda_1 z - \lambda_2 = 0,$$

respectively. Subtracting the first equation from the second one and from the third one leads to

$$xz - yz - 2\lambda_1 y + 2\lambda_1 x = 0,$$

$$xy - yz - 2\lambda_1 z + 2\lambda_1 x = 0,$$

i. e.,

$$(x - y)(z + 2\lambda_1) = 0,$$

$$(x - z)(y + 2\lambda_1) = 0.$$

The last equations are satisfied in these four cases:

$$x = y, x = z; \quad x = y, y = -2\lambda_1;$$

$$z = -2\lambda_1, x = z; \quad z = -2\lambda_1, y = -2\lambda_1,$$

thus (including the constraint  $G = 0$ )

$$x = y = z = 0; \quad x = y = -2\lambda_1, z = 4\lambda_1;$$

$$x = z = -2\lambda_1, y = 4\lambda_1; \quad x = 4\lambda_1, y = z = -2\lambda_1.$$

Except for the first case (which clearly cannot happen), including the constraint  $F = 0$  yields

$$(4\lambda_1)^2 + (-2\lambda_1)^2 + (-2\lambda_1)^2 = 1, \quad \text{i. e.} \quad \lambda_1 = \pm \frac{1}{2\sqrt{6}}.$$

Altogether, we get the points

$$\left[-\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}}\right], \quad \left[-\frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}}\right], \quad \left[\frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}\right], \\ \left[\frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}, -\frac{2}{\sqrt{6}}\right], \quad \left[\frac{1}{\sqrt{6}}, -\frac{2}{\sqrt{6}}, \frac{1}{\sqrt{6}}\right], \quad \left[-\frac{2}{\sqrt{6}}, \frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}\right].$$

We will not verify that these really are stationary points. The only important thing is that all stationary points are among these six.

We are looking for the global maximum and minimum of the continuous function  $f$  on the compact set  $M$ . However, the global extrema (we know they exist) can occur only at points of local extrema with respect to  $M$ . And the local extrema can occur only at the aforementioned points. Therefore, it suffices to evaluate the function  $f$  at these points. Thus

then this can be done (even for all initial conditions  $x = a$ ), yet the result is not unique for a given initial condition. It suffices to consider an arbitrary curve on the rotational paraboloid whose projection onto the first coordinate has a non-zero derivative. Then consider  $x$  to be the parameter of the curve, and  $c(x)$  to be its projection onto the plane  $yz$ .

Therefore, it is expected that one function of  $m + 1$  variables defines implicitly a hypersurface in  $\mathbb{R}^{m+1}$  which is to be expressed (at least locally) as the graph of a function of  $m$  variables. It can be anticipated that  $n$  functions of  $m + n$  variables define an intersection of  $n$  hypersurfaces in  $\mathbb{R}^{m+n}$ , which is expected as an “ $m$ -dimensional” object.

**8.1.25. The general theorem.** Consider a differentiable mapping

$$F = (f_1, \dots, f_n) : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^n.$$

The Jacobi matrix of this mapping has  $n$  rows and  $m + n$  columns. Write it symbolically as

$$D^1 F = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_m} & \frac{\partial f_1}{\partial x_{m+1}} & \cdots & \frac{\partial f_1}{\partial x_{m+n}} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1} & \cdots & \frac{\partial f_n}{\partial x_m} & \frac{\partial f_n}{\partial x_{m+1}} & \cdots & \frac{\partial f_n}{\partial x_{m+n}} \end{pmatrix} \\ = (D_x^1 F, D_y^1 F),$$

where  $(x_1, \dots, x_{m+n}) \in \mathbb{R}^{m+n}$  is written as  $(x, y) \in \mathbb{R}^m \times \mathbb{R}^n$ ,  $D_x^1 F$  is a matrix of  $n$  rows and the first  $m$  columns in the Jacobi matrix, while  $D_y^1 F$  is a square matrix of order  $n$ , with the remaining columns. The multidimensional analogy to the previous reasoning with the non-zero partial derivative with respect to  $y$  is the condition that the matrix  $D_y^1 F$  is invertible.

#### THE IMPLICIT MAPPING THEOREM

**Theorem.** Let  $F : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^n$  be a differentiable mapping in an open neighbourhood of a point  $(a, b) \in \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$  at which  $F(a, b) = 0$ , and  $\det D_y^1 F \neq 0$ .

Then there exists a neighbourhood  $U$  of the point  $a \in \mathbb{R}^m$  and a unique differentiable mapping  $G : \mathbb{R}^m \rightarrow \mathbb{R}^n$  defined on  $U$ , with  $G(a) = b$  and such that  $F(x, G(x)) = 0$  for all  $x \in U$ .

Moreover, the Jacobi matrix  $D^1 G$  of the mapping  $G$  is, in the neighbourhood of the point  $a$ , given by the product of matrices

$$D^1 G(x) = -(D_y^1 F)^{-1}(x, G(x)) \cdot D_x^1 F(x, G(x)).$$

**PROOF.** For the sake of comprehensibility, first show the proof for the simplest case of the equation  $F(x, y) = 0$  with a function  $F$  of two variables. At first sight, it might look complicated, but this situation can be discussed in a way which can be extended for the general dimensions as in the theorem, almost without changes.

we find out that the wanted maximum is

$$\begin{aligned} f\left(-\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}}\right) &= f\left(-\frac{1}{\sqrt{6}}, \frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}}\right) = \\ &= f\left(\frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}\right) = \frac{1}{3\sqrt{6}}, \end{aligned}$$

while the minimum is

$$\begin{aligned} f\left(\frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}, -\frac{2}{\sqrt{6}}\right) &= f\left(\frac{1}{\sqrt{6}}, -\frac{2}{\sqrt{6}}, \frac{1}{\sqrt{6}}\right) = \\ &= f\left(-\frac{2}{\sqrt{6}}, \frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}\right) = -\frac{1}{3\sqrt{6}}. \end{aligned}$$

□

**8.H.15.** Find the extrema of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^2 + y^2 + z^2$ , on the plane  $x + y - z = 1$  and determine their types.

**Solution.** We can easily build the equations that describe the linear dependency between the normal to the constraint surface and the examined function:

$$x = k, \quad y = k, \quad z = -k, \quad k \in \mathbb{R}.$$

The only solution is the point  $[\frac{1}{3}, \frac{1}{3}, -\frac{1}{3}]$ . Further, we can notice that the function is increasing in the direction of  $(1, -1, 0)$ , and this direction lies in the constraint plane. Therefore, the examined function has a minimum at this point.

**Another solution.** We will reduce this problem to finding the extrema of a two-variable function on  $\mathbb{R}^2$ . Since the constraint is linear, we can express  $z = x + y - 1$ . Substituting this into the given function then yields a real-valued function of two variables:  $f(x, y) = x^2 + y^2 + (x + y - 1)^2 = 2x^2 + 2xy + y^2 - 2x - 2y + 1$ . Setting both partial derivatives equal to zero, we get the linear equation

$$4x + 2y - 2 = 0, \quad 4y + 2x - 2 = 0,$$

whose only solution is the point  $[\frac{1}{3}, \frac{1}{3}]$ . Since it is a quadratic function with positive coefficients at the unknowns, it is unbounded on  $\mathbb{R}^2$ . Therefore, there is a (global) minimum at the obtained point. Then, we can get the corresponding point  $[\frac{1}{3}, \frac{1}{3}, -\frac{1}{3}]$  in the constraint plane from the linear dependency of  $z$ . □

**8.H.16.** Find the extrema of the function  $x + y : \mathbb{R}^3 \rightarrow \mathbb{R}$  on the circle given by the equations  $x + y + z = 1$  and  $x^2 + y^2 + z^2 = 4$ .

**Solution.** The “suspects” are those points which satisfy

$$(1, 1, 0) = k \cdot (1, 1, 1) + l \cdot (x, y, z), \quad k, l \in \mathbb{R}.$$

Clearly,  $x = y (= 1/l)$ . Substituting this into the equation of the circle then leads to the two solutions

$$\left[ \frac{1}{3} \pm \frac{\sqrt{22}}{6}, \frac{1}{3} \pm \frac{\sqrt{22}}{6}, \frac{1}{3} \mp \frac{\sqrt{22}}{3} \right].$$

Since every circle is compact, it suffices to examine the function values at these two points. We find out that there is a

Extend the function  $F$  to

$$\tilde{F} : \mathbb{R}^2 \rightarrow \mathbb{R}^2, \quad (x, y) \mapsto (x, F(x, y)).$$

The Jacobi matrix of the mapping  $\tilde{F}$  is

$$D^1 \tilde{F}(x, y) = \begin{pmatrix} 1 & 0 \\ F_x(x, y) & F_y(x, y) \end{pmatrix}.$$

It follows from the assumption  $F_y(a, b) \neq 0$ , that the same also holds in a neighbourhood of the point  $(a, b)$ , so the function  $\tilde{F}$  is invertible in this neighbourhood, by the inverse mapping theorem. Therefore, there is a uniquely defined differentiable inverse mapping  $\tilde{F}^{-1}$  in a neighbourhood of the point  $(a, 0)$ .

Denote by  $\pi : \mathbb{R}^2 \rightarrow \mathbb{R}$  the projection onto the second coordinate, and consider the function  $f(x) = \pi \circ \tilde{F}^{-1}(x, 0)$ . This function is well-defined and differentiable. It must be verified that the expression

$$F(x, f(x)) = F(x, \pi(\tilde{F}^{-1}(x, 0)))$$

is zero in a neighbourhood of the point  $x = a$ . It follows directly from the definition of  $\tilde{F}(x, y) = (x, F(x, y))$  that its inverse is of the form  $\tilde{F}^{-1}(x, y) = (x, \pi \tilde{F}^{-1}(x, y))$ . Therefore, the previous calculation can be resumed:

$$\begin{aligned} F(x, f(x)) &= \pi(\tilde{F}(x, \pi(\tilde{F}^{-1}(x, 0)))) \\ &= \pi(\tilde{F}(\tilde{F}^{-1}(x, 0))) = \pi(x, 0) = 0. \end{aligned}$$

This proves the first part of the theorem, and it remains to compute the derivative of the function  $f(x)$ . This derivative can, once again, be obtained by invoking the inverse mapping theorem, using the matrix  $(D^1 \tilde{F})^{-1}$ .

The following equality is easily verified by multiplying the matrices. It can also be computed directly using the explicit formula for the inverse matrix in terms of the determinant and the algebraically adjoint matrix, see paragraph 2.2.11

$$\begin{pmatrix} 1 & 0 \\ F_x(x, y) & F_y(x, y) \end{pmatrix}^{-1} = (F_y(x, y))^{-1} \begin{pmatrix} F_y(x, y) & 0 \\ -F_x(x, y) & 1 \end{pmatrix}.$$

By the definition  $f(x) = \pi \tilde{F}^{-1}(x, 0)$ , and thus the first entry of the second row of this matrix is the derivative  $f'(x)$  with  $y = f(x)$ , i.e. the Jacobi matrix  $D^1 f$ . In this simple case, it is exactly the desired scalar  $-F_x(x, f(x))/F_y(x, f(x))$ .

The general proof is exactly the same, there is no need to change any of the formulae. We obtain the invertible mapping  $\tilde{F} : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^{m+n}$  and define  $G(x) = \pi \tilde{F}^{-1}(x, 0)$ , where  $\pi : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^n$ ,  $\pi(x, y) = y$ . The same check as above reveals that  $F(x, G(x)) = 0$  as requested. Only in the last computation of the derivative of the function do the corresponding parts of the Jacobi matrix  $D_x^1 F$  and  $D_y^1 F$  appear, instead of the particular partial derivatives.

For the calculation of the Jacobi matrix of the mapping  $G$ , use the computation of the inverse matrix. This time the algebraic procedure from paragraph 2.2.11 is not very advantageous. It is better to be guided by the case in dimension

maximum of the considered function on the given circle at the former point and a minimum at the latter one.  $\square$

**8.H.17.** Find the extrema of the function  $f : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,  $f(x, y, z) = x^2 + y^2 + z^2$ , on the plane  $2x + y - z = 1$  and determine their types.  $\circ$

**8.H.18.** Find the maximum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = xy$  on the circle with radius 1 which is centered at the point  $[x_0, y_0] = [0, 1]$ .  $\circ$

**8.H.20.** Find the minimum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f = xy$  on the circle with radius 1 which is centered at the point  $[x_0, y_0] = [2, 0]$ .  $\circ$

**8.H.21.** Find the minimum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f = xy$  on the ellipse  $x^2 + 3y^2 = 1$ .  $\circ$

**8.H.22.** Find the minimum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f = x^2y$  on the circle with radius 1 which is centered at the point  $[x_0, y_0] = [0, 0]$ .  $\circ$

**8.H.23.** Find the maximum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = x^3y$  on the circle  $x^2 + y^2 = 1$ .  $\circ$

**8.H.24.** Find the maximum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = xy$  on the ellipse  $2x^2 + 3y^2 = 1$ .  $\circ$

**8.H.25.** Find the maximum of the function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ ,  $f(x, y) = xy$  on the ellipse  $x^2 + 2y^2 = 1$ .  $\circ$

**I. Volumes, areas, centroids of solids**

**8.I.1.** Find the volume of the solid which lies in the half-plane  $z \geq 0$ , the cylinder  $x^2 + y^2 \leq 1$ , and the half-plane

- a)  $z \leq x$ ,
- b)  $x + y + z \leq 0$ .

**Solution.** a) The volume can be calculated with ease using cylindrical coordinates. There, the cylinder is determined by the inequality  $r \leq 1$ ; the half-plane  $z \leq x$  by  $z \leq r \cos \varphi$ , then. Altogether, we get

$m + n = 2$  and to divide the matrix

$$(D^1 \tilde{F}^{-1}) = \begin{pmatrix} \text{id}_{\mathbb{R}^m} & 0 \\ D_x^1 F(x, y) & D_y^1 F(x, y) \end{pmatrix}^{-1} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$$

into blocks of  $m$  and  $n$  rows and columns (for instance  $A$  is of type  $m \times m$ , while  $C$  is of type  $n \times m$ ). Now, the matrices  $A, B, C, D$  can be determined from the defining equality for the inverse:

$$\begin{pmatrix} \text{id}_{\mathbb{R}^m} & 0 \\ D_x^1 F(x, y) & D_y^1 F(x, y) \end{pmatrix} \cdot \begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} \text{id}_{\mathbb{R}^m} & 0 \\ 0 & \text{id}_{\mathbb{R}^n} \end{pmatrix}.$$

Apparently, it follows that  $A = \text{id}_{\mathbb{R}^m}$ ,  $B = 0$ ,  $D = (D_y^1 F)^{-1}$ , and finally,  $D_x^1 F + D_y^1 F \cdot C = 0$ . The latter equality implies already the desired relation

$$D^1 G = C = -(D_y^1 F)^{-1} \cdot D_x^1 F.$$

This concludes the proof of the theorem.  $\square$

**8.1.26. The gradient of a function.** As seen in the previous paragraph, if  $F$  is a continuously differentiable function of  $n$  variables, the definition  $F(x_1, \dots, x_n) = b$  with a fixed value  $b \in \mathbb{R}$  defines the subset  $M_b \subset \mathbb{R}^n$  which mostly has the properties of an  $(n - 1)$ -dimensional hypersurface. To be more precise, if the vector of the partial derivatives

$$D^1 F = \left( \frac{\partial F}{\partial x_1}, \dots, \frac{\partial F}{\partial x_n} \right)$$

is non-zero, the set  $M$  can be described locally as the graph of a continuously differentiable function of  $n - 1$  variables. In this connection, there are *level sets*  $M_b$ .

The vector  $D^1 F \in \mathbb{R}^n$  is called the *gradient of the function*  $F$ . In technical and physical literature, it is also often denoted as  $\text{grad } F$  or  $\nabla F$ .

Since  $M_b$  is given by a constant value of the function  $F$ , the derivatives of the curves lying in  $M$  have the property that the differential  $dF$  always evaluates to zero along them. For every such curve,  $F(c(t)) = b$ , hence

$$\frac{d}{dt} F(c(t)) = dF(c'(t)) = 0.$$

On the other hand, we can consider a general vector  $v = (v_1, \dots, v_n) \in \mathbb{R}^n$  and the magnitude of the corresponding directional derivative

$$|d_v F| = \left| \frac{\partial F}{\partial x_1} v_1 + \dots + \frac{\partial F}{\partial x_n} v_n \right| = \cos \varphi \|D^1 F\| \|v\|,$$

where  $\varphi$  is the angle between the directions of the vector  $v$  and the gradient  $D^1 F$ , see the discussion about angles of vectors and straight lines in the fourth chapter (cf. definition 4.1.15). Thus, the following result is observed:

Zde by se hodil obrazek, napr. obr. 2

$$V = \int_0^1 \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \int_0^{r \cos \varphi} r \, dz \, d\varphi \, dr = \frac{2}{3}.$$

b) We will reduce this problem to one that is completely analogous to the above part by rotating the solid around the  $z$ -axis by the angle  $\pi/4$  (be it in the positive or the negative direction). Applying the rotation matrix

$$\begin{pmatrix} \sqrt{2}/2 & -\sqrt{2}/2 & 0 \\ \sqrt{2}/2 & \sqrt{2}/2 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

the original inequality  $x+y+z \leq 0$  is transformed to  $\sqrt{2}x' + z' \leq 0$  in the new coordinates. Now, it is easy to express the integral that corresponds to the volume of the examined solid:

$V = \int_0^1 \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_{-\sqrt{2}r \cos \varphi}^0 r \, dz \, d\varphi \, dr = \frac{2\sqrt{2}}{3}$ . We need not have computed the result as we did; instead, we could notice that the solid from part (a) differs only by homothety with coefficient  $\sqrt{2}$  in the direction of the  $y$ -axis. See also note 8.I.11.  $\square$

**8.I.2.** Find the volume of the solid in  $\mathbb{R}^3$  which is given by  $x^2 + y^2 + z^2 \leq 1, 3x^2 + 3y^2 \geq z^2, x \geq 0$ .

**Solution.**

First, we should realize what the examined solid looks like. It is a part of a ball which lies outside a given cone (see the picture).

The best way to determine the volume is probably to subtract half the volume of the sector given by the cone from half the ball's volume (note that the volume of the solid does not change if we replace the condition  $x \geq 0$  with  $z \geq 0$  – the sector is cut either “horizontally” or “vertically”, but always to halves). We will calculate in spherical coordinates.

$$\begin{aligned} x &= r \cos(\varphi) \sin(\psi), \\ y &= r \sin(\varphi) \sin(\psi), \\ z &= r \cos(\psi), \end{aligned}$$

$$\varphi \in [0, 2\pi), \psi \in [0, \pi), r \in (0, \infty).$$

THE MAXIMAL GROWTH OF A FUNCTION

**Proposition.** The gradient  $D^1F = \left( \frac{\partial F}{\partial x_1}, \dots, \frac{\partial F}{\partial x_n} \right)$  provides the directions of maximal growth of the function  $F$  of  $n$  variables.

Moreover, the vanishing directional derivatives are exactly those in directions perpendicular to the gradient.

Therefore, it is clear that the tangent plane to a non-empty level set  $M_b$  in a neighbourhood of its point with non-zero gradient  $D^1F$  is determined by the orthogonal complement to the gradient, and the gradient itself is the *normal vector* of the hypersurface  $M_b$ .

For instance, considering a sphere in  $\mathbb{R}^3$  with radius  $r > 0$ , centered at  $(a, b, c)$ , i.e. given implicitly by the equation

$$F(x, y, z) = (x - a)^2 + (y - b)^2 + (z - c)^2 = r^2,$$

The normal vectors at a point  $P = (x_0, y_0, z_0)$  are obtained as non-zero multiples of the gradient, i.e. multiples of

$$D^1F = (2(x_0 - a), 2(y_0 - b), 2(z_0 - c)),$$

and the tangent vectors are exactly the vectors perpendicular to the gradient. Therefore, the tangent plane to a sphere at the point  $P$  can always be described implicitly in terms of the equation

$$0 = (x_0 - a)(x - x_0) + (y_0 - b)(y - y_0) + (z_0 - c)(z - z_0).$$

This is a special case of the following general formula:

TANGENT HYPERPLANES TO LEVEL SETS

**Theorem.** For a function  $F(x_1, \dots, x_n)$  of  $n$  variables and a point  $P = (p_1, \dots, p_n)$  in a level set  $M_b$  of the function  $F$  such that the gradient  $D^1F$  is non-vanishing at  $P$ , the implicit equation for the tangent hypersurface to  $M_b$  is

$$0 = \frac{\partial F}{\partial x_1}(P)(x_1 - p_1) + \dots + \frac{\partial F}{\partial x_n}(P)(x_n - p_n).$$

**PROOF.** The statement is clear from the previous discussions. The tangent hyperplane must be  $(n - 1)$ -dimensional, so its direction space is given as the kernel of the linear form given by the gradient (zero values of the corresponding linear mapping  $\mathbb{R}^n \rightarrow \mathbb{R}$  given by multiplying the column of coordinates by the row vector  $\text{grad } F$ ). Clearly, the selected point  $P$  satisfies the equation.  $\square$

**8.1.27. Illumination of 3D objects.** Consider the illumination of a three-dimensional object where the direction  $v$  of the light falling onto the two-dimensional surface  $M$  of this object is known. Assume  $M$  is given implicitly by an equation  $F(x, y, z) = 0$ .

The light intensity at a point  $P \in M$  is defined as  $I \cos \varphi$ , where  $\varphi$  is the angle between the normal line to  $M$  and the vector which is opposite to the flow of the light. As seen, the normal line is determined by the gradient of the function  $F$ .

The Jacobian of this transformation  $\mathbb{R}^3 \rightarrow \mathbb{R}^3$  is  $r^2 \sin(\psi)$ .

First of all, let us determine the volume of the ball. As for the integration bounds, it is convenient to express the conditions that bind the solid in the coordinates we will work in. In the spherical coordinates, the ball is given by the inequality

$$x^2 + y^2 + z^2 = r^2 \leq 1.$$

First, let us find the integration bounds for the variable  $\varphi$ . If we denote by  $\pi_\varphi$  the projection onto the  $\varphi$ -coordinate in the spherical coordinates ( $\pi_\varphi(\varphi, \theta, r) = \varphi$ ), then the image of the projection  $\pi_\varphi$  of the solid in question gives the integration bounds for the variable  $\varphi$ . We know that  $\pi_\varphi(\text{ball}) = [0, 2\pi)$  (the equation  $r^2 \leq 1$  does not contain the variable  $\varphi$ , so there are no constraints on it, and it takes on all possible values; this can also easily be imagined in space).

Having the bounds of one of the variables determined, we can proceed with the bounds of other variables. In general, those may depend on the variables whose bounds have already been determined (although this is not the case here). Thus, we choose arbitrarily a  $\varphi_0 \in [0, 2\pi)$ , and for this  $\varphi_0$  (fixed from now on), we find the intersection of the solid (ball) and the surface  $\varphi = \varphi_0$  and its projection  $\pi_\psi$  on the variable  $\psi$ . Similarly like for  $\varphi$ , the variable  $\psi$  is not bounded (either by the inequality  $r^2 \leq 1$  or the equality  $\varphi = \varphi_0$ ), so it can take on all possible values,  $\psi \in [0, \pi)$ .

Finally, let us fix a  $\varphi = \varphi_0$  and a  $\psi = \psi_0$ . Now, we are looking for the projection  $\pi_r(U)$  of the object (line segment)  $U$  given by the constraints  $r^2 \leq 1$ ,  $\varphi = \varphi_0$ ,  $\psi = \psi_0$  on the variable  $r$ . The only constraint for  $r$  is the condition  $r^2 \leq 1$ , so  $r \in (0, 1]$ .

Note that the integration bounds of the variables are independent of each other, so we can perform the integration in any order. Thus, we have

$$V_{\text{koule}} = \int_0^1 \int_0^{2\pi} \int_0^\pi r^2 \sin(\psi) \, d\psi \, d\varphi \, dr = \frac{4}{3}\pi.$$

Now, let us compute the volume of the spherical sector given by  $x^2 + y^2 + z^2 \leq 1$  and  $3x^2 + 3y^2 \geq z^2$ . Again, we express the conditions in the spherical coordinates:  $r^2 \leq 1$ ,  $3 \sin^2(\psi) \geq \cos^2(\psi)$ , i. e.,  $\text{tg}(\psi) \geq \frac{1}{\sqrt{3}}$ . Just like in the case of the ball, we can see that the variables occur independently in the inequalities, so the integration bounds of the variables will be independent of each other as well. The condition  $r^2 \leq 1$  implies  $r \in (0, 1]$ ; from  $\text{tg}(\psi) \geq \frac{1}{\sqrt{3}}$ , we have  $\psi \in [0, \frac{\pi}{6}]$ . The variable  $\varphi$  is not restricted by any condition, so  $\varphi \in [0, 2\pi]$ .

$$V_{\text{sector}} = \int_0^{2\pi} \int_0^1 \int_0^{\frac{\pi}{6}} r^2 \sin \psi \, d\psi \, dr \, d\varphi = \frac{2 - \sqrt{3}}{3}\pi,$$

altogether,

$$V = V_{\text{ball}} - V_{\text{sector}} = \frac{2}{3}\pi - \frac{2 - \sqrt{3}}{3}\pi = \frac{\pi}{\sqrt{3}}.$$

The sign of the expression then says which side of the surface is illuminated.

For example, consider an illumination with constant intensity  $I_0$  in the direction of the vector  $v = (1, 1, -1)$  (i.e. “downward askew”), and let the ball given by the equation  $F(x, y, z) = x^2 + y^2 + z^2 - 1 \leq 0$  be the object of interest. Then, for a point  $P = (x, y, z) \in M$  on the surface, the intensity

$$I(P) = \frac{\text{grad } F \cdot v}{\|\text{grad } F\| \|v\|} I_0 = \frac{-2x - 2y + 2z}{2\sqrt{3}} I_0$$

is obtained. Notice that, as anticipated, the point which is illuminated with the (full) intensity  $I_0$  is the point  $P = \frac{1}{\sqrt{3}}(-1, -1, 1)$  on the surface of the ball, while the antipodal point is fully illuminated with the minus sign (i.e. on the inside of the sphere).

Zde by se mozna hodilo i neco vic, aspon obrazek, neco jako obr. 3

**8.1.28. Tangent and normal spaces.** Ideas about tangent and normal lines can be extended to general dimensions. With a mapping  $F : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^n$ , and coordinate functions  $f_i$ , one can also consider the  $n$  equations for  $n + m$  variables

$$f_i(x_1, \dots, x_{m+n}) = b_i, \quad i = 1, \dots, n,$$

expressing the equality  $F(x) = b$  for a vector  $b \in \mathbb{R}^n$ .

Assuming that the conditions of the implicit function theorem hold, the set of all solutions  $(x_1, \dots, x_{m+n}) \in \mathbb{R}^{m+n}$  is (at least locally) the graph of a mapping  $G : \mathbb{R}^m \rightarrow \mathbb{R}^n$ . Technically, it is necessary to have some submatrix in  $D^1F$  of the maximal possible rank  $n$ .

For a fixed choice  $b = (b_1, \dots, b_n)$ , the set of all solutions is, of course, the intersection of all hypersurfaces  $M(b_i, f_i)$  corresponding to the particular functions  $f_i$ . The same must hold for tangent directions, while normal directions are generated by the individual gradients. Therefore, if  $D^1F$  is the Jacobi matrix of a mapping which implicitly defines a set  $M$  and  $P = (p_1, \dots, p_{m+n}) \in M$  is a point such that  $M$  is the graph of a mapping in the neighbourhood of the point  $P$ ,

$$D^1F = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_{m+n}} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_n}{\partial x_1} & \cdots & \frac{\partial f_n}{\partial x_{m+n}} \end{pmatrix},$$

then the affine subspace in  $\mathbb{R}^{m+n}$  which contains exactly all tangent lines going through the point  $P$  is given implicitly by the following equations:

$$0 = \frac{\partial f_1}{\partial x_1}(P)(x_1 - p_1) + \cdots + \frac{\partial f_1}{\partial x_n}(P)(x_{m+n} - p_{m+n})$$

⋮

$$0 = \frac{\partial f_n}{\partial x_1}(P)(x_1 - p_1) + \cdots + \frac{\partial f_n}{\partial x_n}(P)(x_{m+n} - p_{m+n}).$$

This subspace is called the *tangent space* to the (implicitly given)  $m$ -dimensional surface  $M$  at the point  $P$ .

The *normal space* at the point  $P$  is the affine subspace generated by the point  $P$  and the gradients of all the functions

We could also have computed the volume directly:

$$V = \int_0^\pi \int_0^1 \int_{\frac{\pi}{6}}^{\frac{5\pi}{6}} r^2 \sin \psi \, d\psi \, dr \, d\varphi = \frac{\pi}{\sqrt{3}}.$$

In cylindrical coordinates

$$x = r \cos(\varphi),$$

$$y = r \sin(\varphi),$$

$$z = z$$

with Jacobian  $r$  of this transformation, the calculation of the volume as the difference of the two solids considered above looks as follows:

$$V = \frac{2}{3}\pi - \int_0^{2\pi} \int_{\frac{1}{2}}^1 \int_0^1 r \, dz \, dr \, d\varphi = \frac{\pi}{\sqrt{3}}.$$

Note that we cannot compute the volume of the solid directly in the cylindrical coordinates. Thus, we must split it into two solids defined by the conditions  $r \leq \frac{1}{2}$  and  $r \geq \frac{1}{2}$ , respectively.

$$\begin{aligned} V &= V_1 + V_2 \\ &= \int_0^{2\pi} \int_0^{\frac{1}{2}} \int_0^{\sqrt{3}r} r \, dz \, dr \, d\varphi \\ &\quad + \int_0^{2\pi} \int_{\frac{1}{2}}^1 \int_0^{\sqrt{1-r^2}} r \, dz \, dr \, d\varphi \\ &= \frac{\pi}{\sqrt{3}}. \end{aligned}$$

□

Another alternative is to compute it as the volume of a solid of revolution, again splitting the solid into the two parts as in the previous case (the part “under the cone” and the part “under the sphere”). However, these solids cannot be obtained by rotating around one of the axes. The volume of the former part can be calculated as the difference between the volumes of the cylinder  $x^2 + y^2 \leq \frac{1}{4}$ ,  $0 \leq z \leq \frac{\sqrt{3}}{2}$  and the cone’s part  $3x^2 + 3y^2 \leq z^2$ ,  $0 \leq z \leq \frac{\sqrt{3}}{2}$ . The volume of the latter one is then the difference between the volumes of the solid that is created by rotating the part of the arc  $y = \sqrt{(1-x^2)}$ ,  $\frac{1}{2} \leq x \leq 1$  around the  $z$ -axis and the cylinder  $x^2 + y^2 \leq \frac{1}{4}$ ,  $0 \leq z \leq \frac{\sqrt{3}}{2}$ .

$$\begin{aligned} V &= V_1 + V_2 \\ &= \left( \frac{\pi\sqrt{3}}{8} - \frac{\pi\sqrt{3}}{24} \right) + \left( \pi \int_0^{\frac{\sqrt{3}}{2}} (1-r^2) \, dr - \frac{\pi\sqrt{3}}{8} \right) \\ &= \frac{\pi\sqrt{3}}{4} + \frac{\pi}{4\sqrt{3}} = \frac{\pi}{\sqrt{3}}. \end{aligned}$$

**8.I.3.** Calculate the volume of the spherical segment of the ball  $x^2 + y^2 + z^2 = 2$  cut by the plane  $z = 1$ .

$f_1, \dots, f_n$  at the point  $P$ , i.e. the rows of the Jacobi matrix  $D^1 F$ .

As an illustrative simple example, calculate the tangent and normal spaces to a conic section in  $\mathbb{R}^3$ . Consider the equation of a cone with vertex at the origin,

$$0 = f(x, y, z) = z - \sqrt{x^2 + y^2},$$

and a plane, given by

$$0 = g(x, y, z) = z - 2x + y + 1.$$

The point  $P = (1, 0, 1)$  belongs to both the cone and the plane, so the intersection  $M$  of these surfaces is a curve (draw a diagram!). Its tangent line at the point  $P$  is given by the following equations:

$$\begin{aligned} 0 &= -\frac{1}{2\sqrt{x^2 + y^2}} 2x \Big|_{x=1, y=0} \cdot (x-1) \\ &\quad - \frac{1}{2\sqrt{x^2 + y^2}} 2y \Big|_{x=1, y=0} \cdot y + 1 \cdot (z-1) \\ &= -x + z \end{aligned}$$

$$0 = -2(x-1) + y + (z-1) = -2x + y + z + 1,$$

while the plane perpendicular to the curve, containing the point  $P$ , is given parametrically by the expression

$$(1, 0, 1) + \tau(-1, 0, 1) + \sigma(-2, 1, 1)$$

with real parameters  $\tau$  and  $\sigma$ .

**8.1.29. Constrained extrema.** Now we come with the first really serious application of the differential calculus of more variables. The typical task in optimization is to find the extrema of values depending on several (yet finitely many) parameters, under some further constraints on the parameters of the model.

The problem often has  $m+n$  parameters constrained by  $n$  conditions. In the language of differential calculus, it is desired to find the extrema of a differentiable function  $h$  on the set  $M$  of points given implicitly by a vector equation  $F(x_1, \dots, x_{m+n}) = 0$ . Of course, we might first locally parameterize the solution space of the latter equation by  $m$  free parameters, express the function  $h$  in terms of these parameters and look for the local extrema by inspecting the critical points. However, we have already prepared more efficient procedures for this effort.

For every curve  $c(t) \subset M$  going through  $P = c(0)$ , it must be ensured that  $h(c(t))$  is an extremum of this univariate function. Therefore, the derivative must satisfy

$$\frac{d}{dt} h(c(t))|_{t=0} = d_{c'(0)} h(P) = dh(P)(c'(0)) = 0.$$

This means that the differential of the function  $h$  at the point  $P$  is zero along all tangent increments to  $M$  at  $P$ . This property is equivalent to stating that the gradient of  $h$  lies in the normal subspace (more precisely, in the modelling vector space of the normal subspace). Such points  $P \in M$  are called *stationary points* of the function  $h$  with respect to the constraints given by  $F$ .

**Solution.** We will compute the integral in spherical coordinates. The segment can be perceived as a spherical sector without the cone (with vertex at the point  $[0, 0, 0]$  and the circular base  $z = 1, x^2 + y^2 = 1$ ). In these coordinates, the sector is the product of the intervals  $[0, \sqrt{2}] \times [0, 2\pi] \times [0, \pi/4]$ . We thus integrate in the given bounds, in any order:

$$\int_0^{2\pi} \int_0^{\sqrt{2}} \int_0^{\pi/4} r^2 \sin(\theta) \, d\theta \, dr \, d\varphi = \frac{4}{3}(\sqrt{2} - 1)\pi.$$

In the end, we must subtract the volume of the cone. That is equal to  $\frac{1}{3}\pi R^2 H$  (where  $R$  is the radius of the cone's base and  $H$  is its height; both are equal to 1 in our case), so the total volume is

$$V_{\text{sector}} - V_{\text{cone}} = \frac{4}{3}(\sqrt{2} - 1)\pi - \frac{1}{3}\pi = \frac{1}{3}\pi(4\sqrt{2} - 5).$$

The volume of a general spherical segment with height  $h$  in a ball with radius  $R$  could be computed similarly:

$$\begin{aligned} V &= V_{\text{sector}} - V_{\text{cone}} \\ &= \int_0^{2\pi} \int_0^{\arccos\left(\frac{R-h}{R}\right)} \int_0^R r^2 \sin(\theta) \, dr \, d\theta \, d\varphi \\ &\quad - \frac{1}{3}\pi(2Rh - h^2)(R - h) \\ &= \frac{1}{3}\pi h^2(3R - h). \end{aligned}$$

**8.I.4.** Find the volume of the part of the cylinder  $x^2 + z^2 = 16$  which lies inside the cylinder  $x^2 + y^2 = 16$ .

As seen in the previous paragraph, the normal space to the set  $M$  is generated by the rows of the Jacobi matrix of the mapping  $F$ , so the stationary points are described equivalently by the following proposition:

LAGRANGE MULTIPLIERS

**Theorem.** Let  $F = (f_1, \dots, f_n) : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^n$  be a differentiable function in a neighbourhood of a point  $P$ ,  $F(P) = 0$ . Further, let  $M$  be given implicitly by an equation  $F(x, y) = 0$ , and let the rank of the matrix  $D^1F$  at the point  $P$  be  $n$ . Then  $P$  is a stationary point of a continuously differentiable function  $h : \mathbb{R}^{m+n} \rightarrow \mathbb{R}$  with respect to the constraints  $F$ , if and only if there exist real parameters  $\lambda_1, \dots, \lambda_n$  such that

$$\text{grad } h = \lambda_1 \text{grad } f_1 + \dots + \lambda_n \text{grad } f_n.$$

The procedure suggested by the theorem is called the *method of Lagrange multipliers*. It is of algorithmic character. Consider the numbers of unknowns and equations: the gradients are vectors of  $m + n$  coordinates, so the statement of the theorem yields  $m + n$  equations. The variables are, on one side, the coordinates  $x_1, \dots, x_{m+n}$  of the stationary points  $P$  with respect to the constraints, and, on the other hand, the  $n$  parameters  $\lambda_i$  in the linear combination. It remains to say that the point  $P$  belongs to the implicitly given set  $M$ , which represents  $n$  further equations. Altogether, there are  $2n + m$  equations for  $2n + m$  variables, so it can be expected that the solution is given by a discrete set of points  $P$  (i.e., each one of them is an isolated point).

Very often, the system of equations is a seemingly simple system of algebraic equations, but in fact only rarely can it be solved explicitly. We return to special algebraic methods for systems of polynomial equations in chapter 12. There are also various numerical approaches to such systems. Theoretical details are not discussed here, but there are several solved examples in the other column, including also the illustration of how to use the second derivatives to decide about the local extrema under the constraints.

**8.1.30. Arithmetic mean versus geometric mean.** As an example of practical application of the Lagrange multipliers, we prove the inequality

$$\frac{1}{n}(x_1 + \dots + x_n) \geq \sqrt[n]{x_1 \cdots x_n}$$

for any  $n$  positive real numbers  $x_1, \dots, x_n$ . Equality occurs if and only if all the  $x_i$ 's are equal.

Consider the sum  $x_1 + \dots + x_n = c$  as the constraint for a (non-specified) non-negative constant  $c$ . We look for the maxima and minima of the function

$$f(x_1, \dots, x_n) = \sqrt[n]{x_1 \cdots x_n}$$

with respect to the constraint and the assumption  $x_1 > 0, \dots, x_n > 0$ .

The normal vector to the part of the hyperplane  $M$  defined by the constraints is  $(1, \dots, 1)$ . Therefore, the function  $f$  can have an extremum only at those points where its gradient is a multiple of this normal vector. Hence there is the following system of equations for the desired points (the components  $\frac{\partial f}{\partial x_i}$  of the gradient appear on the left-hand side,  $\lambda$ -multiple of the normal vector is on the right):

$$\frac{1}{n} \frac{1}{x_i} \sqrt[n]{x_1 \cdots x_n} = \lambda,$$

for  $i = 1, \dots, n$  and  $\lambda \in \mathbb{R}$ .

These equations imply  $x_1 = \dots = x_n$  in the set  $M$ . If the variables  $x_i$  are allowed to be zero as well, then the set  $M$  would be compact, so the function  $f$  would have to have both a maximum and a minimum there. However,  $f$  is minimal if and only if at least one of the values  $x_i$  is zero; so the function necessarily has a strict maximum at the point with  $x_i = \frac{c}{n}$ ,  $i = 1, \dots, n$ , and then  $\lambda = \frac{1}{n}$ .

By substituting, the geometric mean equals the arithmetic mean for these extreme values, but it is strictly smaller at all other points with the given sum  $c$  of coordinates, which proves the inequality.

**Solution.** We will compute the integral in Cartesian coordinates. Since the solid is symmetric, it suffices to integrate over the first octant (interchanging  $x$  and  $-x$  does not change the equation of the solid; the same holds for  $y$  and for  $z$ ). The part of the solid that lies in the first octant is given by the space under the graph of the function  $z(x, y) = \sqrt{16 - x^2}$  and over the quarter-disc  $x^2 + y^2 \leq 16$ ,  $x \geq 0$ ,  $y \geq 0$ . Therefore, the volume of the whole solid is equal to

$$V = 8 \int_0^4 \int_0^{\sqrt{16-x^2}} \frac{4}{\sqrt{16-x^2}} dy dx = 128. \quad \square$$

**Remark.** Note that the projection of the considered solid onto both the plane  $y = 0$  and the plane  $z = 0$  is a circle with radius 4, yet the solid is not a ball.

## 2. Integration for the second time

We return to the process of integration, discussed in the second and third parts of chapter six. We saw that the integration with respect to the diverse coordinates can be iterated. Now we extend the concept of the Riemann integration and Jordan measure to general Euclidean spaces and, again, we shall see that the approaches coincide for many reasonable functions.

### 8.2.1. Integrals dependent on parameters.

Recall that integrating a function  $f(x, y_1, \dots, y_n)$  of  $n + 1$  variables with respect to the single variable  $x$ , the result is a function  $F(y_1, \dots, y_n)$  of the remaining variables. Essentially, we proved the following theorem already in 6.3.11 and 6.3.13. This is an extremely useful technical tool, as we saw when handling the Fourier transforms and convolutions in the last chapter. Previous results about extrema of multivariate functions also have a direct application for minimization of areas or volumes of objects defined in terms of functions dependent on parameters, etc.

**8.I.5.** Find the volume of the part of the cylinder  $x^2 + y^2 = 4$  bounded by the planes  $z = 0$  and  $z = x + y + 2$ .

**Solution.** We will work in cylindric coordinates given by the equations  $x = r \cos(\varphi)$ ,  $y = r \sin(\varphi)$ ,  $z = z$ . The Jacobian of this transformation is  $J = r$ . The solid can be divided into two parts: above and below the plane  $z = 0$ , whose volumes will be denoted by  $V_1$  and  $V_2$ , respectively. Further, we can notice that one part of the solid with volume  $V_1$  is a pyramid with vertices  $[0, 0, 0]$ ,  $[0, 0, 2]$ ,  $[-2, 0, 0]$ ,  $[0, -2, 0]$ . Thus, we will further split this solid (above  $z = 0$ ) into two parts, whose volumes we will calculate separately.

$$\begin{aligned}
 V_1 - V_{\text{pyramid}} &= \int_{-\pi/2}^{\pi} \left( \int_0^2 [r \sin \varphi + r \cos \varphi + 2] r \, dr \right) d\varphi, \\
 &= 6\pi + \frac{16}{3}, \\
 V_{\text{pyramid}} &= \frac{4}{3}
 \end{aligned}$$

Further,

$$V_1 - V_2 = \int_{-\pi}^{\pi} \int_0^2 r^2 (\sin(\varphi) + \cos(\varphi)) + 2r \, dr \, d\varphi = 8\pi,$$

so  $V_1 + V_2 = 4\pi + \frac{40}{3}$ .  $\square$

**Remark.** During the calculation, we made use of the fact that integrating a function of two variables over an area in  $\mathbb{R}^2$  yields the difference of the volume of the solid in  $\mathbb{R}^3$  determined by the graph of the integrated function and lying above  $z = 0$  and the one lying below  $z = 0$ .

**8.I.6.** Find the volume of the solid in  $\mathbb{R}^3$  which is given by the intersection of the sphere  $x^2 + y^2 + z^2 = 4$  and the cylinder  $x^2 + y^2 = 1$ .

CONTINUITY AND DIFFERENTIATION

**Theorem.** Consider a continuous function  $f(x, y_1, \dots, y_n)$  defined for all  $x$  from a finite interval  $[a, b]$  and for all  $(y_1, \dots, y_n)$  lying in some neighbourhood  $U$  of a point  $c = (c_1, \dots, c_n) \in \mathbb{R}^n$ , and its integral

$$F(y_1, \dots, y_n) = \int_a^b f(x, y_1, \dots, y_n) \, dx.$$

Then function  $F(y_1, \dots, y_n)$  is continuous on  $U$ .

Moreover, if there exists the continuous partial derivative  $\frac{\partial f}{\partial y_j}$  on a neighbourhood of the point  $c$ , then  $\frac{\partial F}{\partial y_j}(c)$  exists as well and

$$\frac{\partial F}{\partial y_j}(c) = \int_a^b \frac{\partial f}{\partial y_j}(x, c_1, \dots, c_n) \, dx.$$

**PROOF.** In Chapter 6, we dealt with two variables  $x, y$  only, but replacing the absolute value  $|y|$  with the norm  $\|y\|$  of the vector of parameters does not change the argumentation at all. Again, the main point is that the continuous real functions on compact sets are uniformly continuous.

Since partial derivative concerns only one of the variables, the rest of the theorem was proved in 6.3.13, too.  $\square$

**8.2.2. Integration of multivariate functions.** In the case of univariate functions, integration is motivated by the idea of the area under the graph of a given function of one variable. Consider now the volume of the part of the three-dimensional space which lies under the graph of a function  $z = f(x, y)$  of two variables, and the multidimensional analogues in general.

In chapter six, small intervals  $[x_i, x_{i+1}]$  were chosen of length  $\Delta x_i$  which divided the whole interval  $[a, b]$ . Then, their representatives  $\xi_i$  were selected, and the corresponding part of the area was approximated by the area of the rectangle with height given by the value  $f(\xi_i)$  at the representative, i.e. the expression  $f(\xi_i)\Delta x_i$ .

In the case of functions of two variables, work with divisions in both variables and the values representing the height of the graph above the particular little rectangles in the plane.

The first thing to deal with is to determine the integration domain, that is, the region the function  $f$  is to be integrated over. As an example, consider the function  $z = f(x, y) = \sqrt{1 - x^2 - y^2}$ , whose graph is, inside the unit disc, half of the unit sphere. Integrating this function over the unit disc yields the volume of the unit semi-ball.

The simplest approach is to consider only those integration domains  $M$  which are given by products of intervals, i.e. given by ranges  $x \in [a, b]$  and  $y \in [c, d]$ . In this context, it is called a *multidimensional interval*. If  $M$  is a different bounded set in  $\mathbb{R}^2$ , work with a sufficiently large area  $[a, b] \times [c, d]$ , rather than with the set itself, and adjust the function so that  $f(x, y) = 0$  for all points lying outside  $M$ . Considering the above case of the unit ball, integrate over the

**Solution.** Thanks to symmetry, it suffices to compute the volume of the part that lies in the first octant. We will integrate in cylindrical coordinates given by the equations  $x = r \cos(\varphi)$ ,  $y = r \sin(\varphi)$ ,  $z = z$  with Jacobian  $J = r$ , and it is the space between the plane  $z = 0$  and the graph of the function  $z = \sqrt{4 - x^2 - y^2} = \sqrt{4 - r^2}$ . Therefore, we can directly write is as the double integral

$$V = 8 \int_0^{\pi/2} \int_0^1 r \sqrt{4 - r^2} dr d\varphi = \frac{2}{3} (8 - 3\sqrt{3})\pi.$$

□

**8.I.7.** Find the volume of the solid in  $\mathbb{R}^3$  which is given by the intersection of the sphere  $x^2 + y^2 + z^2 = 2$  and the paraboloid  $z = x^2 + y^2$ .

**Solution.** Once again, we will work in cylindrical coordinates:

$$V = \int_0^{2\pi} \int_0^1 \int_{r^2}^{\sqrt{2-r^2}} r dz dr d\varphi = \frac{4\sqrt{2}\pi}{3} - \frac{7\pi}{6}.$$

set  $M = [-1, 1] \times [-1, 1]$  the function

$$f(x, y) = \begin{cases} \sqrt{1 - x^2 - y^2} & \text{for } x^2 + y^2 \leq 1 \\ 0 & \text{otherwise.} \end{cases}$$

The definition of the Riemann integral then faithfully follows the procedure from paragraph 6.2.8. This can be done for an arbitrary finite number of variables.

Given an  $n$ -dimensional interval  $I$  and partitions into  $k_i$  subintervals in each variable  $x_i$ , select the partition of  $I$  into  $k_1 \cdots k_n$  small  $n$ -dimensional intervals, and write  $\Delta x_{i_1 \dots i_n}$  for their volumes. The maximum of the lengths of the sides of the multidimensional intervals in such a partition is called its *norm*.

RIEMANN INTEGRAL

**Definition.** The Riemann integral of a real-valued function  $f$  defined on a multidimensional interval  $I = [a_1, b_1] \times [a_2, b_2] \times \dots \times [a_n, b_n]$  exists if for every choice of a sequence of divisions  $\Xi$  (dividing the multidimensional interval in all variables simultaneously), and the representatives  $\xi_{i_1 \dots i_n}$  of the little multidimensional intervals in the partitions, with the norm of the partitions converging to zero, the integral sums

$$S_{\Xi, \xi} = \sum_{i_1 \dots i_n} f(\xi_{i_1 \dots i_n}) \Delta x_{i_1 \dots i_n}$$

always converge to the value

$$S = \int_I f(x_1, \dots, x_n) dx_1 \dots dx_n,$$

independent of the selected sequence of divisions and representatives.

The function  $f$  is then said to be Riemann-integrable over  $I$ .

As a relatively simple exercise, prove in detail that every Riemann-integrable function over an interval  $I$  must be bounded there. The reason is the same as in the case of univariate functions: the control of the norms of the divisions used in the definition is somewhat rough.

The situation gets worse when integrating in this way over unbounded intervals, see more remarks in 8.2.6 below. Therefore, consider integration of functions over  $\mathbb{R}^n$  mainly for functions whose support is compact, that is, functions which vanish outside a bounded interval  $I$ .

A bounded set  $M \subset \mathbb{R}^n$  is said to be *Riemann-measurable*<sup>4</sup> if and only if its indicator function, defined by

$$\chi_M(x_1, \dots, x_n) = \begin{cases} 1 & \text{for } (x_1, \dots, x_n) \in M \\ 0 & \text{for all other points in } \mathbb{R}^n, \end{cases}$$

is Riemann-integrable over  $\mathbb{R}^n$ .

<sup>4</sup> Better to say “measurable via Riemann integration”, the measure itself is commonly called the *Peano–Jordan measure* in the literature.

**8.I.8.** Find the volume of the solid in  $\mathbb{R}^3$  which is bounded by the elliptic cylinder  $4x^2 + y^2 = 1$  and the planes  $z = 2y$  and  $z = 0$ , lying above the plane  $z = 0$ .

**Solution.** Thanks to symmetry, it is advantageous to work in the coordinates  $x = \frac{1}{2}r \cos(\varphi)$ ,  $y = r \sin(\varphi)$ ,  $z = z$  with Jacobian  $J = \frac{1}{2}r$ . The equation of the elliptic cylinder in these coordinates is  $r^2 = 1$ . Thus, the wanted volume is

$$\begin{aligned} V &= \int_0^\pi \int_0^1 r \sin(\varphi) \frac{1}{2}r \, dr \, d\varphi \\ &= \int_0^\pi \int_0^1 r^2 \sin(\varphi) \, dr \, d\varphi = \int_0^\pi \frac{1}{3} \sin(\varphi) \, d\varphi = \frac{2}{3}. \end{aligned}$$

**8.I.9.** Find the volume of the solid in  $\mathbb{R}^3$  which is bounded by the paraboloid  $2x^2 + y^2 = z$  and the plane  $z = 2$ .

**Solution.** Similarly to the above problem, we choose “special” coordinates which respect the symmetry of the solid:  $x = \frac{1}{\sqrt{2}}r \cos(\varphi)$ ,  $y = r \sin(\varphi)$ ,  $z = z$  with Jacobian

□ For any Riemann-measurable set  $M$  and a function  $f$  defined at all points of  $M$ , consider the function  $\tilde{f} = \chi_M \cdot f$  as a function defined on the whole  $\mathbb{R}^n$ . This function  $\tilde{f}$  apparently has a compact support. The Riemann integral of the function  $f$  over the set  $M$  is defined by

$$\int_M f \, dx_1 \dots dx_n = \int_{\mathbb{R}^n} \tilde{f} \, dx_1 \dots dx_n,$$

supposing the integral on the right-hand side exists.

**8.2.3. Properties of Riemann integral.** This definition of the integral does not provide reasonable instructions for computing the values of Riemann integrals. However, it does lead to the following basic properties of the Riemann integral (cf. Theorem 6.2.8):

**Theorem.** The set of Riemann-integrable real-valued functions over a Riemann measurable domain  $M \subset \mathbb{R}^n$  is a vector space over the real scalars, and the Riemann integral is a linear form there.

If the integration domain  $M$  is given as a disjoint union of finitely many Riemann-measurable domains  $M_i$ , then  $f$  is integrable on  $M$  if and only if it is integrable on all  $M_i$ , and the integral over a function  $f$  over  $M$  is given by the sum of the integrals over the individual subdomains  $M_i$ .

**PROOF.** All the properties follows directly from the definition of the Riemann integral and the properties of convergent sequences of real numbers, just as in the case of univariate functions. Think out the details by yourselves. □

For practical use, rewrite the theorem into the usual equalities:

FINITE ADDITIVITY AND LINEARITY

Any linear combination of Riemann-integrable functions  $f_i : \mathbb{I} \rightarrow \mathbb{R}$ ,  $i = 1, \dots, k$  (over scalars in  $\mathbb{R}$ ) is again a Riemann-integrable function, and its integral can be computed as follows:

$$\begin{aligned} &\int_I (a_1 f_1(x_1, \dots, x_n) + \dots + a_k f_k(x_1, \dots, x_n)) \, dx_1 \dots dx_n \\ &= a_1 \int_I f_1(x_1, \dots, x_n) \, dx_1 \dots dx_n + \\ &\quad \dots + a_k \int_I f_k(x_1, \dots, x_n) \, dx_1 \dots dx_n. \end{aligned}$$

Let  $M_1$  and  $M_2$  be disjoint Riemann-measurable sets, consider a function  $f : M_1 \cup M_2 \rightarrow \mathbb{R}$ . Then  $f$  is Riemann-integrable over both sets  $M_i$  if and only if it is integrable over its union, and

$$\begin{aligned} &\int_{M_1 \cup M_2} f(x_1, \dots, x_n) \, dx_1 \dots dx_n \\ &= \int_{M_1} f(x_1, \dots, x_n) \, dx_1 \dots dx_n + \\ &\quad \int_{M_2} f(x_1, \dots, x_n) \, dx_1 \dots dx_n. \end{aligned}$$

$J = \frac{1}{\sqrt{2}}r$ . The equation of the paraboloid in these coordinates is  $z = r^2$ , so the volume of the solid is equal to

$$\begin{aligned} V &= 4 \int_0^{\pi/2} \int_0^{\sqrt{2}} \int_{r^2}^2 \frac{1}{\sqrt{2}}r \, dz \, dr \, d\varphi \\ &= 2\sqrt{2} \int_0^{\pi/2} \int_0^{\sqrt{2}} 2r - r^3 \, dr \, d\varphi = 2\sqrt{2} \int_0^{\pi/2} d\varphi \\ &= \sqrt{2}\pi. \end{aligned}$$

□

**8.I.10.** Calculate the volume of the ellipsoid  $x^2 + 2y^2 + 3z^2 = 1$ .

**Solution.** We will consider the coordinates

$$\begin{aligned} x &= r \cos(\varphi) \sin(\theta), \\ y &= \frac{1}{\sqrt{2}}r \sin(\varphi) \sin(\theta), \\ z &= \frac{1}{\sqrt{3}}r \cos(\theta). \end{aligned}$$

The corresponding Jacobian is  $\frac{1}{\sqrt{6}}r^2 \sin(\theta)$ , so the volume is

$$V = \int_0^{2\pi} \int_0^{\pi} \int_0^1 \frac{1}{\sqrt{6}}r^2 \sin(\theta) \, dr \, d\theta \, d\varphi = \frac{4}{3\sqrt{6}}\pi.$$

□

**8.I.11. Remark.** Note that if the transformation the coordinates is linear (and affine), then the space is deformed “uniformly”. This means that the volume of an arbitrary solid is changed proportionally to the change of the volume of an infinitesimal volume element, which is the Jacobian. Therefore, if we consider the volume of the ball with a given radius  $r$  to be known, (in this case,  $r = 1$ ), we can infer directly that the volume of the ellipsoid is  $V = \frac{1}{\sqrt{6}} \cdot \frac{4}{3}\pi = \frac{4}{3\sqrt{6}}\pi$ .

**8.I.12.** Find the volume of the solid which is bounded by the paraboloid  $2x^2 + 5y^2 = z$  and the plane  $z = 1$ .

**Solution.** We choose the coordinates

$$\begin{aligned} x &= \frac{1}{\sqrt{2}}r \cos(\varphi), \\ y &= \frac{1}{\sqrt{5}}r \sin(\varphi), \\ z &= z. \end{aligned}$$

The determinant of the Jacobian is  $\frac{r}{\sqrt{10}}$ , so the volume is

$$V = \int_0^{2\pi} \int_0^1 \int_{r^2}^1 \frac{r}{\sqrt{10}} \, dz \, dr \, d\varphi = \frac{\pi}{2\sqrt{10}}.$$

□

**8.2.4. Multiple integrals.** Riemann-measurable domains especially involve cases when the boundary of the integration domain  $M$  can be expressed step by step via continuous dependencies between the coordinates in the following way. The first coordinate  $x$  runs within an interval  $[a, b]$ . The interval range of the next coordinate can be defined by two functions, i.e.  $y \in [\varphi(x), \psi(x)]$ , then the range of the next coordinate is expressed as  $z \in [\eta(x, y), \zeta(x, y)]$ , and so on for all of the other coordinates.

For example, this is easy in the case of a ball from the introductory example: for  $x \in [-1, 1]$ , define the range for  $y$  as  $y \in [-\sqrt{1-x^2}, \sqrt{1-x^2}]$ . The volume of the ball can then be computed by integration of the mentioned function  $f$ , or integrate the indicator function of the ball, i.e. the function which takes one on the subset  $M \subset \mathbb{R}^3$  which is further defined by  $z \in [-\sqrt{1-x^2-y^2}, \sqrt{1-x^2-y^2}]$ .

The following fundamental theorem transforms the computation of a Riemann integral to a sequence of computations of univariate integrals (while the other variables are considered to be parameters, which can appear in the integration bounds as well). Notice, we could have defined the multiple integral directly via the one-dimensional integration, but we would face the trouble of ensuring the independence of the result on our way of describing  $M$ . The theorem reveals that the two approaches coincide and there are no unclear points left.

#### MULTIPLE INTEGRALS

**Theorem.** Let  $M \subset \mathbb{R}^n$  be a bounded set, expressed with the help of continuous functions  $\psi_i, \eta_i$

$$M = \{(x_1, \dots, x_n); x_1 \in [a, b], x_2 \in [\psi_2(x_1), \eta_2(x_1)], \dots, x_n \in [\psi_n(x_1, \dots, x_{n-1}), \eta_n(x_1, \dots, x_{n-1})]\},$$

and let  $f$  be a function which is continuous on  $M$ . Then the Riemann integral of the function  $f$  over the set  $M$  exists and is given by the formula

$$\int_M f(x_1, x_2, \dots, x_n) \, dx_1 \dots dx_n = \int_a^b \left( \int_{\psi_2(x_1)}^{\eta_2(x_1)} \dots \left( \int_{\psi_n(x_1, \dots, x_{n-1})}^{\eta_n(x_1, \dots, x_{n-1})} f(x_1, x_2, \dots, x_n) \, dx_n \right) \dots dx_2 \right) dx_1$$

where the individual integrals are the one-variable Riemann integrals.

**PROOF.** Consider first the proof for the case of two variables. It can then be seen that there is no need of further ideas in the general case.

Consider an interval  $I = [a, b] \times [c, d]$  containing the set  $M = \{(x, y); x \in [a, b], y \in [\psi(x), \eta(y)]\}$  and divisions  $\Xi$  of the interval  $I$  with representatives  $\xi_{ij}$ .

**8.I.13.** Find the volume of the solid which lies in the first octant and is bounded by the surfaces  $y^2 + z^2 = 9$  and  $y^2 = 3x$ .

**Solution.** In cylindrical coordinates,

$$V = \int_0^{\pi/2} \int_0^3 \int_0^{\sqrt{\frac{x}{3}} \cos^2(\varphi)} r \, dx \, dr \, d\varphi = \frac{27}{16}\pi.$$

□

**8.I.14.** Find the volume of the solid in  $\mathbb{R}^3$  which is bounded by the cone part  $2x^2 + y^2 = (z-2)^2$ ,  $z \geq 2$  and the paraboloid  $2x^2 + y^2 = 8 - z$ .

**Solution.** First of all, we find the intersection of the given surfaces:

$$(z - 2)^2 = -z + 8, \quad z \geq 2;$$

therefore,  $z = 4$ , and the equation of the intersection is  $2x^2 + y^2 = 4$ . The substitution  $x = \frac{1}{\sqrt{2}}r \cos(\varphi)$ ,  $y = r \sin(\varphi)$ ,  $z = z$  transforms the given surfaces to the form  $r^2 = (z-2)^2$ ,  $z \geq 2$ , and  $r^2 = 8 - z$ , i. e.,  $z = r + 2$  for the former surface and  $z = 8 - r^2$  for the latter. Altogether, the projection of the given solid onto the coordinate  $\varphi$  is equal to the interval  $[0, 2\pi]$ . Having fixed a  $\varphi_0 \in [0, 2\pi]$ , the projection of the intersection of the solid and the plane  $\varphi = \varphi_0$  onto the coordinate  $r$  equals (independently of  $\varphi_0$ ) the interval  $[0, 2]$ . Having fixed both  $r_0$  and  $\varphi_0$ , the projection of the intersection of the solid and the line  $r = r_0$ ,  $\varphi = \varphi_0$ , onto the coordinate  $z$  is equal to the interval  $[r_0 + 2, 8 - r_0^2]$ . The Jacobian of the considered transformation is  $J = \frac{1}{\sqrt{2}}r$ , so we can write

$$V = \int_0^{2\pi} \int_0^2 \int_{r+2}^{8-r^2} \frac{r}{\sqrt{2}} \, dz \, dr \, d\varphi = \frac{16\sqrt{2}}{3}\pi.$$

The corresponding integral sum is

$$\begin{aligned} S_{\Xi, \xi} &= \sum_{i,j} f(\xi_{ij}) \Delta x_{ij} \\ &= \sum_i \left( \sum_j f(\xi_{ij}) \Delta y_j \right) \Delta x_i, \end{aligned}$$

where  $\Delta x_{ij}$  is written for the product of the sizes  $\Delta x_i$  and  $\Delta x_j$  of the intervals which correspond to the choice of the representative  $\xi_{ij}$ .

Assume first that we work only with choices of representatives  $\xi_{ij}$  which all share the same first coordinate  $x_i$ . If the partition of the interval  $[a, b]$  is fixed, and only the partition of  $[c, d]$  is refined, the values of the inner sum of the expression approaches the value of the integral

$$S_i = \int_{\varphi(x_i)}^{\eta(x_i)} f(x_i, y) \, dy,$$

which exists since the function  $f(x_i, y)$  is continuous. In this way, a function is obtained which is continuous in the free parameter  $x_i$ , see 8.2.1. Therefore, further refinement of the partition of the interval  $[a, b]$  leads, in the limit, to the desired formula

$$\sum_i S_i \Delta x_i \rightarrow S = \int_a^b \left( \int_{\psi(x)}^{\eta(x)} f(x, y) \, dy \right) dx.$$

It remains to deal with the case of general choices of representatives of general divisions  $\Xi$ . Since  $M$  is clearly compact (bounded and closed by definition), and  $f$  is a continuous function on  $M$ , it is uniformly continuous there. Therefore, if a small real number  $\varepsilon > 0$  is selected beforehand, there is always a bound  $\delta > 0$  for the norm of the partitions, so that the values of the function  $f$  for the general choices  $\xi_{ij}$  differ by no more than  $\varepsilon$  from the choices used above. Thus, the limit processes results in the same value for general Riemann sums  $S_{\Xi, \xi}$  as seen above.

Now, the general case can be proved easily by induction.

In the case of  $n = 1$ , the result is trivial. The presented reasoning can easily be transformed for a general induction step, writing  $(x_2, \dots, x_n)$  instead of  $y$ , having  $x_1$  instead of  $x$ , and perceiving the particular little cubes of the divisions as  $(n - 1)$ -dimensional cubes Cartesian-multiplied by the last interval. In the last-but-one step of the proof, the induction hypothesis is used, rather than the simple one-dimensional integration. The final argument about uniform continuity remains the same. It is advised to write this proof in detail as an exercise. □

**8.2.5. Fubini theorem.** The latter theorem has a particularly simple shape in the case of a multidimensional interval  $M$ . Then all the functions in bounds for integration are just the constant bounds from the definition of  $M$ . But this means that the integration process can be carried out coordinate by coordinate in

□

**8.I.15.** Find the volume of the solid which lies inside the cylinder  $y^2 + z^2 = 4$  and the half-space  $x \geq 0$  and is bounded by the surface  $y^2 + z^2 + 2x = 16$ .

**Solution.** In cylindrical coordinates,

$$V = \int_0^{2\pi} \int_0^2 \int_0^{8-\frac{r^2}{2}} r \, dx \, dr \, d\varphi = 28\pi. \quad \square$$

**8.I.16. The centroid of a solid.** The coordinates  $(x_t, y_t, z_t)$  of the centroid of a (homogeneous) solid  $T$  with volume  $V$  in  $\mathbb{R}^3$  are given by the following integrals:

$$\begin{aligned} x_t &= \iiint_T x \, dx \, dy \, dz, \\ y_t &= \iiint_T y \, dx \, dy \, dz, \\ z_t &= \iiint_T z \, dx \, dy \, dz. \end{aligned}$$

The centroid of a figure in  $\mathbb{R}^2$  or other dimensions can be computed analogously.

**8.I.17.** Find the centroid of the part of the ellipse  $3x^2 + 2y^2 = 1$  which lies in the first quadrant of the plane  $\mathbb{R}^2$ .

**Solution.** First, let us calculate the volume of the given ellipse. The transformation  $x = \frac{1}{\sqrt{3}}x', y = \frac{1}{\sqrt{2}}y'$  with Jacobian  $\frac{1}{\sqrt{6}}$  leads to

$$\begin{aligned} S &= \int_0^{\frac{1}{\sqrt{3}}} \int_0^{\sqrt{\frac{1-3x^2}{2}}} dy \, dx = \frac{1}{\sqrt{6}} \int_0^1 \int_0^{\sqrt{1-x^2}} dy' \, dx' \\ &= \frac{\pi}{4\sqrt{6}}. \end{aligned}$$

The other integrals we need can be computed directly in Cartesian coordinates  $x$  and  $y$ :

$$\begin{aligned} T_x &= \int_0^{\frac{1}{\sqrt{3}}} \int_0^{\sqrt{\frac{1-3x^2}{2}}} x \, dy \, dx = \int_0^{\frac{1}{\sqrt{3}}} x \sqrt{\frac{1-3x^2}{2}} \, dx = \\ &= \frac{1}{2} \int_0^{\frac{1}{\sqrt{3}}} \sqrt{\frac{1-3t}{2}} \, dt = \frac{\sqrt{2}}{18}, \end{aligned}$$

$$\begin{aligned} T_y &= \int_0^{\frac{1}{\sqrt{3}}} \int_0^{\sqrt{\frac{1-3x^2}{2}}} y \, dy \, dx = \frac{1}{2} \int_0^{\frac{1}{\sqrt{3}}} \frac{1-3x^2}{2} \, dx = \\ &= \frac{1}{4} \int_0^{\frac{1}{\sqrt{3}}} (1-3x^2) \, dx = \frac{\sqrt{3}}{18}. \end{aligned}$$

Therefore, the coordinates of the centroid are  $[\frac{4\sqrt{3}}{9\pi}, \frac{2\sqrt{2}}{\pi}]$ .  $\square$

**8.I.18.** Find the volume and the centroid of a homogeneous cone of height  $h$  and circular base with radius  $r$ .

**Solution.** Positioning the cone so that the vertex is at the origin and points downwards, we have in cylindrical coordinates that

$$V = 4 \int_0^{\pi/2} \int_0^r \int_{\frac{h}{r}\rho}^h \rho \, dz \, d\rho \, d\varphi = \frac{1}{3}\pi hr^2.$$

any order. We have exploited this behavior already in Chapter 6, cf. 6.3.12. In this way is proved the important corollary:<sup>5</sup>

FUBINI THEOREM

**Theorem.** Every continuous function  $f(x_1, \dots, x_n)$  on a multidimensional interval  $M = [a_1, b_1] \times [a_2, b_2] \times \dots \times [a_n, b_n]$  is Riemann integrable on  $M$ , and its integral

$$\begin{aligned} \int_M f(x_1, \dots, x_n) \, dx_1 \dots dx_n \\ = \int_{a_1}^{b_1} \int_{a_2}^{b_2} \dots \int_{a_n}^{b_n} f(x_1, \dots, x_n) \, dx_1 \dots dx_n \end{aligned}$$

is independent of the order in which the multiple integration is performed.

The possibility of changing the order of integration in multiple integrals is extremely useful. We have already taken advantage of this result, namely when studying the relation of Fourier transforms and convolutions, see paragraph 7.1.9.

**8.2.6. Unbounded regions and functions.** There is no simple concept of an improper integral for unbounded multivariate functions. The following example of multiple integration of an unbounded function is illustrative in this direction:

$$\begin{aligned} \int_0^1 \left( \int_0^1 \frac{x-y}{(x+y)^3} \, dy \right) dx &= \frac{1}{2} \\ \int_0^1 \left( \int_0^1 \frac{x-y}{(x+y)^3} \, dx \right) dy &= -\frac{1}{2}. \end{aligned}$$

The reason can be understood by looking at the properties of non-absolutely converging series. There, rearranging the summands can lead to an arbitrary result.

The situation is better if the Riemann integral of a bounded non-negative function  $f(x) \geq 0$  with non-compact support over the whole  $\mathbb{R}^n$  is calculated. Of course some extra information is needed on the decay of the function  $f$  for large arguments. For example, if  $f$  is Riemann integrable over each  $n$ -dimensional interval  $I$  and there is a universal bound

$$\int_I |f(x)| \, dx \leq C$$

with a constant  $C$  independent of the choice of the  $n$ -dimensional interval  $I \subset \mathbb{R}^n$ , then we may define

$$\int_{\mathbb{R}^n} f(x) \, dx = \lim_{r \rightarrow \infty} \int_{I_r} f(x) \, dx,$$

where  $I_r = \{(x_1, \dots, x_n); |x_j| < r, j = 1, \dots, n\}$ . The resulting limit, if it exists, is bounded by the same constant  $C$ .

<sup>5</sup>Guido Fubini (1907-1943) was an important Italian mathematician active also in applied areas of mathematics. Simple derivation of Fubini theorem builds upon the simple properties of Riemann integration and the continuity of the integrated function. Fubini, in fact, proved this result in a much more general context of integration, while the theorem just introduced was used by mathematicians like Cauchy at least a century before Fubini.

Apparently, the centroid lies on the  $z$ -axis. For the  $z$ -coordinate, we get

$$z = \frac{1}{V} \int_{\text{cone}} z dV = \frac{1}{V} \int_0^{\pi/2} \int_0^r \int_{\frac{h}{r}\rho}^h z \rho dz d\rho d\varphi = \frac{3}{4}h.$$

Thus, the centroid lies  $\frac{1}{4}h$  over the center of the cone's base.  $\square$

**8.I.19.** Find the centroid of the solid which is bounded by the paraboloid  $2x^2 + 2y^2 = z$ , the cylinder  $(x+1)^2 + y^2 = 0$ , and the plane  $z = 0$ .

**Solution.** First, we will compute the volume of the given solid. Again, we use the cylindric coordinates  $(x = r \cdot \cos \varphi, y = r \cdot \sin \varphi, z = z)$ , where the equation of the paraboloid is  $z = 2r^2$  and the equation of the cylinder reads  $r = -2 \cos(\varphi)$ . Moreover, taking into account the fact that the plane  $x = 0$  is tangent to the given cylinder, we can easily determine the bounds of the integral that corresponds to the volume of the examined solid:

$$\begin{aligned} V &= \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_0^{-2 \cos \varphi} \int_0^{2r^2} r dz dr d\varphi \\ &= \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_0^{-2 \cos \varphi} 2r^3 dr d\varphi \\ &= \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} 8 \cos^4 \varphi d\varphi = 3\pi, \end{aligned}$$

where the last integral can be computed using the method of recurrence from 6.2.6.

Now, let us find the centroid. Since the solid is symmetric with respect to the plane  $y = 0$ , the  $y$ -coordinate of the centroid must be zero. Then, the remaining coordinates  $x_T$  and  $z_T$  of the centroid can be computed by the following integrals:

$$\begin{aligned} x_T &= \frac{1}{V} \int \int \int_{\text{B}} x dx dy dz \\ &= \frac{1}{V} \int_0^{2r^2} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_0^{-2 \cos \varphi} r^2 \cos \varphi dz dr d\varphi \\ &= \frac{1}{V} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_0^{-2 \cos \varphi} 2r^4 \cos \varphi dr d\varphi \\ &= \frac{1}{V} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} -\frac{64}{5} \cos^6 \varphi d\varphi = -\frac{4}{3}, \end{aligned}$$

where the last integral was computed by 6.2.6 again.

Analogously for the  $z$ -coordinate of the centroid:

$$z_T = \frac{1}{V} \int_0^{2r^2} \int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_0^{-2 \cos \varphi} zr \cos \varphi dz dr d\varphi = \frac{20}{9}.$$

The coordinates of the centroid are thus  $[-\frac{4}{3}, 0, \frac{20}{9}]$ .  $\square$

In this case, the Fubini theorem is true in the form

$$\int_{\mathbb{R}^n} f(x) dx = \int_{-\infty}^{\infty} \dots \left( \int_{-\infty}^{\infty} f(x) dx_1 \right) \dots dx_n.$$

**8.2.7. Further remarks on integration.** The Riemann

integral of multivariate functions behaves even worse than in the case of functions of one variable in the sixth chapter. Therefore, more sophisticated approaches to integrations have been developed. They are mainly based on the concept of the measure of a set. We consider this problem briefly now.

As we shall see in 8.2.10, the Riemann integration of the indicator functions  $\chi_M$  of sets  $M \subset \mathbb{R}^n$  leads to a finitely additive measure. In probability theory in chapter 10, even elementary problems require a concept of measure which is additive over countable systems of disjoint sets. Having such a measure, measurable functions  $f$  can be defined by the condition that their preimages of bounded intervals,  $f^{-1}([a, b])$ , are measurable sets and the integral is built by approximation via such "horizontal strips", see the illustration. This is the starting point of Lebesgue integration.

add a regular diagram on Lebesgue integration

We omit further details here, but note the Riesz representation theorem<sup>6</sup> saying that for each linear functional  $I$  (i.e. a linear mapping valued in  $\mathbb{R}$ ) on continuous functions with compact support on a metric space  $X$ , there is the unique measure (with certain regularity properties) such that the integral associated to this measure extends  $I$ . In the case of the Riemann integral  $I$  on functions on  $\mathbb{R}^n$  this provides the Lebesgue measure and the Lebesgue integral.

Another point of view is the completion procedure for metric spaces. Consider the vector space  $X = \mathcal{S}_c(\mathbb{R}^n)$  of all continuous functions with compact support. It can be equipped with the  $L_p$  norms, similar to the univariate case from the seventh chapter, i.e.

$$\|f\|_p = \left( \int_{\mathbb{R}^n} |f(x_1, \dots, x_n)|^p dx_1 \dots dx_n \right)^{1/p}$$

for any  $1 \leq p < \infty$ . Since the Riemann integral is defined again in terms of partitions and the representative values, the properties of the norm can be verified in the same way as for univariate functions, using Hölder's and Minkowski's inequalities.

There are the metrics  $\|\cdot\|_p$  on  $X$ . The general theory provides its completion  $\tilde{X}$ , unique up to isometry, and it can be shown that it is again a space of functions. The Lebesgue integral mentioned above defines exactly these norms. Hence the spaces of functions with Lebesgue integrable powers  $|f|^p$  are obtained.

<sup>6</sup>Frigyes Riesz (1880-1956) was a famous Hungarian mathematician active in particular in functional analysis. He introduced this theorem in the special case of  $X$  being an interval in  $\mathbb{R}^n$  in 1909

**8.I.20.** Find the centroid of the homogeneous solid in  $\mathbb{R}^3$  which lies between the planes  $z = 0$  and  $z = 2$ , bounded by the cones  $x^2 + y^2 = z^2$  and  $x^2 + y^2 = 2z^2$ .

**Solution.** The problem can be solved in the same way as the previous ones. It would be advantageous to work in cylindrical coordinates.

However, we can notice that the solid in question is an “annular cone”: it is formed by cutting out a cone  $K_1$  with base radius 4 of a cone  $K_2$  with base radius 8, of common height 2.

The centroid of the examined solid can be determined by the “rule of lever”: the centroid of a system of two solids is the weighted arithmetic mean of of the particular solids’ centroids, weighed by the masses of the solids. We found out in exercise 8.I.18 that the centroid of a homogeneous cone is situated at quarter its height. Therefore, the centroids of both cones lie at the same point, and this points thus must be the centroid of the examined solid as well. Hence, the coordinates of the wanted centroid are  $[0, 0, \frac{3}{2}]$ .  $\square$

**8.I.21.** Find the volume of the solid in  $\mathbb{R}^3$  which is bounded by the cone part  $x^2 + y^2 = (z - 2)^2$  and the paraboloid  $x^2 + y^2 = 4 - z$ .

**Solution.** We build the corresponding integral in cylindrical coordinates, which evaluates as follows:

$$V = \int_0^{2\pi} \int_0^1 \int_{r+2}^{4-r^2} r \, dz \, dr \, d\varphi = \frac{5}{6}\pi.$$

**8.I.22.** Find the volume of the solid in  $\mathbb{R}^3$  which lies under the cone  $x^2 + y^2 = (z - 2)^2$ ,  $z \leq 2$  and over the paraboloid  $x^2 + y^2 = z$ .

**Solution.**

$$V = \int_0^{2\pi} \int_0^1 \int_{r^2}^{2-r} r \, dz \, dr \, d\varphi = \frac{5}{6}\pi.$$

**8.2.8. Change of coordinates.** When calculating integrals of univariate functions, the “substitution method” is used as one of the powerful tools, cf. 6.2.5. The method works similarly in the case of functions of more variables, when understanding its geometric meaning.

Recall and reinterpret the univariate case. There, the integrated expression  $f(x) \, dx$  infinitesimally describes the two-dimensional area of the rectangle whose sides are the (linearized) increment  $\Delta x$  of the variable  $x$ , i.e. the one-dimensional rectangle, and the value  $f(x)$ . If the variable  $x$  is transformed by the relation  $x = u(t)$ , then the linearized increment can be expressed with the help of the differential as

$$dx = \frac{du}{dt} dt,$$

and so the corresponding contribution for the integral is given by

$$f(u(t)) \frac{du}{dt} dt.$$

Here one either supposes that the sign of the derivative  $u'(t)$  is positive, or one interchanges the bounds of the integral, so that the sign does not effect the result.

Intuitively, the procedure for  $n$  variables should be similar. It is only necessary to recall the formula for (change of) the volume of parallelepipeds. The Riemann integrals are approximated by Riemann sums, which are based on the  $n$ -dimensional volume (area) of small multidimensional intervals  $\Delta x_{i_1 \dots i_n}$  in the variables, multiplied by the values of the function at the representative points  $\xi_{i_1 \dots i_n}$ . If the coordinates are transformed by means of a mapping  $x = G(y)$ , not only the function values  $f(G(\xi_{i_1 \dots i_n}))$  are obtained at the representative points  $\tilde{\xi}_{i_1 \dots i_n} = G^{-1}(\xi_{i_1 \dots i_n})$  in the new coordinate expression, but also the change of the volume of the corresponding small multidimensional intervals needs care.

Once again, this is the case of a linear approximation of a change, which is well known — the best linear approximation of  $G(y)$  is its derivative  $D^1 G(y)$ , which is given by the Jacobi matrix of  $G$ , see 8.1.19. The change of the volume is then given (in absolute value) by the determinant of this matrix (see a discussion of this topic in chapter 4 devoted to analytic geometry and linear algebra, especially 4.1.19).

Summarizing, the formulation of the next theorem should not be surprising and its proof consists in formalization of the latter ideas. However, this needs some effort and so the proof is split into several steps.

Note that the considered solid is symmetric with the solid from the previous exercise 8.I.21 (the center of the symmetry is the point  $[0, 0, 2]$ ). Therefore, it must have the same volume.  $\square$

8.I.23. Find the centroid of the surface bounded by the parabola  $y = 4 - x^2$  and the line  $y = 0$ .  $\circ$

8.I.24. Find the centroid of the circular sector corresponding to the angle of  $60^\circ$  that was cut out of a disc with radius 1.  $\circ$

8.I.25. Find the centroid of the semidisc  $x^2 + y^2 = 1, y \geq 0$ .  $\circ$

8.I.26. Find the centroid of the circular sector corresponding to the angle of  $120^\circ$  that was cut out of a disc with radius 1.  $\circ$

8.I.27. Find the volume of the solid in  $\mathbb{R}^3$  which is given by the inequalities  $z \geq 0, z - x \leq 0$ , and  $(x - 1)^2 + y^2 \leq 1$ .  $\circ$

8.I.28. Find the volume of the solid in  $\mathbb{R}^3$  which is given by the inequalities  $z \geq 0, z - y \leq 0$ .  $\circ$

8.I.29. Find the volume of the solid bounded by the surface

$$3x^2 + 2y^2 + 3z^2 + 2xy - 2yz - 4xz = 1.$$

8.I.30. Find the volume of the part of  $\mathbb{R}^3$  lying inside the ellipsoid  $2x^2 + y^2 + z^2 = 6$  and in the half-space  $x \geq 1$ .  $\circ$

8.I.31. **The area of the graph of a real-valued function  $f(x, y)$  in variables  $x$  and  $y$ .** The area of the graph of a function of two variables over an area  $S$  in the plane  $xy$  is given by the integral

$$P = \int_S \sqrt{1 + f_x^2 + f_y^2} \, dx \, dy.$$

Considering the cone  $x^2 + y^2 = z^2$ , find the area of the part of its lateral surface which lies above the plane  $z = 0$  and inside the cylinder  $x^2 + y^2 = y$ .

**Solution.** The wanted area can be calculated as the area of the graph of the function  $z = \sqrt{x^2 + y^2}$  over the disc  $K: x^2 - (y - \frac{1}{2})^2$ . We can easily see that

$$f_x = \frac{x}{x^2 + y^2}, \quad f_y = \frac{y}{x^2 + y^2},$$

so the area is expressed by the integral

$$\begin{aligned} \iint_K \sqrt{1 + f_x^2 + f_y^2} \, dx \, dy &= \iint_K \sqrt{2} \, dx \, dy = \\ &= \sqrt{2} \int_0^\pi \int_0^{\sin \pi} r \, dr \, d\varphi = \frac{\sqrt{2}}{2} \int_0^\pi \sin^2 \varphi \\ &= \frac{\sqrt{2}\pi}{4}. \end{aligned}$$

**Theorem.** Let  $G(t) : \mathbb{R}^n \rightarrow \mathbb{R}^n$  be a continuously differentiable and invertible mapping, and write

$$t = (t_1, \dots, t_n), \quad x = (x_1, \dots, x_n) = G(t_1, \dots, t_n).$$

Further let  $M = G(N)$  be a Riemann-measurable sets, and  $f : M \rightarrow \mathbb{R}$  a continuous function. Then,  $N$  is also Riemann-measurable and

$$\int_M f(x) \, dx_1 \dots dx_n = \int_N f(G(t)) |\det(D^1 G(t))| \, dt_1 \dots dt_n.$$

**8.2.9. The invariance of the integral.** The first thing to be verified is the coincidence of two definitions of volume of parallelepipeds (taken for granted in the above intuitive explanation of the latter theorem). Volumes and similar concepts were dealt with in chapter 4 and a crucial property was the invariance of the concepts with respect to the choice of Euclidean frames of  $\mathbb{R}^n$ , cf. 4.1.19 on page 334, which followed directly from the expression of the volumes in terms of determinants. It is needed to show that the same result holds in terms of the Riemann integration as defined above. It turns out that it is easier to deal with invariance with respect to general invertible linear mappings  $\Psi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ .

**Proposition.** Let  $\Psi : \mathbb{R}^n \rightarrow \mathbb{R}^n$  be an invertible linear mapping and  $I \subset \mathbb{R}^n$  a multidimensional interval. Consider a function  $f$ , such that  $f \circ \Psi$  is integrable on  $I$ . Then  $M = \Psi(I)$  is Riemann-measurable,  $f$  is Riemann integrable on  $M$  and

$$\begin{aligned} \int_M f(x_1, \dots, x_n) \, dx_1 \dots dx_n &= \\ &= |\det \Psi| \int_I (f \circ \Psi)(y_1, \dots, y_n) \, dy_1 \dots dy_n. \end{aligned}$$

**PROOF.** Each linear mapping is a composition of the elementary transformations of three types (see the discussion in chapter 2, in particular paragraphs 2.1.7 and 2.1.9).

The first one is a multiplication of one of the coordinates with a constant:  $\Psi(y_1, \dots, y_n) = (y_1, \dots, \alpha y_i, \dots, y_n)$ . In this case  $|\det \Psi| = |\alpha|$ . The second one consists of an exchange of two coordinates, i.e. for given  $1 \leq i < j \leq n$ ,  $\Psi(y_1, \dots, y_n) = (y_1, \dots, y_j, \dots, y_i, \dots, y_n)$ . The determinant of  $\Psi$  is  $-1$  in this case. The third type of transformations is of the form  $\Psi(y_1, \dots, y_n) = (y_1, \dots, y_i + y_j, \dots, y_j, \dots, y_n)$ , with determinant one. Without loss of generality,  $i = 1$  can be chosen in the first case and  $i = 1, j = 2$ , in the second case. Since the determinant of the composition of the mappings (i.e. the determinant of the product of the matrices) is the product of the individual determinants, it is enough to prove the proposition for all three special types of  $\Psi$ .

Express the right hand integrals for these three types of  $\Psi$  by means of the multiple integrals and Fubini theorem. Write

**8.I.32.** Find the area of the parabola  $z = x^2 + y^2$  over the disc  $x^2 + y^2 \leq 4$ .  $\square$

**8.I.33.** Find the area of the part of the plane  $x + 2y + z = 10$  that lies over the figure given by  $(x - 1)^2 + y^2 \leq 1$  and  $y \geq x$ .  $\square$

In the following exercise, we will also apply our knowledge of the theory of Fourier transforms from the previous chapter.

**8.I.34. Fourier transform and diffraction.** Light intensity is a physical quantity which expresses the transmission of energy by waves. The intensity of a general light wave is defined as the time-averaged magnitude of the Poynting vector, which is the vector product of mutually orthogonal vectors of electric and magnetic fields. A monochromatic plane wave spreading in the direction of the  $y$ -axis satisfies

$$I = c\varepsilon_0 \frac{1}{\tau} \int_0^\tau E_y^2 dt,$$

where  $c$  is the speed of light and  $\varepsilon_0$  is the vacuum permittivity. The monochromatic wave is described by the harmonic function  $E_y = \psi(x, t) = A \cos(\omega t - kx)$ . The number  $A$  is the maximal amplitude of the wave,  $\omega$  is the angular frequency, and for any fixed  $t$ , the so-called wave length  $\lambda$  is the prime period. The number  $k$  then represents the speed  $k = \frac{2\pi}{\lambda}$  at which the wave propagates. We have

$$\begin{aligned} I &= c\varepsilon_0 \frac{1}{\tau} \int_0^\tau E_y^2 dt = c\varepsilon_0 \frac{1}{\tau} \int_0^\tau A^2 \cos^2(\omega t - kx) dt \\ &= c\varepsilon_0 A^2 \frac{1}{\tau} \int_0^\tau \frac{1 + \cos(2(\omega t - kx))}{2} dt \\ &= \frac{1}{2} c\varepsilon_0 A^2 \frac{1}{\tau} \left[ t + \frac{\sin(2(\omega t - kx))}{2\omega} \right]_0^\tau \\ &= \frac{1}{2} c\varepsilon_0 A^2 \frac{1}{\tau} \left( \tau + \frac{\sin(2(\omega\tau - kx)) - \sin(2(-kx))}{2\omega} \right) \\ &= \frac{1}{2} c\varepsilon_0 A^2 \left( 1 + \frac{\sin(2(\omega\tau - kx)) - \sin(2(-kx))}{2\omega\tau} \right) \\ &\doteq \frac{1}{2} c\varepsilon_0 A^2 \end{aligned}$$

The second term in the parentheses can be neglected since it is always less than  $\frac{2}{2\omega\tau} = \frac{T}{2\pi\tau} < 10^{-6}$  for real detectors of light, so it is much inferior to 1. The light intensity is directly proportional to the squared amplitude.

A diffraction is such a deviation from straight-line propagation of light which cannot be explained as the result of a refraction or reflection (or the change of the ray's direction in a medium with continuously varying refractive index). The diffraction can be observed when a lightbeam propagates through a bounded space. The diffraction phenomena are strongest and easiest to see if the light goes through openings or obstacles whose size is roughly the wavelength of the light. In the case of the Fraunhofer diffraction, with which we will deal in the following example, a monochromatic plane wave goes through a very thin rectangular opening and projects on

$I = [a_1, b_1] \times \dots \times [a_n, b_n]$  and  $x = \Psi(y)$  for the transformation. In the first case (notice we can deal with the first variable and  $\alpha > 0$  without loss of generality),

$$\begin{aligned} |\det \Psi| \int_I f(\alpha y_1, y_2, \dots, y_n) dy_1 \dots dy_n &= \\ &= \alpha \int_{a_n}^{b_n} \dots \left( \int_{a_1}^{b_1} f(\alpha y_1, y_2, \dots, y_n) dy_1 \right) \dots dy_n \\ &= \alpha \alpha^{-1} \int_{a_n}^{b_n} \dots \left( \int_{\alpha a_1}^{\alpha b_1} f(x_1, x_2, \dots, x_n) dx_1 \right) \dots dx_n \\ &= \int_{\Psi(I)} f(x_1, x_2, \dots, x_n) dx_1 \dots dx_n. \end{aligned}$$

The second case is even easier, since the order of integration does not matter due to the Fubini theorem. The third case is similar to the first one:

$$\begin{aligned} |\det \Psi| \int_I f(y_1 + y_2, y_2, \dots, y_n) dy_1 \dots dy_n &= \\ &= \int_{a_n}^{b_n} \dots \left( \int_{a_1}^{b_1} f(y_1 + y_2, y_2, \dots, y_n) dy_1 \right) \dots dy_n \\ &= \int_{a_n}^{b_n} \dots \left( \int_{a_1 + x_2}^{b_1 + x_2} f(x_1, x_2, \dots, x_n) dx_1 \right) \dots dx_n \\ &= \int_{\Psi(I)} f(x_1, x_2, \dots, x_n) dx_1 \dots dx_n. \end{aligned}$$

The reader should check the details that the last multiple integral describes the image  $\Psi(I)$ .  $\square$

As a direct corollary of the proposition, the Riemann integral is invariant with respect to the Euclidean affine mappings. That is, the integral cannot depend on the choice of the orthogonal frame in the Euclidean  $\mathbb{R}^n$ .

**8.2.10. Riemann-measurable sets.** It is necessary to understand how to recognize Riemann-measurable domains  $M$ .

When defining the Riemann integral, a strict analogy of the lower and upper Riemann integrals for univariate functions can be considered. This means taking infima or suprema of the integrated function over the corresponding multidimensional intervals instead of the function values at the representatives in the Riemann sums. For bounded functions, there are well-defined values of the upper and lower integrals found in this way. If this is done for the indicator function  $\chi_M$  of a fixed set  $M$ , the *inner and outer Riemann measure* of the set  $M$  is obtained. Evidently, the inner measure is the supremum of the areas given by the (finite) sums of the volumes of all multi-dimensional intervals from the partitions which are inside  $M$ , and on the other hand, the outer measure is the infimum of the (finite) sums of the volumes of intervals covering  $M$ . It follows directly from the definition that a set  $M$  is *Riemann-measurable* if and only if its inner and outer measures are equal.

The sets whose outer measure is zero are, of course, Riemann-measurable. They are called *measure zero sets* or null sets. The finite additivity of the Riemann integral makes

a distant surface. For instance, we can highlight a spot on the wall with a laser pointer. The image we get is the Fourier transform of the function describing the permeability of the shade - opening.

Let us choose the plane of the diffraction shade as the coordinate plane  $z = 0$ . Let a plane wave  $A \exp(ikz)$  (independent of the point  $(x, y)$  of landing on the shade) hit this plane perpendicularly. Let  $s(x, y)$  denote the function of the permeability of the shade, then the resulting waves falling onto the projection surface at a point  $(\xi, \eta)$  can be described as the integral sum of the waves (Huygens-Fresnel principle) which have gone through the shade and propagate through the medium from all points  $(x, y, 0)$  (as a spherical wave) into the point  $(\xi, \eta, z)$ :

$$\begin{aligned} \psi(\xi, \eta) &= A \iint_{\mathbb{R}^2} s(x, y) e^{-ik(\xi x + \eta y)} dx dy \\ \psi(\xi, \eta) &= A \int_{-p/2}^{p/2} \int_{-q/2}^{q/2} e^{-ik(\xi x + \eta y)} dy dx \\ \psi(\xi, \eta) &= A \int_{-p/2}^{p/2} e^{-ik\xi x} dx \int_{-q/2}^{q/2} e^{-ik\eta y} dy \\ &= A \left[ \frac{e^{-ik\xi x}}{-ik\xi} \right]_{-p/2}^{p/2} \left[ \frac{e^{-ik\eta y}}{-ik\eta} \right]_{-q/2}^{q/2} \\ &= A \frac{2 \sin(k \xi p/2)}{k\xi} \frac{2 \sin(k \eta q/2)}{k\eta} \\ &= Apq \frac{\sin(k \xi p/2)}{k\xi p/2} \frac{\sin(k \eta q/2)}{k\eta q/2} \end{aligned}$$

The graph of the function  $f(x) = \frac{\sin x}{x}$  looks as follows:

The graph of the function  $\psi(\xi, \eta) = \frac{\sin \xi}{\xi} \frac{\sin \eta}{\eta}$  then does:

the measure finitely additive. Hence, a disjoint union of finitely many measurable sets is again a measurable set, and its measure is given by the sum of the measures of the individual sets in the union.

Consider the measurability of any given set  $M \subset I \subset \mathbb{R}^n$  inside a sufficiently large multidimensional interval  $I$ . Consider the boundary  $\partial M$ , i.e. the set of all boundary points of  $M$ . For any partition  $\Xi$  of  $I$  from the definition of the Riemann integral of  $\chi_M$ , each of the intervals  $I_{i_1 \dots i_n}$  with non-trivial intersection with  $\partial M$  contributes to the upper integral but might not contribute to the lower integral. On the contrary, for every point in the interior  $M_o \subset M$  its interval  $I_{i_1 \dots i_n}$  contributes to both the same way as soon as the norm of the partition is small enough. This observation leads to the first part of the following claim:

**Proposition.** *A bounded set  $M \subset \mathbb{R}^n$  is Riemann-measurable if and only if its boundary is of Riemann-measure zero.*

*If  $M$  is a Riemann-measurable set and  $G : M \subset \mathbb{R}^n \rightarrow \mathbb{R}^n$  is a continuously differentiable and invertible mapping, then  $G(M)$  is again Riemann-measurable.*

**PROOF.** The first claim is already verified. Since both  $G$  and  $G^{-1}$  are continuous,  $G$  maps internal points of  $M$  to internal points of  $G(M)$ . To finish the proof, it must be verified that  $G$  maps the boundary  $\partial M$ , which is a set of measure zero, again to a set of measure zero.

Since every Riemann integrable set  $M$  is bounded, its closure  $\bar{M}$  must be compact. It follows that  $G$  and all partial derivatives of its components are uniformly continuous on  $\bar{M}$ , and in particular on the boundary  $\partial M$ .

Next, consider a partition  $\Xi$  of an interval  $I$  containing  $\partial M$  and a fixed tiny interval  $J$  in the partition including a point  $t \in \partial M$ . Write  $R = G(t) + D^1G(t)(J - t)$ , which is to be understood as follows:  $J$  is first shifted to the origin by translation, then the derivative of  $G$  is applied obtaining a parallelepiped. This is shifted back to be around  $G(t)$ . By the uniform continuity of  $G$  and  $D^1G$ , for each  $\varepsilon > 0$  there is a bound  $\delta$  for the norm of a partition for which

$$G(J) \subset G(t) + (1 + \varepsilon)D^1G(t)(J - t)$$

can be guaranteed. The entire image of  $J$  lies inside a slightly enlarged linear image of  $J$  by the derivative. Now, the outer measure  $\alpha$  of the image  $G(J)$  satisfies:

$$\alpha \leq (1 + \varepsilon)^n \text{vol}_n R = (1 + \varepsilon)^n |\det G(t)| \text{vol}_n J.$$

If  $\mu$  is the upper Riemann sum for the measure of  $\partial M$  corresponding to the chosen partition, the outer measure of  $G(\partial M)$  must be bounded by  $(1 + \varepsilon)^n \max_{t \in \partial M} |\det G(t)| \mu$ . Finally, we exploit the assumption that  $\partial M$  has got measure zero and thus, for the same  $\varepsilon$  we may further decrease the bound on the norm of the partition so that  $\mu \leq \varepsilon$ , too. But then the outer measure is bounded by a constant multiple of  $(1 + \varepsilon)^n \varepsilon$ , with the universal constant  $\max_{t \in \partial M} |\det G(t)|$ . So the outer measure is zero, as required.  $\square$

And the diffraction we are describing:

Since  $\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1$ , the intensity at the middle of the image is directly proportional to  $I_0 = A^2 p^2 q^2$ . The Fourier transform can be easily scrutinized if we aim a laser pointer through a subtle opening between the thumb and the index finger; it will be the image of the function of its permeability. The image of the last picture can be seen if we create a good rectangular opening by, for instance, gluing together some stickers with sharp edges.

### J. First-order differential equations

**8.J.1.** Find all solutions of the differential equation

$$y' = \frac{\sqrt{1-y^2}}{\cos^2 x} (1 + \cos^2 x).$$

**Solution.** We are given an ordinary first-order differential equation in the form  $y' = f(x, y)$ , which is called an explicit form of the equation. Moreover, we can write it as  $y' = f_1(x) \cdot f_2(y)$  for continuous univariate functions  $f_1$  and  $f_2$  (on certain open intervals), i. e., it is a differential equation with separated variables.

First, we replace  $y'$  with  $dy/dx$  and rewrite the differential equation in the form

$$\frac{1}{\sqrt{1-y^2}} dy = \frac{1+\cos^2 x}{\cos^2 x} dx.$$

Since

$$\int \frac{1+\cos^2 x}{\cos^2 x} dx = \int \frac{1}{\cos^2 x} + 1 dx,$$

we can integrate using the basic formulae, thereby obtaining

$$(1) \quad \arcsin y = \operatorname{tg} x + x + C, \quad C \in \mathbb{R}.$$

However, we must keep in mind that the division by the expression  $\sqrt{1-y^2}$  is valid only if it is non-zero, i. e., only for  $y \neq \pm 1$ . Substituting the constant functions  $y \equiv 1$ ,  $y \equiv -1$  into the given differential equation, we can immediately see that they satisfy it. We have thus obtained two more solutions, which are called singular. We do not have to pay attention to the case  $\cos x = 0$  since this only loses points of the domains (but not any solutions).

Now, we will comment on several parts of the computation. The expression  $y' = dy/dx$  allows us to make many symbolic manipulations. For instance, we have

A slightly extended argumentation as in the proof above leads to understanding that the Riemann integrable functions are exactly those bounded functions with compact support whose set of discontinuity points has (Riemann) measure zero.

**8.2.11. Proof of Theorem 8.2.8.** A continuous function  $f$  and a differentiable change of coordinates is under consideration. So the inverse  $G^{-1}$  is continuously differentiable, and the image  $G^{-1}(M) = N$  is Riemann-measurable. Hence the integrals on both sides of the equality exist and it remains to prove that their values are equal.

Denote a composite continuous function by

$$g(t_1, \dots, t_n) = f(G(t_1, \dots, t_n)),$$

and choose a sufficiently large  $n$ -dimensional interval  $I$  containing  $N$  and its partition  $\Xi$ . The entire proof is nothing more than a more exact writing of the discussion presented before the formulation of the theorem.

Repeat the estimates on the volumes of images from the previous paragraph on Riemann measurability. It is already known that the images  $G(I_{i_1 \dots i_n})$  of the intervals from the partition are again Riemann-measurable sets. For each small part  $I_{i_1 \dots i_n}$  of the partition  $\Xi$ , the integral of  $f$  over  $J_{i_1 \dots i_n} = G(I_{i_1 \dots i_n})$  certainly exists, too.

Further, if the center  $t_{i_1 \dots i_n}$  of the interval  $I_{i_1 \dots i_n}$  is fixed, then the linear image of this interval

$$R_{i_1 \dots i_n} = G(t_{i_1 \dots i_n}) + D^1 G(t_{i_1 \dots i_n})(I_{i_1 \dots i_n} - t_{i_1 \dots i_n}),$$

is obtained. This is an  $n$ -dimensional parallelepiped (note that the interval is shifted to the origin, then mapped by the linear mapping given by the Jacobi matrix, and the result is then added to the image of the center).

If the partition is very fine, this parallelepiped differs only a little from the image  $J_{i_1 \dots i_n}$ . By the uniform continuity of the mapping  $G$ , there is, for an arbitrarily small  $\varepsilon > 0$ , a norm of the partition such that for all finer partitions

$$G(t_{i_1 \dots i_n}) + (1 + \varepsilon)D^1 G(t_{i_1 \dots i_n})(I_{i_1 \dots i_n}) \supset J_{i_1 \dots i_n}.$$

However, then the  $n$ -dimensional volumes also satisfy

$$\begin{aligned} \operatorname{vol}_n(J_{i_1 \dots i_n}) &\leq (1 + \varepsilon)^n \operatorname{vol}_n(R_{i_1 \dots i_n}) \\ &= (1 + \varepsilon)^n |\det G(t_{i_1 \dots i_n})| \operatorname{vol}_n(I_{i_1 \dots i_n}). \end{aligned}$$

Now, it is possible to estimate the entire integral:

$$\begin{aligned} \int_M f(x_1, \dots, x_n) dx_1 \dots dx_n &= \\ &= \sum_{i_1 \dots i_n} \int_{J_{i_1 \dots i_n}} f(x_1, \dots, x_n) dx_1 \dots dx_n \\ &\leq \sum_{i_1 \dots i_n} \left( \sup_{t \in I_{i_1 \dots i_n}} g(t) \right) \operatorname{vol}_n(J_{i_1 \dots i_n}) \\ &\leq (1 + \varepsilon)^n \sum_{i_1 \dots i_n} \left( \sup_{t \in I_{i_1 \dots i_n}} g(t) \right) |\det G(t_{i_1 \dots i_n})| \operatorname{vol}_n(I_{i_1 \dots i_n}). \end{aligned}$$

If  $\varepsilon$  approaches zero, then the norms of the partitions approach zero too, the left-hand value of the integral remains the same, while on the right-hand side, the Riemann integral

$$\frac{dz}{dy} \cdot \frac{dy}{dx} = \frac{dz}{dx}, \quad \frac{1}{\frac{dy}{dx}} = \frac{dx}{dy}.$$

The validity of these two formulae is actually guaranteed by the chain rule theorem and the theorem for differentiating an inverse function, respectively. It was just the facility of the manipulations that inspired G. W. Leibniz to introduce this notation, which has been in use up to now. Further, we should realize why we have not written the general solution (1) in the suggesting form

$$(2) \quad y = \sin(\operatorname{tg} x + x + C), \quad C \in \mathbb{R}.$$

As we will not mention the domains of differential equations (i. e., for which values of  $x$  the expressions are well-defined), we will not change them by “redundant” simplifications, either. It is apparent that the function  $y$  from (2) is defined for all  $x \in (0, \pi) \setminus \{\pi/2\}$ . However, for the values of  $x$  which are close to  $\pi/2$  (having fixed  $C$ ), there is no  $y$  satisfying (1). In general, the solutions of differential equations are curves which may not be expressible as graphs of elementary functions (on the whole intervals where we consider them). Therefore, we will not even try to do that.  $\square$

**8.J.2.** Find the general solution of the equation  $y' = (2 - y) \operatorname{tg} x$ .

**Solution.** Again, we are given a differential equation with separated variables.

We have

$$\begin{aligned} \frac{dy}{dx} &= (2 - y) \operatorname{tg} x, \\ -\frac{dy}{y - 2} &= \frac{\sin x}{\cos x} dx, \\ -\ln|y - 2| &= -\ln|\cos x| - \ln|C|, \quad C \neq 0. \end{aligned}$$

Here, the shift obtained from the integration has been expressed by  $\ln|C|$ , which is very advantageous (bearing in mind what we want to do next) especially in those cases when we obtain a logarithm on both sides of the equation. Further, we have

$$\begin{aligned} \ln|y - 2| &= \ln|C \cos x|, \quad C \neq 0, \\ |y - 2| &= |C \cos x|, \quad C \neq 0, \\ y - 2 &= C \cos x, \quad C \neq 0, \end{aligned}$$

where we should write  $\pm C$  (after removing the absolute value). However, since we consider all non-zero values of  $C$ , it makes no difference whether we write  $+C$  or  $-C$ . We should pay attention to the fact that we have made a division by the expression  $y - 2$ . Therefore, we must examine the case  $y \equiv 2$  separately. The derivative of a constant function is zero, so we have found another solution,  $y \equiv 2$ . However, this solution is not singular since it is contained in the general solution as the case  $C = 0$ . Thus, the correct result is

$$y = 2 + C \cos x, \quad C \in \mathbb{R}. \quad \square$$

of  $g(t)|\det G(t)|$  is obtained. Instead of the desired equality, the inequality:

$$\int_M f(x) dx_1 \dots dx_n \leq \int_N f(G(t)) |\det(D^1 G(t))| dt_1 \dots dt_n$$

is obtained.

The same reasoning can be repeated after interchanging  $G$  and  $G^{-1}$ , the integration domains  $M$  and  $N$ , and the functions  $f$  and  $g$ . The reverse inequality is immediately obtained:

$$\begin{aligned} &\int_N g(t) |\det(D^1 G(t))| dt_1 \dots dt_n \\ &\leq \int_M f(x) |\det(D^1 G(G^{-1}(x)))| \\ &\quad |\det(D^1 G^{-1}(x))| dx_1 \dots dx_n \\ &= \int_M f(x) dx_1 \dots dx_n. \end{aligned}$$

The proof is complete.

**8.2.12. An example in two dimensions.** The coordinate transformations are quite transparent for the integral of a continuous function  $f(x, y)$  of two variables. Consider the differentiable transformation  $G(s, t) = (x(s, t), y(s, t))$ . Denoting  $g(s, t) = f(x(s, t), y(s, t))$ ,

$$\int_{G(N)} f(x, y) dx dy = \int_N g(s, t) \left| \frac{\partial x}{\partial s} \frac{\partial y}{\partial t} - \frac{\partial x}{\partial t} \frac{\partial y}{\partial s} \right| ds dt$$

is obtained.

As a truly simple example, calculate the integral of the indicator function of a disc with radius  $R$  (i.e. its area) and the integral of the function  $f(t, \theta) = \cos t$  defined in polar coordinates inside a circle with radius  $\frac{1}{2}\pi$  (i.e. the volume hidden under such a “cap placed above the origin”, see the illustration).

First, determine the Jacobi matrix of the transformation  $x = r \cos \theta, y = r \sin \theta$

$$D^1 G = \begin{pmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{pmatrix}.$$

Hence, the determinant of this matrix is equal to

$$\det D^1 G(r, \theta) = r(\sin^2 \theta + \cos^2 \theta) = r.$$

**8.J.3.** Find the solution of the differential equation

$$(1 + e^x)yy' = e^x$$

which satisfies the initial condition  $y(0) = 1$ .

**Solution.** If the functions  $f : (a, b) \rightarrow \mathbb{R}$  and  $g : (c, d) \rightarrow \mathbb{R}$  are continuous and  $g(y) \neq 0$ ,  $y \in (c, d)$ , then the initial problem

$$y' = f(x)g(y), \quad y(x_0) = y_0$$

has a unique solution for any  $x_0 \in (a, b)$ ,  $y_0 \in (c, d)$ . This solution is determined implicitly as

$$\int_{y_0}^{y(x)} \frac{dt}{g(t)} = \int_{x_0}^x f(t) dt.$$

In practical problems, we first find all solutions of the equation and then select the one which satisfies the initial condition.

Let us compute:

$$(1 + e^x)y dy/dx = e^x,$$

$$y dy = \frac{e^x}{1 + e^x} dx,$$

$$\frac{y^2}{2} = \ln(1 + e^x) + \ln|C|, \quad C \neq 0,$$

$$\frac{y^2}{2} = \ln(C[1 + e^x]), \quad C > 0.$$

The substitution  $y = 1$ ,  $x = 0$  then gives

$$\frac{1}{2} = \ln(C \cdot 2), \quad \text{i. e. } C = \frac{\sqrt{e}}{2}.$$

We have thus found the solution

$$\frac{y^2}{2} = \ln\left(\frac{\sqrt{e}}{2}[1 + e^x]\right),$$

i. e.,

$$y = \sqrt{2 \ln\left(\frac{\sqrt{e}}{2}[1 + e^x]\right)}$$

on a neighborhood of the point  $[0, 1]$  where  $y > 0$ . □

**8.J.4.** Find the solution of the differential equation

$$y' = \frac{y^2+1}{x+1}$$

which satisfies  $y(0) = 1$ .

**Solution.** Similarly to the previous example, we get

$$\frac{dy}{y^2+1} = \frac{dx}{x+1},$$

$$\arctan y = \ln|x+1| + C, \quad C \in \mathbb{R}.$$

The initial condition (i. e., the substitution  $x = 0$  and  $y = 1$ ) gives

$$\arctan 1 = \ln|1| + C, \quad \text{i. e., } C = \frac{\pi}{4}.$$

Therefore, the solution of the given initial problem is the function

$$y(x) = \text{tg}\left(\ln|x+1| + \frac{\pi}{4}\right)$$

on a neighborhood of the point  $[0, 1]$ . □

Therefore, the calculation can be done directly for the disc  $S$  which is the image of the rectangle  $(r, \theta) \in [0, R] \times [0, 2\pi] = T$ . In this way the area of the disc is obtained:

$$\int_S dx dy = \int_0^{2\pi} \int_0^R r dr d\theta = \int_0^R 2\pi r dr = \pi R^2.$$

The integration of the function  $f$  is very similar, using multiple integration and integration by parts:

$$\int_S f(x, y) dx dy = \int_0^{2\pi} \int_0^{\pi/2} r \cos r dr d\theta = \pi^2 - 2\pi.$$

In many real life applications, a much more general approach to integration is needed which allows for the dealing with objects over curves, surfaces, and their higher dimensional analogues. For many simple cases, such tools can be built now with the help of parametrization of such  $k$ -dimensional surfaces and employ the letter theorem to show the independence of the result on such a parametrization. These topics are postponed to the beginning of the next chapter where a more general and geometric approach is discussed, see e.g. 9.1.9 and 9.1.12.

### 3. Differential equations

In this section, we return to (vector) functions of one variable, defined and examined in terms of their instantaneous changes.

**8.3.1. Linear and non-linear difference models.** The concept of derivative was introduced in order to work with instantaneous changes of the examined quantities. In the introductory chapter, difference equations based on similar concepts in relation to sequences of scalars were discussed. As a motivating introduction to equations containing derivatives of unknown functions, recall first the difference equations.

The simplest difference equations are formulated as  $y_{n+1} = F(y_n, n)$ , with a function  $F$  of two variables. For example, the model describing interests of deposits or loans (this included the Malthusian model of populations) was considered. The increment was proportional to the value,  $y_{n+1} = a y_n$ , see 1.2.2. Growths by 5% is represented by  $a = 1.05$ . Considering continuous modeling, the same request leads to an equation connecting the derivative  $y'(t)$  of a function with its value

(1) 
$$y'(t) = r y(t)$$

with the proportionality constant  $r$ . Here, the instantaneous growth by 5% corresponds to  $r = 0.05$ .

It is easy to guess the *solution* of the latter equation, i.e. a function  $y(t)$  which satisfies the equality identically,

$$y(t) = C e^{rt}$$

with an arbitrary constant  $C$ . This constant can be determined uniquely by choosing the *initial value*  $y_0 = y(t_0)$  at some point  $t_0$ . If a part of the increment in a model should be given as a constant independent of the value  $y$  or  $t$  (like bank charges

**8.J.5.** Solve

$$(1) \quad y' = \frac{x + y + 1}{2x + 2y - 1}.$$

**Solution.** Let a function  $f : (a, b) \times (c, d) \rightarrow \mathbb{R}$  have continuous second-order partial derivatives and  $f(x, y) \neq 0$ ,  $x \in (a, b)$ ,  $y \in (c, d)$ . Then, the differential equation  $y' = f(x, y)$  can be transformed to an equation with separated variables if and only if

$$\begin{vmatrix} f(x, y) & f'_y(x, y) \\ f'_x(x, y) & f''_{xy}(x, y) \end{vmatrix} = 0, \quad x \in (a, b), y \in (c, d).$$

With a bit of effort, it can be shown that a differential equation of the form  $y' = f(ax + by + c)$  can be transformed to an equation with separated variables, and this can be done by the substitution  $z = ax + by + c$ . Let us emphasize that the variable  $z$  replaces  $y$ .

We thus set  $z = x + y$ , which gives  $z' = 1 + y'$ . Substitution into (1) yields

$$\begin{aligned} z' - 1 &= \frac{z + 1}{2z - 1}, \\ \frac{dz}{dx} &= \frac{z + 1}{2z - 1} + 1, \\ \frac{dz}{dx} &= \frac{3z}{2z - 1}, \\ \left(\frac{2}{3} - \frac{1}{3z}\right) dz &= 1 dx, \\ \frac{2}{3} z - \frac{1}{3} \ln |z| &= x + C, \quad C \in \mathbb{R}, \end{aligned}$$

or

$$\frac{2}{3} z - \frac{1}{3} \ln |Cz| = x, \quad C \neq 0.$$

Now, we must get back to the original variable  $y$  in one of these forms. The general solution can be written as

$$\frac{2}{3} x + \frac{2}{3} y - \frac{1}{3} \ln |x + y| = x + C, \quad C \in \mathbb{R},$$

i. e.,

$$x - 2y + \ln |x + y| = C, \quad C \in \mathbb{R}.$$

At the same time, we have the singular solution  $y = -x$ , which follows from the constraint  $z \neq 0$  of the operations we have made (we have divided by the value  $3z$ ).  $\square$

**8.J.6.** Solve the differential equation

$$xy' + y \ln x = y \ln y.$$

**Solution.** Using the substitution  $u = y/x$ , every homogeneous differential equation  $y' = f(y/x)$  can be transformed to an equation (with separated variables)

$$u' = \frac{1}{x} (f(u) - u), \quad \text{i. e.} \quad u'x + u = f(u).$$

The name of this differential equation is comes from the following definition. A function  $f$  of two variables is called homogeneous of degree  $k$  iff  $f(tx, ty) = t^k f(x, y)$ . Then, a differential equation of the form

$$P(x, y) dx + Q(x, y) dy = 0$$

or the natural decrease of stock population as a result of sending some part of it to slaughterhouses), an equation can be used with a constant  $s$  on the right-hand side.

$$(2) \quad y'(t) = r \cdot y(t) + s.$$

The solution of this equation is the function

$$y(t) = C e^{rt} - \frac{s}{r}.$$

It is a straightforward matter to produce this solution when it is realized that the set of all solutions of the equation (1) is a one-dimensional vector space, while the solutions of the equation (2) are obtained by adding any one of its solutions to the solutions of the previous equation. The constant solution  $y(t) = k$  for  $k = -\frac{s}{r}$  is easily found.

Similarly, in paragraph 1.4.1, the *logistic model* of population growth was created. Based on the assumption that the ratio of the change of the population size  $p(n + 1) - p(n)$  and its size  $p(n)$  is affine with respect to the population size itself. The model behaves similar as the Malthusian one for small values of the population size and to cease growing when reaching a limit value  $K$ . Now, the same relation for the continuous model can be formulated for a population  $p(t)$  dependent on time  $t$  by the equality

$$(3) \quad p'(t) = p(t) \left( -\frac{r}{K} p(t) + r \right).$$

At the value  $p(t) = K$  for a (large) constant  $K$ , the instantaneous increment of the function  $p$  is zero, while for  $p(t) > 0$  near zero, the ratio of the rate of increment of the population and its size is close to  $r$ , which is the (small) number expressing the rate of increment of the population in good conditions (e.g. 0.05 would again mean immediate growth by 5%).

It is not easy to solve such an equation without knowing any theory (although this type of equations will be dealt with in a moment). However, as an exercise on differentiation, it is easily verified that the following function is a solution for every constant  $C$ :

$$p(t) = \frac{K}{1 + CK e^{-rt}}.$$

For the continuous and discrete versions of the logistic models, the values  $K = 100$ ,  $r = 0.05$ , and  $C = 1$  in the left hand illustration are chosen. The same 1.4.1 result occurs in the right hand illustration (i.e. with  $a = 1.05$  and  $p_1 = 1$ , as expected). The choice  $C = 1$  yields  $p(0) = K/(1 + K)$  which is very close to 1 if  $K$  is large enough.

is a homogeneous differential equation iff the functions  $P$  and  $Q$  are homogeneous of the same degree  $k$ .

For instance, we can discover that the given equation

$$x dy + (y \ln x - y \ln y) dx = 0$$

is homogeneous. Of course, it is not difficult to write it explicitly in the form

$$y' = \frac{y}{x} \ln \frac{y}{x}.$$

The substitution  $u = y/x$  then leads to

$$\begin{aligned} u'x + u &= u \ln u, \\ \frac{du}{dx} x &= u (\ln u - 1), \\ \frac{du}{u (\ln u - 1)} &= \frac{dx}{x}, \end{aligned}$$

where  $u (\ln u - 1) \neq 0$ . Using another substitution, namely  $t = \ln u - 1$ , we can integrate

$$\begin{aligned} \int \frac{du}{u (\ln u - 1)} &= \int \frac{dx}{x}, \\ \int \frac{dt}{t} &= \int \frac{dx}{x}, \\ \ln |t| &= \ln |x| + \ln |C|, \quad C \neq 0, \\ \ln |\ln u - 1| &= \ln |Cx|, \quad C \neq 0, \\ \ln u - 1 &= Cx, \quad C \neq 0, \\ \ln \frac{y}{x} &= Cx + 1, \quad C \neq 0, \\ y &= xe^{Cx+1}, \quad C \neq 0. \end{aligned}$$

The excluded cases  $u = 0$  and  $\ln u = 1$  do not lead to two more solutions since  $u = 0$  implies  $y = 0$ , which cannot be put into the original equation. On the other hand,  $\ln u = 1$  gives  $y/x = e$ , and the function  $y = ex$  is clearly a solution. Therefore, the general solution is

$$y = xe^{Cx+1}, \quad C \in \mathbb{R}.$$

□

**8.J.7.** Compute

$$y' = -\frac{4x+3y+1}{3x+2y+1}.$$

**Solution.** In general, we are able to solve every equation of the form

$$(1) \quad y' = f\left(\frac{ax + by + c}{Ax + By + C}\right).$$

If the system of linear equations

$$(2) \quad ax + by + c = 0, \quad Ax + By + C = 0$$

has a unique solution  $x_0, y_0$ , then the substitution  $u = x - x_0$ ,  $v = y - y_0$  transforms the equation (1) to a homogeneous equation

$$\frac{dv}{du} = f\left(\frac{au + bv}{Au + Bv}\right).$$

In particular, both versions of this logistic model yield quite similar results. For example, the left hand illustration also contains the dashed line of the graph of the solution of the equation (1) with the same constant  $r$  and initial condition (i.e. the Malthusian model of growth).

**8.3.2. First-order differential equations.** By an (ordinary) first-order differential equation, is usually meant the relation between the derivative  $y'(t)$  of a function with respect to the variable  $t$ , its value  $y(t)$ , and the variable itself, which can be written in terms of some real-valued function  $F : \mathbb{R}^3 \rightarrow \mathbb{R}$  as the equality

$$F(y'(t), y(t), t) = 0.$$

This equation resembles the implicitly defined functions  $y(t)$ ; however, this time there is a dependency on the derivative of the function  $y(t)$ . We also often suppress the dependence of  $y = y(t)$  on the other variable  $t$  and write  $F(y', y, t) = 0$  instead.

If the implicit equation is solved at least explicitly with regard to the derivative, i.e.

$$y' = f(t, y)$$

for some function  $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ , it is clear graphically what this equation defines. For every value  $(t, y)$  in the plane, the arrow corresponding to the vector  $(1, f(t, y))$ , can be considered. That is the velocity with which the point of the graph of the solution moves through the plane, depending on the free parameter  $t$ .

For instance, the equation (3) in the previous subsection determines the following: (illustrating the solution for the initial condition as above).

Such illustrations should invoke the idea that differential equations define a “flow” in the plane, and each choice of the initial value  $(t_0, y(t_0))$  should correspond to a unique flow-line expressing the movement of the initial point in the time  $t$ . It can be anticipated intuitively that for reasonably behaved functions  $f(t, y)$  in the equations  $y' = f(t, y)$ , there is a unique solution for all initial conditions.

If the system (2) has no solution or has infinitely many solutions, the substitution  $z = ax + by$  transforms the equation (1) to an equation with separated variables (often, the original equation is already such).

In this problem, the corresponding system of equations

$$4x + 3y + 1 = 0, \quad 3x + 2y + 1 = 0$$

has a unique solution  $x_0 = -1, y_0 = 1$ . The substitution  $u = x+1, v = y-1$  then leads to the homogeneous equation

$$\frac{dv}{du} = -\frac{4u+3v}{3u+2v},$$

which can be solved by further substitution  $z = v/u$ . We thus obtain

$$\begin{aligned} z'u + z &= -\frac{4 + 3z}{3 + 2z}, \\ \frac{dz}{du} u &= -\frac{2z^2 + 6z + 4}{3 + 2z}, \\ \frac{2z + 3}{2z^2 + 6z + 4} dz &= -\frac{du}{u} \end{aligned}$$

provided  $z^2 + 3z + 2 \neq 0$ . Integrating, we get

$$\begin{aligned} \frac{1}{2} \ln |z^2 + 3z + 2| &= -\ln |u| + \ln |C|, \quad C \neq 0, \\ \frac{1}{2} \ln |(z^2 + 3z + 2) u^2| &= \ln |C|, \quad C \neq 0, \\ \ln |(z^2 + 3z + 2) u^2| &= \ln C^2, \quad C \neq 0, \\ (z^2 + 3z + 2) u^2 &= \pm C^2, \quad C \neq 0. \end{aligned}$$

We thus have

$$(z^2 + 3z + 2) u^2 = D, \quad D \neq 0$$

and returning to the original variables,

$$\begin{aligned} \left(\frac{v^2}{u^2} + 3\frac{v}{u} + 2\right) u^2 &= D, \quad D \neq 0, \\ v^2 + 3vu + 2u^2 &= D, \quad D \neq 0, \\ (y - 1)^2 + 3(y - 1)(x + 1) + 2(x + 1)^2 &= D, \quad D \neq 0. \end{aligned}$$

Making simple rearrangements, the general solution can be expressed as

$$(x + y)(2x + y + 1) = D, \quad D \neq 0.$$

Now, let us return to the condition  $z^2 + 3z + 2 \neq 0$ . It follows from  $z^2 + 3z + 2 = 0$  that  $z = -1$  or  $z = -2$ , i. e.,  $v = -u$  or  $v = -2u$ . For  $v = -u$ , we have  $x = u - 1$  and  $y = v + 1 = -u + 1$ , which means that  $y = -x$ . Similarly, for  $v = -2u$ , we have  $y = -2u + 1$ , hence  $y = -2x - 1$ . However, both functions  $y = -x, y = -2x - 1$  satisfy the original differential equations and are included in the general solution for the choice  $D = 0$ . Therefore, every solution is known from the implicit form

$$(x + y)(2x + y + 1) = D, \quad D \in \mathbb{R}.$$

**8.3.3. Integration of differential equations.** Before examining the conditions for existence and uniqueness of the solutions, we present a truly elementary method for finding the solutions. The idea, mentioned briefly already in 6.2.21 on page 552, is to transform the problem to ordinary integration, which usually leads to an implicit description of the solution.

EQUATIONS WITH SEPARATED VARIABLES

Consider a differential equation in the form

$$(1) \quad y' = f(t) \cdot g(y)$$

for two continuous functions of a real variable,  $f$  and  $g$ .

The solution of this equation can be obtained by integration, finding the antiderivatives

$$G(y) = \int \frac{dy}{g(y)}, \quad F(t) = \int f(t) dt.$$

This procedure reliably finds solutions  $y(t)$  which satisfy  $g(y(t)) \neq 0$ , given implicitly by the formula

$$(2) \quad F(t) + C = G(y)$$

with an arbitrary constant  $C$ .

Differentiating the latter equation (2) using the chain rule for the composite function  $G(y(t))$  leads to  $\frac{1}{g(y)} y'(t) = f(t)$ , as required.

As an example, find the solution of the equation

$$y' = t y.$$

Direct calculation gives  $\ln |y(t)| = \frac{1}{2} t^2 + C$  with arbitrary constant  $C$ . Hence it looks (at least for positive values of  $y$ ) as

$$y(t) = e^{\frac{1}{2} t^2 + C} = D e^{\frac{1}{2} t^2},$$

where  $D$  is an arbitrary positive constant. It is helpful to examine the resulting formula and signs thoroughly. The constant solution  $y(t) = 0$  also satisfies the equation. For negative values of  $y$ , the same solution can be used with negative constants  $D$ . In fact, the constant  $D$  can be arbitrary, and a solution is found satisfying any initial value.

The illustration shows two solutions which demonstrate the instability of the equation with regard to the initial values: For every  $t_0$ , if we change a small  $y_0$  from a negative value to a positive one, then the behaviour of the resulting solution changes dramatically. Notice the constant solution  $y(t) = 0$ , which satisfies the initial condition  $y(t_0) = 0$ .

□

**8.J.8.** Find the general solution of the differential equation

$$(x^2 + y^2) dx - 2xy dy = 0.$$

**Solution.** For  $y \neq 0$ , simple rearrangements lead to

$$y' = \frac{x^2 + y^2}{2xy} = \frac{1 + (\frac{y}{x})^2}{2\frac{y}{x}}.$$

Using the substitution  $u = y/x$ , we get to the equation

$$u'x + u = \frac{1+u^2}{2u}.$$

For  $u \neq \pm 1$  and  $D = -1/C$ , we have

$$\begin{aligned} \frac{du}{dx} x &= \frac{1 + u^2 - 2u^2}{2u}, \\ \frac{2u}{1 - u^2} du &= \frac{dx}{x}, \\ -\ln |1 - u^2| &= \ln |x| + \ln |C|, \quad C \neq 0, \\ \ln \frac{1}{|1 - u^2|} &= \ln |Cx|, \quad C \neq 0, \\ \frac{1}{1 - u^2} &= Cx, \quad C \neq 0, \\ 1 &= Cx \left(1 - \frac{y^2}{x^2}\right), \quad C \neq 0, \\ -\frac{D}{x} &= 1 - \frac{y^2}{x^2}, \quad D \neq 0, \\ -Dx &= x^2 - y^2, \quad D \neq 0. \end{aligned}$$

The condition  $u = \pm 1$  corresponds to  $y = \pm x$ . While  $y \equiv 0$  is not a solution, both the functions  $y = x$  and  $y = -x$  are solutions and can be obtained by the choice  $D = 0$ . The general solution is thus

$$y^2 = x^2 + Dx, \quad D \in \mathbb{R}. \quad \square$$

**8.J.9.** Solve

$$y' = x - \frac{2y}{x^2 - 1}.$$

**Solution.** The given equation is of the form  $y' = a(x)y + b(x)$ , i. e., a non-homogeneous linear differential equation (the function  $b$  is not identically equal to zero). The general solution of such an equation can be obtained using the method of integration factor (the non-homogeneous equation is multiplied by the expression  $e^{-\int a(x) dx}$ ) or the method of variable separation (the integration constant that arises in the solution of the corresponding homogeneous equations is considered to be a function in the variable  $x$ ). We will illustrate both of these methods on this problem.

As for the former method, we multiply the original equation by the expression

$$e^{\int \frac{2}{x^2-1} dx} = e^{\ln \left| \frac{x-1}{x+1} \right|} = \frac{x-1}{x+1},$$

where the corresponding integral is understood to stand for any antiderivative and where any non-zero multiple of the obtained function can be considered (that is why we could remove the absolute value). Thus, consider the equation

$$y' \frac{x-1}{x+1} + \frac{2y}{(x+1)^2} = \frac{x(x-1)}{x+1}.$$

The core of the method of integration factor is that fact that the expression on the left-hand side is the derivative of  $y \frac{x-1}{x+1}$ . Integrating this leads to

Using separation of variables, the non-linear equation is easily solved from the previous paragraph which describes the logistic population model. Try this as an exercise.

**8.3.4. First order linear equations.** In the first chapter, we

paid much attention to linear difference equations. Their general solution was determined in paragraph 1.2.2 on page 11. Although it is clear beforehand that it is a one-dimensional affine space of sequences, it is a hardly transparent sum, because all the changing coefficients need to be taken into account.

Consequently this can be used as a source of inspiration for the following construction of the solution of a general first-order linear equation

$$(1) \quad y' = a(t)y + b(t)$$

with continuous coefficients  $a(t)$  and  $b(t)$ .

First, find the solution of the homogeneous equation  $y' = a(t)y$ . This can be computed easily by separation of variables, obtaining the solution with  $y(s) = y_0$ ,

$$y(t) = y_0 F(t, t_0), \quad F(t, s) = e^{\int_s^t a(x) dx}.$$

In the case of difference equations, the solution of the general non-homogeneous equation was “guessed”. Then it was proved by induction that it was correct. It is even simpler now, as it suffices to differentiate the correct solution to verify the statement, once we are told what the right result is:

#### THE SOLUTION OF FIRST-ORDER LINEAR EQUATIONS

The solution of the equation (1) with initial values  $y(t_0) = y_0$  is (locally in a neighbourhood of  $t_0$ ) given by the formula

$$y(t) = y_0 F(t, t_0) + \int_{t_0}^t F(t, s) b(s) ds,$$

where  $F(t, s) = e^{\int_s^t a(x) dx}$ .

Verify the correctness of the solution by yourselves (pay proper attention to the differentiation of the integral where  $t$  is both in the upper bound and a free parameter in the integrand, cf. 6.3.13).

In fact, there is the general method called *variation of constants* which directly yields this solution, see e.g. the problem 8.J.9. It consists in taking the solution for the homogenous equation in the form  $y(t) = cF(t, t_0)$  and consider instead an ansatz for a solution to the non-homogeneous equation in the form  $y(t) = c(t)F(t, t_0)$  with an unknown function  $c(t)$ . Differentiating yields the equation  $c' = e^{-\int_{t_0}^t a(x) dx} b(t)$  and integrating this leads to  $c(t) = \int_{t_0}^t e^{\int_s^{t_0} a(x) dx} b(s) ds$ , i.e.  $y(t) = c(t) e^{\int_{t_0}^t a(x) dx}$  as in the above formula. Check the details!

Notice also the similarity to the solution for the equations with constant coefficients explicitly computed in the form of convolution in 7.B.13 on the page 663, which could serve as inspiration, too.

As an example, the equation

$$y' = 1 - xy,$$

$$y \frac{x-1}{x+1} = \int \frac{x(x-1)}{x+1} dx = \frac{x^2}{2} - 2x + 2 \ln|x+1| + C, \quad C \in \mathbb{R}.$$

Therefore, the solutions are the functions

$$y = \frac{x+1}{x-1} \left( \frac{x^2}{2} - 2x + 2 \ln|x+1| + C \right), \quad C \in \mathbb{R}.$$

As for the latter method, we first solve the corresponding homogeneous equation

$$y' = -\frac{2y}{x^2-1},$$

which is an equation with separated variables. We have

$$\begin{aligned} \frac{dy}{dx} &= -\frac{2y}{x^2-1}, \\ \frac{dy}{y} &= -\frac{2}{x^2-1} dx, \end{aligned}$$

$$\ln|y| = -\ln|x-1| + \ln|x+1| + \ln|C|, \quad C \neq 0,$$

$$\ln|y| = \ln \left| C \frac{x+1}{x-1} \right|, \quad C \neq 0,$$

$$y = C \frac{x+1}{x-1}, \quad C \neq 0,$$

where we had to exclude the case  $y = 0$ . However, the function  $y \equiv 0$  is always a solution of a homogeneous linear differential equation, and it can be included in the general solution. Therefore, the general solution of the corresponding homogeneous equation is

$$y = \frac{C(x+1)}{x-1}, \quad C \in \mathbb{R}.$$

Now, we will consider the constant  $C$  to be a function  $C(x)$ . Differentiating leads to

$$y' = \frac{C'(x)(x+1)(x-1) + C(x)(x-1) - C(x)(x+1)}{(x-1)^2}.$$

Substituting this into the original equation, we get

$$\frac{C'(x)(x+1)(x-1) + C(x)(x-1) - C(x)(x+1)}{(x-1)^2} = x - \frac{2C(x)(x+1)}{(x-1)(x^2-1)}.$$

It follows that

$$C'(x) = \frac{x(x-1)}{x+1},$$

i. e.,

$$C(x) = \int \frac{x(x-1)}{x+1} dx,$$

$$C(x) = \frac{x^2}{2} - 2x + 2 \ln|x+1| + C, \quad C \in \mathbb{R}.$$

Now, it suffices to substitute:

$$\begin{aligned} y &= C(x) \frac{x+1}{x-1} = \\ \frac{x+1}{x-1} \left( \frac{x^2}{2} - 2x + 2 \ln|x+1| + C \right), \quad C \in \mathbb{R}. \end{aligned}$$

We can see that the result we have obtained here is of the same form as in the former case. This should not be surprising as the differences between the two methods are insignificant and the computed integrals are the same.

Finally, we can notice that the solution  $y$  of an equation  $y' = a(x)y$  can be found in the same way for any continuous function  $a$ . We thus always have

$$y = Ce^{\int a(x) dx}, \quad C \in \mathbb{R}.$$

can be solved directly (although the so-called error function appears when integrating the particular solution and this cannot be expressed via elementary functions), this time encountering stable behaviour, visible in the following illustration.

**8.3.5. Transformation of coordinates.** The illustrations suggest that differential equations can be perceived as geometric objects (the “directional field of the arrows”), so the solution can be found by conveniently chosen coordinates. We return to this point of view later. Here are three simple examples of typical tricks as seen from the explicit form of the equations in coordinates.

We begin with *homogeneous equations* of the form

$$y' = f\left(\frac{y}{t}\right).$$

Considering the transformation  $z = z(t) = \frac{y}{t}$  and assuming that  $t \neq 0$ , then by the chain rule,

$$z' = \frac{1}{t^2}(ty' - y) = \frac{1}{t}(f(z) - z),$$

which is an equation with separated variables.

Other examples are the *Bernoulli differential equations*, which are of the form

$$y' = f(t)y + g(t)y^n,$$

where  $n \neq 0, 1$ . The choice of the transformation  $z = y^{1-n}$  leads to the equation

$$\begin{aligned} z' &= (1-n)y^{-n}(f(t)y + g(t)y^n) \\ &= (1-n)f(t)z + (1-n)g(t), \end{aligned}$$

which is a linear equation, easily integrated.

We conclude with the extraordinarily important *Riccati equation*. It is a form of the Bernoulli equation with  $n = 2$ , extended by an absolute term

$$y' = f(t)y + g(t)y^2 + h(t).$$

This equation can also be transformed to a linear equation provided that a particular solution  $x = x(t)$  can be guessed. Then, use the transformation

$$z = \frac{1}{y-x}.$$

Verify by yourselves that this transformation leads to the equation

$$z' = -(f(t) + 2x(t)g(t))z - g(t).$$

Similarly, the solution of an equation  $y' = a(x)y + b(x)$  with an initial condition  $y(x_0) = y_0$  can be determined explicitly as (provided the coefficients, i. e. the functions  $a$  and  $b$ , are continuous)

$$y = e^{\int_{x_0}^x a(t) dt} \left( y_0 + \int_{x_0}^x b(t) e^{-\int_{x_0}^t a(s) ds} dt \right).$$

Let us remark that the linear equation has no singular solution, and the general solution contains a  $C \in \mathbb{R}$ .  $\square$

**8.J.10.** Solve the linear equation

$$(y' + 2xy) e^{x^2} = \cos x.$$

**Solution.** If we used the method of integration factor, we would only rewrite the equation trivially since it is already of the desired form – the expression on the left-hand side is the derivative of  $y e^{x^2}$ . Thus, we can immediately calculate

$$\begin{aligned} (y e^{x^2})' &= \cos x, \\ y e^{x^2} &= \int \cos x dx, \\ y e^{x^2} &= \sin x + C, \quad C \in \mathbb{R}, \\ y &= e^{-x^2} (\sin x + C), \quad C \in \mathbb{R}. \end{aligned}$$

$\square$

**8.J.11.** Find all non-zero solutions of the Bernoulli equation

$$y' - \frac{y}{x} = 3xy^2.$$

**Solution.** The Bernoulli equation

$$y' = a(x)y + b(x)y^r, \quad r \neq 0, r \neq 1, r \in \mathbb{R}$$

can be solved by first dividing by the term  $y^r$  and then using the substitution  $u = y^{1-r}$ , which leads to the linear differential equation

$$u' = (1 - r) [a(x)u + b(x)].$$

In this very problem, the substitution  $u = y^{1-2} = 1/y$  gives

$$u' + \frac{u}{x} = -3x.$$

Similarly to the previous exercise, we have

$$u = e^{-\ln|x|} \left[ \int -3x e^{\ln|x|} dx \right],$$

where  $\ln|x|$  was obtained as an (arbitrary) antiderivative to  $1/x$ . Further,

$$\begin{aligned} u &= e^{\ln \frac{1}{|x|}} \left[ \int -3x e^{\ln|x|} dx \right], \\ u &= \frac{1}{|x|} \left[ \int -3x |x| dx \right]. \end{aligned}$$

The absolute value can be replaced with a sign that can be canceled, i. e., it suffices to consider

$$u = \frac{1}{x} \left[ \int -3x^2 dx \right] = \frac{1}{x} [-x^3 + C], \quad C \in \mathbb{R}.$$

Returning to the original variable, we get

$$y = \frac{1}{u} = \frac{x}{C - x^3}, \quad C \in \mathbb{R}.$$

The excluded case  $y \equiv 0$  is a singular solution (which, of course, is true for every Bernoulli equation with  $r$  positive).  $\square$

As seen in the case of integration of functions (the simplest type of equations with separated variables), the equations usually do not have a solution expressible explicitly in terms of elementary functions.

As with standard engineering tables of values of special functions, books listing the solutions of basic equations are compiled as well.<sup>7</sup> Today, the wisdom concealed in them is essentially transferred to software systems like Maple or Mathematica. Here, any task about ordinary differential equations can be assigned, with results obtained in surprisingly many cases. Yet, explicit solutions are not possible for most problems.

**8.3.6. Existence and uniqueness.** The way out of this is numerical methods, which try only to approximate the solutions. However, to be able to use them, good theoretical starting points are still needed regarding existence, uniqueness, and stability of the solutions.

We begin with the *Picard–Lindelöf theorem*:

EXISTENCE AND UNIQUENESS OF THE SOLUTIONS OF ODES

**Theorem.** Consider a function  $f(t, y) : \mathbb{R}^2 \rightarrow \mathbb{R}$  with continuous partial derivatives on an open set  $U$ . Then for every point  $(t_0, y_0) \in U \subset \mathbb{R}^2$ , there exists the maximal interval  $I = (t_0 - a, t_0 + b)$ , with positive  $a, b \in \mathbb{R}$ , and the unique function  $y(t) : I \rightarrow \mathbb{R}$  which is the solution of the equation  $y' = f(t, y)$  on the interval  $I$ .

**PROOF.** If a differentiable function  $y(t)$  is a solution of an equation satisfying the initial condition  $y(t_0) = y_0$ , then it also satisfies the equation

$$y(t) = y_0 + \int_{t_0}^t y'(s) ds = y_0 + \int_{t_0}^t f(s, y(s)) ds,$$

where the Riemann integrals exist due to the continuity of  $f$  and hence also  $y'$ . However, the right-hand side of this expression is the integral operator

$$L(y)(t) = y_0 + \int_{t_0}^t f(s, y(s)) ds$$

acting on functions  $y$ . Solving first-order differential equations, is equivalent to finding fixed points for this operator  $L$ , that is, to find a function  $y = y(t)$  satisfying  $L(y) = y$ .

On the other hand, if a Riemann-integrable function  $y(t)$  is a fixed point of the operator  $L$ , then it immediately follows from the fundamental theorem of calculus that  $y(t)$  satisfies the given differential equation, including the initial conditions.

<sup>7</sup>For example, the famous book *Differentialgleichungen reeller Funktionen*, Akademische Verlagsgesellschaft, Leipzig 1930, by E. Kamke, a German mathematician, contains many hundreds of solved equations. They appeared in many editions in the last century.

**8.J.12.** Interchanging the variables, solve the equation

$$y dx - (x + y^2 \sin y) dy = 0.$$

**Solution.** When the variable  $x$  occurs only in the first power in the differential equation and  $y$  occurs in the arguments of elementary functions, we can apply the so-called method of variable interchange, when we look for the solution as for a function  $x$  of the independent variable  $y$ .

First, we write the equation explicitly:

$$y' = \frac{y}{x + y^2 \sin y}.$$

This equation is not of any of the previous types, so we rewrite it as follows:

$$\begin{aligned} \frac{dy}{dx} &= \frac{y}{x + y^2 \sin y}, \\ \frac{dx}{dy} &= \left( \frac{y}{x + y^2 \sin y} \right)^{-1} = \frac{x}{y} + y \sin y, \\ x' &= \frac{1}{y} x + y \sin y. \end{aligned}$$

We have thus obtained a linear differential equation. Now, we can easily compute its general solution

$$x = -y \cos y + Cy, \quad C \in \mathbb{R}.$$

□

Further problems concerning first-order differential equations can be found on page 795.

### K. Practical problems leading to differential equations

**8.K.1.** A water purification plant with volume  $2000 \text{ m}^3$  was contaminated with lead which is spread in the water with density  $10 \text{ g/m}^3$ . Water is flowing in and out of the basin at  $2 \text{ m}^3/\text{s}$ . In what time does the amount of lead in the basin decrease below  $10 \text{ } \mu\text{g/m}^3$  (which is the hygienic norm for the amount of lead in drinkable water by a regulation of the European Community) provided the water keeps being mixed uniformly?

**Solution.** Let us denote the water's volume in the basin by  $V \text{ (m}^3\text{)}$ , the speed of the water's flow by  $v \text{ (m}^3/\text{s}\text{)}$ . In an infinitesimal (infinitely small) time unit  $dt$ ,  $\frac{m}{V} \cdot v dt$  grams of lead runs out of the basin, so we can construct the differential equation

$$dm = -\frac{m}{V} \cdot v dt$$

for the change of the lead's mass in the basin. Separating the variables, we get the equation

$$\frac{dm}{m} = -\frac{v}{V} dt.$$

Integration both sides of the equation and getting rid of the logarithms, we get the solution in the form  $m(t) = m_0 e^{-\frac{v}{V}t}$ , where  $m_0$  is the lead's mass at time  $t = 0$ . Substituting the concrete values, we find out that  $t \doteq 6 \text{ h } 35 \text{ min}$ . □

It is easy to estimate how much the values  $L(y)$  and  $L(z)$  differ for various functions  $y(t)$  and  $z(t)$ . Since both partial derivatives of  $f$  are continuous,  $f$  is itself locally Lipschitz. This means that restricting the values  $(t, y)$  to a neighbourhood  $U$  of the point  $(t_0, y_0)$  with compact closure, there is the estimate

$$|f(t, y) - f(t, z)| \leq C|y - z|,$$

with some constant  $C$  depending only on  $U$ . This immediately leads to the following bound (for the sake of simplicity,  $t \geq t_0$ , but the final conclusion works for  $t < t_0$  the same way)

$$\begin{aligned} |(L(y) - L(z))(t)| &= \left| \int_{t_0}^t f(s, y(s)) - f(s, z(s)) ds \right| \\ &\leq \int_{t_0}^t |f(s, y(s)) - f(s, z(s))| ds \\ &\leq C \int_{t_0}^t |y(s) - z(s)| ds \\ &\leq C \left( \max_{t_0 \leq s \leq t} |y(s) - z(s)| \right) |t - t_0| \\ &= D \left( \max_{t_0 \leq s \leq t} |y(s) - z(s)| \right), \end{aligned}$$

where the constant  $D$  comes from substituting the maximum of  $|t - t_0|$  on  $U$ .

If the operator  $L$  is viewed as an operator on a metric space of continuous functions on a compact interval with the max norm, this yields

$$\|L(y) - L(z)\| \leq D \|y - z\|.$$

Some further restrictions on the choice of  $U$  and the considered functions  $y$  and  $z$  are required, in order to make the constant  $D$  smaller than one. Then the Banach fixed point theorem, based on the notion of a contraction, can be applied. See 7.3.9 on the page 676. At the same time, the operator must leave the chosen space of functions  $y$  invariant, i.e. the images  $L(y)$  are also there.

To begin, choose  $\varepsilon > 0$  and  $\delta > 0$ , both small enough so that  $[t_0 - \delta, t_0 + \delta] \times [y_0 - \varepsilon, y_0 + \varepsilon] = V \subset U$ , and consider only those functions  $y(t)$  which satisfy for  $J = [t_0 - \delta, t_0 + \delta]$  the estimate  $\max_{t \in J} |y(t) - y_0| < \varepsilon$ . The uniform continuity of  $f(t, y)$  on  $V$  ensures that fixing  $\varepsilon$  and further shrinking  $\delta$ , implies

$$\max_{t \in J} |L(y)(t) - y_0| < \varepsilon.$$

Finally, the above estimate for  $\|L(y) - L(z)\|$  shows that if  $\delta$  is decreased sufficiently further, then the latter constant  $D$  becomes smaller than one, as required for a contraction. At the same time,  $L$  maps the above space of functions into itself.

However, for the assumptions of the Banach contraction theorem, which guarantees the uniquely determined fixed point, completeness of the space  $X$  of functions on which the operator  $L$  works is needed.

Since the mapping  $f(t, y)$  is continuous, there follows a uniform bound for all of the functions  $y(t)$  considered above

**8.K.2.** The speed of transmission of a message in a population consisting of  $P$  people is directly proportional to the number of people who have not heard the message yet. Determine the function  $f$  which describes the dependency of the number of people who *have* heard the message on time. Is it appropriate to use this model of message transmission for small or large values of  $P$ ?

**Solution.** We construct a differential equation for  $f$ . The speed of the transmission  $\frac{df}{dt} = f'(t)$  should be directly proportional to the number of people who have not heard of it, i. e. the value  $P - f(t)$ . Altogether,

$$\frac{df}{dt} = k(P - f(t)).$$

Separating the variables and introducing a constant  $K$  (the number of people who know the message at time  $t = 0$  must be  $P - K$ ), we get the solution

$$f(t) = P - Ke^{-kt},$$

where  $k$  is a positive real constant.

Apparently, this model makes sense for large values of  $P$  only. □

**8.K.3.** The speed at which an epidemic spreads in a given closed population consisting of  $P$  people is directly proportional to the product of the number of people who have been infected and the number of people who have not. Determine the function  $f(t)$  describing the number of infected people in time.

**Solution.** Just like in the previous problem, we construct a differential equation:

$$\frac{df}{dt} = k \cdot f(t) (P - f(t)).$$

Again, separating the variables and introducing suitable constants  $K$  and  $L$ , we obtain

$$f(t) = \frac{K}{1 + Le^{-Kkt}}.$$

□

**8.K.4.** The speed at which a given isotope of a given chemical element decays is directly proportional to the amount of the given isotope. The half-life of the isotope of plutonium  ${}_{94}^{239}\text{Pu}$  is 24,100 years. In what time does a hundredth of a nuclear bomb whose active component is the mentioned isotope disappear?

**Solution.** Denoting the amount of plutonium by  $m$ , we can build a differential equation for the rate of the decay:

$$\frac{dm}{dt} = k \cdot m,$$

where  $k$  is an unknown constant. The solution is thus the function  $m(t) = m_0 e^{-kt}$ . Substituting into the equation for half-life ( $e^{-kt} = \frac{1}{2}$ ), we get the constant  $k \doteq 2.88 \cdot 10^5$ . The wanted time is then approximately 349 years. □

and the values  $t > s$  in their domain:

$$|L(y)(t) - L(y)(s)| \leq \int_s^t |f(s, y(s))| ds \leq A |t - s|$$

with a universal constant  $A > 0$ . Besides the conditions mentioned above, there is a restriction to the subset of all equicontinuous functions in the sense of the Definition 7.3.15. According to the Arzelà-Ascoli Theorem proved in the same paragraph at the page 683, this set of continuous functions is already compact, hence it is a complete set of continuous functions on the interval.

Therefore, there exists a unique fixed point  $y(t)$  of this contraction  $L$  by the Theorem 7.3.9. This is the solution of the equation.

It remains to show the existence of a maximal interval  $I = (t_0 - a, t_0 + b)$ . Suppose that a solution  $y(t)$  is found on an interval  $(t_0, t_1)$ , and, at the same time, the one-sided limit  $y_1 = \lim_{t \rightarrow t_1^-} y(t)$  exists and is finite.

It follows from the already proven result that there exists a solution with this initial condition  $(t_1, y_1)$ , in some neighbourhood of the point  $t_1$ . Clearly, it must coincide with the discussed solution  $y(t)$  on the left-hand side of  $t_1$ . Therefore, the solution  $y(t)$  can be extended on the right-hand side of  $t_1$ .

There are only two possibilities when the extension of the solution behind  $t_1$  does not exist: either there is no finite left limit  $y(t)$  at  $t_1$ , or the limit  $y_1$  exists, yet the point  $(t_1, y_1)$  is on the boundary of the domain of the function  $f$ . In both cases, the maximal extension of the solution to the right of  $t_0$  is found.

The argumentation for the maximal solution left of  $t_0$  is analogous. □

**8.3.7. Iterative approximations of solutions.** The proof of the previous theorem can be reformulated as an iterative procedure which provides approximate solutions using step-by-step integration. Moreover, an explicit estimate for the constant  $C$  from the proof yields bounds for the errors.

Think this out as an exercise (see the proof of Banach fixed-point theorem in paragraph 7.3.9). It can then be shown easily and directly that it is a uniformly convergent sequence of continuous functions, so the limit is again a continuous function (without invoking the complicated theorems from the seventh chapter).

**8.K.5.** The acceleration of an object falling in a constant gravitational field with a certain resistance of the environment is given by the formula

$$\frac{dv}{dt} = g - kv,$$

where  $k$  is a constant which expresses the resistance of the environment. An object was dropped in a gravitational field with  $g = 10 \text{ ms}^{-2}$  at the initial speed of  $5 \text{ ms}^{-1}$ , the resistance constant is  $k = 0.5 \text{ s}^{-1}$ . What will the speed of the object be in three seconds?

**Solution.**

$$v = \frac{g}{k} - \left(\frac{g}{k} - v_0\right) e^{-kt},$$

$v(3) = 20 - 15e^{-\frac{3}{2}} \text{ ms}^{-1}$  after substitution. □

**8.K.6.** The rate of increase of a population of a certain type of bug is indirectly proportional to its size. At time  $t = 0$ , the population had 100 bugs. In a month, the population doubled. What will the size of the population be in two months?

**Solution.** Let us consider a continuous approximation of the number of bugs, and let their amount be denoted by  $P$ . Then, we can build the following equation:

$$\frac{dP}{dt} = \frac{k}{P},$$

$P = \sqrt{Kt + c}$ . Substituting the given values, we get  $P(2) = \sqrt{7} \cdot 100$ , which is an estimate of the actual number of bugs. □

**8.K.7.** Find the equation of the curve with the following properties: It lies in the first quadrant, goes through the point  $[1, 3/4]$ , and its tangent at any point marks on the positive half-axis  $y$  a segment whose length is the same as the distance of that point from the origin. ○

**8.K.8.** Consider a chemical compound  $C$  isolated in a container.  $C$  is unstable, with half-time of a molecule equal to  $q$  time units. If there were  $M$  moles of the compound  $C$  in the container at the beginning (i. e., at time  $t = 0$ ), how many moles of it will be there at time  $t \geq 0$ ? ○

**8.K.9.** A 100-gram body lengthens a spring of 5 cm if hung on it. Express the dependency of its position on time  $t$  provided the speed of the body is 10 cm/s when going through the equilibrium point. ○

Further practical problems that lead to differential equations can be found on page 795.

### L. Higher-order differential equations

**8.L.1. Underdamped oscillation.** Now, we will describe a simple model for the movement of a solid object attached to a point with a strong spring. If  $y(t)$  is the deviation of our object from the point  $y_0 = y(0) = 0$ , then we can assume that the acceleration  $y''(t)$  in time  $t$  is proportional to the magnitude of the deviation, yet with the other sign. The proportionality constant  $k$  is called the spring constant. Considering the

### PICARD'S APPROXIMATIONS

**Theorem.** *The unique solution of the equation*

$$y' = f(t, y)$$

*whose right-hand side  $f$  has continuous partial derivatives can be expressed, on a sufficiently small interval, as the limit of step-by-step iterations beginning with the constant function (Picard's approximation):*

$$y_0(t) = y_0, \quad y_{n+1}(t) = L(y_n), \quad n = 1, \dots$$

*It is a uniformly converging sequence of differentiable functions with differentiable limit  $y(t)$ .*

Only the Lipschitz condition is needed for the function  $f$ , so the latter two theorems are true with this weaker assumption as well. It is seen in the next paragraph that continuity of the function  $f$  guarantees the existence of the solution. Yet it is insufficient for the uniqueness.

**8.3.8. Ambiguity of solutions.** We begin with a simple example. Consider the equation

$$y' = \sqrt{|y|}.$$

Separating the variables, the solution is

$$y(t) = \frac{1}{4}(t + C)^2,$$

for positive values  $y$ , with an arbitrary constant  $C$  and  $t + C > 0$ . For the initial values  $(t_0, y_0)$  with  $y_0 \neq 0$ , this is an assignment matching the previous theorem, so there is locally exactly one solution. The solution must apparently remain non-decreasing, hence for negative values  $y_0$ , the solution is the same, only with the opposite sign and  $t + C < 0$ .

However, for the initial condition  $(t_0, y_0) = (t_0, 0)$ , there is not only the already discussed solution continuing to the left of  $t_0$  and to the right, but also the identically zero solution  $y(t) = 0$ . Therefore, these two branches can be glued arbitrarily (see the diagram, where the thick solution can be continued along the  $t$  axis and branch along the parabola at any value  $t$ .)

Nevertheless, the existence of a solution is guaranteed by the following theorem, known as *Peano existence theorem*:

vylepsit obrazek, aby ukazoval vic reseni ...

case  $k = 1$ , we get the so-called oscillation equation

$$y''(t) = -y(t).$$

This equation corresponds to the system of equations

$$x'(t) = -y(t), \quad y'(t) = x(t)$$

from 1. The solution of this system is given by

$$x(t) = R \cos(t - \tau), \quad y(t) = R \sin(t - \tau)$$

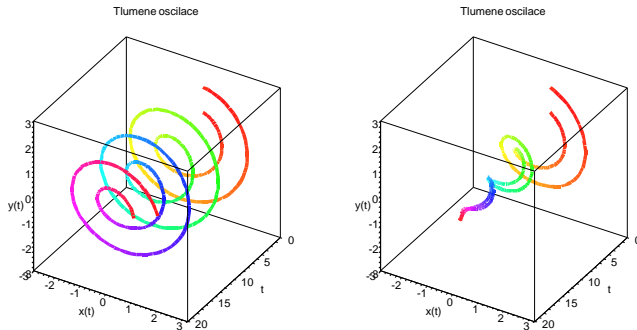

with an arbitrary non-negative constant  $R$ , which determines the maximum amplitude, and a constant  $\tau$ , which determines the initial phase.

Therefore, in order to determine a unique solution, we need to know not only the initial position  $y_0$ , but also the speed of the motion at that moment. These two pieces of information uniquely determine both the amplitude and the initial phase.

Moreover, let us imagine that as a result of the properties of the spring material, there is another force which is directly proportional to the instantaneous speed of our object, with the other sign than the amplitude again. This is expressed by one more term with the first derivative, so our equation is now

$$y''(t) = -y(t) - \alpha y'(t),$$

where  $\alpha$  is a constant which expresses the magnitude of the damping. In the following picture, there are the so-called phase diagrams for solutions with two distinct initial conditions, namely with zero damping on the left, and for the value of the coefficient  $\alpha = 0.3$  on the right.

The oscillations are expressed by the  $y$ -axis values; the  $x$ -axis values describe the speed of the motion.

**8.L.2. Undamped oscillation.** Find the function  $y(t)$  which satisfies the following differential equation and initial conditions:

$$y''(t) + 4y(t) = f(t), \quad y(0) = 0, \quad y'(0) = -1,$$

where the function  $f(t)$  is piecewise continuous:

$$f(t) = \begin{cases} \cos(2t) & \text{for } 0 \leq t < \pi, \\ 0 & \text{for } t \geq \pi. \end{cases}$$

**Solution.** This problem is a model of undamped oscillation of a spring (omitting friction, non-linearities in the toughness of the spring, and other factors) which is initiated by an outer force.

**Theorem.** Consider a function  $f(t, y) : \mathbb{R}^2 \rightarrow \mathbb{R}$  which is continuous on an open set  $U$ . Then for every point  $(t_0, y_0) \in U \supset \mathbb{R}^2$ , there exists a solution of the equation

$$y' = f(t, y)$$

locally in some neighbourhood of  $t_0$ .

**PROOF.** The proof is presented only roughly, with the details left to the reader.

We construct a solution to the right of the initial point  $t_0$ . For this purpose, select a small step  $h > 0$  and label the points

$$t_k = t_0 + kh, \quad k = 1, 2, \dots$$

The value of the derivative  $f(t_0, y_0)$  of the corresponding curve of the solution  $(t, y(t))$  is defined at the initial point  $(t_0, y_0)$ , so a parametrized line with the same derivative can be substituted:

$$y_{(0)}(t) = y_0 + f(t_0, y_0)(t - t_0).$$

Label  $y_1 = y_{(0)}(t_1)$ . Construct inductively the functions and points

$$y_{(k)}(t) = y_k + f(x_k, y_k)(t - t_k), \quad y_{k+1} = y_{(k)}(t_{k+1}).$$

Now, define  $\tilde{y}_h(t)$  by gluing the particular linear parts, i.e., ad picture!!!

$$\tilde{y}_h(t) = y_{(k)}(t) \quad \text{if } t \in [kh, (k+1)h].$$

This is a continuous function, called the *Euler's approximation* of the solution.

It "only" remains to prove that the limit of the functions  $\tilde{y}_h$  for  $h$  approaching zero exists and is a solution. For this, one must observe (as done already in the proof of the theorem on uniqueness and existence of the solution) that  $f(t, y)$  is uniformly continuous on a sufficiently small neighbourhood  $U$  where the solution is sought. For any selected  $\varepsilon > 0$ , a sufficiently small  $\delta$  such that  $|f(t, y) - f(s, z)| < \varepsilon$ , exists whenever  $\|(t - s, y - z)\| < \delta$ .

Especially, all functions  $\tilde{y}_h$  are in the set of uniformly continuous and equicontinuous functions on a sufficiently small interval. By the Arzelà-Ascoli theorem (see paragraph 7.3.15 on page 683), the constructed continuous functions  $\tilde{y}_h$  are all in a compact set of functions. So there exists a sequence of values  $h_n \rightarrow 0$  such that the corresponding sequence of functions  $\tilde{y}_{h_n}$  converges uniformly to a continuous function  $y(n)$ . Write  $\hat{y}_n(t) = \tilde{y}_{h_n}(t)$ , i.e.  $\hat{y}_n \rightarrow y$  uniformly.

For each of the continuous functions  $\tilde{y}_h$ , there are only finitely many points in the interval  $[t_0, t]$  where it is not differentiable, so

$$\hat{y}_n(t) = y_0 + \int_{t_0}^t \hat{y}'_n(s) ds.$$

On the other hand, the derivatives on the particular intervals are constant, so (here,  $k$  is the largest such that  $t_0 + kh_n \leq$

The function  $f(t)$  can be written as a linear combination of Heaviside's function  $u(t)$  and its shift, i. e.,

$$f(t) = \cos(2t)(u(t) - u_\pi(t))$$

Since

$$\mathcal{L}(y'')(s) = s^2 \mathcal{L}(y) - sy(0) - y'(0) = s^2 \mathcal{L}(y) + 1,$$

we get, applying the results of the above exercises 7 and 8 to the Laplace transform of the right-hand side

$$\begin{aligned} s^2 \mathcal{L}(y) + 1 + 4\mathcal{L}(y) &= \mathcal{L}(\cos(2t)(u(t) - u_\pi(t))) \\ &= \mathcal{L}(\cos(2t) \cdot u(t)) - \mathcal{L}(\cos(2t) \cdot u_\pi(t)) \\ &= \mathcal{L}(\cos(2t)) - e^{-\pi s} \mathcal{L}(\cos(2(t + \pi))) \\ &= (1 - e^{-\pi s}) \frac{s}{s^2 + 4}. \end{aligned}$$

Hence,

$$\mathcal{L}(y) = -\frac{1}{s^2 + 4} + (1 - e^{-\pi s}) \frac{s}{(s^2 + 4)^2}.$$

Performing the inverse transform, we obtain the solution in the form

$$y(t) = -\frac{1}{2} \sin(2t) + \frac{1}{4} t \sin(2t) + \mathcal{L}^{-1} \left( e^{-\pi s} \frac{s}{(s^2 + 4)^2} \right).$$

However, by formula (1), we have

$$\begin{aligned} \mathcal{L}^{-1} \left( e^{-\pi s} \frac{s}{(s^2 + 4)^2} \right) &= \frac{1}{4} \mathcal{L}^{-1}(e^{-\pi s} \mathcal{L}(t \sin(2t))) \\ &= (t - \pi) \sin(2(t - \pi)) \cdot H_\pi(t). \end{aligned}$$

Since Heaviside's function is zero for  $t < \pi$  and equal to 1 for  $t > \pi$ , we get the solution in the form

$$y(t) = \begin{cases} -\frac{1}{2} \sin(2t) + \frac{1}{4} t \sin(2t) & \text{for } 0 \leq t < \pi \\ \frac{\pi-2}{4} \sin(2t) & \text{for } t \geq \pi \end{cases}$$

□

**8.L.3.** Find the general solution of the equation

$$y''' - 5y'' - 8y' + 48y = 0.$$

**Solution.** This is a third-order linear differential equation with constant coefficients since it is of the form

$$y^{(n)} + a_1 y^{(n-1)} + a_2 y^{(n-2)} + \dots + a_{n-1} y' + a_n y = f(x)$$

for certain constants  $a_1, \dots, a_n \in \mathbb{R}$ . Moreover, we have  $f(x) \equiv 0$ , i. e., the equation is homogeneous.

First of all, we will find the roots of the so-called characteristic polynomial

$$\lambda^n + a_1 \lambda^{n-1} + a_2 \lambda^{n-2} + \dots + a_{n-1} \lambda + a_n.$$

Each real root  $\lambda$  with multiplicity  $k$  corresponds to the  $k$  solutions

$$e^{\lambda x}, x e^{\lambda x}, \dots, x^{k-1} e^{\lambda x}$$

and every pair of complex roots  $\lambda = \alpha \pm i\beta$  with multiplicity  $k$  corresponds to the  $k$  pairs of solutions

$$\begin{aligned} e^{\alpha x} \cos(\beta x), x e^{\alpha x} \cos(\beta x), \dots, x^{k-1} e^{\alpha x} \cos(\beta x), \\ e^{\alpha x} \sin(\beta x), x e^{\alpha x} \sin(\beta x), \dots, x^{k-1} e^{\alpha x} \sin(\beta x). \end{aligned}$$

$t$ , while  $y_j$  and  $t_j$  are the points from the definition of the function  $\hat{y}_{n_n}$ )

$$\hat{y}_n(t) = y_0 + \sum_{j=0}^{k-1} \int_{t_j}^{t_{j+1}} f(t_j, y_j) ds + \int_{t_k}^t f(t_k, y_k) ds.$$

Instead, the equation

$$\hat{y}_n(t) = y_0 + \int_{t_0}^t f(s, \hat{y}_n(s)) ds$$

is wanted, but the difference between this integral and the last two terms in the previous expression is bounded by the possible variation of the function values  $f(t, \hat{y})$  and the lengths of the intervals. By the universal bound for  $f(t, y)$  above, the last integral can be used instead of the actual values in the limit process  $\lim_{n \rightarrow \infty} y_n(t)$ , thereby obtaining

$$\begin{aligned} y(t) &= \lim_{n \rightarrow \infty} \left( y_0 + \int_{t_0}^t f(s, \hat{y}_n(s)) ds \right) \\ &= y_0 + \int_{t_0}^t \left( \lim_{n \rightarrow \infty} f(s, \hat{y}_n(s)) \right) ds \\ &= y_0 + \int_{t_0}^t f(s, y(s)) ds, \end{aligned}$$

where the uniform convergence  $\hat{y}_n(t) \rightarrow y(t)$  is employed.

This proves the theorem. □

**8.3.9. Coupled first-order equations.** The problem of finding the solution of the equation  $y' = f(x, y)$  can

also be viewed as looking for a (parametrized) curve  $(x(t), y(t))$  in the plane where the parametrization of the variable  $x(t) = t$  is fixed beforehand. If this point of view is accepted, then this fixed choice for the variable  $x$  can be forgotten, and the work can be carried out with an arbitrary (finite) number of variables.

In the plane, for instance, such a system can be written in the form

$$x' = f(t, x, y), \quad y' = g(t, x, y)$$

with two functions  $f, g : \mathbb{R}^3 \rightarrow \mathbb{R}$ .

A simple example in the plane might be the system of equations

$$x' = -y, \quad y' = x.$$

It is easily guessed (or at least verified) that there is a solution of this system,

$$x(t) = R \cos t, \quad y(t) = R \sin t,$$

with an arbitrary non-negative constant  $R$ , and the curves of the solution are exactly the parametrized circles with radius  $R$ .

In the general case, the vector notation of the system can be used in the form

$$x' = f(t, x)$$

for a vector function  $x : \mathbb{R} \rightarrow \mathbb{R}^n$  and a mapping  $f : \mathbb{R}^{n+1} \rightarrow \mathbb{R}^n$ . The validity of the theorem on uniqueness and existence of the solution to such systems can be extended:

Then, the general solution corresponds to all linear combinations of the above solutions.

Therefore, let us consider the polynomial

$$\lambda^3 - 5\lambda^2 - 8\lambda + 48$$

with roots  $\lambda_1 = \lambda_2 = 4$ ,  $\lambda_3 = -3$ . Since we know the roots, we can deduce the general solution as well:

$$y = C_1 e^{4x} + C_2 x e^{4x} + C_3 e^{-3x}, \quad C_1, C_2, C_3 \in \mathbb{R}. \quad \square$$

**8.L.4.** Compute

$$y''' + y'' + 9y' + 9y = e^x + 10 \cos(3x).$$

**Solution.** First, we will solve the corresponding homogeneous equation. The characteristic polynomial is equal to

$$\lambda^3 + \lambda^2 + 9\lambda + 9,$$

with roots  $\lambda_1 = -1$ ,  $\lambda_2 = 3i$ ,  $\lambda_3 = -3i$ . The general solution of the corresponding homogeneous equation is thus

$$y = C_1 e^{-x} + C_2 \cos(3x) + C_3 \sin(3x), \quad C_1, C_2, C_3 \in \mathbb{R}.$$

The solution of the non-homogeneous equation is of the form

$$C_1 e^{-x} + C_2 \cos(3x) + C_3 \sin(3x) + y_p, \quad C_1, C_2, C_3 \in \mathbb{R}$$

for a particular solution  $y_p$  of the non-homogeneous equation.

The right-hand side of the given equation is of a special form. In general, if the non-homogeneous part is given by a function

$$P_n(x) e^{\alpha x},$$

where  $P_n$  is a polynomial of degree  $n$ , then there is a particular solution of the form

$$y_p = x^k R_n(x) e^{\alpha x},$$

where  $k$  is the multiplicity of  $\alpha$  as a root of the characteristic polynomial and  $R_n$  is a polynomial of degree at most  $n$ . More generally, if the non-homogeneous part is of the form

$$e^{\alpha x} [P_m(x) \cos(\beta x) + S_n(x) \sin(\beta x)],$$

where  $P_m$  is a polynomial of degree  $m$  and  $S_n$  is a polynomial of degree  $n$ , there exists a particular solution of the form

$$y_p = x^k e^{\alpha x} [R_l(x) \cos(\beta x) + T_l(x) \sin(\beta x)],$$

where  $k$  is the multiplicity of  $\alpha + i\beta$  as a root of the characteristic polynomial and  $R_l, T_l$  are polynomials of degree at most  $l = \max\{m, n\}$ .

In our problem, the non-homogeneous part is a sum of two functions in the special form (see above). Therefore, we will look for (two) corresponding particular solutions using the method of undetermined coefficients, and then we will add up these solutions. This will give us a particular solution of the original equation (as well as the general solution, then). Let us begin with the function  $y = e^x$ , which has particular solution  $y_{p_1}(x) = Ae^x$  for some  $A \in \mathbb{R}$ . Since

$$y_{p_1}(x) = y'_{p_1}(x) = y''_{p_1}(x) = y'''_{p_1}(x) = Ae^x,$$

substitution into the original equation, whose right-hand side contains only the function  $y = e^x$ , leads to

$$20Ae^x = e^x, \quad \text{i. e.} \quad A = \frac{1}{20}.$$

For the right-hand side with the function  $y = 10 \cos(3x)$ , we are looking for a particular solution in the form

EXISTENCE AND UNIQUENESS FOR SYSTEMS OF ODEs

**Theorem.** Consider functions  $f_i(t, x_1, \dots, x_n) : \mathbb{R}^{n+1} \rightarrow \mathbb{R}$ ,  $i = 1, \dots, n$ , with continuous partial derivatives. Then, for every point  $(t_0, c) \in \mathbb{R}^{n+1}$ ,  $c = (c_1, \dots, c_n)$ , there exists a maximal interval  $(t_0 - a, t_0 + b)$ , with positive numbers  $a, b \in \mathbb{R}$ , and a unique (vector) function  $x(t) : \mathbb{R} \rightarrow \mathbb{R}^n$  which is the solution of the system of equations

$$x'_1 = f_1(t, x_1, \dots, x_n)$$

⋮

$$x'_n = f_n(t, x_1, \dots, x_n)$$

with the initial condition  $x(t_0) = c$ , i.e.

$$x_1(t_0) = c_1, \dots, x_n(t_0) = c_n.$$

**PROOF.** The proof is almost identical to the one of the existence and uniqueness of the solution for a single equation with a single unknown function as shown in Theorem 8.3.6. The unknown function  $x(t) = (x_1(t), \dots, x_n(t))$  is a curve in  $\mathbb{R}^n$  satisfying the given equation, so its components  $x_i(t)$  are again expressed in terms of integrals

$$x_i(t) = x_i(t_0) + \int_{t_0}^t x'_i(s) ds = c_i + \int_{t_0}^t f_i(s, x(s)) ds.$$

We work with the integral operator  $y \mapsto L(y)$ , this time mapping curves in  $\mathbb{R}^n$  to curves in  $\mathbb{R}^n$ . It is desired to find its fixed point. The proof proceeds in much the same way as in the case 8.3.6. It is only necessary to observe that the size of the vector

$$\|f(t, z_1, \dots, z_n) - f(t, y_1, \dots, y_n)\|$$

is bounded from above by the sum

$$\|f(t, z_1, \dots, z_n) - f(t, y_1, z_2, \dots, z_n)\| + \dots + \|f(t, y_1, \dots, y_{n-1}, z_n) - f(t, y_1, \dots, y_n)\|.$$

It is recommended to go through the proof of Theorem 8.3.6 from this point of view and to think out the details.  $\square$

**8.3.10. Example.** When dealing with models in practice, it is of interest to consider the qualitative behaviour of the solution in dependence on the initial conditions and free parameters of the system

We consider a simple example of a system of first-order equations from this point of view. The standard population model “predator – prey”, was introduced in the 1920s by Lotka and Volterra.

Let  $x(t)$  denote the evolution of the number of individuals in the prey population and  $y(t)$  for the predators. Assume that the increment of the prey would correspond to the Malthusian model (i.e. exponential growth with coefficient  $\alpha$ ) if they were not hunted. On the other hand, assume that the predator would only naturally die out if there were no prey (i.e. exponential decrease with coefficient  $\gamma$ ). Further, consider an

$$y_{p_2}(x) = x [B \cos(3x) + C \sin(3x)].$$

Recall that the number  $\lambda = 3i$  was obtained as a root of the characteristic polynomial. We can easily compute the derivatives

$$\begin{aligned} y'_{p_2}(x) &= [B \cos(3x) + C \sin(3x)] \\ &\quad + x [-3B \sin(3x) + 3C \cos(3x)], \\ y''_{p_2}(x) &= 2[-3B \sin(3x) + 3C \cos(3x)] \\ &\quad + x [-9B \cos(3x) - 9C \sin(3x)], \\ y'''_{p_2}(x) &= 3[-9B \cos(3x) - 9C \sin(3x)] \\ &\quad + x [27B \sin(3x) - 27C \cos(3x)]. \end{aligned}$$

Substituting them into the equation, whose right-hand side contains the function  $y = 10 \cos(3x)$ , we get

$$-18B \cos(3x) - 18C \sin(3x) - 6B \sin(3x) + 6C \cos(3x) = 10 \cos(3x).$$

Confronting the coefficients leads to the system of linear equations

$$-18B + 6C = 10, \quad -18C - 6B = 0$$

with the only solution  $B = -1/2$  and  $C = 1/6$ , i. e.,

$$y_{p_2}(x) = x \left[ -\frac{1}{2} \cos(3x) + \frac{1}{6} \sin(3x) \right].$$

Altogether, the general solution is

$$\begin{aligned} y &= C_1 e^{-x} + C_2 \cos(3x) + C_3 \sin(3x) + \frac{1}{20} e^x \\ &\quad - \frac{1}{2} x \cos(3x) + \frac{1}{6} x \sin(3x), \quad C_1, C_2, C_3 \in \mathbb{R}. \end{aligned}$$

□

**8.L.5.** Determine the general solution of the equation

$$y'' + 3y' + 2y = e^{-2x}.$$

**Solution.** The given equation is a second-order (the highest derivative of the wanted function is of order two) linear (all derivatives are in the first power) differential equation with constant coefficients. First, we solve the homogenized equation

$$y'' + 3y' + 2y = 0.$$

Its characteristic polynomial is

$$x^2 + 3x + 2 = (x + 1)(x + 2),$$

with roots  $x_1 = -1$  and  $x_2 = -2$ . Hence, the general solution of the homogenized equation is

$$c_1 e^{-x} + c_2 e^{-2x},$$

where  $c_1, c_2$  are arbitrary real constants.

Now, using the method of undetermined coefficients, we will find a particular solution of the original non-homogeneous equation. According to the form of the non-homogeneity and since  $-2$  is a root of the characteristic polynomial of the given equation, we are looking for the solution in the form  $y_0 = a x e^{-2x}$  for  $a \in \mathbb{R}$ .

Substituting into the original equation, we obtain

$$a[-4e^{-2x} + 4xe^{-2x} + 3(e^{-2x} - 2xe^{-2x}) + 2xe^{-2x}] = e^{-2x},$$

interaction of the predator and the prey which is expected to be proportional to the number of both with a certain coefficient  $\beta$ , which is in the case of the predator, supplemented by a multiplicative coefficient expressing the hunting efficiency.

#### LOTKA-VOLTERRA MODEL

This is a system of two equations,  $x$  models the prey,  $y$  the predator, with positive constants  $\alpha, \beta, \gamma, \delta$

$$\begin{aligned} x' &= \alpha x - \beta y x \\ y' &= -\gamma y + \delta \beta x y. \end{aligned}$$

The diagram illustrates one of typical behaviours of such dynamical systems – the existence of closed orbits on which the system moves in time. These are the thick black ovals, while the “comets” indicate the field at the individual points (i.e. their expected movement). The left illustration corresponds to  $\alpha = 1, \beta = 1, \gamma = 0.3, \delta = 0.3$  and the initial condition  $(x_0, y_0) = (1, 0.5)$  at  $t_0 = 0$  for the solution, while the other illustration comes with  $\alpha = 1, \beta = 2, \gamma = 2, \delta = 1$  and  $(x_0, y_0) = (1, 1.5)$

In both cases, the system is quite stable in the vicinity of the initial condition, and it would be very stable for  $(x_0, y_0) = (1, 1)$  or  $(1, 0.5)$ , respectively. But their development differs in speed — the depicted solution cycles close in the times about  $t = 12$  in the first case and  $t = 5$  in the other one.

It is interesting that the same model captures quite well the development of the unemployment rate in population, considering the employees to be the predators, while the employers play the role of the prey.

Much information about this and other models can be found in the literature.

Next, we are approaching several qualitative results (i.e., featuring properties of the solutions, without knowing them explicitly). They are all easily understandable as statements, but the complexity of their proofs perhaps would be too demanding, at least in the first reading. Thus, the readers are advised to focus on the Theorems (do not ignore them, they are all absolutely essential!) and their rough explanations, but skip the proofs. The exposition will come back to easily proved topics in 8.3.16 on page 785.

hence  $a = -1$ . We have thus found the function  $-xe^{-2x}$  as a particular solution of the given equation. Hence, the general solution is the function space  $c_1e^{-x} + c_2e^{-2x} - xe^{-2x}$ ,  $c_1, c_2 \in \mathbb{R}$ .  $\square$

**8.L.6.** Determine the general solution of the equation

$$y'' + y' = 1.$$

**Solution.** The characteristic polynomial of the given equation is  $x^2 + x$ , with roots 0 and  $-1$ . Therefore, the general solution of the homogenized equation is  $c_1 + c_2e^{-x}$ , where  $c_1, c_2 \in \mathbb{R}$ .

We are looking for a particular solution in the form  $ax$ ,  $a \in \mathbb{R}$  (since zero is a root of the characteristic polynomial). Substituting into the original equation, we get  $a = 1$ . The general solution of the given non-homogeneous equation is  $c_1 + c_2e^{-x} + x$ ,  $c_1, c_2 \in \mathbb{R}$ .  $\square$

**8.L.7.** Determine the general solution of the equation

$$y'' + 5y' + 6y = e^{-2x}.$$

**Solution.** The characteristic polynomial of the equation is  $x^2 + 5x + 6 = (x + 2)(x + 3)$ , its roots are  $-2$  and  $-3$ . The general solution of the homogenized equation is thus  $c_1e^{-2x} + c_2e^{-3x}$ ,  $c_1, c_2 \in \mathbb{R}$ . We are looking for a particular solution in the form  $axe^{-2x}$ , ( $-2$  is a root of the characteristic polynomial),  $a \in \mathbb{R}$ , using the method of undetermined coefficients. Substitution into the original equation yields  $a = 1$ . Hence, the general solution of the given equation is

$$c_1e^{-2x} + c_2e^{-3x} + xe^{-2x}.$$

**8.L.8.** Determine the general solution of the equation

$$y'' - y' = 5.$$

**Solution.** The characteristic polynomial of the equation is  $x^2 - x$ , with roots 1, 0. Therefore, the general solution of the homogenized equation is  $c_1 + c_2e^x$ , where  $c_1, c_2 \in \mathbb{R}$ . We are looking for a particular solution in the form  $ax$ ,  $a \in \mathbb{R}$ , using the method of undetermined coefficients. The result is  $a = -5$ , and the general solution is of the form

$$c_1 + c_2e^x - 5x.$$

**8.L.9.** Solve the equation

$$y'' - 2y' + y = \frac{e^x}{x^2 + 1}.$$

**Solution.** We will solve this non-homogeneous equation using the method of variation of constants. We will thus obtain the solution in the form

$$y = C_1(x)y_1(x) + C_2(x)y_2(x) + \dots + C_n(x)y_n(x),$$

**8.3.11. Stability of systems of equations.** In order to illustrate the stability questions, we discuss just one basic theorem only.

We are interested in the continuity with respect to the  $L_\infty$  norm on the space of functions (i.e. the supremum norm, see 7.3.5). According to the theorem below, the assumption that the partial derivatives of the functions defining the system are continuous (in fact, it suffices to have them Lipschitz), guarantees the continuity of the solutions in dependence on the initial conditions as well as the defining equations themselves. Note however, that as the distance of  $t$  from the initial value  $t_0$  grows, then the error estimates grow exponentially!

Therefore, this result is of a strictly local character. It is not in contradiction with the example of the unstably behaving equation  $y' = ty$  illustrated in paragraph 8.3.3.<sup>8</sup>

Consider two systems of equations written in the vector form

$$(1) \quad x' = f(t, x), \quad y' = g(t, y)$$

and assume that the mappings  $f, g : U \subset \mathbb{R}^{n+1} \rightarrow \mathbb{R}^n$  have continuous partial derivatives on an open set  $U$  with compact closure. Such functions must be uniformly continuous and uniformly Lipschitz on  $U$ , so there are the finite values

$$C = \sup_{x \neq y; (t,x), (t,y) \in U} \frac{\|f(t, x) - f(t, y)\|}{\|x - y\|}$$

$$B = \sup_{(t,x) \in U} \|f(t, x) - g(t, x)\|$$

With this notation, the fundamental theorem can be formulated:

**Theorem.** Let  $x(t)$  and  $y(t)$  be two fixed solutions

$$x' = f(t, x(t)), \quad y' = g(t, y(t))$$

of the systems (1) considered above, given by initial conditions  $x(t_0) = x_0$  and  $y(t_0) = y_0$ . Then,

$$\|x(t) - y(t)\| \leq \|x_0 - y_0\| e^{C|t-t_0|} + \frac{B}{C} (e^{C|t-t_0|} - 1).$$

**PROOF.** Without loss of generality,  $t_0 = 0$ . From the expression of the solutions  $x(t)$  and  $y(t)$  as fixed points of the corresponding integral operators follows the estimate

$$\|x(t) - y(t)\| \leq \|x_0 - y_0\| + \int_0^t \|f(s, x(s)) - g(s, y(s))\| ds.$$

The integrand can be further estimated as follows:

$$\begin{aligned} \|f(s, x(s)) - g(s, y(s))\| &\leq \\ &\leq \|f(s, x(s)) - f(s, y(s))\| + \|f(s, y(s)) - g(s, y(s))\| \\ &\leq C \|x(s) - y(s)\| + B \end{aligned}$$

If  $F(t) = \|x(t) - y(t)\|$ ,  $\alpha = \|x_0 - y_0\|$ , then

$$F(t) \leq \alpha + \int_0^t (CF(s) + B) ds.$$

<sup>8</sup>Much more information can be found for example in Gerald Teschl's book *Ordinary Differential Equations and Dynamical Systems*, Graduate Studies in Mathematics, Volume 140, Amer. Math. Soc., Providence, 2012.

where  $y_1, \dots, y_n$  give the general solution of the corresponding homogeneous equation and the functions  $C_1(x), \dots, C_n(x)$  can be obtained from the system

$$\begin{aligned} C_1'(x) y_1(x) + \dots + C_n'(x) y_n(x) &= 0, \\ C_1'(x) y_1'(x) + \dots + C_n'(x) y_n'(x) &= 0, \\ &\vdots \\ C_1'(x) y_1^{(n-2)}(x) + \dots + C_n'(x) y_n^{(n-2)}(x) &= 0, \\ C_1'(x) y_1^{(n-1)}(x) + \dots + C_n'(x) y_n^{(n-1)}(x) &= f(x). \end{aligned}$$

The roots of the characteristic polynomial  $\lambda^2 - 2\lambda + 1$  are  $\lambda_1 = \lambda_2 = 1$ . Therefore, we are looking for the solution in the form

$$C_1(x) e^x + C_2(x) x e^x,$$

considering the system

$$\begin{aligned} C_1'(x) e^x + C_2'(x) x e^x &= 0, \\ C_1'(x) e^x + C_2'(x) [e^x + x e^x] &= \frac{e^x}{x^2 + 1}. \end{aligned}$$

We can compute the unknowns  $C_1(x)$  and  $C_2(x)$  using Cramer's rule. It follows from

$$\begin{aligned} \begin{vmatrix} e^x & x e^x \\ e^x & e^x + x e^x \end{vmatrix} &= e^{2x}, \\ \begin{vmatrix} 0 & x e^x \\ \frac{e^x}{x^2+1} & e^x + x e^x \end{vmatrix} &= -x \frac{e^{2x}}{x^2 + 1}, \\ \begin{vmatrix} e^x & 0 \\ e^x & \frac{e^x}{x^2+1} \end{vmatrix} &= \frac{e^{2x}}{x^2 + 1} \end{aligned}$$

that

$$\begin{aligned} C_1(x) &= - \int \frac{x}{x^2 + 1} dx = -\frac{1}{2} \ln(x^2 + 1) + C_1, & C_1 \in \mathbb{R}, \\ C_2(x) &= \int \frac{dx}{x^2 + 1} = \arctan x + C_2, & C_2 \in \mathbb{R}. \end{aligned}$$

Hence, the general solution is

$$y = C_1 e^x + C_2 x e^x - \frac{1}{2} e^x \ln(x^2 + 1) + x e^x \arctan x, \quad C_1, C_2 \in \mathbb{R}.$$

□

**8.L.10.** Find the only function  $y$  which satisfies the linear differential equation

$$y^{(3)} - 3y' - 2y = 2e^x,$$

with initial conditions  $y(0) = 0, y'(0) = 0, y''(0) = 0$ .

**Solution.** The characteristic polynomial is  $x^3 - 3x - 2$ , with roots 2 and  $-1$  (double). We are looking for a particular solution in the form  $ae^x, a \in \mathbb{R}$ , easily finding out that it is the function  $-\frac{1}{2}e^x$ . The general solution of the given equation is thus

$$c_1 e^{2x} + c_2 e^{-x} + c_3 x e^{-x} - \frac{1}{2} e^x.$$

Such an estimate bound can be exploited further, by the following general result, known as *Gronwall's inequality*. Note the similarity with the general solution of linear equations.

**Lemma.** Assume a real-valued function  $F(t)$  satisfies for all  $t$  in the interval  $[0, t_{max}]$

$$F(t) \leq \alpha(t) + \int_0^t \beta(s) F(s) ds$$

for some real-valued functions  $\alpha(t), \beta(t)$ , with  $\beta(t) \geq 0$ . Then

$$F(t) \leq \alpha(t) + \int_0^t \alpha(s) \beta(s) e^{\int_s^t \beta(r) dr} ds$$

for all  $t \in [0, t_{max}]$ . Moreover, if additionally  $\alpha(t)$  is non-decreasing, then

$$F(t) \leq \alpha(t) e^{\int_0^t \beta(s) ds}.$$

**PROOF OF THE LEMMA.** Write

$$G(t) = e^{-\int_0^t \beta(s) ds}.$$

By the first assumption of the theorem,

$$\begin{aligned} \frac{d}{dt} \left( G(t) \int_0^t \beta(s) F(s) ds \right) &= \\ &= \beta(t) G(t) \left( F(t) - \int_0^t \beta(s) F(s) ds \right) \\ &\leq \alpha(t) \beta(t) G(t). \end{aligned}$$

Integrating with respect to  $t$  and dividing by the non-zero function  $G(t)$  gives

$$\int_0^t \beta(s) F(s) ds \leq \int_0^t \alpha(s) \beta(s) \frac{G(s)}{G(t)} ds,$$

which, having added  $\alpha(t)$  to both sides of the inequality, gives the first proposition of the lemma.

Assuming that  $\alpha(t)$  is non-decreasing, there follows:

$$F(t) \leq \alpha(t) \left( 1 + \int_0^t \beta(s) e^{\int_s^t \beta(r) dr} ds \right).$$

The integrand is a derivative:

$$-\beta(s) e^{\int_s^t \beta(r) dr} = \frac{d}{ds} \left( e^{\int_s^t \beta(r) dr} \right),$$

so

$$\begin{aligned} F(t) &\leq \alpha(t) \left( 1 - \int_0^t \frac{d}{ds} e^{\int_s^t \beta(r) dr} ds \right) \\ &= \alpha(t) \left( 1 + e^{\int_0^t \beta(r) dr} - 1 \right), \end{aligned}$$

and the second proposition of the lemma is also proved. □

Now, the proof of the theorem about continuous dependency on the parameters is easily finished. The bound  $F(t) \leq \alpha + \int_0^t (C F(s) + B) ds$  is already obtained, and using a slightly modified function  $\tilde{F}(t) = F(t) + \frac{B}{C}$ , this yields

$$\tilde{F}(t) \leq \frac{B}{C} + \alpha + \int_0^t C \tilde{F}(s) ds.$$

Substituting into the original conditions, we get the only satisfactory function,

$$\frac{2}{9}e^{2x} + \frac{5}{18}e^{-x} + \frac{1}{3}xe^{-x} - \frac{1}{2}e^x.$$

□

Further problems concerning higher-order differential equations can be found on page 798

**M. Applications of the Laplace transform**

Differential equations with constant coefficients can also be solved using the Laplace transform.

**8.M.1.** Let  $\mathcal{L}(y)(s)$  denote the Laplace transform of a function  $y(t)$ . Integrating by parts, prove that

**Solution.**

$$(1) \quad \begin{aligned} \mathcal{L}(y')(s) &= s\mathcal{L}(y)(s) - y(0) \\ \mathcal{L}(y'')(s) &= s^2\mathcal{L}(y) - sy(0) - y'(0) \end{aligned}$$

and, by induction:

$$\sum_{i=1}^n s^{n-i} y^{(i-1)}(0) . \quad \square$$

**8.M.2.** Find the function  $y(t)$  which satisfies the differential equation

$$y''(t) + 4y(t) = \sin 2t$$

as well as the initial conditions  $y(0) = 0, y'(0) = 0$ .

**Solution.** It follows from the above exercise 7.D.18 that

$$s^2\mathcal{L}(y)(s) + 4\mathcal{L}(y)(s) = \mathcal{L}(\sin 2t)(s).$$

We also have

$$\mathcal{L}(\sin 2t)(s) = \frac{2}{s^2 + 4},$$

i. e.,

$$\mathcal{L}(y)(s) = \frac{2}{(s^2 + 4)^2}.$$

The inverse transform leads to

$$y(t) = \frac{1}{8} \sin 2t - \frac{1}{4}t \cos 2t . \quad \square$$

**8.M.3.** Find the function  $y(t)$  which satisfies the differential equation

$$y''(t) + 6y'(t) + 9y(t) = 50 \sin t$$

and the initial conditions  $y(0) = 1, y'(0) = 4$ .

**Solution.** The Laplace transform yields

$$s^2\mathcal{L}(y)(s) - s - 4 + 6(s\mathcal{L}(y)(s) - 1) + 9\mathcal{L}(y)(s) = 50\mathcal{L}(\sin t)(s),$$

i. e.,

$$(s^2 + 6s + 9)\mathcal{L}(y)(s) = \frac{50}{s^2 + 1} + s + 10,$$

$$\mathcal{L}(y)(s) = \frac{50}{(s^2 + 1)(s + 3)^2} + \frac{s + 10}{(s + 3)^2}.$$

Decomposing the first term to partial fractions, we obtain

$$\frac{50}{(s^2 + 1)(s + 3)^2} = \frac{As + B}{s^2 + 1} + \frac{C}{s + 3} + \frac{D}{(s + 3)^2},$$

This is the assumption of Gronwall's inequality with even constant parameters, so by the second claim of the lemma,

$$F(t) + \frac{B}{C} \leq (\alpha + \frac{B}{C}) e^{\int_0^t C ds},$$

which is the statement

$$F(t) \leq \alpha e^{Ct} + \frac{B}{C}(e^{Ct} - 1)$$

as desired. □

The continuous dependency on both the initial conditions and the potential further parameters in which the function  $f$  would be Lipschitz-continuous follows immediately from the statement of the theorem.

The extremely simple equations in one variable  $x' = ax$ , where  $a$  are small constants, with their exponential solution  $x(t) = e^{at}$  show that better general results cannot be expected.

**8.3.12. Differentiable dependance.** In practical problems, the differentiability of the obtained solutions is often of interest, especially with regard to the initial conditions or other parameters of the system.

In the general vector notation of the system of ordinary equations

$$y' = f(t, y),$$

it can always be supposed that the vector function does not depend explicitly on  $t$ . If it does, then another variable  $y_0$  can be added to the other variables  $y_1, \dots, y_n$ . Then there is the same system of equations for the curve  $\tilde{y}'(t) = (y_0(t), y_1(t), \dots, y_n(t))$  as

$$\begin{aligned} y'_0 &= 1 \\ y'_1 &= f_1(y_0, y_1, \dots, y_n) \\ &\vdots \\ y'_n &= f_n(y_0, y_1, \dots, y_n) \end{aligned}$$

with the initial conditions

$$y_0(t_0) = t_0, y_1(t_0) = x_1, \dots, y_n(t_0) = x_n.$$

Such systems, which do not explicitly depend on time, are called *autonomous systems of ordinary differential equations*.

Without loss of generality, we deal with autonomous systems in finite dimension  $n$ , dependent on parameters  $\lambda$  and with initial conditions

$$(1) \quad y' = f(y, \lambda), y(t_0) = x.$$

Without loss of generality, consider the initial value  $t_0 = 0$ , and write the solution with  $y(0) = x$  in the form  $y(t, x, \lambda)$  to emphasize the dependency on the parameters.

For fixed values of the initial conditions (and the potential parameters  $\lambda$ ), the solution is always once more differentiable than the function  $f$ . This can be derived inductively by applying the chain rule. If  $f$  is continuously differentiable and  $y(t)$  is a solution, then (use the matrix notation where

so

$$50 = (As + B)(s + 3)^2 + C(s^2 + 1)(s + 3) + D(s^2 + 1).$$

Substituting  $s = -3$ , we get

$$50 = 10D \quad \text{hence} \quad D = 5$$

and confronting the coefficients at  $s^3$ , we have

$$0 = A + C, \quad \text{hence} \quad A = -C.$$

Confronting the coefficients at  $s$ , we obtain

$$0 = 9A + 6B + C = 8A + 6B, \quad \text{hence} \quad B = \frac{4}{3}C.$$

Finally, confronting the absolute term, we infer

$$50 = 9B + 3C + D = 12C + 3C + 5$$

$$\text{hence} \quad C = 3, \quad B = 4, \quad A = -3.$$

Since

$$\frac{s + 10}{(s + 3)^2} = \frac{s + 3 + 7}{(s + 3)^2} = \frac{1}{s + 3} + \frac{7}{(s + 3)^2},$$

we have

$$\begin{aligned} \mathcal{L}(y)(s) &= \frac{-3s + 4}{s^2 + 1} + \frac{3}{s + 3} + \frac{5}{(s + 3)^2} + \frac{1}{s + 3} + \frac{7}{(s + 3)^2} \\ &= \frac{-3s}{s^2 + 1} + \frac{4}{s^2 + 1} + \frac{4}{s + 3} + \frac{12}{(s + 3)^2}. \end{aligned}$$

Now, the inverse Laplace transform yields the solution in the form

$$y(t) = -3 \cos t + 4 \sin t + 4e^{-3t} + 12te^{-3t}. \quad \square$$

**8.M.4.** Find the function  $y(t)$  which satisfies the differential equation

$$y''(t) = \cos(\pi t) - y(t), \quad t \in (0, +\infty)$$

and the initial conditions  $y(0) = c_1, y'(0) = c_2$ .

**Solution.** First, we should emphasize that it follows from the theory of ordinary differential equations that this equation has a unique solution. Further, we should recall that

$$\mathcal{L}(f'')(s) = s^2 \mathcal{L}(f)(s) - s \lim_{t \rightarrow 0^+} f(t) - \lim_{t \rightarrow 0^+} f'(t)$$

and

$$\mathcal{L}(\cos(bt))(s) = \frac{s}{s^2 + b^2}, \quad b \in \mathbb{R}.$$

Applying the Laplace transform to the given differential equation then gives

$$s^2 \mathcal{L}(y)(s) - sc_1 - c_2 = \frac{s}{s^2 + \pi^2} - \mathcal{L}(y)(s),$$

i. e.,

$$(1) \quad \mathcal{L}(y)(s) = \frac{s}{(s^2 + 1)(s^2 + \pi^2)} + \frac{c_1 s}{s^2 + 1} + \frac{c_2}{s^2 + 1}.$$

Therefore, it suffices to find a function  $y$  which satisfies (1). Performing partial fraction decomposition, we obtain

$$\frac{s}{(s^2 + 1)(s^2 + \pi^2)} = \frac{1}{\pi^2 - 1} \left( \frac{s}{s^2 + 1} - \frac{s}{s^2 + \pi^2} \right).$$

The above expression of  $\mathcal{L}(\cos(bt))(s)$  and the already proved formula

$$\mathcal{L}(\sin t)(s) = \frac{1}{s^2 + 1}$$

the Jacobi matrix  $D^1 f(y)$  of the mapping  $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$  is multiplied with the column vector  $y'$

$$y'' = D^1 f(y) \cdot y' = D^1 f(y) \cdot f(y)$$

exists and is continuous.

With all the derivatives up to order two continuous, there is an expression for the third derivative:

$$y^{(3)} = D^2 f(y)(f(y), f(y)) + (D^1 f(y))^2 \cdot f(y).$$

Here, the chain rule is used again, starting with the differential of the bilinear mapping of matrix multiplication and viewing the second derivative as a bilinear object evaluated on  $y'$  in both arguments. Think out the argumentation for this and higher orders in detail.

Assume for a while that there is a solution  $y(t, x)$  of the system (1) which is continuously differentiable in the parameters  $x \in \mathbb{R}^n$ , i.e. the initial condition as well, and forget about the further parameters  $\lambda$  for now. Write

$$\Phi(t, x) = D_x^1(y(t, x)),$$

for the Jacobi matrix of all partial derivatives with respect to the coordinates  $x_i$ , which depends on the time  $t$  as well as the initial condition  $x$ . Its derivative  $\Phi'(t, x)$  with respect to  $t$  can be computed using the symmetry of partial derivatives and the chain rule:

$$\begin{aligned} \Phi'(t, x) &= \frac{d}{dt}(D_x^1 y(t, x)) = D_x^1(y'(t, x)) \\ &= D^1 f(y(t, x)) \cdot D_x^1 y(t, x) \\ &= D^1 f(y(t, x)) \cdot \Phi(t, x). \end{aligned}$$

So the derivatives with respect to the initial conditions along the solution  $y(t, x)$  of the system (1) are given as the solutions of a system of  $n^2$  first-order equations with initial condition

$$(2) \quad \Phi'(t, x) = F(t, x) \cdot \Phi(t, x), \quad \Phi(0, x) = E,$$

where  $F(t, x) = D^1 f(y(t, x))$ , and the initial condition comes out from the identity  $y(0, x) = x$ . The unique existence of the solution of this (matrix) system and its continuous dependence on the parameters have already been proved.

The following theorem says that for systems (1) with continuously differentiable right-hand sides  $f$ , the derivatives with respect to the initial condition can be obtained in this way.

#### DIFFERENTIABILITY OF THE SOLUTIONS

**Theorem.** Consider an open subset  $U \subset \mathbb{R}^{n+k}$  and a mapping  $f : U \rightarrow \mathbb{R}^n$  with continuous first derivatives. Then, a system of differential equations dependent on a parameter  $\lambda \in \mathbb{R}^k$  with initial condition at a point  $x \in U$

$$y' = f(y, \lambda), \quad y(0) = x$$

has a unique solution  $y(t, x, \lambda)$ , which is a mapping with continuous first derivatives with respect to each variable.

then yield the wanted solution

$$y(t) = \frac{1}{\pi^2 - 1} (\cos t - \cos(\pi t)) + c_1 \cos t + c_2 \sin t. \quad \square$$

**8.M.5.** Solve the system of differential equations

$$x''(t) + x'(t) = y(t) - y''(t) + e^t, \quad x'(t) + 2x(t) = -y(t) + y'(t) + e^{-t}$$

with the initial conditions  $x(0) = 0, y(0) = 0, x'(0) = 1, y'(0) = 0$ .

**Solution.** Again, we apply the Laplace transform. This, using

$$\mathcal{L}(e^{\pm t})(s) = \frac{1}{s \mp 1},$$

transforms the first equation to

$$s^2 \mathcal{L}(x)(s) - s \lim_{t \rightarrow 0+} x(t) - \lim_{t \rightarrow 0+} x'(t) + s \mathcal{L}(x)(s) - \lim_{t \rightarrow 0+} x(t) =$$

$$\mathcal{L}(y)(s) - \left( s^2 \mathcal{L}(y)(s) - s \lim_{t \rightarrow 0+} y(t) - \lim_{t \rightarrow 0+} y'(t) \right) + \frac{1}{s-1}$$

and the second one to

$$s \mathcal{L}(x)(s) - \lim_{t \rightarrow 0+} x(t) + 2 \mathcal{L}(x)(s) = -\mathcal{L}(y)(s) + s \mathcal{L}(y)(s) - \lim_{t \rightarrow 0+} y(t) + \frac{1}{s+1}.$$

Evaluating the limits (according to the initial conditions), we obtain the linear equations

$$s^2 \mathcal{L}(x)(s) - 1 + s \mathcal{L}(x)(s) = \mathcal{L}(y)(s) - s^2 \mathcal{L}(y)(s) + \frac{1}{s-1}$$

and

$$s \mathcal{L}(x)(s) + 2 \mathcal{L}(x)(s) = -\mathcal{L}(y)(s) + s \mathcal{L}(y)(s) + \frac{1}{s+1}$$

with the only solution

$$\mathcal{L}(x)(s) = \frac{2s-1}{2(s-1)(s+1)^2}, \quad \mathcal{L}(y)(s) = \frac{3s}{2(s^2-1)^2}.$$

Once again, we perform partial fraction decomposition, getting

$$\mathcal{L}(x)(s) = \frac{1}{8} \frac{1}{s-1} + \frac{3}{4} \frac{1}{(s+1)^2} - \frac{1}{8} \frac{1}{s+1} = \frac{3}{4} \frac{1}{(s+1)^2} + \frac{1}{4} \frac{1}{s^2-1}.$$

Since we have already computed that

$$\mathcal{L}(t e^{-t})(s) = \frac{1}{(s+1)^2}, \quad \mathcal{L}(\sinh t)(s) = \frac{1}{s^2-1},$$

$$\mathcal{L}(t \sinh t)(s) = \frac{2s}{(s^2-1)^2},$$

we get

$$x(t) = \frac{3}{4} t e^{-t} + \frac{1}{4} \sinh t, \quad y(t) = \frac{3}{4} t \sinh t.$$

We definitely advise the reader to verify that these functions of  $x$  and  $y$  are indeed the wanted solution. The reason is that the Laplace transforms of the functions  $y = e^t, y = \sinh t$  and  $y = t \sinh t$  were obtained only for  $s > 1$ .  $\square$

**8.M.6.** Find the solution of the following system of differential equations:

$$x'(t) = -2x(t) + 3y(t) + 3t^2,$$

$$y'(t) = -4x(t) + 5y(t) + e^t, \quad x(0) = 1, y(0) = -1$$

**Solution.**

$$\mathcal{L}(x')(s) = \mathcal{L}(-2x + 3y + 3t^2)(s),$$

$$\mathcal{L}(y')(s) = \mathcal{L}(-4x + 5y + e^t)(s).$$

**PROOF.** Consider a general system dependent on parameters, but viewed as an ordinary autonomous system with no parameters. More explicitly, consider the parameters to be additional space variables and add (vector) conditions  $\lambda'(t) = 0$  and  $\lambda(0) = \lambda$ . Therefore, the theorem is proved for autonomous systems with no further parameters. There is dependency on the initial conditions.

Just as in the proof of the fundamental existence theorem 8.3.6, build on the expression of the solutions as fixed points of the integral operators and prove that the expected derivative, as discussed above, enjoys the properties of the differential. Fix a point  $x_0$  as the initial condition, together with a small neighbourhood  $x_0 \in V$ , which if necessary can be further decreased during the following estimates, so that

$$\|f(y) - f(z)\| \leq C \|y - z\|$$

on this neighbourhood by the Lipschitz property. It is already deduced that if the derivative

$$\Phi(t, x) = D_x^1 y(t, x)$$

of the solution  $y(t, x)$  exists, then it must be uniquely given by the equation (2) with the proper initial conditions. Therefore, define  $\Phi(t, x)$  by this equation and examine the expression

$$G(t, h) = \|y(t, x_0 + h) - y(t, x_0) - \Phi(t, x_0)(h)\|$$

with small increments  $h \in \mathbb{R}^n$ . In order to prove that the continuous derivative exists, it is necessary to show that

$$\lim_{h \rightarrow 0} \frac{1}{\|h\|} G(t, h) = 0.$$

Several estimates are needed for this purpose.

First, from the latter theorem 8.3.11 about continuous dependence on initial conditions, the estimate

$$\|y(t, x_0 + h) - y(t, x_0)\| \leq \|h\| e^{C|t|}$$

follows immediately. In the next step, use Taylor's expansion of  $f$  with remainder:

$$f(y) - f(z) = D^1 f(z) \cdot (y - z) + R(y, z),$$

where  $R(y, z)$  satisfies

$$\frac{R(y, z)}{\|y - z\|} \rightarrow 0 \text{ for } \|y - z\| \rightarrow 0.$$

This implies the crucial estimate. In the first equality substitute in the expression of solutions in terms of fixed points of the integral operators. Next, exploit the definition of the mapping  $\Phi(t, x_0)$  in terms of its derivative (write  $F(t, x) = D^1 f(y(t, x))$  again and notice that its initial condition  $\Phi(0, x)(h) = h$  implies the vanishing of the  $h$

The left-hand sides can be written using (1), while the right-hand sides can be rewritten thanks to linearity of the  $\mathcal{L}$  operator. Since  $\mathcal{L}(3t^2)(s) = \frac{6}{s^3}$  and  $\mathcal{L}(e^t)(s) = \frac{1}{s-1}$ , we get the system of linear equations

$$\begin{aligned} s\mathcal{L}(x)(s) - 1 &= -2\mathcal{L}(x)(s) + 3\mathcal{L}(y)(s) + \frac{6}{s^3}, \\ s\mathcal{L}(y)(s) + 1 &= -4\mathcal{L}(x)(s) + 5\mathcal{L}(y)(s) + \frac{1}{s-1}. \end{aligned}$$

In matrices, this is  $\mathbf{A}(s)\hat{\mathbf{x}}(s) = \mathbf{b}(s)$ , where

$$\mathbf{A}(s) = \begin{pmatrix} s+2 & -3 \\ 4 & s-5 \end{pmatrix}, \quad \hat{\mathbf{x}}(s) = \begin{pmatrix} \mathcal{L}(x)(s) \\ \mathcal{L}(y)(s) \end{pmatrix} \quad \text{and} \quad \mathbf{b}(s) = \begin{pmatrix} 1 + \frac{6}{s^3} \\ -1 + \frac{1}{s-1} \end{pmatrix}.$$

Cramer's rule says that

$$\mathcal{L}(x)(s) = \frac{|\mathbf{A}_1|}{|\mathbf{A}|}, \quad \mathcal{L}(y)(s) = \frac{|\mathbf{A}_2|}{|\mathbf{A}|}, \quad \text{where}$$

$$|\mathbf{A}| = \begin{vmatrix} s+2 & -3 \\ 4 & s-5 \end{vmatrix} = s^2 - 3s + 2,$$

$$|\mathbf{A}_1| = \begin{vmatrix} 1 + \frac{6}{s^3} & -3 \\ -1 + \frac{1}{s-1} & s-5 \end{vmatrix} = (s-5)\left(1 + \frac{6}{s^3}\right) + 3\left(-1 + \frac{1}{s-1}\right)$$

$$|\mathbf{A}_2| = \begin{vmatrix} s+2 & 1 + \frac{6}{s^3} \\ 4 & -1 + \frac{1}{s-1} \end{vmatrix} = (s+2)\left(-1 + \frac{1}{s-1}\right) - 4 - \frac{24}{s^3}.$$

Hence,

$$\mathcal{L}(x)(s) = \frac{1}{(s-1)(s-2)} \left( \frac{(s-5)(s^3+6)}{s^3} - 3\frac{s-2}{s-1} \right),$$

$$\mathcal{L}(y)(s) = \frac{1}{(s-1)(s-2)} \left( \frac{(s+2)(2-s)}{s-1} - \frac{4s^3+24}{s^3} \right).$$

Decomposing to partial fractions, the Laplace images of the solutions can be expressed as follows:

$$\mathcal{L}(x)(s) = -\frac{39}{2s^2} - \frac{3}{(s-1)^2} + \frac{28}{s-1} - \frac{21}{4(s-2)} - \frac{15}{s^3} - \frac{87}{4s},$$

$$\mathcal{L}(x)(s) = -\frac{18}{s^2} - \frac{3}{(s-1)^2} + \frac{27}{s-1} - \frac{7}{s-2} - \frac{12}{s^3} - \frac{21}{s}.$$

Now, the inverse transform yields the solution of this Cauchy problem:

$$\begin{aligned} x(t) &= -\frac{39}{2}t - 3te^t + 28e^t - \frac{21}{4}e^{2t} - \frac{15}{2}t^2 - \frac{87}{4}, \\ y(t) &= -18t - 3te^t + 27e^t - 7e^{2t} - 6t^2 - 21. \quad \square \end{aligned}$$

## N. Numerical solution of differential equations

Now, we present two simple exercises on applying the Euler method for solving differential equations.

**8.N.1.** Use the Euler method to solve the equation  $y' = -y^2$  with the initial condition  $y(1) = 1$ . Determine the approximate solution on the interval  $[1, 3]$ . Try to estimate for which value  $h$  of the step is the error less than one tenth.

**Solution.** The Euler method for the considered equation is given by

$$y_{k+1} = y_k - h \cdot y_k^2$$

for

$$x_0 = 1, \quad y_0 = 1, \quad x_k = x_0 + k \cdot h, \quad y_k = y(x_k).$$

We begin the procedure with step value  $h = 1$  and halve it in each iteration. The estimate for the "sufficiency" of  $h$  will be made somewhat imprecisely by comparing two adjacent

summand).

$$\begin{aligned} G(t, h) &= \left\| x_0 + h + \int_0^t f(y(s, x_0 + h)) ds - x_0 \right. \\ &\quad \left. - \int_0^t f(y(s, x_0)) ds - \Phi(t, x_0)(h) \right\| \\ &= \left\| h + \int_0^t \left( f(y(s, x_0 + h)) - f(y(s, x_0)) \right) \right. \\ &\quad \left. - F(s, x_0)\Phi(s, x_0)(h) ds - h \right\| \\ &\leq \int_0^t \|f(y(s, x_0 + h)) - f(y(s, x_0)) \\ &\quad - F(s, x_0)\Phi(s, x_0)(h)\| ds \\ &\leq \int_0^t \|F(s, x_0)\| \|y(s, x_0 + h) - y(s, x_0) - \Phi(s, x_0)(h)\| ds \\ &\quad + \int_0^t \|R(y(s, x_0 + h), y(s, x_0))\| ds, \end{aligned}$$

where the norm on the matrices is taken as the maximum of the absolute values of their entries.

Since  $F(t, x)$  is continuous, there is a uniform bound of its norm in the neighbourhood  $V$  given by

$$\|F(t, x_0)\| \leq B,$$

for all  $|t| < T$  with a sufficiently small  $T$  to ensure the solutions remain in the neighbourhood  $V$ . At the same time, for any fixed constant  $\varepsilon > 0$ , there is a bound  $\|h\| < \delta$  for which the remainder  $R$  satisfies

$$\begin{aligned} \|R(y(t, x_0 + h), y(t, x_0))\| &\leq \varepsilon \|y(t, x_0 + h) - y(t, x_0)\| \\ &\leq \|h\| \varepsilon e^{CT}. \end{aligned}$$

Therefore, the estimate on  $G(t, h)$  can be improved as follows:

$$G(t, h) \leq B \int_0^t G(s, h) ds + \varepsilon \|h\| e^{CT}.$$

Gronwall's lemma now gives

$$G(t, h) \leq \varepsilon \|h\| e^{(C+B)T}.$$

This implies that  $\lim_{h \rightarrow 0} \frac{1}{\|h\|} G(t, h) = 0$  as requested.  $\square$

In the same way, it can be proved that continuous differentiability of the right-hand side up to order  $k$  (inclusive) guarantees the same order of differentiability of solutions in all input parameters.

**8.3.13. The analytic case.** Let us pay additional attention to the case when the right hand side  $f$  of the system of equations

$$(1) \quad y' = f(y), \quad y(t_0) = y_0$$

is analytic in all arguments (i.e., a convergent multidimensional power series  $f(y) = \sum_{|\alpha|=0}^{\infty} \frac{1}{\alpha!} \frac{\partial f^{\alpha}}{\partial y^{\alpha}} y^{\alpha}$ , see 8.1.15). Exactly as in the previous discussion, we may hide the time variable  $t$  as well as further parameters in the variables.

approximate values of the function  $y$  at common points, terminating the procedure if the maximum of the absolute difference of these values is not greater than the tolerated error (0.1).

The results

$h_0 = 1$					
$y^{(0)} = (1 \ 0 \ 0)$					
$h_1 = 0.5$					
$y^{(1)} = (1 \ 0.5 \ 0.375 \ 0.3047 \ 0.2583)$					
Maximal difference: 0.375.					
$h_2 = 0.25$					
$y^{(2)} = (1.0000 \ 0.7500 \ 0.6094 \ 0.5165 \ 0.4498$					
$0.3992 \ 0.3594 \ 0.3271 \ 0.3004)$					
Maximal difference: 0.1094.					
$h_3 = 0.125$					
$y^{(3)} = (1.0000 \ 0.8750 \ 0.7793 \ 0.7034 \ 0.6415$					
$0.5901 \ 0.5466 \ 0.5092 \ 0.4768 \ 0.4484$					
$0.4233 \ 0.4009 \ 0.3808 \ 0.3627$					
$0.3462 \ 0.3312 \ 0.3175)$					
Maximal difference: 0.0322.					

Using suitable software, the following graphical representation of the results can be obtained, where the dashed curve corresponds to the exact solution, which is the function  $y = 1/x$ .

2

□

**8.N.2.** Using the Euler method, solve the equation  $y' = -2y$  with the initial condition  $y(0) = 1$  and step value  $h = 1$ . Explain the phenomenon which occurs here and suggest another procedure.

**Solution.** In this case, the Euler method is given by

$$y_{k+1} = y_k - h \cdot 2y_k = -y_k.$$

For the initial condition  $y_0 = 1$ , we get the alternating values  $\pm 1$  as the result. This is a typical manifestation of the instability of this method for large step values  $h$ . If the step cannot be reduced for some reasons (for instance, when processing digital data, the step value is fixed), better results can be achieved by the so-called *implicit Euler method*. For a general equation  $y' = f(x, y)$ , that is given by the formula

$$y_{k+1} = y_k + h \cdot f(x_{k+1}, y_{k+1}).$$

The famous theorem below says that the solution of the most general system with analytic right-hand side is analytic in all the parameters as well (including the initial conditions).

ODE VERSION OF CAUCHY-KOVALEVSKAYA THEOREM

**Theorem.** Assume  $f(y)$  is a real analytic vector valued function on a domain in  $\mathbb{R}^n$  and consider the differential equation (1). Then the unique solution of this initial problem is real analytic, including the dependency on the initial condition.

**PROOF.** The idea of the proof is identical as in the simple one-dimensional case in 6.2.22. As we saw in the beginning of the previous paragraph, there are universal (multidimensional) polynomial expressions for all derivatives of the vector function  $y(t)$  in terms of the partial derivatives of the vector function  $f$ . If we expand them in terms of the individual partial derivatives of the mapping  $f$  all of their coefficients are obviously non-negative. Let us write again

$$y^{(k)}(0) = P_k(f(y(0)), \dots, \partial_\beta f(y(0)), \dots)$$

for these multivariate vector valued polynomials (the multi-indices  $\beta$  in the arguments are all of size up to  $k - 1$ ).

Without loss of generality we may consider the initial condition  $t_0 = 0, y(0) = 0$ . Indeed, constant shifts of the variables (say  $z = y - y_0, x = t - t_0$ ) transform the general case to this one. Once we know that the components of the solution are power series, the transformed quantities will be analytic too, including the dependency on the values of the incital conditions.

In order to prove that the solution to the problem  $y' = f(y), y(0) = 0$  is analytic on a neighborhood of the origin, we shall again look for a majorant  $g$  for the vector equation  $y' = f(y)$ , i.e. we want an analytic function on a neighborhood of the origin  $0 \in \mathbb{R}^n$  with  $\partial_\alpha g(0) \geq |\partial_\alpha f(0)|$ , for all multi-indices  $\alpha$ . Then, by the universal computations of all the coefficients of the power series  $y(t) = \sum_{k=0}^\infty \frac{1}{k!} y^{(k)}(0) t^k$  solving potentially our problem, and similarly for  $z' = g(z)$ , the convergence of the series for  $z$  implies the same for  $y$ :

$$\begin{aligned} z^{(k)}(0) &= P_k(g(0), \dots, \partial_\beta g(0), \dots) \\ &\geq P_k(|f(0)|, \dots, |\partial_\beta f(0)|) \geq |y^{(k)}(0)|. \end{aligned}$$

As usual, knowing already how to find a majorant in a simpler case, we try to apply a straightforward modification.

By the analycity of  $f$ , for  $r > 0$  small enough there is a constant  $C$  such that  $|\frac{1}{\alpha!} \partial_\alpha f_i(0) r^{|\alpha|}| \leq C$ , for all  $i = 1, \dots, n$  and mutli-indices  $\alpha$ . This means  $|\partial_\alpha f_i(0)| \leq C \frac{\alpha!}{r^{|\alpha|}}$ . In the 1-dimensional case, we considered the multiple of a geometric series  $g(z) = C \frac{r}{r-z}$  with the right derivatives  $g^{(n)} = C \frac{n!}{r^n}$ . Now the most similar mapping is  $g(z_1, \dots, z_n) = (g_1(z_1, \dots, z_n), \dots, g_n(z_1, \dots, z_n))$  with

In general, we thus have to solve a non-linear equation in each step. However, in our problem, we get

$$y_{k+1} = y_k - 2h \cdot y_{k+1},$$

so we have  $y_{k+1} = \frac{1}{3}y_k$  for  $h = 1$ . Again, the obtained results can be represented graphically, including the exact solution of the equation.

all the components  $g_i$  equal to

$$h : \mathbb{R}^n \rightarrow \mathbb{R}, \quad h(z_1, \dots, z_n) = C \frac{r}{r - z_1 - \dots - z_n}.$$

Then the values of all the partial derivatives with  $|\alpha| = k$  at  $z = 0$  are

$$\partial_\alpha h(0) = Crk!(r - z_1 - \dots - z_n)^{-k-1}|_{z=0} = C \frac{k!}{r^k},$$

exactly as suitable. (Check the latter simple computation yourself!)

So it remains to prove that the majorant system  $z' = g(z)$  has got the converging power series solution  $z$ . Obviously, by the symmetry of  $g$  (all components equal to the same  $h$  and  $h$  is symmetric in the variables  $z_i$ ), also the solution  $z$  with  $z(0) = 0$  must have all the components equal (the system does not see any permutation of the variables  $z_i$  at all). Let us write  $z_i(t) = u(t)$  for the common solution components. With this ansatz,

$$u'(t) = h(u(t), u(t), \dots, u(t)) = C \frac{r}{r - nu(t)}.$$

This is nearly exactly the same equation as the one in 6.2.22 and we can easily see its solution with  $u(0) = 0$ :

□

$$u = \frac{r}{n} \left( 1 - \sqrt{1 - \frac{2nCt}{r}} \right).$$

Clearly, this is an analytic solution and the proof is finished. □

**8.3.14. Vector fields and their flows.** Before going to

higher-order equations, pause to consider systems of first-order equations from the geometrical point of view. When drawing illustrations of solutions earlier, we already viewed the right hand side of an autonomous system as a “field of vectors”  $f(x) \in \mathbb{R}^n$ . This shows how fast and in which direction the solution should move in time.

This can be formalized. A *tangent vector* with a footpoint  $x \in \mathbb{R}^n$  is a couple  $(x, v) \in \mathbb{R}^n \times \mathbb{R}^n$ . The set of all vectors with footpoints in an open set  $U \subset \mathbb{R}^n$  is called the *tangent bundle*  $TU$ , with the footpoint projection  $p : (x, v) \mapsto x$ . A *vector field*  $X$  defined on an open set  $U \subset \mathbb{R}^n$  is a mapping  $X : U \rightarrow TU$  which is a section of the projection  $p$ , i.e.,  $p \circ X = \text{id}_U$ . The *derivative in the direction of the vector field*  $X$  is defined for all differentiable functions  $g$  on  $U$  by

$$X(g) : U \rightarrow \mathbb{R}, \quad X(g)(x) = d_{X(x)}g = dg(x)(X(x)).$$

So the vector field  $X$  is a first order linear differential operator mapping functions into functions. Apply pointwise the properties of directional derivative to obtain the *derivative rule* (also called the *Leibniz rule*) for products of functions:

$$(1) \quad X(gh) = hX(g) + gX(h).$$

In fixed coordinates,  $X(x) = (X_1(x), \dots, X_n(x))$  and

$$X(g)(x) = X_1(x) \frac{\partial g}{\partial x_1}(x) + \dots + X_n(x) \frac{\partial g}{\partial x_n}(x).$$

Clearly, there are the special vector fields with coordinate functions equal to zero except for one function  $X_i$  which is identically one. Such a field then corresponds to the partial derivatives with respect to the variable  $x_i$ . This is also matched by the common notation  $\frac{\partial}{\partial x_i}$  for such vector fields and in general,

$$X(x) = X_1(x) \frac{\partial}{\partial x_1} + \cdots + X_n(x) \frac{\partial}{\partial x_n}.$$

**Remark.** Actually, each derivative on functions, i.e., a linear operator  $D$  satisfying (1), is given by a unique vector field. This may be seen as follows. First  $D(1) = D(1 \cdot 1) = 2D(1)$  and, thus,  $D(c) = 0$  for constant functions. Next, each function  $f(x)$  can be written on a neighborhood of a point  $q \in \mathbb{R}^n$  as  $f(x) = f(q) + \int_0^1 \frac{d}{dt} f(q + t(x - q)) dt = f(q) + \sum_{i=1}^n \int_0^1 \frac{\partial f}{\partial x_i}(q + t(x - q)) dt (x_i - q_i) = f(q) + \sum_{i=1}^n \alpha_i(x)(x_i - q_i)$ . Thus,  $D(f) = 0 + \sum_{i=1}^n D(\alpha_i)(q_i - q_i) + \sum_{i=1}^n \alpha_i(q) D(x_i) = \sum_{i=1}^n \frac{\partial f}{\partial x_i}(q) D(x_i)$ . Defining the components  $X_i = D(x_i)$  of the vector field  $X$ , we have obtained  $D$  as the derivative in the direction of  $X$ .

We shall write  $\mathcal{X}(U)$  for the set of all smooth vector fields on  $U$ , i.e. those with all components  $X_i$  smooth. Vector fields  $\frac{\partial}{\partial x_i}$  can be perceived as generators of  $\mathcal{X}(U)$ , admitting smooth functions as the coefficients in linear combinations.

We return to the problem of finding the solution of a system of equations. Rephrase it equivalently as finding a curve which satisfies

$$x'(t) = X(x(t))$$

for each value  $x(t)$  in the domain of the vector field  $X$ . In words: the tangent vector of the curve is given, at each of its points, by the vector field  $X$ . Such a curve is called an *integral curve* of the vector field  $X$ , and the mapping

$$\text{Fl}_t^X : \mathbb{R}^n \rightarrow \mathbb{R}^n,$$

defined at a point  $x_0$  as the value of the integral curve  $x(t)$ , satisfying  $x(0) = x_0$  is called the *flow of the vector field*  $X$ . The theorem about existence and uniqueness of the solution of the systems of equations says (cf. 8.3.6) that for every continuously differentiable vector field  $X$ , its flow exists at every point  $x_0$  of the domain for sufficiently small values of  $t$ . The uniqueness guarantees that

$$\text{Fl}_{t+s}^X(x) = \text{Fl}_t^X \circ \text{Fl}_s^X(x),$$

whenever both sides exist. In particular, the mappings  $\text{Fl}_s^X$  and  $\text{Fl}_t^X$  always commute.

Moreover, the mapping  $\text{Fl}_t^X(x)$  with a fixed parameter  $t$  is differentiable at all points  $x$  where it is defined, cf. 8.3.12.

If a vector field  $X$  is defined on all of  $\mathbb{R}^n$ , and if its support is compact (i.e.,  $X(x) = 0$  off a compact set  $K \subset \mathbb{R}^n$ ), then its flow clearly exists at all points and for all values of  $t$ . Vector fields with flows existing for all  $t \in \mathbb{R}$  are called *complete*. The flow of a complete vector field consists of (mutually commuting) diffeomorphisms  $\text{Fl}_t^X : \mathbb{R}^n \rightarrow \mathbb{R}^n$  with inverse diffeomorphisms  $\text{Fl}_{-t}^X$ .

A simple example of a complete vector field is the field  $X(x) = \frac{\partial}{\partial x_1}$ . Its flow is given by

$$\text{Fl}_t^X(x_1, \dots, x_n) = (x_1 + t, x_2, \dots, x_n).$$

On the other hand, the vector field  $X(t) = t^2 \frac{d}{dt}$  on the one-dimensional space  $\mathbb{R}$  is not complete as the solutions  $x(t)$  of the corresponding equation  $dx = x^2 dt$  are of the form  $x(t) = \frac{1}{C-t}$ , except for the initial condition  $x(0) = 0$ , so they “run away” towards infinite values in a finite time.

The points  $x_0$  in the domain of a vector field  $X : U \subset \mathbb{R}^n \rightarrow \mathbb{R}^n$  where  $X(x_0) = 0$  are called *singular points* of the vector field  $X$ . Clearly  $\text{Fl}_t^X(x_0) = x_0$  for all  $t$  at all singular points.

**8.3.15. Local qualitative description.** The description of vector fields as assigning the tangent vector in the modelling space to each point of the Euclidean space is independent of the coordinates. It follows that the flows exhibit a geometric concept which must be coordinate-free.

It is necessary to know what happens to the fields and their flows, when coordinates are transformed. Suppose  $y = F(x)$  is such a transformation with  $F : \mathbb{R}^n \rightarrow \mathbb{R}^n$  (or on some smaller domain there). Then the solutions  $x(t)$  to a system  $x' = X(x)$  satisfy  $x'(t) = X(x(t))$ , and in the transformed coordinates this reads

$$\begin{aligned} y'(t) &= (F(x(t)))'(t) = D^1 F(x(t)) \cdot x'(t) \\ &= D^1 F(x(t)) \cdot X(x(t)). \end{aligned}$$

This means that the “transformed field”  $Y$  in the new coordinates is  $Y(F(x)) = D^1 F(x) \cdot X(x)$ . At the same time, the flows of these vector fields are related as follows:

$$\text{Fl}_t^Y \circ F(x) = F \circ \text{Fl}_t^X(x).$$

By fixing  $x = x_0$  and writing  $x(t) = \text{Fl}_t^X(x_0)$ , the curve  $F(x(t))$  is the unique solution for the system of equations  $y' = Y(y)$  with initial condition  $y_0 = F(x_0)$ , which equals the right-hand side.

The following theorem offers a geometric local qualitative description of all solutions of systems of first order ordinary differential equations in a neighbourhood of each point  $x$  which is not singular.

THE FLOWBOX THEOREM

**Theorem.** *If  $X$  is a differentiable vector field defined on a neighbourhood of a point  $x_0 \in \mathbb{R}^n$  and  $X(x_0) \neq 0$ , then there exists a transformation of coordinates  $F$  such that in the new coordinates  $y = F(x)$ , the vector field  $X$  is given as the field  $\frac{\partial}{\partial y_1}$ .*

**PROOF.** Construct a diffeomorphism  $F$  with the required properties, step by step. Geometrically, the essence of the proof can be summarized as follows: first select a hypersurface which goes through the point  $x_0$  and is complementary to the directions  $X(x)$  near to  $x_0$ . Then fix the coordinates

on it, and finally, extend them to some neighbourhood of the point  $x_0$  using the flow of the field  $X$ .

Without loss of generality, move the point  $x_0$  to the origin by a translation. Then by a suitable linear transformation on  $\mathbb{R}^n$ , set  $X(0) = \frac{\partial}{\partial x_1}(0)$ . Let us write  $\xi$  for the vector field in question, independent of any coordinates.

In the standard coordinates on  $\mathbb{R}^n$ , write the flow  $\text{Fl}_t^\xi$  of the field  $X$  going through the point  $(x_1, \dots, x_n)$  at time  $t = 0$  as  $x_i(t) = \varphi_i(t, x_1, \dots, x_n)$ ,  $i = 1, \dots, n$ . Next, define the new coordinates  $y = (y_1, \dots, y_n)$  by  $y = \text{Fl}_{y_1}^\xi(0, y_2, \dots, y_n)$ , which corresponds to the inverse transformation  $F^{-1}$  to the diffeomorphism  $F = (f_1, \dots, f_n)$  with the components

$$f_i(x_1, \dots, x_n) = \varphi_i(x_1, 0, x_2, \dots, x_n).$$

This follows exactly the strategy using the hypersurface  $x_1 = 0$ . Since  $\xi(0, \dots, 0) = \frac{\partial}{\partial x_1}$

$$\begin{aligned} \frac{\partial F}{\partial x_1}(0, \dots, 0) &= \frac{d}{dt}\bigg|_0 (\varphi_1(t, 0, \dots, 0), \dots, \varphi_n(t, 0, \dots, 0)) \\ &= (1, 0, \dots, 0), \end{aligned}$$

while the flow  $\text{Fl}_0^\xi$  at the time  $t = 0$  yields

$$\varphi_i(0, 0, x_2, \dots, x_n) = (0, x_2, \dots, x_n),$$

and in particular

$$\frac{\partial F}{\partial x_i}(0, \dots, 0) = (0, \dots, 1, \dots, 0), \quad i = 2, \dots, n.$$

Therefore, the Jacobi matrix of the mapping  $F$  at the origin is the identity matrix  $E$ , so it is a transformation of coordinates on some neighbourhood (see the inverse mapping theorem in paragraph 8.1.23).

Directly from the definition of the mapping  $F^{-1}$  we can compute

$$\begin{aligned} F^{-1}(\text{Fl}_t^\xi(y)) &= F^{-1}(\text{Fl}_{t+y_1}^\xi(0, y_2, \dots, y_n)) \\ &= F^{-1} \circ F(t + y_1, \dots, y_n) = (t + y_1, y_2, \dots, y_n), \end{aligned}$$

and this is the desired coordinate description of the flow in the new coordinates.  $\square$

**8.3.16. Higher-order equations.** An ordinary differential equation of order  $k$  (solved with respect to the highest derivative) is an equation

$$(1) \quad y^{(k)} = f(t, y, y', \dots, y^{(k-1)}),$$

where  $f$  is a known function of  $k + 1$  variables,  $t$  is the independent variable, and  $y(t)$  is an unknown function of one variable. This type of equation is always equivalent to a system of  $k$  first-order equations.

Introduce new unknown functions in a variable  $t$  as follows:

$$y_0(t) = y(t), \quad y_1(t) = y'(t), \dots, \quad y_{k-1}(t) = y^{(k-1)}(t).$$

Now, the function  $y(t)$  is a solution of the original equation (1) if and only if it is the first component of the solution of the system of equations

$$\begin{aligned} y_0' &= y_1 \\ y_1' &= y_2 \\ &\vdots \\ y_{k-2}' &= y_{k-1} \\ y_{k-1}' &= f(t, y_0, y_1, \dots, y_{k-1}). \end{aligned}$$

Hence the following direct corollary of the theorems 8.3.9–8.3.12:

SOLUTIONS OF HIGHER-ORDER ODES

**Theorem.** Consider a function  $f(t, y_0, \dots, y_{k-1}) : U \subset \mathbb{R}^{k+1} \rightarrow \mathbb{R}$  with continuous partial derivatives on an open set  $U$ . Then for every point  $(t_0, z_0, \dots, z_{k-1}) \in U$ , there exists a maximal interval  $I_{max} = (x_0 - a, x_0 + b)$ , with positive numbers  $a, b \in \mathbb{R}$ , and a unique function  $y(t) : I_{max} \rightarrow \mathbb{R}$  which is a solution of the  $k$ -th order equation

$$y^{(k)} = f(t, y, y', \dots, y^{(k-1)})$$

with the initial condition

$$y(t_0) = z_0, y'(t_0) = z_1, \dots, y^{(k-1)}(t_0) = z_{k-1}.$$

This solution depends differentiably on the initial conditions and on potential further parameters differentiably entering the function  $f$ . Moreover, the solution is analytic if the latter dependence is analytic.

In particular, the theorem shows that in order to determine unambiguously the solution of an ordinary  $k$ -th order differential equation, the values of the solution and its first  $k - 1$  derivatives must be determined at one point

With a system of  $\ell$  equations of order  $k$ , the same procedure transforms this system to a system of  $k\ell$  first-order equations. Therefore, an analogous statement about existence, uniqueness, continuity, and differentiability is also true.

If the right-hand side  $f$  of the equation is differentiable up to order  $r$  or analytic, including the parameters, than the same property is enjoyed by the solutions as well.

**8.3.17. Linear differential equations.** The operation of differentiation can be viewed as a linear mapping from (sufficiently) smooth functions to functions. Multiplying the derivatives  $(\frac{d}{dt})^j$  of the particular orders  $j$  by fixed functions  $a_j(t)$  and adding these expressions, gives the *linear differential operators*  $y(t) \mapsto D(y)(t)$ :

$$D(y)(t) = a_k(t)y^{(k)}(t) + \dots + a_1(t)y'(t) + a_0(t)y(t).$$

To solve the corresponding *homogeneous linear differential equation* of order  $k$  then means finding a function  $y$  satisfying  $D(y) = 0$ .

The sum of two solutions is again a solution, since for any functions  $y_1$  and  $y_2$ ,

$$D(y_1 + y_2)(t) = D(y_1)(t) + D(y_2)(t).$$

A constant multiple of a solution is again a solution. So the set of all solutions of a  $k$ -th order linear differential equation is a vector space. Apply the previous theorem about existence and uniqueness, to obtain the following:

#### THE SPACE OF SOLUTIONS OF LINEAR EQUATIONS

**Theorem.** *The set of all solutions of a homogeneous linear differential equation of order  $k$  with continuously differentiable coefficients is a vector space of dimension  $k$ . Therefore, the solutions can be described as linear combinations of any set of  $k$  linearly independent solutions. Such solutions are determined uniquely by linearly independent initial conditions on the value of the function  $y(t)$  and its first  $k - 1$  derivatives at a fixed point  $t_0$ .*

**PROOF.** Choose  $k$  linearly independent initial conditions at a fixed point. For each of them, there is a unique solution. A linear combination of these initial condition then leads to the same linear combination of the corresponding solutions. All of the possible initial conditions are exhausted, so the entire space of solutions of the equation is obtained in this way.  $\square$

The same arguments as with the first order linear differential equations in the paragraph 8.3.4 reveal that all solutions of the non-homogeneous  $k$ -th order equation  $D(y) = b(t)$  with a fixed continuous function  $b(t)$  are the sums of one fixed solution  $y(t)$  of this problem and all solutions  $\tilde{y}$  of the corresponding homogeneous equation. Thus the entire space of solutions is an affine  $k$ -dimensional space of functions. The method of variation of constants exploited in 8.3.4 is one of the possible approaches to guess one non-homogeneous solution if we know the complete solution to the homogeneous problem.

We shall illustrate the latter results on the most simple case:

**8.3.18. Linear equations with constant coefficients.** The previous discussion recalls the situation with homogeneous linear difference equations dealt with in paragraph 3.2.1 of the third chapter. The analogy goes further when all of the coefficients  $a_j$  of the differential operator  $D$  are constant. Such first-order equations (1) have solutions as an exponential with an appropriate constant at the argument. Just as in the case of difference equations, it suggests trying whether such a form of the solution  $y(t) = e^{\lambda t}$  with an unknown parameter  $\lambda$  can satisfy an equation of order  $k$ . Substitution yields

$$D(e^{\lambda t}) = (a_k \lambda^k + a_{k-1} \lambda^{k-1} + \cdots + a_1 \lambda + a_0) e^{\lambda t}.$$

The parameter  $\lambda$  leads to a solution of a linear differential equation with constant coefficients if and only if  $\lambda$  is a root of the *characteristic polynomial*  $a_k \lambda^k + \cdots + a_1 \lambda + a_0$ .

If the root  $\lambda = a + ib \in \mathbb{C}$  is not real, then we may consider the complex valued solution  $e^{\lambda t}$ . Since the conjugate root is also involved, we may consider the linear combinations of the solutions  $e^{\lambda t}$  and  $e^{\bar{\lambda}t}$ , providing the real solutions  $e^{at} \sin(bt)$  and  $e^{at} \cos(bt)$ .

If the characteristic polynomial has  $k$  distinct roots, then we have the basis of the whole vector space of solutions. Otherwise, if  $\lambda$  is a multiple root, then direct calculation, making use of the fact that  $\lambda$  is then a root of the derivative of the characteristic polynomial as well, yields that the function  $y(t) = t e^{\lambda t}$  is also a solution. Similarly, for higher multiplicities  $\ell$ , There are  $\ell$  distinct solutions  $e^{\lambda t}, t e^{\lambda t}, \dots, t^{\ell-1} e^{\lambda t}$ .

In the case of a general linear differential equation, a non-zero value of the differential operator  $D$  is wanted. Again, as for systems of linear equations or linear difference equations, the general solution of this type of (non-homogeneous) equations

$$D(y) = b(t),$$

for a fixed function  $b(t)$ , is the sum of an arbitrary solution of this equation and the set of all solutions of the corresponding homogeneous equation  $D(y)(t) = 0$ . The entire space of solutions is a finite-dimensional affine space, hidden in the huge space of functions.

The methods for finding a particular solution are introduced in concrete examples in the other column. In principle, they are based on looking for the solution in a similar form as the right-hand side is, or the method of variation of the constants.

**8.3.19. Matrix systems with constant coefficients.** Before

leaving the area of differential equations, consider a very special case of first-order systems, whose right-hand side is given by multiplication of a matrix  $A \in \text{Mat}_n(\mathbb{R})$  of constant coefficients and an  $n^2$ -dimensional unknown matrix function  $Y(t)$ :

$$(1) \quad Y'(t) = A \cdot Y(t).$$

Clearly this is a strict analogy to the iterative models in chapter 3 and we also met such a system of  $n^2$  equations 8.3.12(2) when preparing the proof of Theorem 8.3.12.

Combine knowledge from linear algebra and univariate function analysis to guess the solution. Define the *exponential of a matrix* by the formula

$$B(t) = e^{tA} = \sum_{k=0}^{\infty} \frac{t^k}{k!} A^k.$$

The right-hand expression can be formally viewed as a matrix whose entries  $b_{ij}$  are infinite series created from the mentioned products. If all entries of  $A$  are estimated by the maximum of their absolute values  $\|A\| = C$ , then the absolute value of the  $k$ -th summand in  $b_{ij}(t)$  is at most  $\frac{|t|^k}{k!} n^k C^{2k}$ . Hence, every series  $b_{ij}(t)$  is necessarily absolutely and uniformly convergent, and it is bound above by the value  $e^{|t|nC^2}$ . Differentiate the terms of the series one by one, to get a uniformly convergent series with limit  $A e^{tA}$ . Therefore, by the

general properties of uniformly convergent series, the derivative

$$\frac{d}{dt}(e^{tA}) = A e^{tA}$$

also equals this expression. The general solution of the system (1) is obtained in the form

$$Y(t) = e^{tA} \cdot Y_0,$$

where  $Y_0 \in \text{Mat}_n(\mathbb{R})$  is the arbitrary initial condition  $Y(0) = Y_0$ . The exponential  $e^{tA}$  is a well defined invertible matrix for all  $t$ . So we have a vector space of the proper dimension, and hence all solutions to the system (1). Notice that in order to get a solution, it is necessary to multiply by  $Y_0$  from the right.

It is remarkable that dealing with a vector equation with a constant matrix  $A \in \text{Mat}_n(\mathbb{R})$ ,

$$(2) \quad y' = A \cdot y,$$

for an unknown function  $y : \mathbb{R} \rightarrow \mathbb{R}^n$ , then the columns of the matrix exponential  $e^{tA}$  provide  $n$  linearly independent solutions. The general solution is then given by linear combinations of them.

The general solutions of the system (2) may be understood much better by invoking some linear algebra – the Jordan canonical form of linear mappings, see e.g. 3.4.10. In terms of vector fields  $X$ , the system has the linear expression  $X(y) = \Phi(y)$  where  $\Phi$  is the linear mapping with the matrix  $A$  in coordinates. Clearly linear transformations of the system lead to another vector field with such linear description, since the differential of a linear mapping is the mapping itself.

Any linear transformation of coordinates with the (constant) matrix  $T$  transforms the system into

$$\tilde{y}' = (Ty)' = (TAT^{-1}) \cdot (Ty) = \tilde{A} \cdot \tilde{y}.$$

In particular, a suitable change of coordinates  $T$  provides the matrix  $\tilde{A}$  in the Jordan canonical form expressing  $\Phi$  as a sum of two commuting linear mappings  $\Phi = \Phi_d + \Phi_n$  with  $\Phi_d$  diagonalisable and  $\Phi_n$  nilpotent. Moreover, the decomposition of the nilpotent part into the sum of cyclic nilpotent mappings provides the Jordan blocks

$$\begin{aligned} J_\lambda &= \begin{pmatrix} \lambda & 1 & \cdots & 0 \\ 0 & \lambda & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda \end{pmatrix} = (J_\lambda)_d + (J_\lambda)_n \\ &= \begin{pmatrix} \lambda & 0 & \cdots & 0 \\ 0 & \lambda & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda \end{pmatrix} + \begin{pmatrix} 0 & 1 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix}. \end{aligned}$$

Splitting the system (2) into block-wise diagonal form splits also the space of the solutions generated by the exponential  $e^{tA}$  into the corresponding blocks (all the powers  $A^k$  enjoy the same block structure). So we can work with the matrix  $A$  already in the form on one such block  $J_\lambda = (J_\lambda)_d + (J_\lambda)_n$ . But for any two commuting matrices  $C$  and  $D$ , the exponentials  $e^{tC}$  and  $e^{tD}$  commute. So the exponential  $e^{tD}$  of the

nilpotent  $D = (J_\lambda)_n$  can be computed as the finite sum

$$E + t \begin{pmatrix} 0 & 1 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} + \cdots + \frac{t^{k-1}}{(k-1)!} \begin{pmatrix} 0 & 0 & \cdots & 1 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix}.$$

where  $k$  is the size of the block and  $E$  is the identity matrix. The solution of the corresponding matrix system is

$$Y(t) = e^{\lambda t E} \cdot e^{Dt} = e^{\lambda t} e^{Dt} = \begin{pmatrix} e^{\lambda t} & t e^{\lambda t} & \cdots & \frac{t^{k-1}}{(k-1)!} e^{\lambda t} \\ 0 & e^{\lambda t} & \cdots & \frac{t^{k-2}}{(k-2)!} e^{\lambda t} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e^{\lambda t} \end{pmatrix}$$

Finally,  $k$  independent solutions can be written down by inspecting the individual columns in  $Y(t)$ . Notice that the canonical basis  $(e_1, \dots, e_k)$  provides just the chain of vectors with  $D(e_k) = e_{k-1}$ ,  $k = 2, \dots, k$ , while  $D(e_1) = 0$ . Now the  $k$  independent solutions are:

$$\begin{aligned} y_1(t) &= e^{\lambda t} e_1 \\ y_2(t) &= e^{\lambda t} (t e_1 + e_2) \\ &\vdots \\ y_k(t) &= e^{\lambda t} \left( \frac{t^{k-1}}{(k-1)!} e_1 + \frac{t^{k-2}}{(k-2)!} e_2 + \cdots + t e_{k-1} + e_k \right). \end{aligned}$$

The result can be easily transferred back to the original coordinates in which the system (2) was given. Finding the decomposition of the space into Jordan blocks and finding the chains of basis vectors  $v_i$  realizing the cyclic nilpotent components, we arrive at the independent solutions by replacing the  $e_i$  by  $v_i$ .

The findings are summarised in the following theorem, one of many attributed to Euler.

**Theorem.** *All solutions of the system (2) are linear combinations of those in the form combining exponential and polynomial expressions*

$$y(t) = e^{\lambda t} \sum_{j=0}^k p_j t^j$$

where  $k$  is the order of nilpotency of the Jordan block corresponding to the eigenvalue  $\lambda$  of the matrix  $A$ ,  $p_j$  are suitable constant vectors. In particular, if the nilpotent part of  $A$  is trivial, then  $k = 0$ .

This important result allows many generalizations. For example, the Floquet-Lyapunov theory generalizes this behaviour of solutions to systems with periodically time-dependent matrices  $A(t)$ .

**8.3.20. Return to singular points.** Finally, recall the first-order matrix system in paragraph 8.3.12 when the derivative of the solutions of vector equations with respect to the initial conditions was discussed. Consider a differentiable vector field  $X(x)$  defined on a neighbourhood of its singular point  $x_0 \in \mathbb{R}^n$ , i.e.  $X(x_0) = 0$ . Then, the point  $x_0$  is a fixed point of its flow  $\text{Fl}_t^X(x)$ .

The differential  $\Phi(t) = D_x \text{Fl}_t^X(x_0)$  satisfies the matrix system with initial condition (see (2) on page 778)

$$\Phi'(t) = D^1 X(x_0) \cdot \Phi(t), \quad \Phi(0) = E.$$

The important point is that the differential  $D^1 X$  is evaluated along the constant flow line  $x_0$ , since this is a singular point of the system.

The solution is known explicitly, and this describes the evolution of the differential  $\Phi(t)$  of the vector field's flow at the singular point  $x_0$ ,

$$\Phi(t) = e^{tA}, \quad A = D^1 X(x_0).$$

This is a useful step in analysing the qualitative behaviour in a neighbourhood of the stationary point  $x_0$ .

Consider the Lotka-Volterra system from this point of view. Use the coordinates  $(x, y)$  and parameters  $\alpha, \beta, \gamma, \delta$  exactly as in 8.3.10. In particular all these quantities are assumed to be positive.

The vector field in question is

$$X(x, y) = (x(\alpha - \beta y), y(-\gamma + \beta \delta x)).$$

So there is a single singular point (except  $(0, 0)$ )

$$(x_0, y_0) = \left( \frac{\gamma}{\delta \beta}, \frac{\alpha}{\beta} \right)$$

and the differential of  $X$  at this point is

$$D^1 X(x_0, y_0) = \begin{pmatrix} \alpha - \beta y_0 & -\beta x_0 \\ \delta \beta y_0 & \delta \beta x_0 - \gamma \end{pmatrix} = \begin{pmatrix} 0 & -\frac{\gamma}{\delta} \\ \alpha \delta & 0 \end{pmatrix}$$

The characteristic polynomial of the latter matrix is  $\lambda^2 + \gamma\alpha$  and so there are two complex conjugated roots  $\lambda = \pm i\sqrt{\alpha\gamma}$ . As is known from linear algebra, such a matrix describes a rotation in suitable coordinates. Compute the real and imaginary components of the eigenvectors corresponding to  $\lambda$  (as developed in linear algebra), to obtain the matrix solution in the form

$$Y(t) = \begin{pmatrix} \cos \sqrt{\alpha\gamma} t & -\sin \sqrt{\alpha\gamma} t \\ \delta \sqrt{\frac{\alpha}{\gamma}} \sin \sqrt{\alpha\gamma} t & \delta \sqrt{\frac{\alpha}{\gamma}} \cos \sqrt{\alpha\gamma} t \end{pmatrix}.$$

The columns are the two independent solutions  $y(t)$  (they differ just by the phase of the linearly distorted rotation).

This might be useful information for further analysis of the model around its singular point. For example, the parameter  $\beta$  does not appear explicitly here, while  $\delta$  influences the distortion of the flow lines from being circles. Compare this with the illustrations on page 774. For a first approximation, guess that the sizes of the populations of both the prey and the predator oscillate regularly around the values of the singular point if the initial conditions are near this point.

**8.3.21. A note about Markov chains.** In the third chapter, we dealt with iterative processes, where the stochastic matrices and Markov processes determined by them played an interesting role. Recall that a matrix  $A$  is stochastic if the sum of each of its columns is one. In other words,

$$(1 \dots 1) \cdot A = (1 \dots 1).$$

Take the exponential  $e^{tA}$  to obtain

$$(1 \dots 1) \cdot e^{tA} = \sum_{k=0}^{\infty} \frac{t^k}{k!} (1 \dots 1) \cdot A^k = e^t (1 \dots 1).$$

Therefore, for every  $t$ , the invertible matrix

$$B(t) = e^{-t} e^{tA}$$

is stochastic, if  $A$  is stochastic. Add stochastic initial conditions  $B_0$ , to get the flow  $B(t) = e^{-t} e^{tA} \cdot B_0$ , which is a continuous version of the Markov process (infinitesimally) generated by the stochastic matrix  $A$ .

Differentiating with respect to  $t$ , yields

$$\frac{d}{dt} B(t) = -e^{-t} e^{tA} \cdot B_0 + e^{-t} A e^{tA} \cdot B_0 = (-E + A)B(t),$$

so the matrix  $B(t)$  is the solution of the matrix system of equations with constant coefficients

$$Y'(t) = (A - E) \cdot Y(t)$$

with the stochastic matrix  $A$ .

This can be explained intuitively. If the matrix  $A$  is stochastic, then the instantaneous increment of the stochastic vector  $y(t)$  in the vector system with the matrix  $A$ ,  $y'(t) = A \cdot y(t)$ , is again a stochastic vector. However, it is desired that the Markov process keeps the vector  $y(t)$  stochastic for all  $t$ . Hence, the sum of increments of the particular components of the vector  $y(t)$  must be zero, which is guaranteed by subtracting the identity matrix.

As seen above, the columns of the matrix solution  $Y'(t)$  create a basis of all solutions  $y'(t)$  of the vector system.

Much information can be obtained about the solutions by using some linear algebra. For example, suppose that the matrix  $A$  is primitive, that is, suppose one of its powers has only positive entries, see 3.3.3 on page 214. Then its powers converge to a matrix  $A_\infty$ , all of whose columns are eigenvectors corresponding to the eigenvalue 1.

Next, estimate the difference between the solution  $Y'(t)$  for large  $t$  and the constant matrix  $A_\infty$ . There are two consequences from the latter convergence. First, there exists a universal constant bound for all powers  $\|A^k - A_\infty\| \leq C$ . Second, for every small positive  $\varepsilon$ , there is an  $N \in \mathbb{N}$  such that for all  $k \geq N$ ,  $\|A^k - A_\infty\| \leq \varepsilon$ . Hence,

$$\begin{aligned} \left\| e^{-t} \sum_{k=0}^{\infty} \frac{t^k}{k!} A^k - e^{-t} \sum_{k=0}^{\infty} \frac{t^k}{k!} A_\infty \right\| \\ \leq e^{-t} \sum_{k < N} \frac{t^k}{k!} C \|A_\infty\| + \varepsilon \|A_\infty\|. \end{aligned}$$

Let  $t \rightarrow \infty$ . The limit of the expression  $f(t) = e^{-t} \sum_{k < N} \frac{t^k}{k!}$  can easily be computed by iterative application of l'Hospital's rule. Differentiation of the sum yields the same, only for  $N$  smaller by one, and the derivative in the denominator is not changed, so the limit is zero. Therefore, for fixed  $\varepsilon$ , there is a time  $T$  such that  $f(t)$  would be less than  $\varepsilon$  for  $t \geq T$ . The whole expression has

been estimated (for  $n \geq N$  and  $t \geq T > 0$ ) by the value  $\varepsilon(C + 1)\|A_\infty\|$ .

Summarizing, a very interesting statement is proved, which resembles the discrete version of Markov processes:

#### CONTINUOUS PROCESSES WITH A STOCHASTIC MATRIX

**Theorem.** Every primitive stochastic matrix  $A$  determines a vector system of equations

$$y' = (A - E) \cdot y$$

with the following properties:

- the basis of the vector space of all solutions is given by the columns of the stochastic matrix

$$Y(t) = e^{-t} e^{tA},$$

- if the initial condition  $y_0 = y(t_0)$  is a stochastic vector, then the solution  $y(t)$  is also a stochastic vector for all values of  $t$ ,
- every stochastic solution converges for  $t \rightarrow \infty$  to the stochastic eigenvector  $y_\infty$  of the matrix  $A$  corresponding to the eigenvalue 1.

**8.3.22. Remarks on numerical methods.** Except for the exceptionally simple equations, for example, linear equations with constant coefficients, analytically solvable equations are seldom encountered in practice. Therefore, some techniques are required to approximate the solutions of the equations.

Approximations have already been considered in many other situations. (Recall the interpolation polynomials and splines, exploitation of Taylor polynomials in methods for numerical differentiation and integration, Fourier series etc.). With a little courage, consider difference and differential equations to be mutual approximations. In one direction, replace differences with differentials (for example, in economical or population models). For other situations the differences may imitate well continuous changes in models.

Use the terminology for asymptotic estimates, as introduced in 6.1.12. In particular, an expression  $G(h)$  is asymptotically equal to  $F(h)$  for  $h$  approaching zero or infinity, and write  $G(h) = O(F(h))$ , if the finite limit of  $G(h)/F(h)$  exists.

A good example is the approximation of a multivariate function  $f(x)$  by its Taylor polynomial of order  $k$  at a point  $x_0$ . Taylor's theorem says that the error of this approximation is  $O(\|h\|^{k+1})$ , where  $h$  is the increment of the argument  $h = x - x_0$ .

In the case of ordinary differential equations, the simplest scheme is approximation using *Euler polygons*. Present this method for a single ordinary equation with two quantities: one independent and one dependent. It works analogously for systems of equations where scalar quantities and their derivatives in time  $t$  are replaced with vectors dependent on time and their derivatives. This procedure was used before in the proof of the Peano's existence theorem, see 8.3.8.

Consider an equation

$$y' = f(t, y)$$

with continuous right-hand  $f$ . Denote the discrete increment of time by  $h$ , i.e. set  $t_n = t_0 + nh$ . It is desired to approximate  $y(t)$ . It follows from Taylor's theorem (with remainder of order two) and the equation that

$$\begin{aligned} y(t_{n+1}) &= y(t_n) + y'(t_n)h + O(h^2) \\ &= y(t_n) + f(t_n, y(t_n))h + O(h^2). \end{aligned}$$

Define recurrently the values  $y_j$  by the first order formula

$$y_{j+1} = y_j + f(t_j, y_j)h.$$

This leads to the local approximation error  $O(h^2)$ , occurring in one step of the recurrence.

If  $n$  such steps are needed with increment  $h$  from  $t_0$  to  $t = t_n$ , the error could be up to  $nO(h^2) = \frac{1}{h}(t-t_0)O(h^2) = O(h)$ . More care is needed, since the function  $f(t, y)$  is evaluated in the approximate points  $(t_i, y_i)$  and the already approximate previous values  $y_j$ . In order to keep control,  $f(t, y)$  must be Lipschitz in  $y$ . Assuming inductively that the estimate is true for all  $i < j$ ,

$$|f(t_j, y(t_j)) - f(t_j, y_j)| \leq C|y(t_j) - y_j| \leq C|t - t_0|O(h)$$

where  $C$  is the Lipschitz constant, assuming that the error does not exceed  $O(h)$  with globally valid constant for  $y_j$ . Inductively, the expected bound  $O(h)$  for the global error estimate is obtained. Think about the details.

The Euler procedure is the simplest method within the class of the *Runge-Kutta* methods.

Dealing with higher order equations, we may either view them as vector valued first order systems (as in the theoretical column) and then even Euler method provides results for the initial condition on the necessary number of derivatives in one point. But in practical problems, it is often needed to find solutions passing through more than one prescribed point. For example, with second order equations, prescribe two values  $y(t_1)$  and  $y(t_2)$  of the solution. This would need completely different methods.

**O. Additional exercises to the whole chapter**

**8.O.1.** A basin with volume 300 hl contains 100 hl of water in which 50 kg of salt is dissolved. Water with 2 kg of salt per 1 hl starts flowing into the basin at 6 hl/min. The mixture, being kept homogeneous by permanent stirring, leaves the basin at 4 hl/min. Express the amount of salt (in kg) in the basin after  $t$  minutes have expired as a function of the variable  $t \in [0, 100]$ .

**8.O.2.** During a controlled experiment, a small smelting furnace is slowly cooling down while the outer temperature keeps at 300 K. The experiment began at noon. At 1 pm, the temperature in the furnace was estimated at 1300 K. At 3 pm, it was only 550 K. Supposing the measurements were accurate, compute what the temperature in the furnace was at 2 pm.

**8.O.3.** The half-life of the radioactive sulfur isotope  $^{35}\text{S}$  is 87.5 days. After what period are there only 900 grams left of the original amount of 1 kilogram of this isotope? (You may express the result in terms of the natural logarithm.)

**8.O.4.** The half-time of a radioactive element  $A$  is 5 years; for an element  $B$ , it is 1 year. If we have 5 kg of element  $B$  and 1 kg of element  $A$ , after what period will we have the same amount of both? (You may express the result in terms of the natural logarithm.)

**8.O.5.** The half-time of a radioactive element  $A$  is 8 years; for an element  $B$ , it is 2 years. If we have 3 kg of element  $B$  and 1 kg of element  $A$ , after what period will we have the same amount of both? (You may express the result in terms of the natural logarithm.)

**8.O.6.** The half-life of the radioactive cobalt isotope  $^{60}\text{Co}$  is 5.27 years. Having 4 kg of this isotope, after what period does 1 kg of it decay? (You may express the result in terms of the natural logarithm.)

**8.O.7.** Solve the following differential equation for the function  $y = y(x)$ :

$$y' = \frac{1 + y^2}{1 + x^2}.$$

**8.O.8.** Determine all solutions of the following equation with separated variables:

$$y - y^2 + xy' = 0.$$

**8.O.9.** Solve the equation

$$1 + \frac{dy}{dx} = e^y.$$

**8.O.10.** Solve the equation  $2y = x^3y'$ .

**8.O.11.** Determine all solutions of the equation

$$\sqrt{4 - y^2} dx + y dy = 0.$$

**8.O.12.** Solve

$$y' \tan x = y^2 + 1 - 2y.$$

**8.O.13.** Determine the general solution of the differential equation

$$\frac{x^2+1}{x} = \frac{y}{1-y^2} y'.$$

**8.O.14.** Find the general solution of the differential equation

$$(x + 1) dy + xy dx = 0.$$

**8.O.15.** Find the solution of the differential equation

$$\sin y \cos x \, dy = \cos y \sin x \, dx$$

which satisfies  $4y(0) = \pi$ .

**8.O.16.** Solve the initial problem

$$(x^2 + 1)(y^2 - 1) + xy y' = 0, \quad y(1) = \sqrt{2}.$$

**8.O.17.** Determine the particular solution of the equation

$$y' \sin x = y \ln y$$

which goes through the point  $[\pi/2, e]$ .

**8.O.18.** Find all solutions of the differential equation

$$2(1 + e^x)yy' = e^x,$$

which satisfy  $y(0) = 0$ .

**8.O.19.** Solve the homogeneous equation

$$(xy' - y) \cos \frac{y}{x} = x.$$

**8.O.20.** Determine the general solution of the homogeneous differential equation  $y^3 = x^3 y'$ .

**8.O.21.** Find all solutions of the equation

$$xy' = \sqrt{x^2 - y^2} + y.$$

**8.O.22.** Determine the general solution if we are given

$$xy' = y \cos \left( \ln \frac{y}{x} \right).$$

**8.O.23.** Solve the equation  $(x + y) \, dx - (x - y) \, dy = 0$  as homogeneous.

**8.O.24.** Calculate  $y' = (x + y)^2$ .

**8.O.25.** Find the general solution for

$$y' = \frac{x-y+3}{x+y-5}.$$

**8.O.26.** Calculate

$$y' = \frac{x-y+1}{x-y}.$$

**8.O.27.** Determine all solutions of the differential equation

$$y' = \frac{5y-5x-1}{2y-2x-1}.$$

**8.O.28.** Find the general solution of the equation

$$y' = \frac{x-y-1}{x+y+3}.$$

8.0.29. Determine the general solution for the equation

$$y' = \frac{2x-y-5}{x-3y-5}.$$

8.0.30. Express the solutions of the equation

$$y' = \frac{x+2y-7}{x-3}$$

as explicitly given functions.

8.0.31. Using the method of constant variation, calculate  $y' + 2y = x$ .

8.0.32. Determine the general solution of the equation  $y' = 6x + 2y + 3$ .

8.0.33. Solve the linear equation

$$y' = 4xy + (2x + 1)e^{2x^2}.$$

8.0.34. Solve the equation  $y'x + y = x \ln x$ .

8.0.35. Calculate the linear differential equation

$$y'x = y + x^2 \ln x.$$

8.0.36. Find all solutions of the equation

$$y' \cos x = (y + 2 \cos x) \sin x.$$

8.0.37. Find the solution of the equation  $y' = 6x - 2y$  which satisfies the initial condition  $y(0) = 0$ .

8.0.38. Solve the initial problem

$$y' + y \sin x = \sin x, \quad y\left(\frac{\pi}{2}\right) = 2.$$

8.0.39. Find the solution of the equation  $y' = 4y + \cos x$  which goes through the point  $[0, 1]$ .

8.0.40. Solve the following equation for any  $a, b \in \mathbb{R}$ :

$$xy' + y = e^x, \quad y(a) = b.$$

8.0.41. Determine the general solution of the equation

$$3x^2y' + xy = \frac{1}{y^2}.$$

8.0.42. Solve the Bernoulli equation

$$y' = xy - y^3 e^{-x^2}.$$

8.0.43. Calculate the Bernoulli equation

$$y' - \frac{y}{x} = y^2 \sin x.$$

8.0.44. Find all solutions of the equation

$$y' = \frac{4y}{x} + x\sqrt{y}.$$

8.0.45. Solve the equation

$$xy' + 2y + x^5y^3e^x = 0.$$

8.0.46. Find the general solution of the following equation provided  $a, b > 0$ :

$$y dy = \left( a \frac{y^2}{x^2} + b \frac{1}{x^2} \right) dx.$$

8.0.47. Interchanging the variables, solve

$$2y + (y^2 - 6x)y' = 0.$$

8.0.48. Solve the equation

$$y' = \frac{y}{2y \ln y + y - x}.$$

8.0.49. Calculate the general solution of the following equation:

$$x dx = \left( \frac{x^2}{y} - y^3 \right) dy.$$

8.0.50. Interchanging the variables, calculate

$$(x + y) dy = y dx + y \ln y dy.$$

8.0.51. Solve

$$y' (e^{-y} - x) = 1.$$

8.0.52. Calculate

$$y' = \frac{1}{2x - y^2}.$$

8.0.53. Solve the equation

$$2y dx + x dy = 2y^3 dy.$$

8.0.54. Calculate

$$y'' + 3y' + 2y = (20x + 29)e^{3x}.$$

8.0.55. Find any solution of the non-homogeneous linear equation

$$y'' + y' + \frac{5}{2}y = 25 \cos(2x).$$

**8.0.56.** Determine the solution of the equation

$$y'' + 2y' + 2y = 3e^{-x} \cos x.$$

**8.0.57.** Find the solution of the equation

$$y'' = 2y' + y + 1,$$

which satisfies  $y(0) = 0$  and  $y'(0) = 1$ .

**8.0.58.** Find the solution of the equation

$$y'' = 4y - 3y' + 1$$

which satisfies  $y(0) = 0$  and  $y'(0) = 2$ .

**8.0.59.** Determine the general solution of the linear equation

$$y'' - 2y' + 5y = 5e^{2x} \sin x.$$

**8.0.60.** Taking advantage of the special form of the right-hand side, find all solutions of the equation

$$y'' + y' = x^2 - x + 6e^{2x}.$$

**8.0.61.** Solve

$$y^{(4)} - 2y'' + y = 8(e^x + e^{-x}) + 4(\sin x + \cos x).$$

**8.0.62.** Using the method of constant variation, calculate

$$y'' - 2y' + y = \frac{e^x}{x}.$$

**8.0.63.** Solve

$$y'' + 4y' + 4y = e^{-2x} \ln x.$$

**8.0.64.** Using the method of constant variation, find the general solution of the equation

$$y'' + 4y = \frac{1}{\sin(2x)}.$$

**8.0.65.** Solve the equation  $y'' + y = \tan^2 x$ .

**8.0.66.** Find the solution of the differential equation

$$y^{(3)} = -2y'' - 2y' - y + \sin(x)$$

which satisfies  $y(0) = -\frac{1}{2}$ ,  $y'(0) = \frac{\sqrt{3}}{2}$ , and  $y''(0) = -1 - \frac{\sqrt{3}}{2}$ .

**8.0.67.** Calculate the equation  $y''' - 2y'' - y' + 2y = 0$ .

**8.0.68.** Find the general solution of the equation

$$y^{(4)} + 2y'' + y = 0.$$

**8.O.69.** Solve

$$y^{(6)} + 2y^{(5)} + 4y^{(4)} + 4y''' + 5y'' + 2y' + 2y = 0.$$

**8.O.70.** Find the general solution of the linear equation

$$y^{(5)} - 3y^{(4)} + 2y''' = 8x - 12.$$

**Key to the exercises**

## Continuous models – further selected topics

*The World might be discrete in reality.  
But the continuous models are useful anyhow ...*

### A. Exterior differential calculus

### B. Applications of Stoke's theorem

9.B.1. Compute

$$\int_c (x - y)dx + x dy,$$

where  $c$  is the positively oriented curve represented by the perimeter of the square  $ABCD$  with vertices  $A = [2, 2]$ ;  $B = [-2, 2]$ ;  $C = [-2, -2]$ ;  $D = [2, -2]$ .

**Solution.** Using Green's theorem (see ??), we reduce the given curve integral to an area (multiple) integral. The integral is of the form  $\int_c f(x, y) dx + g(x, y) dy$ , where  $f(x, y) = x - y$  and  $g(x, y) = x$ . The needed partial derivatives of the functions  $f(x, y)$  and  $g(x, y)$  are thus  $f_y(x, y) = -1$  and  $g_x(x, y) = 1$ . All of the functions  $f(x, y)$ ,  $g(x, y)$ ,  $f_y(x, y)$ , and  $g_x(x, y)$  are continuous on  $\mathbb{R}^2$ , so we can use Green's theorem:

$$\int_c (x - y)dx + xdy = \iint_D (1 + 1)dxdy = 2 \iint_D dxdy$$

This chapter presents several glimpses towards more serious applications of the differential and integral calculus. We cannot be ambitious in covering the displayed topics extensively. Thus, after reasonably detailed introduction to more geometric approach to the differential and integral calculus, we present rather quick surveys and comments on partial differential equations, variational calculus, and complex analysis. We hope the readers will get excited at least by some of them and look for further resources themselves.

many pictures missing!!!

### 1. Exterior differential calculus and integration

We have already seen how to optimize functions on subsets in  $\mathbb{R}^n$ , but how to integrate quantities over such domains? For example, if we have 2-dimensional membrane in  $\mathbb{R}^3$  and we know the infinitesimal flow of some liquid through it, how to compute how much went through within a time interval?

In order to understand such questions properly, we formalize the concept of the level sets  $M_b$  from the paragraph 8.1.24 devoted to the implicit functions and provide a geometric explanation of the integration process. Then we quite easily arrive at several powerful tools, including the Stokes theorem, which is a higher dimensional extension to the fundamental theorem of (univariate) calculus, and the Frobenius theorem which generalizes the integration of prescribed line elements into a solution of an ODE to higher dimensions.

#### 9.1.1. Vector fields and differential forms.

Let us come back to the concept of tangent vectors and vector fields, cf. 8.3.14 where we introduced the *tangent space*  $TU = U \times \mathbb{R}^n$  as the set of all possible tangent vectors at the points of an open subset  $U \subset \mathbb{R}^n$ . There is the projection  $p : TU \rightarrow U$  assigning the foot points to the tangent vectors, we write  $T_x U$  for the vector space of all vectors  $X$  with  $p(X) = x$  at a point  $x \in U$ , and we use the notation  $\mathcal{X}(U)$  for the set of all smooth vector fields on the open subset  $U$ .

The linear combinations of the special vector fields  $\frac{\partial}{\partial x_i}$  admitting smooth functions as the coefficients generate the entire  $\mathcal{X}(U)$ . Thus we write general vector fields as

$$X(x) = X_1(x) \frac{\partial}{\partial x_1} + \dots + X_n(x) \frac{\partial}{\partial x_n}.$$

$$= 2 \int_{-2}^2 \int_{-2}^2 dx dy = 2[x]_{-2}^2 \cdot [y]_{-2}^2 = 32.$$

**9.B.2.** Compute

$$\int_c x^4 dx + xy dy,$$

where  $c$  is the positively oriented curve going through the vertices  $A = [0, 0]$ ;  $B = [1, 0]$ ;  $C = [0, 1]$ .

**Solution.** The curve  $c$  is the boundary of the triangle  $ABC$ . The integrated functions are continuously differentiable on the whole  $\mathbb{R}^2$ , so we can use Green's theorem:

$$\begin{aligned} \int_c x^4 dx + xy dy &= \iint_D y dx dy = \int_0^1 \int_0^{1-x} y dx dy \\ &= \int_0^1 \left[ \frac{y^2}{2} \right]_0^{1-x} dx = \int_0^1 \left[ \frac{x^2 - 2x + 1}{2} \right] dx \\ &= \frac{1}{2} \left[ \frac{x^3}{3} - \frac{2x^2}{2} + x \right]_0^1 = \frac{1}{6}. \end{aligned}$$

**9.B.3.** Calculate

$$\int_c (xy + x + y) dx + (xy + x - y) dy,$$

where  $c$  is the circle with radius 1 centered at the origin.

**Solution.** Again, the prerequisites of Green's theorem are satisfied, so we can use Green's theorem, which now gives

$$\begin{aligned} &\int_c (xy + x + y) dx + (xy + x - y) dy \\ &= \iint_D y + 1 - x - 1 dx dy \\ &= \int_0^1 \int_0^{2\pi} r^2 (\sin \varphi - \cos \varphi) dr d\varphi \\ &= \int_0^1 r^2 dr \int_0^{2\pi} \sin \varphi - \cos \varphi d\varphi \\ &= \frac{1}{3} [-\cos \varphi - \sin \varphi]_0^{2\pi} = 0. \end{aligned}$$

**9.B.4.** Compute  $\int_c (2e^{2x} \sin y - 3y^3) dx + (e^{2x} \cos y + \frac{4}{3}x^3) dy$ , where  $c$  is the positively oriented ellipse  $4x^2 + 9y^2 = 36$ .

**Solution.:** We will use Green's theorem, choosing the linear deformation of polar coordinates  $x = 3r \cos \varphi$ ,  $\varphi \in [0, 2\pi]$ ,

As we know, every differentiable mapping  $F : U \rightarrow V$  between two open sets  $U \subset \mathbb{R}^n$ ,  $V \subset \mathbb{R}^m$  defines the mapping  $F_* : TU \rightarrow TV$  by applying the differential  $D^1F$  to the individual tangent vectors. Thus if  $y = F(x) = (f_1(x), \dots, f_m(x))$  then  $F_* : T_x U \rightarrow T_{F(x)} V$ ,

$$F_* \left( \sum_{i=1}^n X_i(x) \frac{\partial}{\partial x_i} \right) (y) = \sum_{j=1}^m \left( \sum_{i=1}^n \frac{\partial f_j(x)}{\partial x_i} X_i(x) \right) \frac{\partial}{\partial y_j} (y).$$

When we studied the vector spaces in chapter two, we came across the useful concept of linear forms. They were defined in paragraph 2.3.17 on page 122. This idea extends naturally now. A scalar valued linear mapping defined on the tangent space  $T_x U$  is such a linear form at the foot point  $x$ . The vector space of all such forms  $T_x^* U = (T_x U)^*$  is thus naturally isomorphic to  $\mathbb{R}^{n*}$  and the collection  $T^* U$  of these spaces comes equipped by the projection to the foot points, let us denote it again by  $p$ . Having a mapping  $\eta : U \subset \mathbb{R}^n \rightarrow T^* U$  with values  $\eta(x) \in T_x^* U$  on an open subset  $U$ , i.e.,  $p \circ \eta = \text{id}_U$ , we talk about a *differential form*  $\eta$  on  $U$ , or a *linear form*.

Every differentiable function  $f$  on an open subset  $U \subset \mathbb{R}^n$  defines the differential form  $df$  on  $U$  (cf. 8.1.7). We use the notation  $\Omega^1(U)$  for the set of all smooth linear differential forms on the open set  $U$ .

In the chosen coordinates  $(x_1, \dots, x_n)$  we can use the differentials of the particular coordinate functions to express every linear form  $\eta$  as

$$\eta(x) = \eta_1(x) dx_1 + \dots + \eta_n(x) dx_n,$$

where  $\eta_i(x)$  are uniquely determined functions. Such a form  $\eta$  evaluates on a vector field  $X(x) = X_1(x) \frac{\partial}{\partial x_1} + \dots + X_n(x) \frac{\partial}{\partial x_n}$  as

$$\eta(X)(x) = \eta(x)(X(x)) = \eta_1(x) X_1(x) + \dots + \eta_n(x) X_n(x).$$

If the form  $\eta$  is the differential of a function  $f$ , we get just back the expression

$$X(f)(x) = df(X(x)) = \frac{\partial f}{\partial x_1} X_1(x) + \dots + \frac{\partial f}{\partial x_n} X_n(x)$$

for the derivative of  $f$  in the direction of the vector field  $X$ .

**9.1.2. Exterior differential forms.** As we discussed already in chapters 1 and 4, the volume of  $k$ -dimensional parallelepipeds  $S$ , as a quantity depending of the  $k$  vectors spanning  $S$ , is an antisymmetric  $k$ -linear form on the vectors, see 2.3.23 on page 127. Remember also the computation of the volume of parallelepipeds in terms of determinants in 4.1.19 on page 334.

Thus, if we want to talk about the (linearized) volume on  $k$ -dimensional objects, we need a concept which will be linear in  $k$  distinct tangent vector arguments and will assign a scalar quantity to them. Moreover, we will require that interchanging any pair of arguments swaps the sign, in accordance with the orientations.

$y = 2r \sin \varphi$   $r \in [0, 1]$ ,  
 leading to (the Jacobian of the transformation is  $6r$ ):

$$\begin{aligned} & \int_c (2e^{2x} \sin y - 3y^3) dx + (e^{2x} \cos y + \frac{4}{3}x^3) dy = \\ & = \iint_D 2e^{2x} \cos y + 4x^2 - (2e^{2x} \cos y - 9y^2) dx dy = \\ & = \int_0^1 \int_0^{2\pi} 6r [4(3r \cos \varphi)^2 + 9(2r \sin \varphi)^2] = \\ & = 216 \int_0^1 r^3 dr \int_0^{2\pi} d\varphi = 216 \cdot [\frac{r^4}{4}]_0^1 \cdot 2\pi = 108\pi. \end{aligned}$$

**9.B.5.** Compute

$$\int_c (e^x \ln y - y^2 x) dx + \left( \frac{e^x}{y} - \frac{1}{2}x^2 y \right) dy,$$

where  $c$  is the positively oriented circle  $(x-2)^2 + (y-2)^2 = 1$ .

**Solution.**

$$\begin{aligned} & \int_c (e^x \ln y - y^2 x) dx + \left( \frac{e^x}{y} - \frac{1}{2}x^2 y \right) dy = \\ & = \iint_D \frac{e^x}{y} - xy - \frac{e^x}{y} + 2xy dx dy = \\ & = \int_0^1 \int_0^{2\pi} r(r \cos \varphi + 2) \cdot (r \sin \varphi + 2) dr d\varphi = \\ & = \int_0^1 \int_0^{2\pi} r^3 \sin \varphi \cos \varphi + 2r^2(\sin \varphi + \cos \varphi) + 4r dr d\varphi = \\ & = \frac{1}{4} \int_0^{2\pi} \sin \varphi \cos \varphi d\varphi + \frac{2}{3} \int_0^{2\pi} \sin \varphi + \cos \varphi d\varphi + 4\pi = \\ & = \frac{1}{3} \left[ \frac{\sin^2 \varphi}{2} \right]_0^{2\pi} + [-\cos \varphi + \sin \varphi]_0^{2\pi} + 4\pi = 4\pi. \end{aligned}$$

**9.B.6.** Calculate the integral

$$\int_c (e^x \sin y - xy^2) dx + \left( e^x \cos y - \frac{1}{2}x^2 y \right) dy,$$

where  $c$  is the positively oriented circle  $x^2 + y^2 + 4x + 4y + 7 = 0$ .

**9.B.7.** Compute

$$\int_c (3y - e^{\sin x}) dx + (7x + \sqrt{y^4 + 1}) dy,$$

**Definition.** The vector space of all  $k$ -linear antisymmetric forms on a tangent space  $T_x U$ ,  $U \subset \mathbb{R}^n$ , will be denoted by  $\Lambda^k(T_x U)^*$ . We talk about *exterior  $k$ -forms* at the point  $x \in U$ .

The assignment of a  $k$ -form  $\eta(x) \in \Lambda^k T_x^* U$  to every point  $x \in U$  from an open subset in  $\mathbb{R}^n$  defines an *exterior differential  $k$ -form* on  $U$ . The set of smooth exterior  $k$ -forms on  $U$  is denoted  $\Omega^k(U)$ .

Next, let us consider a smooth mapping  $G : V \rightarrow U$  between two open sets  $V \subset \mathbb{R}^m$  and  $U \subset \mathbb{R}^n$ , an exterior  $k$ -form  $\eta(G(x)) \in \Lambda^k(T_{G(x)}^* U)$ , and choose arbitrarily  $k$  vectors  $X_1(x), \dots, X_k(x)$  in the tangent space  $T_x V$ . Just like in the case of linear forms, we can evaluate the form  $\eta$  at the images of the vectors  $X_i$  using the mapping  $y = G(x) = (g_1(x), \dots, g_n(x))$ . This operation is called the *pullback of the form  $\eta$*  by  $G$ .

$$\begin{aligned} G^*(\eta(G(x)))(X_1(x), \dots, X_k(x)) \\ = \eta(G(x))(G_*(X_1(x)), \dots, G_*(X_k(x))), \end{aligned}$$

which is an exterior form in  $\Lambda^k(T_x^* V)$ . In the case of linear forms, this is the dual mapping to the differential  $D^1 G$ . We can compute directly from the definition that, for instance,

$$G^*(dy_i) \left( \frac{\partial}{\partial x_k} \right) = dy_i \left( G_* \left( \frac{\partial}{\partial x_k} \right) \right) = \frac{\partial g_i}{\partial x_k},$$

and so

$$(1) \quad G^*(dy_i) = \frac{\partial g_i}{\partial x_1} dx_1 + \dots + \frac{\partial g_i}{\partial x_m} dx_m,$$

which extends to the linear combinations of all  $dy_i$  over functions.

Another immediate consequence of the definition is the formula for pullbacks of arbitrary  $k$ -forms by composing two diffeomorphisms:

$$(2) \quad (G \circ F)^* \alpha = F^*(G^* \alpha).$$

Indeed, as a mapping on  $k$ -tuples of vectors,

$$\begin{aligned} (G \circ F)^* \alpha &= \alpha \circ ((D^1 G \circ D^1 F) \times \dots \times (D^1 G \circ D^1 F)) \\ &= G^*(\alpha) \circ (D^1 F \times \dots \times D^1 F) = F^* \circ G^* \alpha \end{aligned}$$

as expected.

**9.1.3. Wedge product of exterior forms.** Given a  $k$ -form

$\alpha \in \Lambda^k \mathbb{R}^{n*}$  and an  $\ell$ -form  $\beta \in \Lambda^\ell \mathbb{R}^{n*}$ , we can create a  $(k + \ell)$ -form  $\alpha \wedge \beta$  by all possible permutations  $\sigma$  of the arguments.

We just have to alternate the arguments in all possible orders and take the right sign each time:

$$\begin{aligned} (\alpha \wedge \beta)(X_1, \dots, X_{k+\ell}) = \\ \frac{1}{k! \ell!} \sum_{\sigma \in \Sigma_{k+\ell}} \text{sgn}(\sigma) \alpha(X_{\sigma(1)}, \dots, X_{\sigma(k)}) \beta(X_{\sigma(k+1)}, \dots, X_{\sigma(k+\ell)}). \end{aligned}$$

where  $c$  is the positively oriented circle  $x^2 + y^2 = 9$ .  $\circlearrowleft$

**9.B.8.** Compute the integral

$$\int_c \left( \frac{1}{x} + 2xy - \frac{y^3}{3} \right) dx + \left( \frac{1}{y} + x^2 + \frac{x^3}{3} \right) dy,$$

where  $c$  is the positively oriented boundary of the set  $D = \{(x, y) \in \mathbb{R}^2 : 4 \leq x^2 + y^2 \leq 9, \frac{x}{\sqrt{3}} \leq y \leq \sqrt{3}x\}$ .  $\circlearrowleft$

**9.B.9. Remark.** An important corollary of *Green's theorem* is the formula for computing the area  $D$  that is bounded by a curve  $c$ .

$$m(D) = \frac{1}{2} \int_c -y \, dx + x \, dy.$$

**9.B.10.** Compute the area given by the ellipse  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ .

**Solution.** Using the formula 9.B.9 and the transformation  $x = a \cos t$ ,  $y = b \sin t$ , we get for  $t \in [0, 2\pi]$  that

$$\begin{aligned} m(D) &= \frac{1}{2} \int_c -y \, dx + x \, dy = \\ &= \frac{1}{2} \int_0^{2\pi} a \cos t \cdot b \cos t \, dt - \frac{1}{2} \int_0^{2\pi} b \sin t \cdot (-a \sin t) \, dt = \\ &= \frac{1}{2} ab \int_0^{2\pi} \cos^2 t \, dt + \frac{1}{2} ab \int_0^{2\pi} \sin^2 t \, dt = \\ &= \frac{1}{2} ab \int_0^{2\pi} \cos^2 t + \sin^2 t \, dt = \frac{1}{2} ab 2\pi = \pi ab, \end{aligned}$$

which is indeed the well-known formula for the area of an ellipse with semi-axes  $a$  and  $b$ .  $\square$

**9.B.11.** Find the area bounded by the cycloid which is given parametrically as  $\psi(t) = [a(t - \sin t); a(1 - \cos t)]$ , for  $a \geq 0$ ,  $t \in (0, 2\pi)$ , and the  $x$ -axis.

**Solution.** Let the curves that bound the area be denoted by  $c_1$  and  $c_2$ . As for the area, we get

$$m(D) = \frac{1}{2} \int_{c_1} -y \, dx + x \, dy + \frac{1}{2} \int_{c_2} -y \, dx + x \, dy.$$

Now, we will compute the mentioned integrals step by step. The parametric equation of the curve  $c_1$  (a segment of the  $x$ -axis) is  $(t; 0); t \in [0; 2a\pi]$ , so we obtain for the first integral that

$$\frac{1}{2} \int_{c_1} -y \, dx + x \, dy = \frac{1}{2} \int_0^{2a\pi} 0 \cdot 1 \, dt + \int_0^{2a\pi} t \cdot 0 \, dt = 0.$$

The parametric equation of the curve  $c_2$  is  $\psi(t) \in (a(t - \sin t), a(1 - \cos t)); t \in [2\pi; 0]$ .

The formula for the area expects a positively oriented curve,

It is clear from the definition that  $\alpha \wedge \beta$  is indeed a  $(k + \ell)$ -form. In the simplest case of 1-forms, the definition says that

$$(\alpha \wedge \beta)(X, Y) = \alpha(X)\beta(Y) - \alpha(Y)\beta(X).$$

In the case of a 1-form  $\alpha$  and a  $k$ -form  $\beta$ , we get

$$\begin{aligned} (\alpha \wedge \beta)(X_0, X_1, \dots, X_k) = \\ \sum_{j=0}^k (-1)^j \alpha(X_j) \beta(X_0, \dots, \hat{X}_j, \dots, X_k), \end{aligned}$$

where the hat indicates omission of the corresponding argument. The wedge product of finitely many forms is defined analogously (either directly by a similar formula, or we can notice that the above wedge product of forms is an associative operation – think this out by yourselves!).

Next, remind the generators  $\frac{\partial}{\partial x_i}$  of all vector fields in  $\mathcal{X}(\mathbb{R}^n)$ , as well as the generators  $dx_i$  of all linear exterior forms in  $\Omega^1(\mathbb{R}^n)$ . Their wedge products

$$\varepsilon_{i_1 \dots i_k} = dx_{i_1} \wedge \dots \wedge dx_{i_k}$$

with  $k$ -tuples of indices  $i_1 < i_2 < \dots < i_k$  generate the whole space  $\Omega^k(\mathbb{R}^n)$  by linear combinations with functions standing for coefficients. Indeed, interchanging a pair of adjacent forms in the product merely changes the sign, so the whole expression is identically zero if an index appears twice. Therefore, every  $k$ -form  $\alpha$  is given uniquely by functions  $\alpha_{i_1 \dots i_k}(x)$  in the expression

$$\alpha(x) = \sum_{i_1 < \dots < i_k} \alpha_{i_1 \dots i_k}(x) dx_{i_1} \wedge \dots \wedge dx_{i_k}.$$

Consequently, the vector spaces  $\Lambda^k(T^*U)$  are the trivial zero spaces if  $k > \dim U$ . Thus,  $\Omega^k(U)$  contains only the trivial zero form in this case.

Another straightforward consequence of the definition is that the pullback of the wedge product by a smooth mapping  $G : V \rightarrow U$  satisfies

$$G^*(\alpha \wedge \beta) = G^*\alpha \wedge G^*\beta.$$

We should also notice that 0-forms  $\Omega^0(\mathbb{R}^n)$  are just smooth functions on  $\mathbb{R}^n$ . The wedge product of a 0-form  $f$  and a  $k$ -form  $\alpha$  is just the multiple of the form  $\alpha$  by the function  $f$ . Similarly, the top degree forms in  $\Omega^n(U)$  are all generated by the single generator  $\varepsilon_{12\dots n}$ , since there is just one possibility of  $n$  different choices among  $n$  coordinates, up to the ordering. This means that actually the  $n$ -forms  $\omega$  are identified with functions via the formula

$$\omega(x) = f(x) dx_1 \wedge \dots \wedge dx_n.$$

At the same time, while the pullback on the functions  $f \in \Omega^0(U)$  by a transformation  $F : \mathbb{R}^n \rightarrow \mathbb{R}^n$ ,  $y = F(x)$ , is trivial, i.e.  $F^*f(x) = f(y) = f \circ F(x)$ , a straightforward computation reveals

$$(1) \quad F^*\omega(x) = \det(D^1F)(x) f(F(x)) dx_1 \wedge \dots \wedge dx_n$$

for all  $\omega = f dy_1 \wedge \dots \wedge dy_n$ .

which means for the considered parametric equation that we are moving against the parametrization direction, i. e. from the upper bound to the lower one.

We thus get for the area of the cycloid that

$$\begin{aligned} \frac{1}{2} \int_{c_2} -y \, dx + x \, dy &= \frac{1}{2} \int_{2\pi}^0 a(t - \sin t) \cdot a(\sin t) \, dt - \\ &- \frac{1}{2} \int_{2\pi}^0 a(1 - \cos t) \cdot a(1 - \cos t) \, dt = \\ &= \frac{1}{2} a^2 \int_0^{2\pi} t \sin t - \sin^2 t - 1 + 2 \cos t - \cos^2 t \, dt = \\ &= \frac{1}{2} a^2 \int_{2\pi}^0 t \sin t + 2 \cos t - 2 \, dt = \\ &= \frac{1}{2} a^2 [-t \cos t - \sin t + 2 \cos t - 2]_{2\pi}^0 = 3\pi a^2. \end{aligned}$$

**9.B.12.** Compute  $I = \iint_S x^3 \, dy \, dz + y^3 \, dx \, dz + z^3 \, dx \, dy$ , where  $S$  is given by the sphere  $x^2 + y^2 + z^2 = 1$ .

**Solution.** It is advantageous to work in spherical coordinates

$$\begin{aligned} x &= \rho \sin \varphi \cos \psi & \rho &= [0, 1], \\ y &= \rho \sin \varphi \sin \psi & \varphi &= [0, \pi], \\ z &= \rho \cos \varphi & \psi &= [0, 2\pi]. \end{aligned}$$

The Jacobian of this transformation is  $-\rho^2 \sin \varphi$ .

The given integral is then equal to

$$\begin{aligned} I &= \iiint_S x^3 \, dy \, dz + y^3 \, dx \, dz + z^3 \, dx \, dy = \\ &= \iiint_V 3x^2 + 3y^2 + 3z^2 \, dx \, dy \, dz = \\ &= 3 \int_0^1 \int_0^{2\pi} \int_0^\pi \rho^2 \sin \varphi (\rho^2 \sin^2 \varphi \cos^2 \psi + \rho^2 \sin^2 \varphi \sin^2 \psi + \\ &\quad + \rho^2 \cos^2 \varphi) \, d\rho \, d\varphi \, d\psi = \\ &= 3 \int_0^1 \int_0^{2\pi} \int_0^\pi \rho^4 \sin \varphi (\sin^2 \varphi (\cos^2 \psi + \sin^2 \psi) + \\ &\quad + \cos^2 \varphi) \, d\rho \, d\varphi \, d\psi = \\ &= 3 \int_0^1 \int_0^{2\pi} \int_0^\pi \rho^4 \sin \varphi \, d\rho \, d\varphi \, d\psi = 3 \cdot \left[ \frac{\rho^5}{5} \right]_0^1 [\psi]_0^{2\pi} [\cos \varphi]_0^\pi = \\ &= 3 \cdot \frac{1}{5} \cdot 2\pi \cdot [-1 - 1] = -\frac{12}{5}\pi. \end{aligned}$$

**9.1.4. Integration of exterior forms on  $\mathbb{R}^n$ .** Once we fix coordinates  $(x_1, \dots, x_n)$  on  $\mathbb{R}^n$  (e.g. the standard ones), there is the bijection between functions  $f$  and top degree forms  $\omega(x) = f(x) dx_1 \wedge \dots \wedge dx_n$ . This can be interpreted as defining the scale with which the standard volume in  $\mathbb{R}^n$  is to be taken pointwise due to the function  $f$ .

Notice, that changing the coordinates via a transformation  $F$  will rescale this understanding of the forms exactly as in the formula for coordinate substitution in the Riemann integral. We should view this observation as a new interpretation of the integrands in our earlier procedure of integration of functions  $f$  on Riemann measurable open subsets  $U \subset \mathbb{R}^n$ , independent of any coordinate choice.

Let us check this interpretation in more detail. First, we define the  $n$ -form  $\omega_{\mathbb{R}^n}$ , giving the standard  $n$ -dimensional volume of parallelograms, i.e. in the standard coordinates we obtain

$$\omega_{\mathbb{R}^n} = dx_1 \wedge \dots \wedge dx_n.$$

If we want to integrate a function  $f(x)$  “in the new way”, we consider the form  $\omega = f\omega_{\mathbb{R}^n}$  instead, i.e.  $\omega = f(x) dx_1 \wedge \dots \wedge dx_n$ . We define the integral of the form  $\omega$  as

$$\int_U \omega = \int_U f(x) dx_1 \wedge \dots \wedge dx_n = \int_U f(x) \, dx_1 \cdots dx_n,$$

where the Riemann integral of a function is considered on the right-hand side.

Let us point out, that the  $n$ -form  $\omega$  on the left-hand side is well defined, independently of any choice of coordinates. If we want to express the form  $\omega$  in different coordinates using a diffeomorphism  $G : V \rightarrow U$ ,  $G = (g_1, \dots, g_n)$ , it means we will evaluate  $\omega$  at a point  $G(y) = x$  at the values of the vectors  $G_*(X_1), \dots, G_*(X_n)$ . However, this means we will integrate the form  $G^*\omega$  in coordinates  $(y_1, \dots, y_n)$ , and we already saw in the previous paragraph, cf. 9.1.3(1) that

$$(G^*\omega)(y) = f(G(y)) \det(D^1G(y)) dy_1 \wedge \dots \wedge dy_n.$$

Substituting into our interpretation of the integral, we get

$$\int_V G^*(f\omega_{\mathbb{R}^n}) = \int_{G^{-1}(U)} f(G(y)) \det(D^1G(y)) dy_1 \cdots dy_n,$$

which is, by the theorem 8.2.8 on the coordinate substitution in the integral, the same value as  $\int_U f\omega_{\mathbb{R}^n}$  if the determinant of the Jacobian matrix is positive, and the same value up to the sign if it is negative.

Our new interpretation thus provides the geometrical meaning for the integral of an  $n$ -form on  $\mathbb{R}^n$ , supposing the corresponding Riemann integral exists in some (and hence any) coordinates. This integration takes into account the orientation of the area we are integrating over. We shall come back to this point in a moment.

**9.1.5. Integrals along curves.** Our next goal is to integrate objects over domains which are similar to curves or surfaces in  $\mathbb{R}^3$ . Let us first shape our mind on the simplest case of the lowest

□ dimension, i.e. the curves in  $\mathbb{R}^n$ .

**9.B.13. The vector form of the Gauss–Ostrogradsky theorem.** The divergence of a vector field  $F(x, y, z) = f(x, y, z) \frac{\partial}{\partial x} + g(x, y, z) \frac{\partial}{\partial y} + h(x, y, z) \frac{\partial}{\partial z}$  is defined as  $\operatorname{div} X := f_x + g_y + h_z$ . Then, the Gauss–Ostrogradsky theorem can be formulated as follows:

$$\iiint_V \operatorname{div} \vec{F}(x, y, z) \, dx \, dy \, dz = \iint_S \vec{F}(x, y, z) \cdot \vec{n}(x, y, z) \, dS$$

where  $\vec{n}(x, y, z)$  is the outer unit normal to the surface  $S$  at the point  $[x, y, z] \in S$  ( $S$  is the boundary of the normal domain  $V$ ).

**9.B.14.** Find the flow of the vector field given by the function  $F = (xy^2, yz, x^2z)$  over the cylinder  $x^2 + y^2 = 4, z = 1, z = 3$ .

**Solution.** First of all, we compute the divergence of the vector field:

$$\operatorname{div} F = \nabla \cdot F = \left( \frac{\partial(xy^2)}{\partial x} + \frac{\partial(yz)}{\partial y} + \frac{\partial(x^2z)}{\partial z} \right) = y^2 + z + x^2.$$

Therefore, the flow  $T$  of the vector field is equal to

$$\begin{aligned} \iiint_V y^2 + z + x^2 \, dx \, dy \, dz &= \\ &= \int_0^2 \int_0^{2\pi} \int_1^3 \rho \cdot (\rho^2 \sin^2 \varphi + z + \rho^2 \cos^2 \varphi) \, d\rho \, d\varphi \, dz = \\ &= \int_0^2 \int_0^{2\pi} \int_1^3 \rho \cdot (\rho^2 (\sin^2 \varphi + \cos^2 \varphi) + z) \, d\rho \, d\varphi \, dz = \\ &= \int_0^2 \int_0^{2\pi} \int_1^3 \rho \cdot (\rho^2 (\sin^2 \varphi + \cos^2 \varphi) + z) \, d\rho \, d\varphi \, dz = \\ &= \int_0^2 \int_0^{2\pi} \int_1^3 \rho^3 + \rho z \, d\rho \, d\varphi \, dz = \\ &= 2\pi \int_0^2 \int_1^3 \rho^3 + \rho z \, d\rho \, dz = 2\pi \int_1^3 \left[ \frac{\rho^4}{4} + \frac{\rho^2}{2} z \right]_0^3 dz = \\ &= 2\pi \int_1^3 4 + 2z \, dz = 2\pi [4z + z^2]_1^3 = 2\pi [12 + 9 - 4 - 1] = 22\pi. \end{aligned}$$

**9.B.15.** Find the flow of the vector field given by the function  $F = (y, x, z^2)$ , over the sphere  $x^2 + y^2 + z^2 = 4$ .

**Solution.** The divergence of the given vector field is:

$$\operatorname{div} F = \nabla \cdot F = \left( \frac{\partial y}{\partial x} + \frac{\partial x}{\partial y} + \frac{\partial z^2}{\partial z} \right) = 2z.$$

Recall the calculation of the length of a curve in  $\mathbb{R}^n$  by univariate integrals, which was discussed in paragraph 6.1.10 on page 518. The curve was parametrized as a mapping  $c(t) : \mathbb{R} \rightarrow \mathbb{R}^n$ , and the size of the tangent vector  $\|c'(t)\|$  was expressed in the Euclidean vector space. This procedure was given by the universal relation for an arbitrary tangent vector, i.e., we actually found the function  $\rho : \mathbb{R}^n \rightarrow \mathbb{R}$  which gave the true size when evaluated at  $c'(t)$ . This mapping satisfied  $\rho(av) = |a|\rho(v)$  since we ignored the orientation of the curve given by our parametrization. If we wanted a signed length, respecting the orientation, then our mapping  $\rho$  would be linear on every one-dimensional subspace  $L \subset \mathbb{R}^n$ . Of course we could have multiplied the Euclidean size by a positive function and integrate this quantity.

In view of our geometric approach to integration, we should rather integrate linear forms along curves, while the size of vectors is given by a quadratic form, rather than a linear one. However, in dimension one, we take the square root of the values of the (positive definite) quadratic form, in order to get a linear form (up to sign) which is just the size of the vectors.

Let us proceed in a much similar way dealing with linear differential forms  $\eta$  on  $\mathbb{R}^n$ . The simplest ones are the differentials  $df$  of functions  $f$  on  $\mathbb{R}^n$ .

In order to motivate our development, let us consider the following task. Imagine, we are cycling along a path  $c(t)$  in  $\mathbb{R}^2$ , the function  $f$  is the altitude of the terrain. If we want to compute the total gain of altitude along the path  $c(t)$ , we should “integrate” the immediate infinitesimal gains, which should be the derivatives of  $f$  in the directions of the tangent vectors to the path, i.e.  $df(c'(t))$ .

Thus, let us consider a differentiable curve  $c(t)$  in  $\mathbb{R}^n$ ,  $t \in [a, b]$ , write  $M$  for the image  $c([a, b])$ , and assume that a differentiable function  $f$  is defined on a neighborhood of  $M$ . The differential of this function gives for every tangent vector the increment of the function in the given direction. It is expressed by the differential of the composite mapping  $f \circ c$

$$d(f \circ c)(t) = \frac{\partial f}{\partial x_1}(c(t))c'_1(t) + \dots + \frac{\partial f}{\partial x_n}(c(t))c'_n(t).$$

We can thus try to define the value of the integral in the following way

$$\int_M df = \int_a^b \left( \frac{\partial f}{\partial x_1}(c(t))c'_1(t) + \dots + \frac{\partial f}{\partial x_n}(c(t))c'_n(t) \right) dt,$$

and we immediately verify that the change of the parametrization of the curve has no effect upon the value. Indeed, writing  $c(t) = c(\psi(s))$ ,  $a = \psi(\tilde{a})$ ,  $b = \psi(\tilde{b})$ , our procedure yields

$$\begin{aligned} &\int_{\tilde{a}}^{\tilde{b}} \left( \frac{\partial f}{\partial x_1}(c(\psi(s)))c'_1(\psi(s)) + \dots \right. \\ &\quad \left. + \frac{\partial f}{\partial x_n}(c(\psi(s)))c'_n(\psi(s)) \right) \frac{d\psi}{ds} ds, \end{aligned}$$

and the theorem about coordinate transformations for univariate integrals gives just the same value if we have  $\frac{d\psi}{ds} > 0$ , i.e.,

Thus, the wanted flow equals

$$\begin{aligned} \iiint_V 2z \, dx \, dy \, dz &= \int_0^2 \int_0^\pi \int_0^{2\pi} \rho^2 \sin \varphi \cdot 2\rho \cos \varphi \, d\rho \, d\varphi \, d\psi \\ &= 2 \int_0^2 \rho^3 \, d\rho \int_0^{2\pi} d\psi \int_0^\pi \sin \varphi \cos \varphi \, d\varphi = \\ &= 2 \left[ \frac{\rho^4}{4} \right]_0^2 \cdot [\psi]_0^{2\pi} \cdot \left[ \frac{\sin^2 \varphi}{2} \right]_0^\pi = \\ &= 2 \cdot \frac{16}{4} \cdot 2\pi \cdot 0 = 0. \end{aligned}$$

### C. Equation of heat conduction

**9.C.1.** Find the solution to the so-called equation of heat conduction (equation of diffusion)

$$u_t(x, t) = a^2 u_{xx}(x, t), \quad x \in \mathbb{R}, \quad t > 0$$

satisfying the initial condition  $\lim_{t \rightarrow 0^+} u(x, t) = f(x)$ .

Notes: The symbol  $u_t = \frac{\partial u}{\partial t}$  stands for the partial derivative of the  $u$  with respect to  $t$  (i. e., differentiating with respect to  $t$  and considering  $x$  to be constant), and similarly,  $u_{xx} = \frac{\partial^2 u}{\partial x^2}$  denotes the second partial derivative with respect to  $x$  (i. e., twice differentiating with respect to  $x$  while considering  $t$  to be constant). The physical interpretation of this problem is as follows: We are trying to determine the temperature  $u(x, t)$  in an thermally isolated and homogeneous bar of infinite length (the range of the variable  $x$ ) if the initial temperature of the bar is given as the function  $f$ . The section of the bar is constant and the heat can spread in it by conduction only. The coefficient  $a^2$  then equals the quotient  $\frac{\alpha}{c\rho}$ , where  $\alpha$  is the coefficient of thermal conductivity,  $c$  is the specific heat and  $\rho$  is the density. In particular, we assume that  $a^2 > 0$ .

**Solution.** We apply the Fourier transform to the equation, with respect to variable  $x$ . We have

$$\begin{aligned} \mathcal{F}(u_t)(\omega, t) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} u_t(x, t) e^{-i\omega x} \, dx = \\ &= \left( \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} u(x, t) e^{-i\omega x} \, dx \right)', \end{aligned}$$

where differentiated with respect to  $t$ , i. e.,

$$\mathcal{F}(u_t)(\omega, t) = (\mathcal{F}(u)(\omega, t))' = (\mathcal{F}(u))_t(\omega, t).$$

At the same time, we know that

$$\begin{aligned} \mathcal{F}(a^2 u_{xx})(\omega, t) &= a^2 \mathcal{F}(u_{xx})(\omega, t) = \\ &= -a^2 \omega^2 \mathcal{F}(u)(\omega, t). \end{aligned}$$

Denoting  $y(\omega, t) = \mathcal{F}(u)(\omega, t)$ , we get to the equation

$$y_t = -a^2 \omega^2 y.$$

We already solved a similar differential equation when we were calculating Fourier transforms, so it is now easy for us to determine all of its solutions

$$y(\omega, t) = K(\omega) e^{-a^2 \omega^2 t}, \quad K(\omega) \in \mathbb{R}.$$

if we keep the orientation of the curve, and the same value up to sign if the derivative of the transformation is negative.

If we extend the same definition to an arbitrary linear form  $\eta = \eta_1 dx_1 + \dots + \eta_n dx_n$  we arrive at the same formulae with  $\eta_i$  replacing the derivatives  $\frac{\partial f}{\partial x_i}$ ,

$$\int_M \eta = \int_a^b (\eta_1(c(t))c'_1(t) + \dots + \eta_n(c(t))c'_n(t)) dt,$$

again independent of the parametrization of the curve  $c$  as above.

In the above example with  $n = 2$ ,  $f$  was the altitude of the terrain, and the integral of  $df$  along the path modelled the total gain of elevation. Thus, we should expect that the total gain along the path should depend on the values  $c(a)$  and  $c(b)$  only, while different curves with the same boundary points would produce different integrals of  $\eta$  for a general 1-form  $\eta$ . This will indeed be the special claim of the Stokes theorem below.

Before we treat the higher dimensional analogs, we shall look at more abstract approach to suitable subsets in  $\mathbb{R}^n$  and the role of coordinates on them.

**9.1.6. Manifolds.** The straightforward generalizations of parameterized curves  $c(t) : \mathbb{R} \rightarrow \mathbb{R}^n$  are the differentiable mappings  $\varphi : V \subset \mathbb{R}^k \rightarrow \mathbb{R}^n$ ,  $k \leq n$ ,

with injective differential  $d\varphi(u)$  at every point of its open domain  $V$ . Such mappings are called *immersions*.

With the curves, we did not care about their self-intersections etc. Now, for technical reasons, we shall be more demanding.

#### MANIFOLDS IN $\mathbb{R}^n$

A subset  $M \subset \mathbb{R}^n$  is called a *manifold of dimension  $k$*  if every point  $x \in M$  has a neighborhood  $U \subset \mathbb{R}^n$  which is the image of a diffeomorphism  $\tilde{\varphi} : V \times \tilde{V} \rightarrow U$ ,  $V \subset \mathbb{R}^k$ ,  $\tilde{V} \subset \mathbb{R}^{n-k}$ , such that

- the restriction  $\varphi = \tilde{\varphi}|_V : V \rightarrow M$  is an immersion,
- $\tilde{\varphi}^{-1}(M) = V \times \{0\} \subset \mathbb{R}^n$ .

The manifolds  $M$  are carrying the topology inherited from  $\mathbb{R}^n$ .

./img/0214\_eng.png

It remains to determine  $K(\omega)$ . The transformation of the initial condition gives

$$\mathcal{F}(f)(\omega) = \lim_{t \rightarrow 0^+} \mathcal{F}(u)(\omega, t) = \lim_{t \rightarrow 0^+} y(\omega, t) = K(\omega) e^0 = K(\omega),$$

hence

$$y(\omega, t) = \mathcal{F}(f)(\omega) e^{-a^2 \omega^2 t}, \quad K(\omega) \in \mathbb{R}.$$

Now, using the inverse Fourier transform, we can return to the original differential equation with solution

$$\begin{aligned} u(x, t) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} y(\omega, t) e^{i\omega x} d\omega = \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathcal{F}(f)(\omega) e^{-a^2 \omega^2 t} e^{i\omega x} d\omega = \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \left( \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(s) e^{-i\omega s} ds \right) e^{-a^2 \omega^2 t} e^{i\omega x} d\omega = \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(s) \left( \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-a^2 \omega^2 t} e^{-i\omega(s-x)} d\omega \right) ds. \end{aligned}$$

Computing the Fourier transform  $\mathcal{F}(f)$  of the function  $f(t) = e^{-at^2}$  for  $a > 0$ , we have obtained (while relabeling the variables)

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-cp^2} e^{-irp} dp = \frac{1}{\sqrt{2c}} e^{-\frac{r^2}{4c}}, \quad c > 0.$$

According to this formula (consider  $c = a^2 t > 0$ ,  $p = \omega$ ,  $r = s - x$ ), we have

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-a^2 \omega^2 t} e^{-i\omega(s-x)} d\omega = \frac{1}{\sqrt{2a^2 t}} e^{-\frac{(s-x)^2}{4a^2 t}},$$

Therefore,

$$u(x, t) = \frac{1}{2a\sqrt{\pi t}} \int_{-\infty}^{\infty} f(s) e^{-\frac{(x-s)^2}{4a^2 t}} ds.$$

□

### D. Partial Differential Equations

**9.D.1.** Find general solution and solution for given boundary conditions of homogenous linear equation

$$xu_x + yu_y = 0,$$

- (i)  $u(\cos \sigma, \sin \sigma) = 1$ ,
- (ii)  $u(\sigma, 1) = 1 + \sigma^2$ ,
- (iii)  $u(\sigma, 1 - \sigma) = 3\sigma$ ,
- (iv)  $u(\cos \sigma, \sin \sigma) = \sigma$ ,
- (v)  $u(\sigma, \sigma) = 1$ ,
- (vi)  $u(\sigma, \sigma) = \sigma$ .

**Solution.** Firstly let's look to our problem geometrically. The vector  $\nabla u = (u_x, u_y)$  is the *gradient* of unknown function  $u = u(x, y)$  (its direction is direction of the biggest growing of function  $u$ ). Equation

$$a(x, y)u_x + b(x, y)u_y = 0,$$

tell us, that scalar product of given vector field  $\vec{v} = (a(x, y), b(x, y))$  and  $\nabla u$  is zero, e.g.  $\vec{v}$  is orthogonal to  $\nabla u$  at each point, so  $\vec{v}$  has to be tangent to the contour lines (lines of constant value of  $u$ ), we will call them

This definition is illustrated by the picture above. Manifolds can be typically (at least locally) given implicitly as the level sets of differentiable mappings, see paragraph 8.1.24 and the discussion in 8.1.26.

The mapping  $\varphi$  from the definition is called the *local parametrization* or *local map* of the manifold  $M$ . The manifolds are a straightforward generalization of curves and surfaces in the plane  $\mathbb{R}^2$  or the space  $\mathbb{R}^3$ . We have excluded curves and surfaces which are self-intersecting and even those which are self-approaching.

For instance, we can surely imagine a curve representing the figure 8 parametrized with a mapping  $\varphi$  with everywhere-injective differential. However, we will be unable to satisfy the second property from the manifold definition in a neighborhood of the point where the two branches of the curve meet.

### TANGENT AND COTANGENT BUNDLES OF MANIFOLDS

The tangent bundle  $TM$  of the manifold  $M$  is the collection of vector subspaces  $T_x M \subset T_x \mathbb{R}^n$  which contain all vectors tangent to the curves in  $M$ . There is the footpoint projection  $p: TM \rightarrow M$ .

Similarly, the cotangent bundle  $T^*M$  of the manifold  $M$  is the collection of the dual spaces  $(T_x M)^*$ , together with the footpoint projection.

Clearly, every parametrization  $\varphi$  defines a diffeomorphism

$$\varphi_*: TV \rightarrow T(\varphi(V)) \subset TM, \quad \varphi_*(c'(t)) = \frac{d}{dt} \varphi(c(t)).$$

Due to the chain rule, this definition does not depend of the choice of the representing curve  $c(t)$ . We shall also write  $T\varphi$  for the mapping  $\varphi_*$ .

In particular, the local maps  $\varphi$  (extended to  $\tilde{\varphi}$ , as in the above definition) induce the local maps  $\varphi_*: TU = U \times \mathbb{R}^k \rightarrow TM \subset \mathbb{R}^n \times \mathbb{R}^n$  of the tangent bundle. Thus, the tangent bundle  $TM$  is again a manifold, which locally looks as  $U \times \mathbb{R}^k$  over sufficiently small open subsets  $U \subset M$ . But we shall see that  $TM$  might be quite different from  $M \times \mathbb{R}^k$  globally. Dealing with the cotangent bundle, we can use the dual mappings  $(T\varphi^{-1})^*$  on the individual fibers  $T_x^* M$  to obtain local parametrizations.

*characteristics.* Now it's easy to find general solution — it could be any function, which is constant on characteristics (integral curves of vector field  $\vec{v}$ ). Let's find them for our case by solving system ODE's:

$$\dot{x}(t) = \frac{dx}{dt}(t) = a(x, y) = x, \dot{y}(t) = \frac{dy}{dt}(t) = b(x, y) = y,$$

or by solving equation

$$y'(x) = \frac{dy}{dx} = \frac{\dot{y}}{\dot{x}} = \frac{b}{a}.$$

Solution yields to the curves

$$x = C_1 e^t, \quad y = C_2 e^t, \quad \text{or} \quad \frac{y}{x} = C$$

and characteristics are lines throu the origin (picture P.1). General solution can be written as

$$u(x, y) = \Phi\left(\frac{y}{x}\right), \quad \text{or} \quad u(x, y) = \Psi\left(\frac{x}{y}\right).$$

Look at the test:

$$u_x = \Phi'\left(-\frac{y}{x^2}\right), u_y = \Phi'\left(\frac{1}{x}\right) \implies xu_x + yu_y = 0.$$

On the picture we see characteristics together with given boundary lines. We need to choose solutions satisfying our boundary condition. The questions are: How many solutions we can find? Does the solution exists for any boundary condition?

- (i) Parametrizet boundary curve (circle) intersect any characteristics infinitely many times. But the value  $u(\cos \sigma, \sin \sigma) = 1$  is constant. Solution has to be constant on characteristics, therefore  $u(x, y) = 1$  is unique solution of the equation and boundary condition (i).
- (ii) Parametrized boundary curve (line)  $x = \varphi(\sigma) = \sigma, y = \psi(\sigma) = 1$  intersects almost all characteristic (except line  $y = 0$ ) just once. The value  $u = f(\sigma) = 1 + \sigma^2$  in point of intersection should be the same on the whole characteristics: Without lose of generality, take  $t = 0$  and from  $x = C_1 e^0 = \varphi(\sigma) = \sigma, y = C_2 e^0 = \psi(\sigma) = 1$  we get  $C_1 = \sigma, C_2 = 1$ . Then

$$x = \sigma e^t, \quad y = e^t \implies \sigma = \frac{x}{y}$$

and we have solution

$$u(x, y) = f(\sigma(x, y)) = 1 + [\sigma(x, y)]^2 = 1 + \frac{x^2}{y^2}.$$

This solution exists for  $y \neq 0$ . On the connected component of its domain, including boundary curve ( $\Omega =$

Notice that two differentiable immersions  $\varphi$  and  $\psi$  parametrizing the same open subset  $U \subset M$  provide the composition  $\psi^{-1} \circ \varphi$ . We view this as a coordinate change for  $U$  and we have just seen that coordinate changes on  $M$  induce coordinate changes on  $TM$ .

Further, if  $M$  and  $N$  are two manifolds and  $F : M \rightarrow N$  a mapping, we say that  $F$  is differentiable (up to order  $r$  or smooth or analytic), if the compositions  $\psi^{-1} \circ F \circ \varphi$  with two local parametrizations  $\varphi$  of  $M$  and  $\psi$  of  $N$  (of the same order of differentiability as we want to check) is differentiable (up to order  $r$  or smooth or analytic). Again, the chain rule property of differentiation shows that this definition does not depend on the particular choice of the parametrizations.

Each differentiable mapping  $F : M \rightarrow N$  defines the tangent mapping  $TF : TM \rightarrow TN$  between the tangent spaces, which clearly is differentiable of order one less than the assumed differentiability of  $F$ .

VECTOR FIELDS AND DIFFERENTIAL FORMS ON MANIFOLDS

Smooth vector fields  $X$  on a manifold  $M$  are smooth sections  $X : M \rightarrow TM$  of the footpoint projection  $p : TM \rightarrow M$ , i.e.,  $p \circ X = \text{id}_M$ .

Smooth  $k$ -forms  $\eta$  on a manifold  $M$  are sections  $M \rightarrow \Lambda^k(TM)^*$  such that the pullback of this form by any parametrization  $V \rightarrow M$  yields a smooth exterior  $k$ -form on  $V$ .

We write  $\mathcal{X}(M)$  for the space of smooth vector fields on  $M$ , while  $\Omega^k(M)$  stays for the space of all smooth exterior  $k$ -forms on  $M$ .

Notice that all our coordinate formulae for the vector fields, forms, pullbacks etc. on  $\mathbb{R}^m$  hold true in the more abstract setting of manifolds and their local parametrizations.<sup>1</sup>

9.1.7. Integration of exterior forms on manifolds. Now,

we are almost ready for the definition of the integral of  $k$ -forms on  $k$ -dimensional manifolds. For the sake of simplicity, we will examine smooth forms  $\omega$  with compact support only.

First, let us assume that we are given a  $k$ -dimensional manifold  $M \subset \mathbb{R}^n$  and one of its local parametrizations  $\varphi : V \subset \mathbb{R}^k \rightarrow U \subset M \subset \mathbb{R}^n$ . We consider the standard orientation on  $\mathbb{R}^k$  given by the standard basis (cf. 4.1.19 for the definition of the orientation of a vector space). The choice of the parametrization  $\varphi$  also fixes the *orientation of the manifold*  $U \subset M$ . This orientation will be the same for those choices of local parametrizations, which differ by diffeomorphisms with positive determinants of their Jacobi matrices. The orientation will be the other one in the case of negative determinants. The manifold  $M$  is called *orientable* if there

<sup>1</sup>Actually, instead of dealing with manifolds as subsets of  $\mathbb{R}^n$ , we might use the same concept of local parametrizations of a space  $M$  with differentiable transition functions  $\psi^{-1} \circ \varphi$ . We just need to know what are the "open subsets" in  $M$ , thus we could start at the level of topological spaces. On the other hand, there is the general result (the so called Whitney embedding theorem) that each such abstract  $n$ -dimensional manifold can be realized as embedded in the  $\mathbb{R}^{2n}$ , so we essentially do not loose any generality here.

$\{(x, y) \in \mathbb{R}^2 \mid y > 0\}$  this is unique continuous solution. There is no "natural" way, how to make its prolongation for  $y < 0$ .

- (iii) Parametrized boundary curve (line)  $x = \varphi(\sigma) = \sigma$ ,  $y = \psi(\sigma) = 1 - \sigma$  intersects almost all characteristic (except line  $y = -x$ ) just once. Again, the value  $u = f(\sigma) = 3\sigma$  in point of intersection should be the same on the whole characteristics: Take  $t = 0$  and from  $x = C_1 e^0 = \varphi(\sigma) = \sigma$ ,  $y = C_2 e^0 = \psi(\sigma) = 1$  we get  $C_1 = \sigma$ ,  $C_2 = 1 - \sigma$ . Then  $x = \sigma e^t$ ,  $y = (1 - \sigma)e^t$

$$\implies \frac{\sigma}{1 - \sigma} = \frac{x}{y}, \implies \sigma = \frac{x}{x + y}.$$

and we have the unique solution

$$u(x, y) = f(\sigma(x, y)) = 3\sigma(x, y) = \frac{3x}{x + y}.$$

This solution exists for  $y \neq -x$ . Let's make a test:

$$u_x = \frac{3y}{(x + y)^2}, \quad u_y = \frac{-3x}{(x + y)^2} \implies \implies xu_x + yu_y = 0,$$

$$u(\sigma, 1 - \sigma) = \frac{3\sigma}{\sigma + 1 - \sigma} = 3\sigma.$$

- (iv) Boundary curve intersect any characteristics infinitely many times, but the value at two point on the same characteristic is different. Globally this problem has no solution. We can solve it for example for  $\sigma \in (-\frac{\pi}{2}, \frac{\pi}{2})$ :  $t = 0$ ,  $x = C_1 e^0 = \cos \sigma$ ,  $y = C_2 e^0 = \sin \sigma$ , thus  $C_1 = \cos \sigma$ ,  $C_2 = \sin \sigma$  and

$$x = \cos \sigma e^t, \quad y = \sin \sigma e^t \implies \sigma = \arctg \frac{y}{x}.$$

We get the solution for  $x > 0$ :

$$u(x, y) = \sigma(x, y) = \arctg \frac{y}{x}.$$

Make a test.

- (v) The boundary curve  $y = x$  is one of the characteristics. It has no sense. Condition  $u(\sigma, \sigma) = 1$  gives infinitely many solutions. Any function  $u = \Phi(\frac{y}{x})$  or  $\Psi(\frac{x}{y})$  giving value 1 for  $y = x$  is solution of this problem (for example  $u = \frac{y}{x}$ ,  $u = \frac{y^2}{x^2}$ ,  $u = 1, \dots$ ).
- (vi) The boundary curve  $y = x$  is again one of the characteristics. It has no sense. There is no solution, because condition  $u(\sigma, \sigma) = \sigma$  doesn't give the same value on characteristic  $y = x$ .

Finally it seems (for our equation): If the boundary curve intersects each characteristics at exactly one point, there exists unique continuous solution (on some open set including boundary curve) satisfying boundary condition. Generally is situation more complicated. Requirement, that boundary curve has to intersect each characteristics at exactly one point is not necessary, nor sufficient).  $\square$

**9.D.2.** Find general solution of

$$yu_x + xu_y = 0$$

and solutions for given boundary condition

is a covering of the entire set  $M$  by local parametrizations  $\varphi$  such that their orientations coincide.

Therefore, we apparently have exactly two orientations on every connected orientable manifold. Fixing either of them, we thereby restrict the set of parametrizations to those compatible with this orientation. From now on, we will always proceed in this fashion, and we will talk about *oriented manifolds* only.

Next, let us fix a form  $\omega$  with compact support inside the image of one parametrization  $U \subset M$  of an oriented manifold  $M$ . The pullback form  $\varphi^*(\omega)$  is a smooth  $k$ -form on  $V \subset \mathbb{R}^k$  with compact support. The *integral of the form  $\omega$  on  $M$*  is defined in terms of the chosen parametrization which is compatible with the orientation as follows:

$$\int_M \omega = \int_{\mathbb{R}^k} \varphi^*(\omega).$$

If we choose a different compatible parametrization  $\tilde{\varphi} = \varphi \circ \psi$  where  $\psi$  is a diffeomorphism  $\psi : W \rightarrow V \subset \mathbb{R}^k$ , we can easily compute the result, following the same definition. Let us denote

$$\varphi^*(\omega)(u) = f(u) du_1 \wedge \dots \wedge du_k.$$

Invoking the relation 9.1.2(2) for the pullback of a form by a composite mapping, we get

$$\begin{aligned} \int_M \omega &= \int_{\mathbb{R}^k} \tilde{\varphi}^*(\omega) = \int_{\mathbb{R}^k} \psi^*(\varphi^*\omega) \\ &= \int_{\mathbb{R}^k} \psi^*(f du_1 \wedge \dots \wedge du_k) \\ &= \int_{\mathbb{R}^k} f(\psi(v)) \det(D^1\psi)(v) dv_1 \dots dv_k. \end{aligned}$$

This is again the same value as  $\int_{\mathbb{R}^k} \varphi^*\omega$ .

This proves the correctness of our definition of the integral  $\int_M \omega$  provided the integrated  $k$ -form has compact support lying in the image of a single parametrization.

However, typical manifolds  $M$  are given by implicit equations. For example,  $x^2 + y^2 + z^2 = 1$  defines the surface of the unit ball, i.e., the sphere  $S^2 \subset \mathbb{R}^3$ . If we want to integrate an exterior 2-form on  $S^2$ , we will have to use several parametrizations. Fortunately, our definition of the integral is additive with respect to disjoint unions of integration domains. Therefore, if we can write

$$M = U_1 \cup U_2 \cup \dots \cup U_m \cup B,$$

where  $U_i$  are pairwise disjoint images of parametrizations  $\varphi_i$ , and  $B$  is a set whose inverse image in any parametrization is a Riemann measurable set with measure zero, we can compute

$$\int_M \omega = \int_{U_1} \omega + \dots + \int_{U_m} \omega,$$

and we can easily verify that this value is independent of the choice of the sets  $U_i$  and the parametrizations (in particular, we need not be worried by the set  $B$  since the result of any integration on it is zero). For example, we can imagine splitting a sphere to the upper and lower hemispheres, leaving the equator  $B$  uncovered.

- (i)  $u(x, 0) = |x|$ ,
- (ii)  $u(0, y) = y^2$ ,
- (iii)  $u(\sigma, \sigma) = 2\sigma^2$ .

**9.D.3.** Find general solution of

$$yu_x - xu_y = 0$$

and solutions for given boundary condition

- (i)  $u(\sigma, \sigma) = 2\sigma^2$ ,
- (ii)  $u(0, y) = \frac{1}{1+y^2}$ ,
- (iii)  $u(x, 1) = x^4$ .

**9.D.4.** Find solution of

$$\sin x \sin y u_x + \cos x \cos y u_y = 0, u = \cos 2y \text{ for } x+y = \frac{\pi}{2}.$$

**9.D.5.** Look on general *quasilinear* first order equation:

$$a(x, y, u)u_x + b(x, y, u)u_y = f(x, y, u),$$

its special case is equation *linear in highest order terms* (in some texts, including our, is called *semilinear*):

$$a(x, y)u_x + b(x, y)u_y = f(x, y, u),$$

and again its special case is *linear* equation (generally nonhomogenous):

$$a(x, y)u_x + b(x, y)u_y = f(x, y).$$

In the following sections we show, how to solve each of this type of equation.

Find a solution of quasilinear equation for given boundary condition:

$$u_x - uu_y = -u, \quad u(0, y) = 2y.$$

**Solution.** Let's solve characteristic system:

$$\dot{x} = a = 1, \quad \dot{y} = b = -u, \quad \dot{u} = f = -u.$$

Characteristics are given parametrically:

$$x(t) = t + C_1, \quad y(t) = C_3 e^{-t} + C_2, \quad u(t) = C_3 e^{-t}.$$

If we want general solution of equation, it is given implicitly by

$$\Phi(ue^x, u - y) = 0,$$

where  $u - y = -C_2$ ,  $ue^x = C_3 e^{C_1}$  is some implicit description of characteristics.

From boundary condition for  $t = 0$  we get

$$x(0) = C_1 = 0, \quad y(0) = C_3 + C_2 = \sigma, \quad u(0) = C_3 = 2\sigma,$$

so  $C_2 = -\sigma$  and

$$x(t, \sigma) = t, \quad y(t, \sigma) = \sigma(2e^{-t} - 1) \implies$$

$$\sigma = \frac{y}{2e^{-x} - 1}, \quad e^{-t} = e^{-x}$$

When calculating in practice, we usually divide the entire manifold into several disjoint open areas with compact closures, and we integrate on each of them separately. However, this procedure still does not help if we stick with the strict assumption that the entire support of integrated form has to be inside of one parametrization. Thus, we will develop a global definition of the integral, which is more advantageous from the technical/theoretical point of view (although it usually does not help in computations directly).

**9.1.8. Partition of unity.** Consider a manifold  $M \subset \mathbb{R}^n$  and one of its covers by open images  $U_i$  of parametrizations  $\varphi_i$ . We can surely find a countable cover of each manifold  $M$  (it suffices to realize that we can do with parametrizations which map the origin to points with rational coordinates in  $\mathbb{R}^n$ ). Furthermore, we shall assume that any point in  $x \in M$  belongs to only finitely many sets  $U_i$ . Such a cover is called a *locally finite cover* by parametrizations  $\varphi_i$ .<sup>2</sup>

Now, recall the smooth variants of indicator functions from paragraph 6.1.10. For every pair of positive numbers  $\varepsilon < r$ , we constructed a function  $f_{\varepsilon, r}(t)$  of one real variable  $t$  such that  $f_{\varepsilon, r}(t) = 1$  for  $|t| < r - \varepsilon$ , while  $f_{\varepsilon, r}(t) = 0$  for  $|t| > r + \varepsilon$ , and  $0 \leq f_{\varepsilon, r}(t) \leq 1$  everywhere. At the same time, we had  $f(t) \neq 0$  if and only if  $|t| < r + \varepsilon$ .

Next, if we define

$$\chi_{r, \varepsilon, x_0}(x) = f_{\varepsilon, r}(|x - x_0|),$$

then we get a smooth function which takes the value 1 inside the ball  $B_{r-\varepsilon}(x_0)$ , with support exactly  $B_{r+\varepsilon}(x_0)$ , and with values between 0 and 1 everywhere.

mozna obr. char.fce

**Lemma** (Whitney's theorem). *Every closed set  $K \subset \mathbb{R}^n$  is the set of all zero points of some smooth non-negative function.*

**PROOF.** The idea of the proof is quite simple. If  $K = \mathbb{R}^n$ , the zero function fulfills the conditions, so we can further assume that  $K \neq \mathbb{R}^n$ .

The open set  $U = \mathbb{R}^n \setminus K$  can be expressed as the union of (at most) countably many open balls  $B_{r_i}(x_i)$ , and for each of them, we choose a smooth non-negative function  $f_i$  on  $\mathbb{R}^n$  whose support is just  $\overline{B_{r_i}(x_i)}$ , see the function  $\chi_{r, \varepsilon, x_0}$  above. Now, we add up all these functions into an infinite series

$$f(x) = \sum_{k=1}^{\infty} a_k f_k(x),$$

where the positive coefficients  $a_k$  are selected so small that this series would converge to a smooth function  $f(x)$ .

To this purpose, it suffices to choose  $a_k$  so that all partial derivatives of all functions  $a_k f_k(x)$  up to order  $k$  (inclusive) would be bounded from above by  $2^{-k}$ . Then, the series  $\sum_k a_k f_k$  is bounded from above by the series  $\sum_k 2^{-k}$ , hence by Weierstrass criterion, it converges uniformly on the entire

<sup>2</sup>This property is called *paracompactness* and, actually, each metric space is paracompact. Thus in particular all our manifolds enjoy this property too. But we do not want to go into details of the proof.

and

$$u(t, \sigma) = 2\sigma e^{-t} \implies u(x, y) = \frac{2y}{2 - e^x}.$$

This is unique continuous solution on connected component of its domain including boundary curve (for  $x < \ln 2$ ). Make a test.  $\square$

**9.D.6.** Find a solution of equation for boundary conditions (i)–(iii):

$$yu_x + xu_y = 2u$$

- (i)  $u(x, 0) = 1,$
- (ii)  $u(x, 0) = x^2,$
- (iii)  $u(0, y) = \sqrt{1 + y^2}.$

**Solution.** This is semilinear equation, we will solve it like quasilinear (in the next section we show another method working for semilinear equation):

$$\dot{x} = y, \dot{y} = x, \dot{u} = 2u.$$

Characteristics are given parametrically

$$x(t) = C_1 e^t + C_2 e^{-t}, y(t) = C_1 e^t - C_2 e^{-t}, u(t) = C_3 e^{2t}.$$

- (i) Without lose of generality put  $t = 0$  for the point of intersection of characteristic curve and boundary curve  $x = \varphi(\sigma) = \sigma, y = \psi(\sigma) = 0, u = f(\sigma) = 1$  (boundary curve intersects characteristics for  $x > y$ ),

$$x(0) = C_1 + C_2 = \sigma, y(0) = C_1 - C_2 = 0.$$

Then  $C_1 = C_2 = \frac{\sigma}{2}$  and from

$$x = \frac{\sigma}{2} (e^t + e^{-t}) = \sigma \cosh t, y = \frac{\sigma}{2} (e^t - e^{-t}) = \sigma \sinh t$$

we get  $x^2 - y^2 = \sigma^2, x + y = \sigma e^t,$

$$\sigma = \sqrt{x^2 - y^2}, \quad e^t = \frac{x + y}{\sqrt{x^2 - y^2}}.$$

$$u(0) = C_3 = f(\sigma) = 1,$$

$$u(x, y) = u(\sigma(x, y), t(x, y)) = e^{2t} = \left[ \frac{x + y}{\sqrt{x^2 - y^2}} \right]^2$$

Finally

$$u(x, y) = \frac{x + y}{x - y}, \text{ for } x > y.$$

Make a test.

- (ii) Boundary curve is the same,  $u(0) = C_3 = f(\sigma) = \sigma^2,$  solution is

$$u(x, y) = u(\sigma(x, y), t(x, y)) = \sigma^2 e^{2t} = (x + y)^2, \text{ for } x > y.$$

- (iii) Again put  $t = 0$  for the point of intersection of characteristic curve and boundary curve  $x = \varphi(\sigma) = 0, y = \psi(\sigma) = \sigma, u = f(\sigma) = \sqrt{1 + \sigma^2}$  (boundary curve intersects characteristics for  $y > x$ ),

$$x(0) = C_1 + C_2 = 0, y(0) = C_1 - C_2 = \sigma.$$

Then  $C_1 = -C_2 = \frac{\sigma}{2}$  and from

$$x = \frac{\sigma}{2} (e^t - e^{-t}) = \sigma \sinh t, y = \frac{\sigma}{2} (e^t + e^{-t}) = \sigma \cosh t$$

$\mathbb{R}^n$ . Moreover, we get the same for all series of partial derivatives, since we can always write them as

$$\sum_{k=0}^{r-1} a_k \frac{\partial^r f_k}{\partial x_{i_1} \cdots \partial x_{i_r}} + \sum_{k=r}^{\infty} a_k \frac{\partial^r f_k}{\partial x_{i_1} \cdots \partial x_{i_r}},$$

where the first part is a smooth function as it is a finite sum of smooth functions, and the second part can again be bounded from above by an absolutely converging series of numbers, so this expression will converge uniformly to  $\frac{\partial^r f}{\partial x_{i_1} \cdots \partial x_{i_r}}.$

It is apparent from the definition that the function  $f(x)$  satisfies the conditions of the lemma.  $\square$

#### PARTITION OF UNITY ON A MANIFOLD

**Theorem.** Consider a manifold  $M \subset \mathbb{R}^n$  equipped with a locally finite cover by open images  $U_i$  of parametrizations  $\varphi_i$ . Then, there exists a system of smooth non-negative functions  $f_i$  on the sets  $M$  such that for every point  $x \in M$ , we have  $\sum_i f_i(x) = 1$ , and  $f_i(x) \neq 0$  if and only if  $x \in U_i$ .

The system of functions  $f_i$  from the theorem is called the *partition of unity subordinated to the locally finite cover of the manifold* by the open sets  $U_i$ .

**PROOF.** First, we extend the sets  $U_i$  to open sets  $\tilde{U}_i$  using the extended parametrizations  $\tilde{\varphi}$ , from the definition of manifold and its local parametrizations. We can surely do this in such a way that the sets  $\tilde{U}_i$  keep being a locally finite cover of an open neighborhood  $\tilde{U} = \cup_i \tilde{U}_i \subset \mathbb{R}^n$  of the manifold  $M$ .

For every open set  $\tilde{U}_i$ , we can choose a non-negative function  $g_i(x)$  on the whole  $\mathbb{R}^n$  so that  $g_i(x) \neq 0$  exactly for  $x \in \tilde{U}_i$ . This can be done by Whitney's theorem proved in the above Lemma. Now, the function  $g(x) = \sum_i g_i(x)$  is well-defined for all  $x \in \mathbb{R}^n$  and smooth, thanks to the cover being locally finite (for every fixed point  $x$ , it is a finite sum of non-zero functions on some of its neighborhoods). The function  $g(x)$  is positive for all  $x \in M$ . Thus, instead of functions  $g_i(x)$  restricted to  $M$ , we may rather consider the functions  $f_i(x) = g_i(x)/g(x)$ , which already have both of the required properties of the theorem.  $\square$

**9.1.9. Integration of  $k$ -forms on manifolds.** Now, we are

ready for the definition of the integral of  $k$ -forms on  $k$ -dimensional manifolds. Let us consider an oriented manifold  $M \subset \mathbb{R}^n$  and a form  $\omega \in \Omega^k(M)$  with compact support.

Let us choose a locally finite cover of the manifold  $M$  by parametrizations  $\varphi_i : V_i \rightarrow U_i$  such that the closures of all images  $\varphi_i(V_i)$  are compact and, eventually, choose a partition of unity  $f_i$  subordinated to this cover.

The integral is defined by the formula

$$\int_M \omega = \int_M \sum_i f_i \omega = \sum_i \int_{U_i} f_i \omega,$$

and we get  $y^2 - x^2 = \sigma^2$ ,  $x + y = \sigma e^t$ ,

$$\sigma = \sqrt{y^2 - x^2}, \quad e^t = \frac{x + y}{\sqrt{y^2 - x^2}}.$$

$$u(0) = C_3 = f(\sigma) = \sqrt{1 + \sigma^2},$$

$$u(x, y) = u(\sigma(x, y), t(x, y)) = \sqrt{1 + \sigma^2} e^{2t}$$

Finally

$$u(x, y) = \sqrt{1 + y^2 - x^2} \cdot \frac{x + y}{y - x}, \text{ for } y > x.$$

Make a test.

How to write general solution of equation? Take an implicit description of characteristics, from  $x = C_1 e^t + C_2 e^t$ ,  $y = C_1 e^t - C_2 e^t$ ,  $u = C_3 e^{2t}$  we get

$$\frac{(x + y)^2}{u} = \frac{C_1^2}{C_3} = \Phi, \quad y^2 - x^2 = 2C_1 C_2 = \Psi.$$

General solution of equation is any function constant on characteristics:

$$u : \alpha(\Phi, \Psi) = 0, \text{ or } u = (x + y)^2 K(\Psi) = (x + y)^2 K(y^2 - x^2).$$

Make a test. In the next example we show another way, how to solve semilinear equation.  $\square$

**9.D.7.** Solve equation (S) and equation (L)

$$(S) \quad x^2 u_x + xy u_y = u^2, \quad (L) \quad x^2 u_x + xy u_y = x^2$$

both generally and for boundary conditions (i) — (iv)

- (i)  $u(1, y) = y$ ,
- (ii)  $u(\cos \sigma, \sin \sigma) = 1$ ,  $\sigma \in (-\frac{\pi}{2}, \frac{\pi}{2})$ ,
- (iii)  $u(x, 1 - x) = x$ ,
- (iv)  $u(x, 1 - x) = x^2$ .

**Solution.** Let's start again with characteristic equation

$$y' = \frac{dy}{dx} = \frac{xy}{x^2} \implies \frac{y}{x} = C.$$

Take a new coordinates  $\xi(x, y) = \frac{y}{x}$ ,  $\eta(x, y) = y$  and compute  $u_x = u_\xi \xi_x + u_\eta \eta_x = -\frac{y}{x^2} u_\xi$ ,  $u_y = u_\xi \xi_y + u_\eta \eta_y = -\frac{1}{x} u_\xi + u_\eta$ . The equation (S) will be now

$$u_\eta = \frac{u^2}{\eta^2} \cdot \xi$$

and solution

$$\int \frac{\partial u}{u^2} = \int \xi \frac{\partial \eta}{\eta^2} \implies -\frac{1}{u} = -\frac{\xi}{\eta} + K(\xi),$$

We can write general solution

$$u(\xi, \eta) = \frac{\eta}{\xi + \eta D(\xi)}, \quad u(x, y) = \frac{x}{1 + x D(\frac{y}{x})}.$$

Make a test. Now we can use general solution to find function  $D$ , depending on given boundary condition:

- (i)  $u(1, \sigma) = \frac{1}{1 + D(\frac{\sigma}{1})} = \sigma \implies D(\sigma) = \frac{1}{\sigma} - 1$ . From  $\frac{y}{x} = \frac{\sigma}{1}$  we get solution  $u(x, y) = \frac{x}{1 + x(\frac{x}{y} - 1)} = \frac{xy}{y + x^2 - xy}$ .

where the right-hand integrals have already been defined since each of the forms  $f_i \omega$  has support inside the image under the parametrization  $\varphi_i$  (and they equal to  $\int_M f_i \omega$  for the same reason).

Actually, we can assume that our sum is finite, since it suffices to consider integral over the image of parametrizations covering the compact support of  $\omega$ . Hence, it is a well-defined number, yet it remains to verify that the resulting value is independent of all our choices.

To this purpose, let us choose another system of parametrizations  $\psi : \tilde{V}_j \rightarrow \tilde{U}_j$ , again with compatible orientations, providing a locally finite cover of  $M$ . Let  $g_i$  be the corresponding partition of unity. Then the sets  $W_{ij} = U_i \cap \tilde{U}_j$  form again a locally finite covering and the set of functions  $f_i g_j$  provide the partition of unity subordinated to this covering. We arrive at the following equalities:

$$\begin{aligned} \sum_i \int_M f_i \omega &= \sum_i \int_M f_i (\sum_j g_j) \omega = \sum_{i,j} \int_M f_i g_j \omega \\ \sum_j \int_M g_j \omega &= \sum_j \int_M g_j (\sum_i f_i) \omega = \sum_{i,j} \int_M f_i g_j \omega, \end{aligned}$$

where the potentially infinite sums inside of the integrals are all locally finite, while the sums outside of the integral can be viewed as finite due to the compactness of the support of  $\omega$ . Thus, we have checked that the choices of the partition of unity and the parametrizations do not influence the value of the integral.

**9.1.10. Exterior differential.** As we have seen, the differential of a function can be interpreted as a mapping  $d : \Omega^0(\mathbb{R}^n) \rightarrow \Omega^1(\mathbb{R}^n)$ .

By means of parametrizations, this definition extends (in a coordinate free way) to functions  $f$  on manifolds  $M$ , where the differential  $df$  is a linear form on  $M$ . The following theorem extends this differential to arbitrary exterior forms on manifolds  $M \subset \mathbb{R}^n$ .

EXTERIOR DIFFERENTIAL

**Theorem.** For all  $m$ -dimensional manifolds  $M \subset \mathbb{R}^n$  and  $k = 0, \dots, m$ , there is the unique mapping

$$d : \Omega^k(M) \rightarrow \Omega^{k+1} M,$$

such that

- (1)  $d$  is linear with respect to multiplication by real numbers;
- (2) for  $k = 0$ , this is the differential of functions;
- (3) if  $\alpha \in \Omega^k(M)$ ,  $\beta$  arbitrary, then  $d(\alpha \wedge \beta) = (d\alpha) \wedge \beta + (-1)^k \alpha \wedge (d\beta)$ ;
- (4)  $d(df) = 0$  for every function  $f$  on  $M$ .

The mapping  $d$  is called the exterior differential. The equality  $d \circ d = 0$  is valid for all degrees  $k$ .

(ii)  $u(\cos \sigma, \sin \sigma) = \frac{\cos \sigma}{1 + \cos \sigma} = 1$  we have  $D(\sigma) = 1 - \frac{1}{\cos \sigma}$  and because  $\sigma = \arctan \frac{y}{x}$ ,  $\cos \sigma = \frac{1}{\sqrt{1 + \frac{y^2}{x^2}}}$  so

$D(x, y) = 1 - \sqrt{1 + \frac{y^2}{x^2}}$  and the solution is

$$u(x, y) = \frac{x}{1 + x \left[ 1 - \sqrt{1 + \frac{y^2}{x^2}} \right]}, \quad x > 0.$$

(iii) Analogically  $u(x, y) = x$ ,

(iv) Analogically  $u(x, y) = \frac{x^2}{x + y^2 + xy}$ .

For linear equation (L) is situation much easier. We can see, that  $u = x$  is one of the solutions of both, (L) and (S). For (L) we can use principle of superposition and write general solution like a sum of general solution of homogenous case and any particular solution (make a test):

$$u(x, y) = x + D\left(\frac{y}{x}\right).$$

For boundary conditions we get

(i)  $u(x, y) = x + \frac{y}{x} - 1$ ,

(ii)  $u(x, y) = x + 1 - \frac{x}{\sqrt{x^2 + y^2}}$ ,  $x > 0$ ,

(iii)  $u(x, y) = x$ ,

(iv)  $u(\sigma, 1 - \sigma) = \sigma + D(\sigma) = \sigma^2 \Rightarrow D(\sigma) = \sigma^2 - \sigma$ ,  $\frac{1 - \sigma}{\sigma} = \frac{y}{x} \Rightarrow \sigma = \frac{x}{x + y}$ ,  $D = \sigma^2 - \sigma = -\frac{xy}{(x + y)^2}$  and solution is

$$u(x, y) = x - \frac{xy}{(x + y)^2}, \quad x \neq -y.$$

Make a test for all solutions and use this method also for solving previous problem.  $\square$

**9.D.8.** Find general solution of

$$yu_x + u_y = -u.$$

**9.D.9.** Find general solution of

$$u_x + u_y = -u(x - y)$$

and solutions for given boundary condition

(i)  $u(0, y) = y$ ,

(ii)  $u(\sigma, -\sigma) = \frac{1}{\sigma}$ ,

(iii)  $u(x, 0) = x^2$ .

**9.D.10.** Solve

$$u_x - y^2 u_y = u^2, \quad u(x, 1) = \frac{1}{2x}.$$

**9.D.11.** Solve

$$xu_x + yu_y = 2(x^2 + y^2), \quad u(1, y) = 2y^2 + 1.$$

**9.D.12.** Solve

$$2xu_x - yu_y = x^2 + y^2, \quad u(2, y) = 1 - y^2.$$

**PROOF.** Each  $k$ -form can be written locally in the form

$$\alpha = \sum_{i_1 < \dots < i_k} a_{i_1 \dots i_k} dx_{i_1} \wedge \dots \wedge dx_{i_k}.$$

If the differential  $d$  exists, then by the required properties, it must be equal to

$$\begin{aligned} d\alpha &= \sum_{i_1 < \dots < i_k} da_{i_1 \dots i_k} \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k} \\ (5) \quad &= \sum_{j; i_1 < \dots < i_k} \frac{\partial a_{i_1 \dots i_k}}{\partial x_j} dx_j \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k}. \end{aligned}$$

Indeed, the generators  $dx_i$  of linear forms are in fact the differentials of the coordinate functions, so further differentiation must lead to zero by the last property, while we know the differential of functions. Further, we have  $d(f\beta) = df \wedge \beta + f d\beta$  by property (3).

Thus, let us define the differential  $d$  in coordinates by the formula (5), and we are going to verify all of the required properties. We shall proceed in two steps.

First, we check the requirements in one coordinate patch. The first two requirements are obvious from the formula (5). It is enough to verify the property (3) for the special forms  $\alpha = a dx_{i_1} \wedge \dots \wedge dx_{i_k}$  and  $\beta = b dx_{j_1} \wedge \dots \wedge dx_{j_\ell}$ , since then the property must hold for the sums of such forms too.

We compute

$$\begin{aligned} d(\alpha \wedge \beta) &= d(ab dx_{i_1} \wedge \dots \wedge dx_{i_k} \wedge dx_{j_1} \wedge \dots \wedge dx_{j_\ell}) \\ &= \sum_i \frac{\partial a}{\partial x_i} b dx_i \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k} \wedge dx_{j_1} \wedge \dots \wedge dx_{j_\ell} \\ &\quad + \sum_i \frac{\partial b}{\partial x_i} a dx_{i_1} \wedge \dots \wedge dx_{i_k} \wedge dx_{j_1} \wedge \dots \wedge dx_{j_\ell} \\ &= d\alpha \wedge \beta + (-1)^k \alpha \wedge d\beta, \end{aligned}$$

as expected.

The last property can be again verified for simple forms  $\alpha = a dx_{i_1} \wedge \dots \wedge dx_{i_k}$ . Applying the formula (5) twice, we arrive at

$$\begin{aligned} d(d\alpha) &= d\left(\sum_i \frac{\partial a}{\partial x_i} dx_i \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k}\right) \\ &= \sum_j \sum_i \frac{\partial^2 a}{\partial x_i \partial x_j} dx_j \wedge dx_i \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k} \\ &= \sum_{i < j} \left(\frac{\partial^2 a}{\partial x_i \partial x_j} - \frac{\partial^2 a}{\partial x_j \partial x_i}\right) dx_j \wedge dx_i \wedge dx_{i_1} \wedge \dots \wedge dx_{i_k} \\ &= 0, \end{aligned}$$

where we used the fact that the wedge product  $dx_i \wedge dx_i$  vanishes,  $dx_j \wedge dx_i = -dx_i \wedge dx_j$  and the second partial derivatives of functions are symmetric.

9.D.13. Solve

$$x^2 u_x + y u_y = 2u, \quad u(1, y) = y^3.$$

9.D.14. Solve equation for given boundary condition

$$u = u_x u_y, \quad u(x, 0) = x^2.$$

**Solution.** We show, how to use method of characteristics for general first order equation

$$F(p, q, u, x, y) = 0, \quad \text{where } p = u_x, q = u_y.$$

Our equation we can write in the form  $u - p \cdot q = 0$ . We need to solve system of five ODE's:

$$\begin{aligned} \dot{x} &= F_p = -q, \\ \dot{y} &= F_q = -p, \\ \dot{u} &= pF_p + qF_q = -2pq, \\ \dot{p} &= -F_x - pF_u = -p, \\ \dot{q} &= -F_y - qF_u = -q. \end{aligned}$$

Solution of this characteristic system is

$$\begin{aligned} x &= C_1 e^{-t} + C_2, \\ y &= C_3 e^{-t} + C_4, \\ u &= C_1 C_2 e^{-2t} + C_5, \\ p &= C_3 e^{-t}, \\ q &= C_1 e^{-t}. \end{aligned}$$

Without lose of generality take  $t = 0$  for the point of intersection of characteristic lines with boundary line  $x = \varphi(\sigma) = \sigma, y = \psi(\sigma) = 0, u = f(\sigma) = \sigma^2$  and find  $C_i = C_i(\sigma)$  from

$$\begin{aligned} x(0) &= C_1 + C_2 = \sigma, \\ y(0) &= C_3 + C_4 = 0, \\ u(0) &= C_1 C_2 + C_5 = \sigma^2, \\ p(0) &= C_3 = p_0 = 2\sigma, \\ q(0) &= C_1 = q_0 = \frac{\sigma}{2}. \end{aligned}$$

The value of  $p_0$  and  $q_0$  we get from system of two algebraic equation:

$$F(p_0, q_0, f(\sigma), \varphi(\sigma), \psi(\sigma)) = 0 \implies \sigma^2 = p_0 \cdot q_0,$$

$$u(\varphi(\sigma), \psi(\sigma)) = f(\sigma) \implies \frac{d}{d\sigma} u(\varphi(\sigma), \psi(\sigma)) = \frac{d}{d\sigma} f(\sigma),$$

$$u_x \varphi'(\sigma) + u_y \psi'(\sigma) = f'(\sigma) \implies p_0 \cdot 1 + q_0 \cdot 0 = 2\sigma.$$

Finally we get  $C_1 = \frac{\sigma}{2}, C_2 = \frac{\sigma}{2}, C_3 = 2\sigma, C_4 = -2\sigma, C_5 = 0$ . From

$$x(\sigma, t) = \frac{\sigma}{2} (e^{-t} + 1), \quad y(\sigma, t) = 2\sigma (e^{-t} - 1)$$

we can write

$$\sigma(x, y) = x - \frac{y}{4}, \quad e^{-t}(x, y) = \frac{4x + y}{4x - y},$$

○

○

The second step in the proof is the verification, that the coordinate formula (5) correctly defines a differential operator on general manifolds  $M$ . In order to achieve this, it is sufficient to show that the coordinate expression of the exterior derivative commutes with the pullbacks of forms. Indeed, we may then define the differential operator around any point in any coordinates and the results will coincide.<sup>3</sup>

Thus, consider a change of coordinates  $G : U \rightarrow V, x = G(y) = (g_1(y), \dots, g_m(y))$ , and compute  $G^*(d\alpha)$  of an exterior form  $\alpha = a dx_{i_1} \wedge \dots \wedge dx_{i_k}$  (which gives the result for sums of such expressions too). This is straightforward:

$$\begin{aligned} G^*(d\alpha) &= \sum_i G^*\left(\frac{\partial a}{\partial x_i}\right) G^*(dx_{i_1}) \wedge G^*(dx_{i_2}) \wedge \dots \\ &= \sum_i \left(\frac{\partial a}{\partial x_i} \circ G\right) \left(\frac{\partial g_i}{\partial y_1} dy_1 + \dots\right) \wedge \left(\frac{\partial g_{i_1}}{\partial y_1} dy_1 + \dots\right) \wedge \dots \end{aligned}$$

Now, notice  $d(G^*(dx_j)) = G^*(d(dx_j)) = 0$  and thus

$$\begin{aligned} d(G^*(\alpha)) &= d((a \circ G) G^*(dx_{i_1}) \wedge \dots) \\ &= d(a \circ G) \wedge G^*(dx_{i_1}) \wedge \dots \wedge G^*(dx_{i_k}) \\ &= \sum_i \left(\left(\frac{\partial a}{\partial x_i} \circ G\right) \left(\frac{\partial g_i}{\partial y_1} dy_1 + \dots\right)\right) \wedge G^* dx_{i_1} \wedge \dots, \end{aligned}$$

clearly the same expressions.  $\square$

9.1.11. **Manifolds with boundary.** In practical problems,

we often work with manifolds  $M$  like an open ball in the three-dimensional space. At the same time, we are interested in the boundaries of these manifolds  $\partial M$ , which is a sphere in the case of a ball.

The simplest case is the one of connected curves. It is either a closed curve (like a circle in the plane), then its boundary is empty, or the boundary is formed by two points. These points will be considered including the orientation inherited from the curve, i.e. the initial point will be taken with the minus sign, and the terminal point with the plus sign.

The curve integral is the easiest one, and we can notice that integrating the differential  $df$  of a function along the curve  $M$  defined as the image of a parametrization  $c : [a, b] \rightarrow M$ , then we get directly from the definition that

$$\begin{aligned} \int_M df &= \int_{[a,b]} c^*(df) = \int_a^b \frac{d}{dt} (f \circ c)(t) dt \\ &= f(c(b)) - f(c(a)). \end{aligned}$$

Therefore, the result is not only independent of the selected parametrization, but also of the actual curve. Only the initial and terminal points matter. Splitting the curve into several

<sup>3</sup>Such operators are intrinsically defined on all manifolds. Actually, for all  $k > 0$ , the only operation  $d : \Omega^k \rightarrow \Omega^{k+1}$  commuting with pullbacks and with values depending only on the behavior of the argument  $\alpha$  on any small neighborhood of  $x$  (locality of the operator), is the exterior derivative. Thus even the linearity, as well as the dependence on the first derivatives are direct consequences of naturality. See the book *Natural operations in differential geometry*, Springer, 1993, by I. Kolar, P.W. Michor and J. Slovák for full proof of this astonishing claim.

and

$$u(\sigma(x, y), t(x, y)) = \sigma^2 e^{-2t} = \left[ \left( x - \frac{y}{4} \right) \frac{4x + y}{4x - y} \right]^2,$$

$$u(x, y) = \frac{1}{16} (4x + y)^2.$$

Make a test.

consecutive disjoint intervals, the integral splits into the sum of differences of the values at the splitting points. This sum will be telescoping (i.e., the middle terms cancel out), resulting in the same value again.

Notice, we have already proved the behavior expected in 9.1.5 when dealing with the elevation gain by a cyclist.

- We shall discuss this phenomenon in general dimensions now. To be able to do this, we need to formalize the concept of the boundary of a manifold and its orientation. The simplest case is the closed half-space  $\bar{M} = (-\infty, 0] \times \mathbb{R}^{n-1}$ . Its boundary is  $\partial M = \{(x_1, x_2, \dots, x_n) \in \mathbb{R}^n; x_1 = 0\}$ .
- The orientation on this boundary inherited from the standard orientation is the one determined by the form  $dx_2 \wedge \dots \wedge dx_n$ .

ORIENTED BOUNDARY OF A MANIFOLD

- Let us consider a closed subset  $\bar{M} \subset \mathbb{R}^n$  such that its interior  $M \subset \bar{M}$  is an oriented  $m$ -dimensional manifold covered by compatible parametrizations  $\varphi_i$ . Further, let us assume that for every boundary point  $x \in \partial M = \bar{M} \setminus M$ , there is a neighborhood in  $\bar{M}$  with parametrization  $\varphi : V \subset (-\infty, 0] \times \mathbb{R}^{m-1} \rightarrow M$  such that the points  $x \in \partial M \cap \varphi(V)$  from just the image of the boundary of the half-space  $(-\infty, 0] \times \mathbb{R}^{m-1}$ . The subset  $\bar{M} \subset \mathbb{R}^m$  covered by the above parametrizations with compatible orientations is called an *oriented manifold with boundary*.
- The restrictions of the parametrizations including boundary points to the boundary  $\partial M$  defines the structure of an  $(m - 1)$ -dimensional oriented manifold on  $\partial M$ .

- Think of a closed unit balls  $B(x, r) \subset \mathbb{R}^n$  as such manifolds. Their interiors are an  $n$ -dimensional manifolds, just open subsets in  $\mathbb{R}^n$ , but their boundaries  $S^{n-1}$  are the spheres with the inherited structure of  $(n-1)$ -dimensional manifolds. The inherited orientations are well understood via the outward normals to the spheres. Another example is a plane disc sitting as a 2-dimensional manifold in  $\mathbb{R}^3$  with its 1-dimensional boundary being a circle. Here the chosen position of the normal to the plane defines the orientation of the circle, one or the other way.

pridat obrazek k prikladu

- In practice, we often deal with slightly more general manifolds where we allow for corners in the boundary of all smaller dimensions. A good example is the cube in  $\mathbb{R}^3$  having the sides as 2-dimensional parts of the boundary and also the edges between them as 1-dimensional parts and the vortices as 0-dimensional parts of the boundary. Yet another class of examples is formed by all simplexes and their curved embeddings in  $\mathbb{R}^n$ . Since those lower dimensional parts of the boundary will have Riemann measure zero, we can neglect them when integrating over  $\partial M$ . Thus we shall not go into details of this technical extension of our definitions.

○

**9.D.25.** Find all solutions (if exists) of the system

$$\begin{aligned} u_x &= f(x, y, u) = y(u - xy + 1), \\ u_y &= g(x, y, u) = x(u - xy + 1). \end{aligned}$$

**Solution.** Necessary (and sufficient) condition for existence of solution is  $u_{xy} = u_{yx}$ :

$$\begin{aligned} u_{xy} &= f_y + f_u g = u - 2xy + 1 + xyu - x^2y^2 + xy, \\ u_{yx} &= g_x + g_u f = u - 2xy + 1 + xyu - x^2y^2 + xy. \end{aligned}$$

Let's start with first equation

$$\frac{\partial u}{\partial x} = yu - xy^2 + 1,$$

which is linear and we can find solution in the form

$$u(x, y) = K(x, y)e^{xy}$$

so

$$u_x = K_x e^{xy} + yK e^{xy} = yK e^{xy} - xy^2 + y$$

and

$$K_x = (y - xy^2)e^{-xy},$$

by per partes we have

$$K(x, y) = xy e^{-xy} + D(y).$$

Substituing this to the second equation

$$u(x, y) = xy + D(y)e^{xy} \implies$$

$$u_y = x + D'(y)e^{xy} + xD(y)e^{xy} = g(x, y, u)$$

we get  $D'(y) = 0$ ,  $D$  is constant and all solutions are given by

$$u(x, y) = xy + De^{xy}.$$

Show, that characteristics polynomial of the matrix

$$\begin{pmatrix} A & B \\ B & C \end{pmatrix}$$

has

- (E) two nonzero real roots (not necessarily different) of the same sign ( $\lambda_1 \cdot \lambda_2 > 0$ ) if and only if  $B^2 - AC < 0$ , equation is elliptic,
- (H) two nonzero real roots of different sign ( $\lambda_1 \cdot \lambda_2 < 0$ ) if and only if  $B^2 - AC > 0$ , equation is hyperbolic,
- (P) two real roots from which (at least) one is zero ( $\lambda_1 \cdot \lambda_2 = 0$ ) if and only if  $B^2 - AC = 0$ , equation is parabolic.

**9.1.12. Stokes' theorem.** Now, we get to a very important and useful result. We shall formulate the main theorem about the multidimensional analogy of curve integrals for smooth forms and smooth manifolds. A brief analysis of the proof shows that actually, we need once continuously differentiable exterior forms as integrands on twice continuously differentiable parametrizations of the manifold.

In practice, the boundary of the region is often similar as in the case of the unit cube in  $\mathbb{R}^3$ , i.e., we have discontinuities of the derivatives on a Riemann measurable set with measure zero in the boundary. In such a case, we divide the integration to smooth parts and add the results up. We can notice that although new pieces of boundaries appear, they are adjacent and have opposite orientations in the adjacent regions, so their contribution is canceled out (just like in the above case of boundary points of a piecewise differentiable curve).

#### STOKES' THEOREM

**Theorem.** Consider a smooth exterior  $(k-1)$ -form  $\omega$  with compact support on an oriented manifold  $\bar{M}$  with boundary  $\partial M$  with the inherited orientation. Then we have

$$\int_M d\omega = \int_{\partial M} \omega.$$

**PROOF.** Using an appropriate locally finite cover of the manifold  $\bar{M}$  and a partition of unity subordinated to it, we can express the integrals on both sides as the sum (even a finite sum, since the support of the considered form  $\omega$  is compact) of integrals of forms  $\omega$  supported in individual parametrizations. Thus we can restrict ourselves to just two cases  $\bar{M} = \mathbb{R}^k$  or the half-space  $\bar{M} = (-\infty, 0] \times \mathbb{R}^{k-1}$ .

In both cases,  $\omega$  will surely be the sum of forms  $\omega_j$

$$\omega_j = a_j(x) dx_1 \wedge \cdots \wedge \hat{dx}_j \wedge \cdots \wedge dx_k,$$

where the hat indicates the omission of the corresponding linear form, and  $a_j(x)$  is a smooth function with compact support. Their exterior differentials are

$$d\omega_j = (-1)^{j-1} \frac{\partial a_j}{\partial x_j} dx_1 \wedge \cdots \wedge dx_k.$$

Again, we can verify the claim of the theorem for such forms  $\omega_j$  separately. Let us compute the integrals  $\int_M d\omega_j$  using the Fubini's theorem. This is most simple if  $\bar{M} = \mathbb{R}^n$ ,

$$\begin{aligned} \int_{\mathbb{R}^n} d\omega_j &= (-1)^{j-1} \int_{\mathbb{R}^{k-1}} \left( \int_{-\infty}^{\infty} \frac{\partial a_j}{\partial x_j} dx_j \right) dx_1 \cdots \hat{dx}_j \cdots dx_k \\ &= (-1)^{j-1} \int_{\mathbb{R}^{k-1}} [a_j]_{-\infty}^{\infty} dx_1 \cdots \hat{dx}_j \cdots dx_k = 0. \end{aligned}$$

Notice, we are allowed to use the Fubini's theorem for the entire  $\mathbb{R}^n$  since the support of the integrated function is in fact compact and thus we can replace the integration domain by a large multidimensional interval  $I$ . At the same time, the forms  $\omega_j$  are all zero outside of such a large interval  $I$  and thus

**Solution.** EASY ale FUJ

(H) hyperbolic equation in canonical form

$$u_{xy} = 0$$

is any function  $u(x, y) = F(x) + G(y)$ .

(E) elliptic equation in canonical form

$$\Delta v = v_{xx} + v_{yy} = 0$$

is any function  $v(x, y) = F(x + iy) + G(x - iy)$ .

(P) parabolic equation in canonical form

$$w_{xx} = kw_y,$$

is any function

$$w(x, y) = e^{k(Cx+C^2y)}.$$

**Solution.**

$$u_x = F', u_{xy} = 0.$$

$$v_x = F' + G', v_{xx} = F'' + G'', v_y = iF' - iG',$$

$$v_{yy} = -F'' - G'' \implies u_{xx} + u_{yy} = 0,$$

$$w_x = kCe^{k(Cx+C^2y)}, w_{xx} = k^2C^2e^{k(Cx+C^2y)},$$

$$w_y = kC^2e^{k(Cx+C^2y)} \implies w_{xx} = kw_y.$$

**9.D.30.** Show, that real solution of Laplace equation in polar coordinates  $x = r \cos \varphi, y = r \sin \varphi$  (compute):

$$u_{rr} + \frac{1}{r^2}u_{\varphi\varphi} + \frac{1}{r}u_\varphi = 0,$$

are *harmonic* function given by

$$\alpha_n(r, \varphi) = r^n \cos n\varphi, \beta_n(r, \varphi) = r^n \sin n\varphi, n \in \mathbf{N}_0.$$

Find their expression  $\alpha_n(x, y), \beta_n(x, y)$  for  $n = 0, 1, 2, 3$ .

○

**9.D.31.** Find general solution of second order equation

$$x^2u_{xx} - 2xyu_{xy} + y^2u_{yy} - x^2u_x + (x+2)yu_y = 0.$$

**Solution.** We have

$$A = x^2, B = -xy, C = y^2, B^2 - AC = 0$$

and equation is parabolic. Let's solve characteristic equation

$$\frac{dy}{dx} = y' = \frac{B \pm \sqrt{B^2 - AC}}{A} = \frac{-xy}{x^2} = -\frac{y}{x}.$$

We have solution in implicit form  $xy = C = \xi$  ( $\xi = \xi(x, y)$  will be new coordinate function). For second new coordinate function  $\eta = \eta(x, y)$  we can take any independent ( $\xi_x \eta_y \neq \xi_y \eta_x$ ) function, for example  $\eta = x$ . Inverse transformation is

$$x = \eta, y = \frac{\xi}{\eta}.$$

We get

$$u_x = u_\xi \xi_x + u_\eta \eta_x = \frac{\xi}{\eta} u_\xi + u_\eta, u_y = u_\xi \xi_y + u_\eta \eta_y = \eta u_\xi,$$

□ the integrals  $\int_{\partial M} \omega_j$  all vanish and the claim of the Stokes' theorem is verified in this case. Actually, we may also say that  $\partial M = \emptyset$  and thus the integral is zero.

Next, let us assume  $\bar{M}$  is the half-space  $(-\infty, 0] \times \mathbb{R}^{k-1}$ . If  $j > 1$ , the form  $\omega_j$  evaluates identically to zero on the boundary  $\partial M$ , since  $x_1$  is constant there and thus  $dx_1$  is identically zero on all tangent directions to  $\partial M$ . Integration over the interior  $M$  yields zero, using the same approach as above:

$$\begin{aligned} \int_M d\omega_j &= (-1)^{j-1} \int_{-\infty}^0 \int_{\mathbb{R}^{k-2}} \left( \int_{-\infty}^{\infty} \frac{\partial a_j}{\partial x_j} dx_j \right) dx_1 \cdots \hat{dx}_j \cdots dx_k \\ &= (-1)^{j-1} \int_{-\infty}^0 \int_{\mathbb{R}^{k-1}} [a_j]_{-\infty}^{\infty} dx_1 \cdots \hat{dx}_j \cdots dx_k = 0 \end{aligned}$$

since the function  $a_j$  has compact support. So the theorem is also true in this case.

However, if  $j = 1$ , then we obtain

$$\begin{aligned} \int_M d\omega_1 &= \int_{\mathbb{R}^{k-1}} \left( \int_{-\infty}^0 \frac{\partial a_1}{\partial x_1} dx_1 \right) dx_2 \cdots dx_k \\ &= \int_{\mathbb{R}^{k-1}} a_1(0, x_2, \dots, x_k) dx_2 \cdots dx_k = \int_{\partial M} \omega_1. \end{aligned}$$

This finishes the proof of Stokes' theorem. □

**9.1.13. Green's theorem.** We have proved an extraordinarily strong result which covers several standard integral relations from the classical vector analysis. For instance, we can notice that by Stokes theorem, the integration of exterior differential  $d\omega$  of any  $k$ -form over a compact manifold without boundary is always zero (for example, integral of any 2-form  $d\omega$  over the sphere  $S^2 \subset \mathbb{R}^3$  vanishes).

Let us look step by step at the cases of Stokes' theorem with  $k$  dimensional boundaries  $\partial M$  in  $\mathbb{R}^n$  in low dimensions.

#### GREEN'S THEOREM

In the case  $n = 2, k = 1$ , we are examining a domain  $M$  in the plane, bounded by a closed curve  $C = \partial M$ . Differential 1-forms are  $\omega(x, y) = f(x, y) dx + g(x, y) dy$ , with the differential  $d\omega = \left(-\frac{\partial f}{\partial y} + \frac{\partial g}{\partial x}\right) dx \wedge dy$ . Therefore, Stokes' theorem yields the formula

$$\int_C f(x, y) dx + g(x, y) dy = \int_M \left(-\frac{\partial f}{\partial y} + \frac{\partial g}{\partial x}\right) dx \wedge dy$$

which is one of the standard forms of the *Green's theorem*.

Using the standard scalar product on  $\mathbb{R}^2$ , we can identify the vector field  $X$  with a linear form  $\omega_X$  such that  $\omega_X(Y) = \langle Y, X \rangle$ . In the standard coordinates  $(x, y)$ , this just means that the field  $X = f(x, y) \frac{\partial}{\partial x} + g(x, y) \frac{\partial}{\partial y}$  corresponds to the form  $\omega = f(x, y) dx + g(x, y) dy$  given above.

The integral of  $\omega_X$  over a curve  $C$  has the physical interpretation of the work done by movement along this curve in the force field  $X$ .

Green's theorem then says, besides others, that if  $\omega_X = dF$  for some function  $F$ , then the work done along a closed curve is always zero. Such fields are called potential fields

$$u_{xx} = \frac{\xi^2}{\eta^2} u_{\xi\xi} + 2\frac{\xi}{\eta} u_{\xi\eta} + u_{\eta\eta},$$

$$u_{xy} = \xi u_{\xi\xi} + \eta u_{\xi\eta} + u_{\xi}, u_{yy} = \eta^2 u_{\xi\xi}.$$

Finally the equation has the form

$$\eta^2(u_{\eta\eta} - u_{\eta}) = 0 \implies u_{\eta\eta} = u_{\eta}.$$

Integrating twice we have  $u(\xi, \eta) = G(\xi)e^{\eta} + F(\xi)$ ,

$$u(x, y) = G(xy)e^x + F(xy), \text{ make a test.}$$

Try to solve equation for different choice of the function  $\eta$ .

□

**9.D.32.** Find general solution of second order equation

$$y u_{yy} - x u_{xy} + u_y = 0.$$

**Solution.** We have

$$A = 0, B = -\frac{x}{2}, C = y, B^2 - AC = \frac{x^2}{4} > 0 \text{ for } x \neq 0$$

and this equation is hyperbolic. The characteristic equation (we can't divide by  $A = 0!$ ) is now

$$\frac{dx}{dy} = x' = \frac{B \pm \sqrt{B^2 - AC}}{C} = \frac{1}{y} \left( -\frac{x}{2} \pm \frac{x}{2} \right).$$

We have two solutions in implicit form (new coordinate functions  $\xi = \xi(x, y), \eta = \eta(x, y)$ )

$$x = C_1 = \xi, \quad xy = C_2 = \eta \implies x = \xi, y = \frac{\eta}{\xi}.$$

Finally

$$u_x = u_{\xi} + \frac{\eta}{\xi} u_{\eta}, \quad u_y = \xi u_{\eta},$$

$$u_{xy} = \xi u_{\xi\eta} + \eta u_{\eta\eta} + u_{\eta}, \quad u_{yy} = \xi^2 u_{\eta\eta}$$

and in new coordinates  $\xi, \eta$  has the equation canonical form

$$u_{\xi\eta} = 0.$$

General solution is

$$u(\xi, \eta) = F(\xi) + G(\eta), \quad u(x, y) = F(x) + G(xy).$$

□

**9.D.33.** Find general solution of second order equation

$$u_{xx} - 2 \sin x u_{xy} + (2 - \cos^2 x) u_{yy} - \cos x u_y = 0.$$

**Solution.** We have

$$A = 1, B = -\sin x, C = 2 - \cos^2 x, B^2 - AC < 0$$

and equation is elliptic. Let's solve characteristic equation

$$\frac{dy}{dx} = y' = \frac{B \pm \sqrt{B^2 - AC}}{A} = -\sin x \pm i.$$

We have solution in implicit form

$$y - \cos x - ix = C_1 = \Phi(x, y), \quad y - \cos x + ix = C_2 = \Psi(x, y)$$

and new (real) coordinate function are

$$\xi = \frac{1}{2}(\Phi + \Psi) = y - \cos x, \quad \eta = \frac{1}{2i}(\Psi - \Phi) = x.$$

and the function  $F$  is the potential of the field  $X$ . In other words, the work done when moving in potential fields does not depend on the path, it depends only on the initial and terminal points.

With Green's theorem, we have verified once again that integrating the differential of a function along a curve depends solely on the initial and terminal points of the curve.

**9.1.14. The divergence theorem.** The next case deals with integrating over some open subset in  $\mathbb{R}^3$  and it has got a lot of incarnations in practical use. We shall mention a few.

#### GAUSS–OSTROGRADSKY'S THEOREM

In the case  $n = 3, k = 2$  we are examining a region  $M \subset \mathbb{R}^3$ , bounded by a surface  $S$ . All 2-forms are of the form  $\omega = f(x, y, z) dy \wedge dz + g(x, y, z) dz \wedge dx + h(x, y, z) dx \wedge dy$ , and we get  $d\omega = \left( \frac{\partial f}{\partial x} + \frac{\partial g}{\partial y} + \frac{\partial h}{\partial z} \right) dx \wedge dy \wedge dz$ .

The Stokes' theorem says that

$$\begin{aligned} \int_S f dy \wedge dz + g dz \wedge dx + h dx \wedge dy \\ = \int_M \left( \frac{\partial f}{\partial x} + \frac{\partial g}{\partial y} + \frac{\partial h}{\partial z} \right) dx \wedge dy \wedge dz. \end{aligned}$$

This is the statement of the *Gauss–Ostrogradsky theorem*.

This theorem has a very illustrative physical interpretation, too.

Every vector field  $X = f(x, y, z) \frac{\partial}{\partial x} + g(x, y, z) \frac{\partial}{\partial y} + h(x, y, z) \frac{\partial}{\partial z}$  can be plugged into the first argument of the standard volume form  $\omega_{\mathbb{R}^3} = dx \wedge dy \wedge dz$  on  $\mathbb{R}^3$ . Clearly, the result is a 2-form  $\omega^X(x, y, z) = f(x, y, z) dy \wedge dz + g(x, y, z) dz \wedge dx + h(x, y, z) dx \wedge dy$ .

The latter 2-form infinitesimally describes the volume of the parallelepiped given by the flux caused by the field  $X$  through a linearized piece of surface. If we consider the vector field to be the velocity of the flow of the particular points of the space, this infinitesimally describes the volume transported pointwise by the flow through the given surface  $S$ . Thus the left hand side is the total change of volume inside of  $S$ , caused by the flow of  $X$ .

The integrand of the right-hand side of the integral, is related to the so-called *divergence of the vector field*, which is the expression defined as

$$d(\omega^X) = (\operatorname{div} X) dx \wedge dy \wedge dz.$$

The Gauss–Ostrogradsky theorem says

$$\int_S i_X \omega_{\mathbb{R}^3} = \int_M \operatorname{div} X \omega_{\mathbb{R}^3},$$

i.e. the volume of total flow through a surface is given as the integral of the divergence of the vector field over the interior. In particular, if  $\operatorname{div} X$  vanished identically, then the total volume flow through the boundary surface of the region is zero as well.

We have

$$\xi_x = \sin x, \xi_y = 1, \xi_{xx} = \cos x, \xi_{xy} = 0, \xi_{yy} = 0,$$

$$\eta_x = 1, \eta_y = \eta_{xx} = \eta_{xy} = \eta_{yy} = 0,$$

$$u_y = u_\xi, u_{xy} = u_{\xi\xi} \sin \eta + u_{\xi\eta}, u_{yy} = u_{\xi\xi},$$

$$u_{xx} = u_{\xi\xi} \sin^2 \eta + 2u_{\xi\eta} \sin \eta + u_{\eta\eta} + u_\xi \cos \eta.$$

Finally the equation became canonical

$$\Delta u = u_{\xi\xi} + u_{\eta\eta} = 0.$$

General solution is

$$u(\xi, \eta) = C(\xi + i\eta) + D(\xi - i\eta) \text{ make a test,}$$

$$u(x, y) = C(y - \cos x + ix) + D(y - \cos x - ix).$$

Real solution is given by harmonic functions in variables  $\xi, \eta$ . □

**9.D.34.** Solve

$$x^2 u_{xx} - 2x u_{xy} + u_{yy} + x u_x = 0.$$

**9.D.35.** Solve

$$x u_{xx} - y u_{xy} + u_x = 0$$

**9.D.36.** Solve

$$u_{xx} - u_{xy} + 2u_{yy} = 0.$$

**9.D.37.** Find canonical form of

$$y^2 u_{xx} + x^2 u_{yy} = 0.$$

**9.D.38.** Show, that solution of nonhomogenous wave equation with initial conditions (infinite string):

$$u_{tt}(t, x) = a^2 u_{xx}(t, x) + f(t, x), \quad t \in (0, \infty), x \in \mathbf{R},$$

$$u(0, x) = \varphi(x), \quad u_t(0, x) = \psi(x), \quad x \in \mathbf{R},$$

is given by d'Alembert's formula:

$$u(t, x) = \frac{\varphi(x - at) + \varphi(x + at)}{2} + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi +$$

$$+ \frac{1}{2a} \int_0^t \left( \int_{x-a(t-\sigma)}^{x+a(t-\sigma)} f(\sigma, \xi) d\xi \right) d\sigma.$$

Such fields, with  $\operatorname{div} X = 0$ , are called *divergence free* or *solenoidal* vector fields. They correspond to dynamics without changes of volumes (e.g. modelling dynamics of incompressible liquids).

In order to reformulate the theorem completely in terms of functions, let us observe that the inherited volume form  $\omega_S$  on  $S$  is defined by the property  $\nu^* \wedge \omega_S = \omega_{\mathbb{R}^3}$  at all points of  $S$ , where  $\nu^*$  is dual form to the oriented (outward) unit normal to  $S$ .

All forms of degree 2 are multiples of  $\omega_S$  by functions. In particular,

$$i_X(\nu^* \wedge \omega_S) = \nu \cdot X \omega_S,$$

i.e. we have to integrate the scalar product of the vector field  $X$  with the unit normal vector with respect to the standard volume on  $S$ . Thus, we have proved the following result formulated in the classical vector analysis style.

Actually, a simple check reveals that the above arguments work for all open submanifolds  $M \subset \mathbb{R}^n$  with boundary hypersurface  $S$  and vector fields  $X$ . The reader should easily verify this in detail.

#### DIVERGENCE THEOREM

**Theorem.** Let  $X$  be a vector field on a  $n$ -dimensional manifold  $M \subset \mathbb{R}^n$  with hypersurface boundary  $S$ . Then

$$\int_M \operatorname{div} X \, dx_1 \dots dx_n = \int_S X \cdot \nu \, dS,$$

where  $\nu$  is the oriented (outward) unit normal to  $S$  and  $dS$  stays for the volume inherited from  $\mathbb{R}^n$  on  $S$ .

Notice the 2-dimensional case coincides with the Green's theorem above.

**9.1.15. The original Stokes theorem.** If  $\omega$  is any linear form, then the integral of  $d\omega$  over a surface depends on the boundary curve only. This is the most classical *Stokes' theorem*:

#### THE CLASSICAL STOKES' THEOREM

In the case  $n = 3, k = 1$  we deal with a surface  $M$  in  $\mathbb{R}^3$  bounded by a curve  $C$ . The general linear forms are  $\omega = f \, dx + g \, dy + h \, dz$ , with the integral

$$\int_C f \, dx + g \, dy + h \, dz = \int_M d\omega,$$

where  $d\omega = \left( \frac{\partial h}{\partial y} - \frac{\partial g}{\partial z} \right) dy \wedge dz + \left( \frac{\partial f}{\partial z} - \frac{\partial h}{\partial x} \right) dz \wedge dx + \left( \frac{\partial g}{\partial x} - \frac{\partial f}{\partial y} \right) dx \wedge dy$ .

Again, we use the standard scalar product to identify the vector field  $X = f \frac{\partial}{\partial x} + g \frac{\partial}{\partial y} + h \frac{\partial}{\partial z}$  with the form  $\omega_X = f \, dx + g \, dy + h \, dz$ . Finally, reverting the above relation between the vector fields and two forms on  $\mathbb{R}^3$ , the 2-form  $d\omega_X$  can be identified with the vector field  $\operatorname{rot} X$ ,

$$d\omega_X = \omega_{\mathbb{R}^3}(\operatorname{rot} X, \cdot, \cdot).$$

**9.D.39.** Using d'Alembert's formula solve

$$u_{tt}(t, x) = u_{xx}(t, x) + \cos x, \quad t \in (0, \infty), \quad x \in \mathbf{R},$$

$$u(0, x) = x^2, \quad u_t(0, x) = \arctg x, \quad x \in \mathbf{R}.$$

**Solution.**

$$u_1(t, x) = \frac{\varphi(x - at) + \varphi(x + at)}{2} =$$

$$= \frac{(x - t)^2 + (x + t)^2}{2} = x^2 + t^2,$$

$$u_2(t, x) = \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi = \frac{1}{2} \int_{x-t}^{x+t} \arctg \xi d\xi =$$

$$\left[ \xi \arctg \xi - \frac{1}{2} \ln(1 + \xi^2) \right]_{x-t}^{x+t} = \frac{1}{2} [(x + t) \arctg(x + t) -$$

$$-(x - t) \arctg(x - t) + \ln \sqrt{\frac{1 + (x - t)^2}{1 + (x + t)^2}}],$$

$$u_3(t, x) = \frac{1}{2a} \int_0^t \left( \int_{x-a(t-\sigma)}^{x+a(t-\sigma)} f(\sigma, \xi) d\xi \right) d\sigma =$$

$$= \frac{1}{2} \int_0^t \left( \int_{x-t+\sigma}^{x+t-\sigma} \cos \xi d\xi \right) d\sigma = \frac{1}{2} \int_0^t [\sin \xi]_{x-t+\sigma}^{x+t-\sigma} d\sigma =$$

$$\frac{1}{2} \int_0^t [\sin(x + t - \sigma) - \sin(x - t + \sigma)] d\sigma =$$

$$= \frac{1}{2} [\cos(x + t - \sigma)]_0^t + \frac{1}{2} [\cos(x - t + \sigma)]_0^t =$$

$$= \frac{1}{2} [-\cos(x + t) - \cos(x - t)] + \cos x.$$

$$u(t, x) = u_1(t, x) + u_2(t, x) + u_3(t, x).$$

**9.D.40.** Solve ( $x \in \mathbf{R}, t \in (0, \infty)$ )

- a)  $u_{tt} - u_{xx} = 0, u(0, x) = \sin x, u_t(0, x) = x \cos x$
- b)  $u_{tt} - u_{xx} = 0, u(0, x) = 2x, u_t(0, x) = \ln(1 + x^2)$
- c)  $u_{tt} - u_{xx} = \sin x, u(0, x) = x, u_t(0, x) = \frac{1}{x}$

**9.D.41.** Solve

$$u_{tt}(t, x) = u_{xx}(t, x) + 2 \sin x, \quad t \in (0, \infty), \quad x \in \mathbf{R},$$

$$u(0, x) = x^2 + 2x, \quad u_t(0, x) = x \cos x, \quad x \in \mathbf{R}.$$

**9.D.42.** Solve

$$u_{tt}(t, x) = u_{xx}(t, x) + 2 \cos x, \quad t \in (0, \infty), \quad x \in \mathbf{R},$$

$$u(0, x) = 2x^2 - x, \quad u_t(0, x) = x \sin x, \quad x \in \mathbf{R}.$$

This field is called the *rotation* or *curl* of the vector field  $X$ . The Stokes' theorem now reads:

$$\int_C \omega_X = \int_M \text{rot } X.$$

Consequently, the fields  $X$  with the property  $\omega_X = dF$  for some function  $F$  (the fields of gradients of functions), have got the property  $\text{rot } X = 0$ . They are called *conservative* (or *potential*) vector fields.

**9.1.16. Brouwer's theorem.** Among many useful fixed-point theorems, the *Brouwer theorem* is particularly nice.<sup>4</sup> We present a special case here. In particular, our formulation clearly must hold true for any homeomorphic image of the domain  $K$ . In fact, the convexity ensures that there are no "holes" inside of  $K$ . For example rotating an annulus  $r \leq \|x\| \leq R$  in the plane clearly does not have any fixed point.

**BROUWER'S FIXED-POINT THEOREM**

**Theorem.** Let  $K \subset \mathbf{R}^n$  be a compact convex submanifold of dimension  $n$  with boundary  $\partial K$ . Then every continuous mapping  $f : K \rightarrow K$  has got at least one fixed point  $x$ , i.e.  $f(x) = x$ .

**PROOF.** We shall restrict ourselves to the case of smooth manifold  $K$  and smooth mapping  $f$ . In fact, if a continuous  $f$  had no fixed point, then it is possible to approximate it by a smooth  $\tilde{f}$  without any fixed point (e.g., by taking a convolution  $\tilde{f} = f * \varphi$  with a suitable smooth kernel  $\varphi$  enjoying a very small support).

Assume  $f : K \rightarrow K$  is such a smooth mapping with  $f(x) \neq x$  for all  $x \in K$ . For each  $y \in K$ , consider the ray  $L$  from  $f(y)$  through  $y$ . This ray will leave  $K$  in the unique point  $F(y) \in \partial K$  and  $F : K \rightarrow \partial K$  is smooth. Notice we use the convexity assumption here (it is evident if  $K$  is a ball  $B$  of diameter  $r$  and the general case can be transformed to the ball case by "smoothly expanding"  $K$  from an inner point to a big enough ball  $B$ ). In particular, the construction implies  $F|_{\partial K} = \text{id}_{\partial K}$ . Thus, by our assumptions,  $F : K \rightarrow \partial K$  is a smooth retraction of  $K$  to its boundary.

Now, we may consider a smooth exterior form  $\omega \in \Omega^{n-1}(K)$  providing the standard (inherited) volume on  $\partial K$ , and we employ the general Stokes' theorem:

$$0 < \int_{\partial K} \omega = \int_{\partial K} F^* \omega = \int_K d(F^* \omega)$$

$$= \int_K F^*(d\omega) = \int_K F^*(0) = 0.$$

This is a contradiction and the theorem is proved. □

<sup>4</sup>Its 2-dimensional version is attributed to Luitzen Egbertus Jan Brouwer (1881-1966), a Dutch mathematician and philosopher, who should had noticed that when stirring a cup of coffee with sugar, there always stays at least one point fixed.

9.D.43.

$$u_{tt}(t, x) = 4u_{xx}(t, x) + \cos^2 x, \quad t \in (0, \infty), x \in \mathbf{R},$$

$$u(0, x) = x^3, \quad u_t(0, x) = \frac{1}{\sqrt{1+x^2}}, \quad x \in \mathbf{R}.$$

9.D.44.

$$u_{tt} = 9u_{xx} - 4 \cos x, \quad t \in (0, \infty), x \in \mathbf{R},$$

$$u(0, x) = x^2, \quad u_t(0, x) = xe^x, \quad x \in \mathbf{R}.$$

9.D.45. Solve parabolic equation

$$u_t = ku_{xx}, \quad t \in (0, \infty), x \in (0, l)$$

with *Dirichlet* boundary conditions

$$u(t, 0) = u(t, l) = 0, \quad t \in (0, \infty)$$

and initial condition

$$u(0, x) = \varphi(x) = x(l - x), \quad x \in (0, l).$$

**Solution.** Suppose that solution is in the form

$$u(t, x) = X(x) \cdot T(t)$$

and compute

$$u_t = XT', \quad u_{xx} = X''T,$$

dividing both sides of equation by  $XT$  we get

$$\frac{T'}{kT} = \frac{X''}{X} = -\lambda,$$

where  $\lambda$  is constant number, because left side depend only on variable  $t$  and right side only on variable  $x$ . Solving both ordinary equations

$$T' + \lambda kT = 0, \quad X'' + \lambda X = 0$$

we get

$$T(t) = Ce^{-\lambda kt}, \quad X(x) = C_1 e^{\mu x} + C_2 e^{-\mu x},$$

where  $\mu = \sqrt{-\lambda}$ . Using boundary conditions

$$X(0) = C_1 + C_2 = 0 \implies C_2 = -C_1$$

and

$$X(l) = C_1 (e^{\mu l} - e^{-\mu l}) = 0 \implies e^{2\mu l} = 1 = e^{2\pi ni}.$$

Numbers  $\mu_n = i\frac{n\pi}{l}$  and  $\lambda_n = \frac{n^2\pi^2}{l^2}$ , where  $n = 0, 1, 2, \dots$ . We have

$$T_n = C_n e^{-\frac{n^2\pi^2}{l^2} kt},$$

$$X_n = D_n (e^{i\frac{n\pi}{l}x} - e^{-i\frac{n\pi}{l}x}) = 2iD_n \sin\left(\frac{n\pi}{l}x\right).$$

Solution of equation and boundary condition is series

$$u(t, x) = \sum_{n=0}^{\infty} T_n X_n = \sum_{n=1}^{\infty} K_n \sin\left(\frac{n\pi}{l}x\right) e^{-\frac{n^2\pi^2}{l^2} kt}.$$

9.1.17. **Another kind of integration.** As we have seen, solutions to ODEs are flows of vector fields. As a modification, we can prescribe one-dimensional linear subspaces  $L_x \subset T_x M$  at each point of a manifold  $M$  and look for unparameterized curves  $P$  tangent to them at all points. This is a coordinate-free version of the ODE theory. Indeed, locally we may always choose a vector field  $X$  generating the spaces  $L_x$  and in each coordinate patch, the flow of  $X$  will provide the parameterized one-dimensional submanifolds  $P \subset M$  tangent to  $L_x$  at all points. A change of coordinates or  $X$  will change the parameterizations, but not the curves  $P$ .

If we want to describe an  $n$ -dimensional submanifold  $N \subset M$ ,  $1 < n < M$ , in a similar way, we define the  $n$ -dimensional subspaces  $D_x \subset T_x M$  for all  $x \in M$  and seek for a submanifold  $N$  with  $T_y N = D_y$  at all  $y \in N$ .

#### INTEGRABILITY OF DISTRIBUTIONS

The union  $D \subset TM$  of individual linear subspaces  $D_x \subset T_x M$ ,  $x \in M$ , is called a *distribution*  $D$  on  $M$ . We say that the distribution is  $n$ -dimensional and smooth if each fixed point  $x$  allows for a neighborhood  $U$  and  $n$  linearly independent smooth vector fields  $X_1, \dots, X_n$  generating  $D_y$  at all  $y \in U$ . The distribution is called *integrable* if for each point  $x \in M$ , there is a submanifold  $N \subset M$  such that  $x \in N$  and  $T_y N = D_y$  for all  $y \in N$ .

Our goal is to give necessary and sufficient conditions for smooth distributions to be integrable. Clearly, the case of  $n = 1$  is trivial, since we already know that the conditions are empty – each such distribution is integrable.

The core idea is to use the so called flow box theorem for vector fields proved in 8.3.15 and to exploit the individual flows of the chosen generators  $X_1, \dots, X_n$  in order to “draw” new coordinates, in which the integral submanifold would appear as given by  $x_{n+1} = 0, \dots, x_m = 0$ . The problem we face is that the flows do not commute in general and thus our idea will not work.

9.1.18. **Lie bracket of vector fields.** Fortunately, the commutativity of the flows is captured by a simple differential operation.

Consider two vector fields on  $\mathbb{R}^m$ ,  $X = X_1(x)\frac{\partial}{\partial x_1} + \dots + X_m(x)\frac{\partial}{\partial x_m}$ ,  $Y = Y_1(x)\frac{\partial}{\partial x_1} + \dots + Y_m(x)\frac{\partial}{\partial x_m}$ . The commutator of the derivatives of functions in the directions of these vector fields is

$$Y(Xf) - X(Yf) = \sum_{i,j} Y_i \frac{\partial}{\partial x_i} (X_j \frac{\partial f}{\partial x_j}) - X_i \frac{\partial}{\partial x_i} (Y_j \frac{\partial f}{\partial x_j})$$

$$= \sum_{i,j} (Y_j \frac{\partial X_i}{\partial x_j} - X_j \frac{\partial Y_i}{\partial x_j}) \frac{\partial f}{\partial x_i},$$

thanks to the commutativity of the second derivatives of  $f$ . Thus, the commutator of the two vector fields behaves as the

Coefficients  $K_n$  we get from initial condition

$$u(0, x) = \sum_{n=1}^{\infty} K_n \sin\left(\frac{n\pi}{l}x\right) = \varphi(x) = x(l-x).$$

So  $K_n$  are Fourier coefficient of odd extension of function  $\varphi(x)$  to the interval  $[-l, l]$ :

$$K_n = \frac{2}{l} \int_0^l x(l-x) \sin\left(\frac{n\pi}{l}x\right) dx.$$

After integration per partes we get  $K_n = \frac{4l^2}{n^3\pi^3} [(-1)^{n+1} + 1]$  and final solution

$$u(t, x) = \sum_{n=0}^{\infty} \frac{8l^2}{(2n+1)^3\pi^3} \sin\left(\frac{(2n+1)\pi}{l}x\right) e^{-\frac{(2n+1)^2\pi^2}{l^2}kt}.$$

**9.D.46.** Solve elliptic equation on square

$$\Delta u = 0, \quad x \in (0, 1), \quad y \in (0, 1)$$

with *Dirichlet* boundary conditions for  $x$

$$u(0, y) = u(1, y) = 0, \quad y \in (0, 1)$$

and boundary condition for  $y$

$$u(x, 0) = \varphi(x) = \sin(\pi x) \cos(\pi x), \quad x \in (0, 1),$$

$$u(x, 1) = \psi(x) = -\sin(\pi x), \quad x \in (0, 1).$$

**Solution.** Suppose again that solution is in the form

$$u(x, y) = X(x) \cdot Y(y) \implies \Delta u = X''Y + XY'' = 0.$$

Dividing equation by  $XY$  we get

$$\frac{X''}{X} = -\frac{Y''}{Y} = -\lambda.$$

Solution (using Dirichlet boundary conditions for  $x$ ) is

$$X_n = C_n \sin(n\pi x), \quad Y_n = K_n e^{n\pi y} + H_n e^{-n\pi y}, \quad n \in \mathbf{N}$$

and

$$u(x, y) = \sum_{n=1}^{\infty} X_n Y_n = \sum_{n=1}^{\infty} [k_n e^{n\pi y} + h_n e^{-n\pi y}] \sin(n\pi x).$$

Using boundary conditions for  $y$  we get

$$u(x, 0) = \sum_{n=1}^{\infty} (k_n + h_n) \sin(n\pi x) = \varphi(x),$$

$$u(x, 1) = \sum_{n=1}^{\infty} (k_n e^{n\pi} + h_n e^{-n\pi}) \sin(n\pi x) = \psi(x).$$

Numbers  $b_n = k_n + h_n$  are Fourier coefficients of odd extension of function  $\varphi(x)$  on  $[-1, 1]$ ,  $b_2 = \frac{1}{2}$  and  $b_n = 0$  for  $n \neq 2$ . Numbers  $\beta_n = k_n e^{n\pi} + h_n e^{-n\pi}$  are Fourier coefficients of odd extension of function  $\psi(x)$  on  $[-1, 1]$ ,  $\beta_1 = -1$  and  $\beta_n = 0$  for  $n \neq 1$ . We need to solve algebraic equations

$$k_2 + h_2 = \frac{1}{2}, \quad k_2 e^{2\pi} + h_2 e^{-2\pi} = 0,$$

$$k_1 + h_1 = 0, \quad k_1 e^{\pi} + h_1 e^{-\pi} = -1.$$

vector field  $[X, Y]$ ,

$$[X, Y] = \sum_{i,j=1}^m (Y_j \frac{\partial X_i}{\partial x_j} - X_j \frac{\partial Y_i}{\partial x_j}) \frac{\partial}{\partial x_i}.$$

This vector field is called the *Lie bracket*<sup>5</sup> of its arguments. It is easy to see that  $[ , ]$  is a bilinear antisymmetric operation (over the real scalars) on the differentiable vector fields, and expanding the commutators explicitly we arrive at the so called *Jacobi identity*

$$[X, [Y, Z]] = [[X, Y], Z] + [Y, [X, Z]]$$

valid for all triples of vector fields, and the *Leibnitz derivative property*

$$[X, fY] = (Xf)Y + f[X, Y].$$

□

**Remark.** In fact, it is quite straightforward to see that the vector fields  $X$  and the diffeomorphisms  $\text{Fl}_t^X$  in their flows are linked in a very similar manner to the square matrices  $A$  and their exponential images  $e^{tA}$ . The Lie bracket encodes the composition of the diffeomorphisms like the commutators of matrices encode the matrix multiplication. Thus, it is not surprising that the flows of two vector fields are commuting if and only if their Lie bracket vanishes. We shall not go into the technical proof here since we shall not need the result explicitly below.

**9.1.19. Back to distributions.** We say that  $D \subset TM$  is an *involutive distribution* if for all vector fields  $X, Y$  valued in  $D$ , their Lie bracket  $[X, Y]$  has got values in  $D$ , too.

FROBENIUS' THEOREM

**Theorem.** Let  $D \subset TM$  be a smooth  $n$ -dimensional distribution in an  $m$ -dimensional manifold  $M$ . Then  $D$  is integrable if and only if it is involutive.

**PROOF.** Remind integrability means the local existence of the integral submanifolds through each point in  $M$ . One of the implications of the proof is nearly trivial.

If  $D$  is integrable, then through each  $x \in M$  there is the integral submanifold  $N$ . Consider the embedding  $i : N \rightarrow M$  and any vector fields  $\tilde{X}, \tilde{Y}$  on  $M$  valued in  $D$ . Since  $D_y = T_y N$  for all  $y \in N$ ,  $\tilde{X}$  and  $\tilde{Y}$  are tangent to  $i(N) \subset M$ . We claim that the restriction of the Lie bracket  $[\tilde{X}, \tilde{Y}]$  to  $i(N)$  is the image  $i_*([X, Y])$ , where the vector fields  $X, Y$  are viewed as the given fields on  $N$ , i.e.,  $i_*X(x) = \tilde{X}(i(x))$ ,  $i_*Y(x) = \tilde{Y}(i(x))$ . Thus, the bracket has to be in the image again. The latter claim is a consequence of a more general statement:

<sup>5</sup>Marius Sophus Lie (1842–1899) was an excellent Norwegian mathematician, the father of the Lie theory. Originally invented to deal with systems of partial differential equation via continuous groups of their symmetries, the theory of Lie groups and Lie algebras is nowadays in the core of a vast part of Mathematics. It is a pity we do not have time and space to devote more attention to this marvelous mathematical story in this textbook.

Finally

$$k_1 = \frac{1}{e^{-\pi} - e^{\pi}}, \quad h_1 = \frac{1}{e^{\pi} - e^{-\pi}},$$

$$k_2 = \frac{1}{2 - 2e^{4\pi}}, \quad h_2 = \frac{1}{2 - 2e^{-4\pi}},$$

other coefficients are all zero. Solution is

$$u(x, y) = \sin(\pi x) \left[ \frac{1}{e^{-\pi} - e^{\pi}} e^{\pi y} + \frac{1}{e^{\pi} - e^{-\pi}} e^{-\pi y} \right] +$$

$$+ \sin(2\pi x) \left[ \frac{1}{2 - 2e^{4\pi}} e^{2\pi y} + \frac{1}{2 - 2e^{-4\pi}} e^{-2\pi y} \right].$$

Make a test.  $\square$

**9.D.47.** Solve hyperbolic equation

$$u_{tt} = a^2 u_{xx}, \quad t \in (0, \infty), \quad x \in (0, \pi)$$

with Neumann boundary conditions

$$u_x(t, 0) = u_x(t, \pi) = 0, \quad t \in (0, \infty)$$

and initial conditions

$$u(0, x) = \varphi(x) = 0, \quad u_t(0, x) = 5 \cos(3x), \quad x \in (0, \pi).$$

**Solution.** Again, looking for solution in the form

$$u(t, x) = X(x) \cdot T(t)$$

we get

$$XT'' = a^2 X''T \implies \frac{T''}{a^2 T} = \frac{X''}{X} = -\lambda.$$

So  $X(x) = C_1 e^{\mu x} + C_2 e^{-\mu x}$ , where  $\mu = \sqrt{-\lambda}$  and using Neumann boundary condition we have

$$X'(0) = \mu(C_1 - C_2) = 0 \implies C_1 = C_2,$$

$$X'(\pi) = \mu C_1 (e^{\mu\pi} - e^{-\mu\pi}) = 0,$$

$$e^{2\mu\pi} = 1 = e^{i2n\pi} \implies \mu_n = in, \lambda_n = -n^2, n = 0, 1, 2, \dots$$

We have solutions

$$X_n(x) = C_1 (e^{inx} + e^{-inx}) = 2C_1 \cos(nx),$$

$$T_n(t) = a_n \cos(nat) + b_n \sin(nat),$$

$$u(t, x) = \sum_{n=0}^{\infty} X_n T_n =$$

$$= \sum_{n=0}^{\infty} [A_n \cos(nat) + B_n \sin(nat)] \cos(nx).$$

Now we have to apply initial conditions

$$u(0, x) = \sum_{n=0}^{\infty} A_n \cos(nx) = \varphi(x),$$

$$u_t(0, x) = \sum_{n=0}^{\infty} naB_n \cos(nx) = \psi(x)$$

and numbers  $A_n$  are Fourier coefficients of even extension of function  $\varphi(x)$  to  $[-\pi, \pi]$ :

$$A_0 = \frac{1}{\pi} \int_0^{\pi} \varphi(x) dx, \quad A_n = \frac{2}{\pi} \int_0^{\pi} \varphi(x) \cos(nx) dx,$$

**Claim.** If  $\varphi : N \rightarrow M$  is a smooth map and two couples of vector fields  $X, Y$  and  $\tilde{X}, \tilde{Y}$  satisfy

$$T\varphi \circ X = \tilde{X} \circ \varphi, \quad T\varphi \circ Y = \tilde{Y} \circ \varphi,$$

then their Lie brackets satisfy the same relation:

$$T\varphi \circ [X, Y] = [\tilde{X}, \tilde{Y}] \circ \varphi.$$

Indeed, consider a smooth function  $f$  on  $M$  and compute, using  $X(f \circ \varphi)(x) = (T\varphi X)f = (\tilde{X} \circ \varphi)(x)f = \tilde{X}(\varphi(x))f$ , and similarly for  $Y$ :

$$\begin{aligned} [X, Y](f \circ \varphi)(x) &= XY(f \circ \varphi)(x) - YX(f \circ \varphi)(x) \\ &= X((\tilde{Y}f) \circ \varphi)(x) - Y((\tilde{X}f) \circ \varphi)(x) \\ &= \tilde{X}(\tilde{Y}f)(\varphi(x)) - \tilde{Y}(\tilde{X}f)(\varphi(x)) \\ &= ([\tilde{X}, \tilde{Y}]f) \circ \varphi(x). \end{aligned}$$

Now we employ the latter claim for the inclusion  $i$  in the role of  $\varphi$  and obviously every integrable distribution must be involutive.

As we already revealed, each one-dimensional distribution is involutive and locally integrable. The main idea of the proof is to start with any set of (locally) generating vector fields for  $D$ , to use some nice coordinates with respect to the first vector field and to employ the induction on the dimension to the rest of them.

Assume the theorem is true for dimensions less than  $n$  and consider an involutive smooth distribution  $D$  of dimension  $n$ , generated by fields  $X_1, \dots, X_n$ . Actually, we shall prove a much stronger version of the theorem. We claim that if  $D$  is involutive, then there are coordinates  $(x_1, \dots, x_m)$  around each point  $x \in M$ , such that the equations  $x_{n+1} = a_{n+1}, \dots, x_m = a_m$  with small constants  $a_i$  are defining all the individual integral submanifolds of  $D$  through points close to  $x$ . This is indeed true in dimension  $n = 1$ .

By the flowbox theorem 8.3.15, for each point  $x \in M$  there are coordinate functions  $y_1, \dots, y_m$  on a neighborhood  $U$  of  $x$ , for which  $X_1 = \frac{\partial}{\partial y_1}$ . Let us consider the submanifold  $Q \subset M$  defined by  $y_2 = 0, \dots, y_m = 0$  and the “projections”  $Y_j$  of the other fields to make them tangent to  $Q$ . This requires that  $Y_j$  leave constant the coordinate  $y_1$ , i.e. we set

$$Y_j = X_j - X_j(y_1)X_1, \quad j = 2, \dots, m.$$

Indeed, this definition ensures  $Y_j(y_1) = 0$  and thus the fields are tangent to  $Q$  as required. We leave  $Y_1 = X_1$ , and clearly  $Y_1, \dots, Y_n$  generate the same involutive distribution  $D$ . Thus

$$[Y_i, Y_j] = \sum_{i,j} c_{ijk} Y_k$$

for some set of functions  $c_{ijk}$ . Moreover, we may view  $Q$  as one leaf of all the subsets defined by  $y_2 = b_2, \dots, y_m = b_m$  with small constants  $b_i$  and there is the projection  $p : U \rightarrow Q$  forgetting the first coordinate.

On the submanifold  $Q$ , there is the  $(n-1)$ -dimensional involutive distribution  $\tilde{D}$  generated by the fields  $\tilde{Y}_i = Y_i|_Q$ ,  $i = 2, \dots, n$  (notice we again use the argument from the

numbers  $naB_n$  are Fourier coefficients of even extension of function  $\psi(x)$  to  $[-\pi, \pi]$ :

$$B_0 = \frac{1}{na\pi} \int_0^\pi \psi(x) dx, \quad B_n = \frac{2}{na\pi} \int_0^\pi \psi(x) \cos(nx) dx.$$

Because  $\varphi(x) = 0$ , all  $A_n$  are zero,  $\psi(x) = 5 \cos(3x)$ , so  $B_3 = \frac{5}{3a}$  and all other  $B_n$  are again zero. Finally solution of our problem is

$$u(t, x) = \frac{5}{3a} \sin(3at) \cos(3x).$$

Make a test.

**9.D.48.** Solve

$$\begin{aligned} \Delta u &= u_{xx} + u_{yy} = 0, \quad (x, y) \in (0, \pi) \times (0, \pi), \\ u(x, 0) &= u(x, \pi) = 0, \quad x \in (0, \pi) \\ u(\pi, y) &= 0, \quad u(0, y) = \sin y, \quad y \in (0, \pi). \end{aligned}$$

**9.D.49.** Solve

$$\begin{aligned} u_{xx} &= u_{tt}, \quad x \in (0, l), \quad t \in (0, \infty), \\ u_x(t, 0) &= u_x(t, l) = 0, \quad t \in (0, \infty), \\ u(0, x) &= -\cos \frac{\pi x}{l}, \quad x \in (0, l), \\ u_t(0, x) &= \cos^2 \frac{\pi x}{l} - \sin^2 \frac{\pi x}{l}, \quad x \in (0, l). \end{aligned}$$

**9.D.50.** Solve

$$\begin{aligned} u_{xx} &= u_t, \quad x \in (0, \pi), \quad t \in (0, \infty), \\ u(t, 0) &= u(t, \pi) = 0, \quad t \in (0, \infty), \\ u(0, x) &= 2 \cos(3x) \sin x, \quad x \in (0, \pi). \end{aligned}$$

**9.D.51.** Solve

$$\begin{aligned} u_{xx} &= u_{tt}, \quad x \in (0, \pi), \quad t \in (0, \infty), \\ u(t, 0) &= u(t, \pi) = 0, \quad t \in (0, \infty), \\ u(0, x) &= -6 \sin(2x) \cos(2x), \quad x \in (0, \pi), \\ u_t(0, x) &= -\sin x + 4 \sin x \cos x, \quad x \in (0, \pi). \end{aligned}$$

**9.D.52.** Solve

$$\begin{aligned} u_t &= u_{xx}, \quad x \in (0, a), \quad t \in (0, \infty), \\ u(t, 0) &= u_x(t, a) = 0, \quad t \in (0, \infty), \\ u(0, x) &= x(2a - x), \quad x \in (0, a). \end{aligned}$$

**9.D.53.**

$$\begin{aligned} u_{tt} &= u_{xx}, \quad x \in (0, A), \quad t \in (0, \infty), \\ u(t, 0) &= u(t, A) = 0, \quad t \in (0, \infty), \\ u(0, x) &= x(A - x), \quad u_t(0, x) = 0, \quad x \in (0, A). \end{aligned}$$

beginning of the proof about the brackets of restricted fields). Now, our assumption says we find suitable coordinates  $(q_2, \dots, q_m)$  on  $Q$  around the point  $x \in Q$ , so that for all small constants  $b_{n+1}, \dots, b_m$ , the integral submanifolds of  $\tilde{D}$  are defined by  $q_{n+1} = b_{n+1}, \dots, q_m = b_m$ .

Finally, we need to adjust the original coordinate functions  $y_i$  all over the neighborhood  $U$  of  $x$ . The obvious idea is to use the flow of  $X_1 = Y_1$  to extend the latter coordinates on  $Q$ . Thus we define the coordinate functions in all  $y \in U$  using the projection  $p$ ,

$$x_1(y) = y_1(y), x_2(y) = q_2(p(y)), \dots, x_m = q_m(p(y)).$$

The hope is that all submanifolds  $N$  given by equations  $x_{n+1} = b_{n+1}, \dots, x_m = b_m$  (for small  $b_j$ ) will be tangent to all fields  $Y_1, \dots, Y_n$ . Technically, this means  $Y_i(x_j) = 0$  for all  $i = 1, \dots, n, j = n + 1, \dots, m$ . By our definition, this is obvious for the restriction to  $Q$ , and obviously  $Y_1(x_j) = 0$  in all other points, too.

Let us look closely on what is happening with one of our functions  $Y_i(x_j)$  along the flows of the field  $X_1$ . We easily compute with the help of the definition of the Lie bracket

$$\begin{aligned} \frac{\partial}{\partial x_1}(Y_i(x_j)) &= Y_1(Y_i(x_j)) = Y_i(Y_1(x_j)) + [Y_1, Y_i](x_j) \\ &= Y_i(Y_1(x_j)) + c_{1i1}Y_1(x_j) + \sum_{k=2}^m c_{1ik}Y_k(x_j) \\ &= \sum_{k=2}^m c_{1ik}Y_k(x_j). \end{aligned}$$

This is a system of linear ODEs for the unknown functions  $Y_i(x_j)$  in one variable  $x_1$  along the flow lines of  $Y_1$ . The initial condition at the point in  $Q$  is zero and thus this constant zero value has to propagate along the flow lines, as requested.

The induction step is complete.  $\square$

**9.1.20. Formulation via exterior forms.** As we know from linear algebra, a vector subspace of codimension  $k$  is defined by  $k$  independent linear forms. Thus, every smooth  $n$ -dimensional distribution  $D \subset TM$  on a manifold  $M$  can be (at least) locally defined by  $m - n$  linear forms  $\omega_j$  on  $M$ .

A direct computation in coordinates reveals that the differential of linear form  $\omega$  evaluates on two vector fields as follows

$$(1) \quad d\omega(X, Y) = X(\omega(Y)) - Y(\omega(X)) - \omega([X, Y]).$$

Indeed, if  $X = \sum_i X_i \frac{\partial}{\partial x_i}$ ,  $Y = \sum_i Y_i \frac{\partial}{\partial x_i}$ ,  $\omega = \sum_i \omega_i dx_i$ , then

$$\begin{aligned} X(\omega(Y)) - Y(\omega(X)) &= \sum_{i,j} (X_i \frac{\partial}{\partial x_i} (\omega_j Y_j) - Y_i \frac{\partial}{\partial x_i} (\omega_j X_j)) \\ &= \sum_{i,j} (X_i \frac{\partial \omega_j}{\partial x_i} Y_j - Y_i \frac{\partial \omega_j}{\partial x_i} X_j + \omega_j (X_i \frac{\partial Y_j}{\partial x_i} - Y_i \frac{\partial X_j}{\partial x_i})) \\ &= d\omega(X, Y) + \omega([X, Y]). \end{aligned}$$

Thus, the involutivity of a distribution defined by linear forms  $\omega_{n+1}, \dots, \omega_m$  should be closely linked to properties of the

9.D.54.

$$\begin{aligned} \Delta u &= u_{xx} + u_{yy} = 0, \quad x \in (0, a), \quad y \in (0, a), \\ u(0, y) &= u(a, y), \quad y \in (0, a), \\ u(x, a) &= 0, \quad u(x, 0) = x(a - x), \quad x \in (0, a). \end{aligned}$$

9.D.55.

$$\begin{aligned} u_t &= 4u_{xx}, \quad x \in (0, 1), \quad t \in (0, \infty), \\ u_x(t, 0) &= u(t, 1) = 0, \quad t \in (0, \infty), \\ u(0, x) &= x - 1, \quad x \in (0, 1). \end{aligned}$$

9.D.56. Find bounded solution of Laplace equation and boundary condition on the circle (*Dirichlet internal boundary problem*):

$$\begin{aligned} \Delta u(x, y) &= 0, \quad x^2 + y^2 < A^2, \\ u(A \cos \varphi, A \sin \varphi) &= \alpha(\varphi) = \sin^4 \varphi. \end{aligned}$$

**Solution.** After transformation to the polar coordinates

$$x = r \cos \varphi, \quad y = r \sin \varphi,$$

Laplace equation for function  $u = u(r, \varphi)$  become

$$u_{rr} + \frac{1}{r}u_r + \frac{1}{r^2}u_{\varphi\varphi} = 0.$$

We are looking for solution in the form  $u(r, \varphi) = R(r) \cdot \Phi(\varphi)$ , where  $\Phi(\varphi + 2\pi) = \Phi(\varphi)$  and  $u(A, \varphi) = \alpha(\varphi) = \sin^4 \varphi$ ,  $u(0, \varphi) = C$  is constant. Let's compute

$$R''\Phi + \frac{1}{r}R'\Phi + \frac{1}{r^2}R\Phi'' = 0,$$

multiplying by  $r^2$  and dividing by  $R\Phi$  we get

$$r^2 \frac{R'}{R} + r \frac{R'}{R} = -\frac{\Phi'}{\Phi} = -\lambda.$$

Solving equation

$$\Phi'' - \lambda\Phi = 0 \implies \Phi = B_1 e^{\mu\varphi} + B_2 e^{-\mu\varphi},$$

where  $\mu = \sqrt{\lambda}$ , using condition  $\Phi(\varphi) = \Phi(\varphi + 2\pi)$ ,  $\Phi(\varphi)$  have to be periodical with period  $2\pi$ , so

$$\mu = in \quad \text{and} \quad \lambda_n = -n^2, \quad n \in \mathbf{N}_0.$$

Finally for function  $\Phi(\varphi)$  we have

$$\Phi_n = a_n \cos(n\varphi) + b_n \sin(n\varphi).$$

Let's solve equation for  $R = R(r)$ , which is Euler

$$r^2 R'' + rR' - n^2 R_n = 0.$$

Substituing  $s = \ln t$ ,  $r = e^t$ ,

$$R'_n = \frac{1}{r} \dot{R}_n, \quad R''_n = (R'_n)' = -\frac{1}{r^2} \dot{R}_n + \frac{1}{r^2} \ddot{R}_n,$$

we get

$$\begin{aligned} \ddot{R}_n - n^2 R_n &= 0, \\ R_n(t) &= \begin{cases} C_0 + D_0 t, & n = 0, \\ C_n e^{nt} + D_n e^{-nt}, & n \in \mathbf{N}, \end{cases} \end{aligned}$$

- differentials on the common kernel. Indeed, there is the following version of the latter theorem:

FROBENIUS' THEOREM

**Theorem.** *The distribution  $D$  defined on an  $m$ -dimensional manifold  $M$  by  $(m - n)$  independent smooth linear forms  $\omega_{n+1}, \dots, \omega_m$  is integrable if and only if there are linear forms  $\alpha_{ij}$  such that  $d\omega_k = \sum_{\ell} \alpha_{k\ell} \wedge \omega_{\ell}$ .*

- **PROOF.** Let us write  $\omega = (\omega_{n+1}, \dots, \omega_m)$  for the  $\mathbb{R}^{m-n}$ -valued form. The distribution is  $D = \ker \omega$ . Now, the formula (1) (applied to all components of  $\omega$ ) implies that involutivity of  $D$  is equivalent to  $d\omega|_{\ker \omega} = 0$ .

If the assumption of the theorem on the forms holds true,  $d\omega$  clearly vanishes on the kernel of  $\omega$  and therefore  $D$  is involutive, and one of the implications of the theorem is proved.

Next, assume  $D$  is integrable. By the stronger claim proved in the latter Frobenius theorem, for each point  $x \in M$ , there are coordinates  $(x_1, \dots, x_m)$  such that  $D$  is the common kernel of all  $dx_{n+1}, \dots, dx_m$ . In particular, our forms  $\omega_j$  are linear combinations (over functions) of the latter  $(m - n)$  differentials. Moreover, there must be smooth invertible matrices of functions  $A = (a_{k\ell})$  such that

$$dx_k = \sum_{\ell} a_{k\ell} \omega_{\ell}, \quad k, \ell = n + 1, \dots, m.$$

Finally,  $d\omega_k$  includes only terms with  $dx_i \wedge dx_j$  with  $j > n$  and all  $dx_j$  can be expressed via our forms  $\omega_{\ell}$  from the previous equation. Thus the differentials have got the requested forms. □

## 2. Remarks on Partial Differential Equations

The aim of our excursion into the landscape of differential equations is modest. We do not have space in this rather elementary guide to come close enough to this subtle, beautiful, and extremely useful part of mathematics dealing with differential equations. Still we mention a few issues.

First, the simplest method reducing the problem to already mastered ordinary differential equations is explained, based on the so called characteristics. Then we show more simple methods how to get some families of solutions.

Next, we present a more complicated theoretical approach dealing with formal solvability of even higher order systems of differential equations and its convergence – the famous Cauchy-Kovalevskaya theorem. This is the only instance of general existence and uniqueness theorem for differential equations involving partial derivatives. Unfortunately, it does not cover many of interesting problems of practical importance.

Finally, we display a few classical methods to solve boundary problems involving some of the most common equations of second order.

$$R_n(r) = \begin{cases} C_0 + D_0 \ln r, & n = 0, \\ C_n r^n + D_n r^{-n}, & n \in \mathbf{N}. \end{cases}$$

Solution has to be bounded for  $r \rightarrow 0$  (inside circle), so  $D_0 = D_n = 0$  and finally

$$\begin{aligned} u(r, \varphi) &= R_n(r) \cdot \Phi_n(\varphi) = \\ &= a_0 C_0 + \sum_{n=1}^{\infty} C_n r^n [a_n \cos(n\varphi) + b_n \sin(n\varphi)]. \end{aligned}$$

Coefficients we compute from boundary condition

$$U(A, \varphi) = K_0 + \sum_{n=1}^{\infty} A^n [K_n \cos(n\varphi) + H_n \sin(n\varphi)] =$$

$$\begin{aligned} &= \alpha(\varphi) = \sin^4 \varphi = \left( \frac{1 - \cos(2\varphi)}{2} \right)^2 = \\ &= \frac{1 - 2\cos(2\varphi) + \cos^2(2\varphi)}{4} = \\ &= \frac{1}{4} - \frac{\cos(2\varphi)}{2} + \frac{1}{4} \left( \frac{1 + \cos(4\varphi)}{2} \right) = \\ &= \frac{3}{8} - \frac{\cos(2\varphi)}{2} + \frac{1}{8} \cos(4\varphi), \end{aligned}$$

$K_0 = 3/8$ ,  $K_2 = \frac{-1}{2A^2}$ ,  $K_4 = \frac{1}{8A^4}$  and all other  $K_n, H_n$  are zero.

$$\begin{aligned} u(r, \varphi) &= \frac{3}{8} - \frac{r^2}{2A^2} \cos(2\varphi) + \frac{r^4}{8A^4} \cos(4\varphi), \\ u(x, y) &= \frac{3}{8} - \frac{x^2 - y^2}{2A^2} + \frac{x^4 + y^4 - 6x^2y^2}{8A^4}, \end{aligned}$$

where we use  $\cos(2\varphi) = \cos^2 \varphi - \sin^2 \varphi = \frac{x^2}{r^2} - \frac{y^2}{r^2}$ ,  $\cos(4\varphi) = \cos^2(2\varphi) - \sin^2(2\varphi)$ .  $\square$

**9.D.57.** Find bounded solution of Laplace equation and boundary condition on the circle (*Dirichlet external boundary problem*):

$$\begin{aligned} \Delta u(x, y) &= 0, \quad x^2 + y^2 > A^2, \\ u(A \cos \varphi, A \sin \varphi) &= \alpha(\varphi) = \cos^2 \varphi. \end{aligned}$$

**Solution.** From previous exercise we get

$$\begin{aligned} \Phi_n &= a_n \cos(n\varphi) + b_n \sin(n\varphi), \quad n \in \mathbf{N}_0, \\ R_n(r) &= \begin{cases} D_0 + C_0 \ln r, & n = 0, \\ C_n r^n + D_n r^{-n}, & n \in \mathbf{N}. \end{cases} \end{aligned}$$

Functions  $R_n(r)$  have to be bounded for  $r \rightarrow \infty$  (outside of the circle), so  $C_0 = C_n = 0$  and we have

$$\begin{aligned} u(r, \varphi) &= R_n(r) \cdot \Phi_n(\varphi) = \\ &= a_0 D_0 + \sum_{n=1}^{\infty} D_n r^{-n} [a_n \cos(n\varphi) + b_n \sin(n\varphi)]. \end{aligned}$$

Coefficients we compute from boundary condition

$$\begin{aligned} U(A, \varphi) &= K_0 + \sum_{n=1}^{\infty} A^{-n} [K_n \cos(n\varphi) + H_n \sin(n\varphi)] = \\ &= \alpha(\varphi) = \cos^2 \varphi = \frac{1 - \cos(2\varphi)}{2}. \end{aligned}$$

**9.2.1. Initial observations.** In practical problems, we often meet equations relating unknown functions of more variables and their derivatives. We already handled the very special case where the relations concerned functions  $x(t)$  of just one variable  $t$ . More explicitly, we dealt with vector equations

$$x^{(k)} = F(t, x, \dot{x}, \ddot{x}, \dots, x^{(k-1)}), \quad F: \mathbb{R}^{n \times k+1} \rightarrow \mathbb{R}^n,$$

where the dots over  $x \in \mathbb{R}^n$  meant the (iterated) derivatives of  $x(t) = (x_1(t), \dots, x_n(t))$ , up to the order  $k$ . The goal was to find a (vector) curve  $x(t)$  in  $\mathbb{R}^n$  which makes this equation valid.

Two more comments are due: 1) we can omit the explicit appearance of  $t$  on the cost of adding one more variable and equation  $\dot{x}_0 = 1$ ; and 2) giving new names to the iterated derivatives  $x_j = x^{(j)}$  and adding equations  $\dot{x}_j = x_{j+1}$ ,  $j = 1, \dots, k-1$ , we reduce always the problem to a first order system of equations (on a much bigger space).

Thus, we should like to work similarly with the equations

$$F(x, y, u_x, u_{xx}, u_{xy}, u_{yy}, \dots) = 0,$$

where  $u$  is an unknown function (possibly vector valued) of two variables  $x$  and  $y$  (or even more variables) and, as usual, the indices denote the partial derivatives. Even if we expect the implicit equation to be solved in some sense with respect to some of the highest partial derivatives, we cannot hope for a general existence and uniqueness result similar to the ODE case.

Let us start with a most simple example illustrating the general problem related to the choice of the initial conditions.

**9.2.2. The simplest linear case.** Consider one real function  $u = u(x, y)$ , subject to the linear homogeneous equation

$$(1) \quad a(x, y)u_x + b(x, y)u_y = 0$$

where  $a$  and  $b$  are known functions of two variables defined for  $x, y$  in a domain  $\Omega \subset \mathbb{R}^2$ . We consider the equation in the tubular domain  $\Omega \times \mathbb{R} \subset \mathbb{R}^3$ . Usually,  $\Omega$  is an open set together with a nice boundary, a curve  $\partial\Omega$  in our case.

An obvious simple idea suggests to write  $\Omega$  as a union of non-intersecting curves and look for  $u$  constant along those curves. Moreover, if those curves were transversal to the boundary  $\partial\Omega$ , then initial conditions along the boundary should extend inside of  $\Omega$ . Thus, consider such a potentially existing curve  $c(t) = (x(t), y(t))$  and write

$$0 = \frac{d}{dt} u(c(t)) = u_x(c(t))\dot{x}(t) + u_y(c(t))\dot{y}(t).$$

This yields the conditions for the requested curves:

$$(2) \quad \dot{x} = a(x, y), \quad \dot{y} = b(x, y).$$

Since  $u$  is considered constant along the curve, we obtain a unique possibility for the function  $u$  along the curves for all initial conditions  $x(0), y(0)$ , and  $u(x(0), y(0))$ , if the coefficients  $a$  and  $b$  are at least Lipschitz in  $x$  and  $y$ .

The latter curves are called the *characteristics* of the first order partial differential equation (1) and they are solutions

We get  $K_0 = \frac{1}{2}$ ,  $K_2 = \frac{A^2}{2}$  and all other  $K_n, H_n$  are zero.

$$u(r, \varphi) = \frac{1}{2} + \frac{1A^2}{2r^2} \cos(2\varphi),$$

$$u(x, y) = \frac{1}{2} + \frac{x^2 - y^2}{2(x^2 + y^2)^2} A^2.$$

**9.D.58.** Solve internal Dirichlet problem on the circle:

$$\Delta u(x, y) = 0, \quad x^2 + y^2 < A^2,$$

$$u(A \cos \varphi, A \sin \varphi) = \alpha(\varphi) = \sin \varphi \cos \varphi.$$

**9.D.59.** Solve external Dirichlet problem on the circle:

$$\Delta u(x, y) = 0, \quad x^2 + y^2 > A^2,$$

$$u(A \cos \varphi, A \sin \varphi) = \alpha(\varphi) = 2 \sin^2 \varphi + 3 \cos^2 \varphi.$$

**9.D.60.** Solve internal Dirichlet problem on the circle:

$$\Delta u(x, y) = 0, \quad x^2 + y^2 < 1,$$

$$u(\cos \varphi, \sin \varphi) = \alpha(\varphi) = \sin \varphi + \cos^2 \varphi.$$

**9.D.61.** Solve parabolic equation

$$u_t = \kappa u_{xx}, \quad x \in \mathbf{R}, \quad t \in (0, \infty),$$

with initial condition

$$u(0, x) = \varphi(x) = \begin{cases} 1 & \text{for } x \in (-1, 1), \\ 0 & \text{otherwise.} \end{cases}$$

Suppose  $u(t, x) \rightarrow 0$  and  $u_x(t, x) \rightarrow 0$  for  $x \rightarrow \pm\infty$ .

**Solution.** Let's compute Fourier image

$$\begin{aligned} \tilde{u}_{xx}(\xi) &= \int_{-\infty}^{\infty} u_{xx} e^{-i\xi x} dx = \left| \begin{array}{ll} a' = u_{xx} & a = u_x \\ b = e^{-i\xi x} & b' = -i\xi e^{-i\xi x} \end{array} \right| = \\ &= [u_x e^{-i\xi x}]_{-\infty}^{\infty} - (-i\xi) \int_{-\infty}^{\infty} u_x(x) e^{-i\xi x} dx = \\ &= \left| \begin{array}{ll} a' = u_x & a = u \\ b = e^{-i\xi x} & b' = -i\xi e^{-i\xi x} \end{array} \right| = [u_x e^{-i\xi x}]_{-\infty}^{\infty} + \\ &+ i\xi [u e^{-i\xi x}]_{-\infty}^{\infty} + (-i\xi)^2 \int_{-\infty}^{\infty} u e^{-i\xi x} dx = 0 + 0 - \xi^2 \tilde{u}, \end{aligned}$$

because  $u \rightarrow 0$  and  $u_x \rightarrow 0$  for  $x \rightarrow \pm\infty$ . After Fourier transformation the equation became

$$\tilde{u}_t(t, \xi) = -\kappa \xi^2 \tilde{u}(t, \xi)$$

and together with initial condition  $\tilde{u}(0, \xi) = \tilde{\varphi}(\xi)$ , where  $\tilde{\varphi}(\xi)$  is Fourier image of  $\varphi(x)$ , we have Fourier image of solution

$$\tilde{u}(t, \xi) = \tilde{\varphi}(\xi) e^{-\kappa \xi^2 t},$$

of its *characteristic equations* (2). If the coefficients are differentiable in all variables, then also the solution  $u$  will be differentiable for differentiable choices of initial conditions on a curve transversal to the characteristics and we might have solved the problem (1) locally. Still it might fail.

Let us look at the homogeneous linear problem

$$\square \quad (3) \quad yu_x - xu_y = 0, \quad u(x, 0) = x.$$

We saw already the solutions to the characteristic equations

$$\dot{x} = y, \quad \dot{y} = -x$$

and the characteristics are circles with centers in the origin,  $x(t) = R \sin t, y(t) = R \cos t$ . If we choose any even differentiable function  $\psi(x) = u(x, 0)$  for the initial conditions at points  $(x, 0)$ , we are lucky to see that the solution will work. But for odd functions, e.g. our choice  $\psi(x) = x$ , there will be no solution of our problem in any neighbourhood of the origin. Clearly, this failure is linked to the fact that the origin is a singular point for characteristic equations.

**9.2.3. The quasi-linear case.** The situation seems to get more tricky once we add a nontrivial right-hand value  $f(x, y, u)$  to the equation (1), i.e. we try to solve the problem (allowing  $a$  and  $b$  to depend on  $u$ )

$$\circ \quad (1) \quad a(x, y, u)u_x + b(x, y, u)u_y = f(x, y, u).$$

But in fact, the very same idea leads to characteristic equations on  $\mathbb{R}^3$ , writing  $z = u(x, y)$  for the unknown function along the characteristics. Geometrically, we seek for a vector field tangent to all graphs of solutions in the tubular domain  $\Omega \times \mathbb{R}$ . Remind  $z = u(x, y)$ , restricted to a curve in the graph, implies  $\dot{z} = u_x \dot{x} + u_y \dot{y}$ , and thus we may set  $\dot{z} = f(x, y, z), \dot{x} = a(x, y, z), \dot{y} = b(x, y, z)$  in order to get such a *characteristic vector field*.

#### CHARACTERISTIC EQUATIONS AND INTEGRALS

The *characteristic equations* of the equation (1) are

$$(2) \quad \dot{x} = a(x, y, z), \quad \dot{y} = b(x, y, z), \quad \dot{z} = f(x, y, z).$$

This autonomous system of three equations is uniquely solvable for each initial condition if  $a, b$ , and  $f$  are Lipschitz.

A function  $\psi$  on  $\Omega \times \mathbb{R}$  which is constant on each flow line of the characteristic vector field, i.e.,  $\psi(x(t), y(t), z(t)) = \text{const}$  for all solutions of (2), is called an *integral* of the equation (1). If  $\psi_z \neq 0$ , then the implicit function theorem guarantees the unique existence of the function  $z = u(x, y)$  satisfying the chosen initial conditions.

Check yourself that the latter functions  $u$  are solutions to our problem. This approach covers the homogeneous case as well, we just consider the autonomous characteristic equations with  $\dot{z} = 0$  added.

Let us come back to our simple equation 9.2.2(3) and choose  $f(x, y, u) = y$  for the right-hand side. The characteristic equations yield  $x = R \sin t, y = R \cos t$  as before, while  $\dot{z} = y = R \cos t$  and hence  $z = R \sin t + z(0)$ . Thus, we

(solve this separable equation with initial condition thoroughly). If Fourier image of solution is product of two functions, the original solution has to be convolution of inverse Fourier images of this functions:

$$u(t, x) = \int_{-\infty}^{\infty} \varphi(y) \frac{1}{2\sqrt{\pi\kappa t}} e^{-\frac{(x-y)^2}{4\kappa t}} dy.$$

We have used the fact, that inverse Fourier image of Gaussian function  $e^{-\kappa\xi^2 t}$  is again Gaussian function  $\frac{1}{2\sqrt{\pi\kappa t}} e^{-\frac{x^2}{4\kappa t}}$  and formula for convolution

$$f * g(x) = \int_{-\infty}^{\infty} f(y)g(x - y)dy.$$

We will express  $u(t, x)$  using the *error function*

$$\operatorname{erf}(x) = \frac{2}{\pi} \int_0^x e^{-a^2} da.$$

Take  $\varphi(x)$  from assignment and compute

$$\begin{aligned} u(t, x) &= \int_{-1}^1 \frac{1}{2\sqrt{\pi\kappa t}} e^{-\frac{(x-y)^2}{4\kappa t}} dy = \\ &= \left| \begin{array}{l} a = \frac{x-y}{2\sqrt{\kappa t}} \\ da = \frac{-1}{2\sqrt{\kappa t}} dy \end{array} \right| = \int_{\frac{x+1}{2\sqrt{\kappa t}}}^{\frac{x-1}{2\sqrt{\kappa t}}} \frac{-1}{\sqrt{\pi}} e^{-a^2} da = \\ &= \frac{1}{\sqrt{\pi}} \int_0^{\frac{x+1}{2\sqrt{\kappa t}}} e^{-a^2} da - \frac{1}{\sqrt{\pi}} \int_0^{\frac{x-1}{2\sqrt{\kappa t}}} e^{-a^2} da, \\ u(t, x) &= \frac{1}{2} \left[ \operatorname{erf} \left( \frac{x+1}{2\sqrt{\kappa t}} \right) - \operatorname{erf} \left( \frac{x-1}{2\sqrt{\kappa t}} \right) \right]. \end{aligned}$$

**9.D.62.** Solve parabolic equation

$$u_t = u_{xx}, \quad x \in \mathbf{R}, \quad t \in (0, \infty),$$

with initial condition

$$u(0, x) = \varphi(x) = \begin{cases} 2 & \text{for } x \in (0, 1), \\ 0 & \text{otherwise.} \end{cases}$$

Suppose  $u(t, x) \rightarrow 0$  and  $u_x(t, x) \rightarrow 0$  for  $x \rightarrow \pm\infty$  and express solution using error function. ○

**E. Variational Problems**

**F. Complex analytic functions**

**9.F.1.** Check that the mapping  $z \mapsto z^n$ ,  $n \in \mathbb{N}$ , defined on the entire  $\mathbb{C}$  has got the complex derivative  $z \mapsto nz^{n-1}$ .

**Solution.** We can proceed two ways. Either check the definition of the complex derivative directly, cf. ??, or use the detour via the explicit expression of the mapping  $f(x+iy) = (x+iy)^n$  in two real coordinates  $x, y$  and see that its derivative is complex.

may choose  $\psi(x, y, z) = z - x$  as an integral of the equation, and the solution  $u(x, y) = x + C$  with any constant  $C$ .

Notice, there will be plenty of solutions here since we may add any solution of the homogenous problem, i.e. all functions of the form

$$(3) \quad u(x, y) = h(x^2 + y^2)$$

with any differentiable function  $h$ . Thus, the general solution  $u(x, y) = x + h(x^2 + y^2)$  depends on one function of one variable (the above constant  $C$  is a special case of  $h$ ).

We may also conclude that for “reasonable” curves  $\partial\Omega \subset \mathbb{R}^2$  (those transversal to the circles centred at the origin and not containing the origin) and “reasonable” initial value  $u|_{\partial\Omega}$  (we have to watch the multiple intersection of the circles with  $\partial\Omega$ ) there will be (at least locally) a unique solution extending the initial values to an open neighborhood of  $\partial\Omega$ .

Of course, we may similarly use characteristics and integrals for any finite number of variables  $x = (x_1, \dots, x_n)$  and equations of the form

$$a_1(x, u) \frac{\partial u}{\partial x_1} + \dots + a_n(x, u) \frac{\partial u}{\partial x_n} = f(x, u)$$

with the unknown function  $u = u(x_1, \dots, x_n)$ . As we shall see later, typically we obtain generic solutions dependent on one function of  $n - 1$  variables, similarly to the above example.

**9.2.4. Systems of equations.** Let us look what happens if we add more equations. There are two quite different ways how to couple the equations.

We may seek for an unknown vector valued functions  $u = (u_1, \dots, u_m) : \mathbb{R}^n \rightarrow \mathbb{R}^m$ , subject to  $m$  equations

$$(1) \quad A_i(x, u) \cdot \nabla u_i = f_i(x, u), \quad i = 1, \dots, m,$$

where the left hand side means the scalar product of a vector valued function  $A_i : \mathbb{R}^{m+n} \rightarrow \mathbb{R}^n$  and the gradient vector of the function  $u_i$ . Such systems behave similarly as the scalar ones and we shall come back to them later. □

The other option leads to the so called *overdetermined systems* of equations. Actually we shall not pay more attention to this case in the sequel and so the reader might jump to 9.2.6 if getting lost.

Consider a (scalar) function  $u$  on a domain in  $\Omega \subset \mathbb{R}^n$  and its gradient vector  $\nabla u$ . For each matrix  $A = (a_{ij})$  with  $m$  rows and  $n$  columns, with differentiable functions  $a_{ij}(x, u)$  on  $\Omega \times \mathbb{R}$ , and the right hand value function  $F(x, u) : \Omega \times \mathbb{R} \rightarrow \mathbb{R}^m$ , we can consider the system of equations

$$(2) \quad A(x, u) \cdot \nabla u = F(x, u).$$

Of course, in both cases, we have got  $m$  individual equations of the type from the previous paragraph and we could apply the same idea of characteristic vector fields for all of them. The problem consists in coupling of the equations and obtaining possibly inconsistent necessary conditions from the individual characteristic fields.

The first very simple possibility repeats the computation with polynomials in one real variable and is shown in 9.4.1.  $\square$

Let us look at the overdetermined case now. We can get most close to the situation with the ordinary differential equations if  $A$  is invertible and we move it to the right hand side, arriving at the system of equations

$$(3) \quad \nabla u = A^{-1}(x, u) \cdot F(x, u) = G(x, u).$$

The simplest non-trivial case consists of two equations in two variables:

$$u_x = f(x, y, u), \quad u_y = g(x, y, u).$$

Geometrically, we describe the graph of the solution as a surface in  $\mathbb{R}^3$  by prescribing its tangent plane through each point. An obvious condition for the existence of such  $u$  is obtained by differentiating the equations and employing the symmetry of the higher order partial derivatives, i.e. the condition  $u_{xy} = u_{yx}$ . Indeed,

$$u_{xy} = f_y + f_u g = g_x + g_u f = u_{yx},$$

where we substituted the original equations after applying the chain rule. We shall see in a moment that this condition is also sufficient for the existence of the solutions. Moreover, if the solutions exist, then they are determined by their values in one point, similarly to the ordinary differential equations.

**9.2.5. Frobenius' theorem again.** Similarly, we can deal with the gradient  $\nabla u$  of an  $m$ -dimensional vector valued function  $u$ . For example, if  $m = 2$  and  $n = 2$  we are describing the tangent planes to the two-dimensional graph of the solution  $u$  in  $\mathbb{R}^4$ . In general we face  $mn$  equations

$$(1) \quad \frac{\partial u_p}{\partial x_i} = F_{pi}(x, u), \quad i = 1, \dots, n, \quad p = 1, \dots, m.$$

The necessary conditions imposed by the symmetry of higher order derivatives then read

$$(2) \quad \frac{\partial^2 u_p}{\partial x_i \partial x_j} = \frac{\partial F_{pi}}{\partial x_j} + \sum_q \frac{\partial F_{pi}}{\partial u_q} F_{qj} = \frac{\partial F_{pj}}{\partial x_i} + \sum_q \frac{\partial F_{pj}}{\partial u_q} F_{qi}$$

for all  $i, j$  and  $p$ .

Let us reconsider our problem from the geometric point of view now. We are seeking for the graph of the mapping  $u : \mathbb{R}^n \rightarrow \mathbb{R}^m$ . The equations (1) describe the  $n$ -dimensional distribution  $D$  on  $\mathbb{R}^{m+n}$  and the graphs of possible solutions  $u = (u_1, \dots, u_m)$  are just the integral manifolds of  $D$ . The distribution  $D$  is clearly defined by the  $m$  linear forms

$$\omega_p = du_p - \sum_i F_{pi} dx_i, \quad p = 1, \dots, m,$$

while the vector fields generating the common kernel of all  $\omega_p$  can be chosen as

$$X_i = \frac{\partial}{\partial x_i} + \sum_p F_{pi} \frac{\partial}{\partial u_p}.$$

Now we compute differentials  $d\omega_p$  and evaluate them on the fields  $X_i$

$$\begin{aligned} -d\omega_p &= \sum_{i,j} \frac{\partial F_{pi}}{\partial x_j} dx_j \wedge dx_i + \sum_{i,q} \frac{\partial F_{pi}}{\partial u_q} du_q \wedge dx_i \\ &= \sum_{i,j} \left( \frac{\partial F_{pi}}{\partial x_j} + \sum_q \frac{\partial F_{pi}}{\partial u_q} F_{qj} \right) dx_j \wedge dx_i \\ -d\omega_p(X_j, X_i) &= \left( \frac{\partial F_{pi}}{\partial x_j} + \sum_q \frac{\partial F_{pi}}{\partial u_q} F_{qj} \right) \\ &\quad - \left( \frac{\partial F_{pj}}{\partial x_i} + \sum_q \frac{\partial F_{pj}}{\partial u_q} F_{qi} \right). \end{aligned}$$

Thus, vanishing of the differentials on the common kernel is equivalent to the necessary conditions deduced above, and the Frobenius theorem says that the latter conditions are sufficient, too. We have proved the following:

**Theorem.** *The system of equations (1) admits solutions if and only if the conditions (2) are satisfied. Then the solutions are determined uniquely locally around  $x \in \Omega$  by the initial conditions  $u(x) \in \mathbb{R}^m$ .*

**Remark.** The Frobenius' theory deals with the so called *overdetermined systems of PDEs*, i.e. we have got too many equations and this causes obstructions towards their integrability. Although the case in the last paragraph sounds very special, the actual use of the theory consists in considering differential consequences of a given system until we reach a point, where the special theorem applies and gives not only further obstructions but also the sufficient conditions.

**9.2.6. General solutions to PDE's.** In a moment, we shall deal with diverse boundary conditions for the solutions of PDEs. In most cases we shall be happy to have good families of simple "guessed" solutions which are not subject to any further conditions. We talk about *general solutions* in this context. Unlike the situation with ODEs, we should not hope to get a universal expression for all possible solutions this way (although we can come close to that in some cases, cf. 9.2.3(3)). Instead, we often try to find the right superpositions (i.e. linear combinations) or integrals built from suitable general solutions.

Let us look at the simplest linear second order equations in two variables, homogeneous with constant coefficients:

$$(1) \quad Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu = 0$$

where  $A, B, C, D, E, F$  are real constants and at least one of  $A, B, C$  is non-zero.

Similarly to the method of characteristics, we try to reduce the problem to ODEs. Let us again assume solution in the form  $u = f(p)$ , where  $f$  is an unknown function of  $p$  and  $p(x, y)$  should be nice enough to get close to solutions. The necessary derivatives are  $u_x = f'p_x$ ,  $u_y = f'p_y$ ,  $u_{xx} = f''p_x p_x + f'p_{xx}$ ,  $u_{xy} = f''p_x p_y + f'p_{xy}$ ,  $u_{yy} =$

$f''p_y p_y + f'p_{yy}$ . Thus (1) becomes too complicated in general, but restricting to affine  $p(x, y) = \alpha x + \beta y$  with constants  $\alpha, \beta$ , we arrive at

$$(2) (A\alpha^2 + 2B\alpha\beta + C\beta^2)f'' + (D\alpha + E\beta)f' + Ff = 0.$$

This is a nice ODE as soon as we fix the values of  $\alpha$  and  $\beta$ . Let us look at several simple cases of special importance.

Assume  $D = E = F = 0$ ,  $A \neq 0$ . Then, after dividing by  $\alpha^2$ , we solve the equation  $(A + 2B\frac{\beta}{\alpha} + C\frac{\beta^2}{\alpha^2})f'' = 0$  and the right choice of the ratio  $\lambda = \beta/\alpha \neq 0$  kills the entire coefficient at  $f''$ . Thus, (2) will hold true for any (twice differentiable) function  $f$  and we arrive at the general solution  $u(x, y) = f(p(x, y))$ , with  $p(x, y) = x + \lambda y$ . Of course, the behavior will very much depend on the number of real roots of the quadratic equation

$$A + 2B\lambda + C\lambda^2 = 0.$$

**The wave equation.** Put  $A = 1$ ,  $C = -\frac{1}{c^2}$ ,  $B = 0$ , thus our equation is  $u_{xx} = \frac{1}{c^2}u_{yy}$ , the *wave equation* in dimension 1. Then the equation  $1 - \frac{1}{c^2}\lambda^2 = 0$  has got two real roots  $\lambda = \pm c$ , and we obtain  $p = x \pm cy$  leading to the general solution

$$u(x, y) = f(x - cy) + g(x + cy)$$

with two arbitrary twice differentiable functions of one variable  $f$  and  $g$ .

In Physics, the equation models one-dimensional wave development in the space parametrized by  $x$  while  $y$  stays for the time. Notice  $c$  corresponds to the speed of the wave  $u(x, 0) = f(x) + g(x)$  initiated in the time  $y = 0$ , and while the  $f$  part moves forwards, the other part moves backwards. Indeed, imagine  $u(x, y) = f(x - cy)$  describes the displacement of a string at point  $x$  in time  $y$ . This remains constant along the lines  $x - cy = \text{constant}$ . Thus, a stationary observer sees the initial displacement  $u(x, 0)$  moving along  $x$ -axis with the speed  $c$ .

In particular, we see that the initial condition along a line in the plane is not enough to determine the solution, unless we request the solution will move only in one of the possible directions (i.e. we posit either  $f$  or  $g$  to be zero).

**The Laplace equation.** Now we consider  $A = C = 1$ ,  $B = 0$ , i.e. the equation  $u_{xx} + u_{yy} = 0$ . This is the *Laplace equation* in two dimensions and its solutions are called *harmonic functions*.

Proceeding as before, we obtain two imaginary solutions to the equation  $\lambda^2 + 1 = 0$  and our method produces  $p = x \pm iy$ , a complex valued function instead of the expected real one. This looks ridiculous, but we could consider  $f$  to be a mapping  $f : \mathbb{C} \rightarrow \mathbb{C}$  viewed as a mapping on the complex plane. Remind that some of such mappings have got differentials  $D^1 f(p)$  which actually are multiplications by complex numbers at each point, cf. ???. This is in particular true for any polynomial or converging power series. We may request that this property holds true for all iterated derivatives of this kind. In general, we call such functions on  $\mathbb{C}$  holomorphic and we discuss them in the last part of this chapter. The reader is

advised to come back to this exposition on general solutions to Laplace equation after reading through the beginning of the part on complex analytic functions below, starting in 9.4.1.

Now, assuming  $f$  is holomorphic, we can repeat the above computation and arrive again at

$$(\lambda^2 + 1)f''(p) = 0$$

independently of the choice of  $f$  (here  $f'(p)$  means the complex number given by the differential  $D^1 f$ ,  $f''(p)$  is the iteration of this kind of derivative). Moreover, the derivatives of vector valued functions are computed for the components separately and thus both the real and the imaginary part of the general solution  $f(x + iy) + g(x - iy)$  will be real general solutions.

For example, consider  $f(p) = p^2$  leading to

$$u(x, y) = (x + iy)^2 = (x^2 - y^2) + i2xy$$

and simple check shows that both terms satisfy the equation separately. Notice the two solutions  $x^2 - y^2$  and  $xy$  provide the bases of the 2-dimensional vector space of harmonic homogeneous polynomials of degree two.

**The diffusion equation.** Next assume  $A = \kappa$ ,  $B = C = D = F = 0$ , and add the first order term with  $E = -1$ . This provides the equation

$$u_y = \kappa u_{xx},$$

the *diffusion equation* in dimension one.

Applying the same method again, we arrive at the ODE

$$\kappa\alpha^2 f'' - \beta f' = 0$$

which is easy to solve. We know the solutions are found in the form  $f(p) = e^{\nu p}$  with  $\nu$  satisfying the condition  $\kappa\alpha^2\nu^2 - \beta\nu = 0$ . The zero solution is not interesting, thus we are left with the general solution to our problem by substituting  $p(x, y) = \alpha x + \beta y$  and  $\nu = \frac{\beta}{\kappa\alpha^2}$ :

$$u(x, y) = f(p) = e^{\frac{1}{\kappa}(\frac{\beta}{\alpha}x + \frac{\beta^2}{\alpha^2}y)}.$$

Again, a simple check reveals that this is a solution. But it is not very "general" – it depends just on two scalars  $\alpha$  and  $\beta$ . We have to find much better ways how to find solutions of such equations.

**9.2.7. Nonhomogeneous equations.** As always with linear equations, the space of solutions to the homogeneous linear equations is a real vector space (or complex, if we deal with complex valued solutions).

Let us write the equation as  $Lu = 0$ , where  $L$  is the differential operator on the left hand side. For instance,

$$L = A \frac{\partial^2}{\partial x^2} + B \frac{\partial^2}{\partial x \partial y} + C \frac{\partial^2}{\partial y^2} + D \frac{\partial}{\partial x} + E \frac{\partial}{\partial y} + F$$

in the case of the linear equation 9.2.6(1).

The solutions of the corresponding non-homogeneous equation  $Lu = f$  with a given function  $f$  on the right hand side form an affine space. Indeed, if  $Lu_1 = f$ ,  $Lu_2 = f$ ,  $Lu_3 = 0$ , then clearly  $L(u_1 - u_2) = 0$  while  $L(u_1 + u_3) = f$ . Thus, if we succeed to find a single solution to  $Lu = f$ , then

we can add any general solution to the homogeneous equation to obtain a general solution.

Let us illustrate our observation on some of our basic examples. The non-homogenous wave equation  $u_{xx} - u_{yy} = x + y$  has got the general solution

$$u(x, y) = \frac{1}{6}(x^3 - y^3) + f(x - y) + g(x + y)$$

depending on two twice differentiable functions.

The non-homogeneous Laplace equation is called the *Poisson equation*. A general complex valued solution of the Poisson equation  $u_{xx} + u_{yy} = x + y$  is

$$u(x, y) = \frac{1}{6}(x^3 + y^3) + f(x - iy) + g(x + iy)$$

depending on two holomorphic functions  $f$  and  $g$ .

**9.2.8. Separation of variables.** As we have experienced, a straightforward attempt to get solutions is to expect them in a particular simple form. The method of *separation of variables* is based on the assumption that the solution will appear as a product of single variable functions in all variables in question. Let us apply this method on our three special examples.

**Diffusion equation.** We expect to find a general solution of  $\kappa u_{xx} = u_t$  in the form  $u(x, t) = X(x)T(t)$ . Thus the equation says  $\kappa X''(x)T(t) = T'(t)X(x)$ . Assume further  $u \neq 0$  and divide this equation by  $u = XT$ :

$$\frac{X''(x)}{X(x)} = \frac{T'(t)}{\kappa T(t)}.$$

Now the crucial observation comes. Notice the terms on the left and right are function of different variables and thus the equation may be satisfied only if both the sides become constant. We shall have to distinguish the signs of this *separation constant*, so let us write it as  $-\alpha^2$  (choosing the negative option). Thus we have to solve two independent ODEs

$$X'' + \alpha^2 X = 0, \quad T' + \alpha^2 \kappa T = 0.$$

The general solutions are

$$X(x) = A \cos \alpha x + B \sin \alpha x$$

$$T(t) = C e^{-\alpha^2 \kappa t}$$

with free real constants  $A, B, C$ . When combining these solutions in the product, we may absorb the constant  $C$  into the other ones and thus we arrive at the general solution

$$u(x, t) = (A \cos \alpha x + B \sin \alpha x) e^{-\alpha^2 \kappa t}.$$

This solution depends on three real constants.

If we choose a positive separation constant instead, i.e.  $\lambda^2$ , there will be a sign change in our equations and the resulting general solution is

$$u(x, t) = (A \cosh \alpha x + B \sinh \alpha x) e^{\alpha^2 \kappa t}.$$

If the separation constant vanishes, then we obtain just  $u(x, t) = A + Bx$ , independent of  $t$ .

**The Laplace equation.** Assume  $u(x, y) = X(x)Y(y)$  satisfies the equation  $u_{xx} + u_{yy} = 0$  and proceed exactly as above. Thus,  $X''Y + Y''X = 0$  and dividing by  $XY$  and choosing the separation constant  $\alpha^2$ , we arrive at

$$X'' = \alpha^2 X, \quad Y'' = -\alpha^2 Y.$$

The general solution depends on four real constants  $A, B, C, D$

$$u(x, y) = (A \cosh \alpha x + B \sinh \alpha x)(C \cos \alpha y + D \sin \alpha y).$$

If the separation constant is negative, i.e.  $-\alpha^2$ , the roles of  $x$  and  $y$  swap.

**The wave equation.** Let us look how the method works if there are more variables there. Consider a solution  $u(x, y, z, t) = X(x)Y(y)Z(z)T(t)$  of the 3D wave equation

$$\frac{1}{c^2} u_{tt} = u_{xx} + u_{yy} + u_{zz}.$$

Playing the same game again, we arrive at the equation  $\frac{1}{c^2} T'' XYZ = X'' YZT + Y'' XZT + Z'' XYT$ . Dividing by  $u \neq 0$ ,

$$\frac{1}{c^2} \frac{T''}{T} = \frac{X''}{X} + \frac{Y''}{Y} + \frac{Z''}{Z}$$

and since all the individual terms depend on different single variables, they have to be constant. Again, we shall have to keep attention to the signs of the separation constants. For instance, let us choose all constants negative and look at the individual four ODEs

$$\frac{1}{c^2} \frac{T''}{T} = -\alpha^2, \quad \frac{X''}{X} = -\beta^2, \quad \frac{Y''}{Y} = -\gamma^2, \quad \frac{Z''}{Z} = -\delta^2$$

with the constants satisfying  $-\alpha^2 = -\beta^2 - \gamma^2 - \delta^2$ . The general solution is  $u(x, y, z, t) = X(x)Y(y)Z(z)T(t)$  with linear combinations

$$\begin{aligned} T(t) &= A \cos \alpha t + B \sin \alpha t \\ X(x) &= C \cos \beta x + D \sin \beta x \\ Y(y) &= E \cos \gamma y + F \sin \gamma y \\ Z(z) &= G \cos \delta z + H \sin \delta z \end{aligned}$$

with eight real constants  $A$  through  $H$ .

If we choose any of the separation constants positive, the corresponding component in the product would display hyperbolic sine and cosine instead. Of course, the relation between the constants sees the signs as well.

We can also work with complex valued solutions and choose the exponentials as our building blocks (i.e.  $X(x) = e^{\pm i\beta x}$  or  $X(x) = e^{\pm\beta x}$ , etc). For instance, take one of the solutions with all the separation constants negative

$$u(x, y, z, t) = e^{i\beta x} e^{i\gamma y} e^{i\delta z} e^{-i\alpha t} = e^{i(\beta x + \gamma y + \delta z - \alpha t)}.$$

Similarly to the 1D situation, we can again see a "plane wave" propagating along the direction  $(\beta, \gamma, \delta)$  with angular frequency  $\alpha$ .

**9.2.9. Boundary conditions.** We continue with our examples of second order equations and discuss the three most common boundary conditions for them. Let us consider a domain  $\Omega \subset \mathbb{R}^n$ , bounded or unbounded, and a differential operator  $L$  defined on (real or complex valued) functions on  $\Omega$ . We write  $\partial\Omega$  for the boundary of  $\Omega$  and assume this is a smooth manifold.

Locally, such a submanifold in  $\mathbb{R}^n$  is given by one implicit function  $\rho : \mathbb{R}^n \rightarrow \mathbb{R}$  and the unit normal vector  $\nu(x)$ ,  $x \in \partial\Omega$ , to the hypersurface  $\partial\Omega$  is given by the normalized gradient

$$\nu(x) = \frac{\nabla\rho(x)}{\|\nabla\rho(x)\|}.$$

We say that a function  $u$  is differentiable on  $\Omega$ , if it is differentiable on its interior and the directional derivatives  $D_\nu^1 u(x)$  exist in all points of the boundary. Typically we write  $\frac{\partial}{\partial\nu}$  for the derivative in the normal direction.

For simplicity, let us restrict ourselves to  $L$  of the form

$$L = A(x, y) \frac{\partial^2}{\partial x^2} + 2B(x, y) \frac{\partial}{\partial x \partial y} + C(x, y) \frac{\partial^2}{\partial y^2}$$

and look at the equation  $Lu = F(x, y, u, \frac{\partial u}{\partial x}, \frac{\partial u}{\partial y})$ .

#### CAUCHY BOUNDARY PROBLEM

At each point of the boundary  $x \in \partial\Omega$  we prescribe both the value  $\varphi(x) = u(x)$  and the derivative  $\psi(x) = \frac{\partial u}{\partial\nu}(x)$  in the normal unit direction.

The *Cauchy problem* is to solve the equation  $Lu = F$  on  $\Omega$ , subject to  $u = \varphi$  and  $\frac{\partial u}{\partial\nu} = \psi$  on  $\partial\Omega$ .

We shall see that the Cauchy problems very often lead locally to unique solutions, subject to certain geometric conditions on the boundary  $\partial\Omega$ . At the same time, it is often not the convenient setup for practical problems. We shall illustrate this phenomenon on the 2D Laplace equation in the next but one paragraph.

An even simpler possibility is to request only the condition on the values of  $u$  on the boundary  $\partial\Omega$ . Another possibility, often needed in direct applications, is to prescribe the derivatives only. We shall see, that this is reasonable for the Laplace and Poisson equations.

#### DIRICHLET AND NEUMANN BOUNDARY PROBLEMS

At each point of the boundary  $x \in \partial\Omega$  we prescribe the value  $\varphi(x) = u(x)$  or the derivative  $\psi(x) = \frac{\partial u}{\partial\nu}(x)$  in the normal unit direction.

The *Dirichlet problem* is to solve the equation  $Lu = F$  on  $\Omega$ , subject to the condition  $u = \varphi$  on  $\partial\Omega$ .

The *Neumann problem* is to solve the equation  $Lu = F$  on  $\Omega$ , subject to the condition  $\frac{\partial u}{\partial\nu} = \psi$  on  $\partial\Omega$ .

**9.2.10. Uniqueness for Poisson equations.** Because the proof of the next theorem works in all dimensions  $n \geq 2$ , we

shall formulate it for the general Poisson equation

$$(1) \quad \Delta u = \left( \frac{\partial^2}{\partial x_1^2} + \cdots + \frac{\partial^2}{\partial x_n^2} \right) u = F(x_1, \dots, x_n).$$

**Theorem.** Assume  $u$  is a twice differentiable solution of the Poisson equation (1) on a domain  $\Omega \subset \mathbb{R}^n$ . If  $u$  satisfies the Dirichlet condition  $u = \varphi$  on  $\partial\Omega$ , then  $u$  is the only solution of the Dirichlet problem.

If  $u$  satisfies the Neumann condition  $\frac{\partial u}{\partial \nu} = \psi$  on  $\partial\Omega$ , then  $u$  is the unique solution of the Neumann problem, up to an additive constant.

The proof of this theorem relies on a straightforward consequence of the divergence theorem. Remind 9.1.14, saying that for each vector field  $X$  on a domain  $\Omega \subset \mathbb{R}^n$  with hypersurface boundary  $\partial\Omega$

$$(2) \quad \int_M \operatorname{div} X \, dx_1 \dots dx_n = \int_{\partial\Omega} X \cdot \nu \, d\partial\Omega,$$

where  $\nu$  is the oriented (outward) unit normal to  $\partial\Omega$  and  $d\partial\Omega$  stays for the volume inherited from  $\mathbb{R}^n$  on  $\partial\Omega$ .

#### 1ST AND 2ND GREEN'S IDENTITY

**Lemma.** Let  $M \subset \mathbb{R}^n$  be a  $n$ -dimensional manifold with boundary hypersurface  $S$ , and consider two differentiable functions  $\varphi$  and  $\psi$ . Then

$$(3) \quad \int_M (\varphi \Delta \psi + \nabla \varphi \cdot \nabla \psi) \, dx_1 \dots dx_n = \int_S \varphi \nabla \psi \cdot \nu \, dS.$$

This version of the divergence theorem is called the 1st Green's identity.

Next, let us consider one more differentiable function  $\mu$  and  $X = \varphi \mu \nabla \psi - \psi \mu \nabla \varphi$ . The divergence theorem yields the so called 2nd Green's identity

$$(4) \quad \int_M \varphi (\nabla \cdot (\mu \nabla)) \psi - \psi (\nabla \cdot (\mu \nabla)) \varphi \, dx_1 \dots dx_n = \int_S \mu (\varphi \nabla \psi - \psi \nabla \varphi) \cdot \nu \, dS,$$

where  $\nabla \cdot (\mu \nabla)$  means the formal scalar product of the two vector valued differential operators.

**PROOF OF THE GREEN'S IDENTITIES.** The first claim follows by applying (2) to  $X = \varphi \nabla \psi$ , where  $\varphi$  and  $\psi$  are differentiable functions and  $\nabla \psi$  is the gradient of  $\psi$ . Indeed,

$$\begin{aligned} i_{X\omega_{\mathbb{R}^n}} &= \varphi (\nabla \psi \cdot \nu) dS \\ \operatorname{div} X &= \varphi \Delta \psi + \nabla \varphi \cdot \nabla \psi, \end{aligned}$$

where the dot in the second term denotes the scalar product of the two gradients. Let us also notice that the scalar product  $\nabla \psi \cdot \nu$  is just the derivative of  $\psi$  in the direction of the oriented unit normal  $\nu$ .

The second identity is computed the same way and the two terms with the scalar products of two gradients cancel each other. The reader should check the details.  $\square$

**Remark.** A special case of the 2nd Green's identity is worth mentioning. Namely, if  $\mu = 1$  and both  $\psi$  and  $\varphi$  vanish on the boundary  $\partial\Omega$ , we obtain

$$\int_{\Omega} \varphi \Delta \psi - \psi \Delta \varphi \, dx_1 \dots dx_n = 0.$$

This means that the Laplace operator is self-adjoint with respect to the  $L_2$  scalar product on such functions.

**PROOF OF THE UNIQUENESS.** Assume  $u_1$  and  $u_2$  are solutions of the Poisson equation on  $\Omega$ , thus  $u = u_1 - u_2$  is a solution of the homogeneous Laplace equation,

$$\Delta u = \Delta u_1 - \Delta u_2 = F - F = 0.$$

At same time, either  $u = u_1 - u_2 = 0$  on  $\partial\Omega$  or  $\frac{\partial u}{\partial \nu} = 0$  on  $\partial\Omega$ .

Now we exploit the first Green's identity (3) with  $\varphi = \psi = u$ ,

$$\int_{\Omega} (u \Delta u + \nabla u \cdot \nabla u) \, dx_1 \dots dx_n = \int_{\partial\Omega} u \frac{\partial u}{\partial n} \, dS.$$

In both problems, Dirichlet or Neumann, the right hand side vanishes. The first term in the left hand integrand vanishes, too. We conclude

$$\int_{\Omega} \|\nabla u\|^2 \, dx_1 \dots dx_n = 0,$$

but this is possible only if  $\nabla u = 0$  since the integrand is continuous. Thus,  $u = u_1 - u_2$  is constant. But if we solve a Dirichlet problem, then  $u_1$  and  $u_2$  coincide on the boundary and thus they are equal.  $\square$

**9.2.11. Well posed problems.** Consider the Cauchy boundary problem for  $u_{xx} + u_{yy} = 0$ ,  $\partial\Omega$  given by  $y = 0$  and

$$\varphi(x) = u(x, 0) = A_{\alpha} \sin \alpha x$$

$$\psi(x) = u_y(x, 0) = B_{\alpha} \sin \alpha x$$

with the scalar coefficients  $A_{\alpha}$  and  $B_{\alpha}$  depending on the chosen frequency  $\alpha$ . Simple inspection reveals, that we can find such a solution within the result from the separation method:

$$u(x, y) = (A_{\alpha} \cosh \alpha y + \frac{1}{\alpha} B_{\alpha} \sinh \alpha y) \sin \alpha x.$$

Now, choose  $B_{\alpha} = 0$  and  $A_{\alpha} = \frac{1}{\alpha}$ , i.e.

$$u(x, y) = \frac{1}{\alpha} \cosh \alpha y \sin \alpha x.$$

Obviously, when moving  $\alpha$  towards infinity, the Cauchy boundary conditions can become arbitrarily small and still small change of  $B_{\alpha}$  causes arbitrarily big increase of the values of  $u$  in any close vicinity of the line  $y = 0$ .

Imagine, the equation describes some physical process and the boundary conditions reflect some measurements, including some periodic small errors. The results will be horribly instable with respect to these errors in the derivatives. We should admit that the problem is in some sense ill-posed, even locally. This motivates the following definition.

WELL-POSED AND ILL-POSED BOUNDARY PROBLEMS

The problem  $Lu = F$  on the domain  $\Omega$  with boundary conditions on  $\partial\Omega$  is called *well-posed* if all three conditions hold true:

- (1) The boundary problem has got a solution  $u$  (a classical solution means  $u$  is twice continuously differentiable);
- (2) the solution  $u$  is unique;
- (3) the solution is stable with respect to initial data, i.e. “small” change of the boundary conditions results in a “small” change of the solution.

The problem is called *ill-posed*, if any of the above conditions fails.

Usually, the stability in the third condition means that the solution is continuously dependent on the boundary conditions in a suitable topology on the chosen space of functions.

Also the uniqueness required in the second condition has to be taken reasonably. For instance, only uniqueness up to some additive constant makes sense for the Neumann problems.

**9.2.12. Quasilinear equations.** Now we exploit our experience and focus on the (local) Cauchy type problems for equations of arbitrary order. Similarly to the ODEs, we shall deal with problems, where the highest order derivatives are prescribed (more or less) explicitly and the initial conditions are given on a hypersurface up to the order  $k - 1$ .

Some notation will be useful. We shall use the multi-indices to express multivariate polynomials and derivatives, cf. 8.1.15. Further we shall write  $\nabla^k u = \{\partial_\alpha u; |\alpha| = k\}$  for the vector of all derivatives of order  $k$ . In particular,  $\nabla u$  means again the gradient vector of  $u$ .

Some notation will be useful. We shall use the multi-indices to express multivariate polynomials and derivatives, cf. 8.1.15. Further we shall write  $\nabla^k u = \{\partial_\alpha u; |\alpha| = k\}$  for the vector of all derivatives of order  $k$ . In particular,  $\nabla u$  means again the gradient vector of  $u$ .

QUASI-LINEAR PDES

For unknown scalar function  $u$  on a domain  $\Omega \subset \mathbb{R}^n$  we prescribe its derivatives

$$(1) \quad \sum_{|\alpha|=k} a_\alpha(x, u, \dots, \nabla^{k-1}u) \partial_\alpha u = b(x, u, \dots, \nabla^{k-1}u),$$

where  $b$  and  $a_\alpha$  are functions on the tubular domain  $\Omega \times \mathbb{R}^N$ , accomodating all the derivatives, with at least one of  $a_\alpha$  non-zero. We call such equations the (scalar) *quasilinear partial differential equations* (PDE) of order  $r$ .

We call (1) *semilinear* if all  $a_\alpha$  do not depend on  $u$  and its derivatives (thus all the non-linearity hides in  $b$ ).

The *principal symbol* of a semi-linear PDE of order  $k$  is the symmetric  $k$ -linear form  $P$  on  $\Omega$ ,

$$P(x) : (\mathbb{R}^n)^k \rightarrow \mathbb{R}, \quad P(x, \xi, \dots, \xi) = \sum_{|\alpha|=k} a_\alpha(x) \xi^\alpha.$$

For instance, the Poisson equation  $\Delta u = f(x, y, u, \nabla u)$  on  $\mathbb{R}^2$  is a semi-linear equation and its principal symbol is the positive definite quadratic form  $P(\zeta, \eta) = \zeta^2 + \eta^2$ , independent of  $(x, y)$ .

The diffusion equation  $\frac{\partial u}{\partial t} = \Delta u$  on  $\mathbb{R}^3$  has got the symbol  $P(\tau, \zeta, \eta) = \zeta^2 + \eta^2$ , i.e. a positive semi-definite quadratic form, while the wave equation  $\square u = \frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2} = 0$  has got the indefinite symbol  $P(\tau, \zeta) = \tau^2 - \zeta^2$  on  $\mathbb{R}^2$ .

We shall focus on the scalar equations and reduce the problem to a special situation which allows a further reduction to a system of first order equations (quite similarly to the ODE theory). Thus we extend the previous definition to systems of equations. Notice, these are systems of the first kind mentioned in 9.2.4.

#### SYSTEMS OF QUASI-LINEAR PDES

A system of quasi-linear PDEs determines a vector valued function  $u : \Omega \subset \mathbb{R}^n \rightarrow \mathbb{R}^m$ , subject to the vector equation

$$(2) \quad A(x, u, \dots, \nabla^{k-1}u) \cdot \nabla^k u = b(x, u, \dots, \nabla^{k-1}u).$$

Here  $A$  is a matrix of type  $m \times M$  with functions  $a_{i,\alpha} : \Omega \times \mathbb{R}^N$  as entries,  $M = \binom{n+k-1}{k}$  is the number of  $k$ -combinations with repetition from  $n$  objects,  $\nabla^k u$  is the vector of vectors of all the  $k$ th-order derivatives of the components of  $u$ ,  $b : \Omega \times \mathbb{R}^N \rightarrow \mathbb{R}^m$ , and  $\cdot$  means the scalar products of the individual rows in  $A$  with the vectors  $\nabla^k u_i$  of the individual components of  $u$ , matching the individual components in  $b$ .

**9.2.13. Cauchy data.** Next, we have to clarify the boundary condition data. Let us consider a domain  $U \subset \mathbb{R}^n$  and a smooth hypersurface  $\Gamma \subset U$ , e.g.  $\Gamma$  given by an implicit equation  $f(x_1, \dots, x_n) = 0$  locally. Consider the unit normal vector  $\nu(x)$  at each point  $x \in \Gamma$  (i.e.  $\nu = \frac{1}{\|\nabla f\|} \nabla f$  if given implicitly). We would like to find minimal data along  $\Gamma$  determining a solution of 9.2.12(1), at least locally around a given point.

To make things easy, let us first assume that  $\Gamma$  is prescribed by  $x_n = 0$ . Then  $\nu(x) = (0, \dots, 0, 1)$  at all  $x \in \Gamma$  and knowing the restriction of  $u$  to  $\Gamma$ , we also now all derivatives  $\partial_\alpha$  with  $\alpha = (\alpha_1, \dots, \alpha_{n-1}, 0)$ ,  $0 \leq |\alpha|$ . Thus, we have to choose reasonably differentiable functions  $c_j$  on  $\Gamma$ ,  $j = 0, \dots, k-1$ , and posit for all  $j$

$$\partial_\alpha u(x) = c_j(x), \quad \alpha = (0, \dots, 0, j), \quad x \in \Gamma.$$

All the other derivatives  $\partial_\alpha u$  on  $\Gamma$ ,  $0 \leq |\alpha| < \infty$  with  $\alpha_n < k$  are computed inductively by the symmetry of partial derivatives.

Moreover, if  $a_{(0, \dots, 0, k)} \neq 0$ , we can establish the remaining  $k$ -th order derivative by means of the equation 9.2.12(1) and hope to be able to continue inductively. Indeed, writing  $a = a_{(0, \dots, 0, k)}(x, u, \dots, \nabla^{k-1}(u)) \neq 0$  (and similarly leaving out the arguments of the other functions  $a_\alpha$ ), the equation 9.2.12(1) can be rewritten as

$$(1) \quad \frac{\partial^k}{\partial x_n^k} u = \frac{1}{a} \left( - \sum_{|\alpha|=k, \alpha_n \neq k} a_\alpha \partial_\alpha u + b(x, u, \dots, \nabla^{k-1}u) \right).$$

Now, on  $\Gamma$  we can use the already known derivatives to compute directly all the  $\partial_\alpha u$  with  $\alpha_n < k+1$ . But differentiating

the latter equation by  $\frac{\partial}{\partial x_n}$  we obtain the missing derivative of order  $k + 1$  from the known quantities on the right-hand side. By induction, we obtain all the derivatives, as requested.

In the general situation we can iterate the derivative  $D_{\nu(x)}^1 u$  of  $u$  in the direction of the unit normal vector  $\nu$  to the hypersurface  $\Gamma$ :

#### CAUCHY DATA FOR SCALAR PDE

The (smooth or analytic) *Cauchy data* for the  $k$ th order quasi-linear PDE 9.2.12(1) consist of a hypersurface  $\Gamma \subset U$  and  $k$  (smooth or analytic) functions  $c_j$ ,  $0 \leq j \leq k - 1$ , prescribing the derivatives in the normal directions to  $\Gamma$

$$(2) \quad (D_{\nu(x)}^1)^j u(x) = c_j(x), \quad x \in \Gamma.$$

A normal direction  $\nu(x)$ ,  $x \in \Gamma$ , is called *characteristic* for the given Cauchy data, if

$$(3) \quad \sum_{|\alpha|=k} a_\alpha(x, u, \dots, \nabla^{k-1} u) \nu(x)^\alpha = 0.$$

The Cauchy data are called *non-characteristic* if there are no characteristic normals to  $\Gamma$ .

Notice the situation simplifies for the semi-linear equations. Then the characteristic directions do not depend on the chosen functions  $c_j$  from the Cauchy data and they are directly related to the properties of the principal symbol of the equation. In the case of the hyperplane  $\Gamma = \{x_n = 0\}$  treated above, the Cauchy data are non-characteristic if and only if  $a_{(0, \dots, 0, k)} \neq 0$ .

For instance, semi-linear equations of first order always admit characteristic directions since their principal symbols are linear forms and so they must have non-trivial kernels (hyperplanes of characteristic directions). In the three second order examples of the Laplace equation, diffusion equation, and wave equation very different phenomena occur. Since the symbol of the Laplace equation is a positive definite quadratic form, characteristic directions can never appear, independently of our choice of  $\Gamma$ . On the contrary, there are always non-trivial characteristic directions in the other two cases.

#### CHARACTERISTIC CONES OF SEMI-LINEAR PDES

The characteristic directions of a semi-linear PDE on a domain  $\Omega \subset \mathbb{R}^n$  generate the *characteristic cone*  $\mathcal{C}(x) \subset T_x \Omega$  in the tangent bundle,

$$\mathcal{C}(x) = \{\xi \in T_x \Omega; P(x)(\xi, \dots, \xi) = 0\}.$$

The Cauchy data on a hypersurface  $\Gamma$  are non-characteristic if and only if  $(T\Gamma)^\perp \cap \mathcal{C} = \{0\}$ , i.e. the orthogonal complements to the tangent spaces to  $\Gamma$  with respect to the standard scalar product on  $\mathbb{R}^n$  never meet the characteristic cone.

Notice, cones for linear forms are hyperplanes in the tangent space, quadratic cones appear with second order, etc. The tangent vectors to characteristics of the first order quasi-linear equations (as introduced in 9.2.2) are orthogonal to the characteristic normals. We have learned that the first order equations propagate the solutions along the characteristic

lines and so we are not free to prescribe the Cauchy data for the solution in such a case.

**9.2.14. Cauchy-Kovalevskaya Theorem.** As seen so many times already, the analytic mappings are very rigid and most questions related to them boil down to some estimates and smart combinatorial ideas. It is time to remind what happens for analytic equations and Cauchy data in the very special case of the ODEs.

For a single scalar autonomous ODE of first order, the Cauchy data consist of a single point “hypersurface”  $\Gamma = \{x\}$  in  $\Omega \subset \mathbb{R}$  and the value  $u(x)$ . In particular, the Cauchy data are always non-characteristic in dimension one. Already in 6.2.22 we gave a complete proof that the induced derivatives of  $u$  provide a converging power series and thus the only solution, on certain neighborhood of  $x$ . In 8.3.13 we extended the same proof to autonomous systems of ODEs, which verified the same phenomenon for general systems of ODEs of any order  $k$ . Here the Cauchy data again consist of the only point in  $\Gamma$  and all derivatives of  $u$  of orders less than  $k$  (and again, they are always non-characteristic).

In subsequent paragraphs we shall comment on how to extend the ODE proof to the following very famous theorem. In particular, the statement says that we have to expect general solutions to  $k$ th order scalar equations in  $n$  variables to depend on  $k$  independent functions of  $n - 1$  variables. This is in accordance with our experience from simple examples.

CAUCHY-KOVALEVSKAYA THEOREM

**Theorem.** *The analytic Cauchy problem consisting of quasi-linear equation 9.2.12(1) with analytic coefficients and right hand side, and analytic non-characteristic Cauchy data 9.2.13(2) has got a unique analytic solution on a neighborhood of each point in  $\Gamma$ .*

Notice that we have computed explicitly the formal power series for the solution (by an inductive procedure) for the special case when  $\Gamma$  is defined by  $x_n = 0$ . In this case, the theorem claims that this formal series always converges with non-trivial radius of convergence.

The full proof is very technical and we do not have space to bother the readers with all details. In the next paragraphs, we shall provide indications toward the steps in the proof. If the track (or interest) will be lost, the reader should rather jump to 9.2.18.

**9.2.15. Flattening the Cauchy data.** The first step in the proof is to transform the non-characteristic data to the “flat” hypersurface  $\Gamma$  discussed in the beginning of 9.2.13. Remind that for such  $\Gamma$  the non-characteristic condition in 9.2.13(3) reads  $a_{(0,\dots,0,k)} \neq 0$ .

Let us start with the general equation and its analytic Cauchy data on an analytic  $\Gamma \subset \mathbb{R}^n$  (we omit the arguments

of all the functions and  $\ell = 0, \dots, k-1$ )

$$(1) \quad \sum_{|\alpha|=k} a_\alpha \partial_\alpha u = b, \quad \frac{\partial^\ell u}{\partial n^\ell}(x) = c_\ell(x), \quad x \in \Gamma.$$

We shall work locally around some unspecified fixed point in  $\Gamma$ . Since  $\Gamma$  is an analytic hypersurface in  $\mathbb{R}^n$ , there are new local coordinates  $y = \Psi(x)$ , such that

$$\Gamma = \{x; \Psi_n(x) = 0\}.$$

Moreover,  $\Psi$  can be chosen again analytic. Thus, the unit normal vector  $\nu$  to  $\Gamma$  equals to  $\nabla \Psi_n$ , up to a multiple  $\mu^{-1}$  at each point of  $\Gamma$ .

Let  $\Phi = \Psi^{-1}$ , i.e.  $x = \Phi(y)$ , and  $v(y) = u(\Phi(y))$ . Then  $\Phi$  is analytic and the equation transforms to another equation in the coordinates  $y$ ,

$$(2) \quad \sum_{|\alpha|=k} \tilde{a}_\alpha \partial_\alpha v = \tilde{b}$$

with analytic coefficients (they can be all expressed by means of the chain rule and the mutually inverse transformations  $\Phi, \Psi$ ). By the very definition,  $\frac{\partial \Phi}{\partial y_n}$  is a vector (the last column in the matrix  $D^1 \Phi$ ) perpendicular to  $\Gamma$  and thus it must be  $\mu \nu$  (remind the product of the Jacobi matrices  $D^1(\Psi)D^1(\Phi)$  is the identity matrix and the rows  $\nabla \Psi_j$ ,  $j = 1, \dots, n-1$  generate the tangent space  $T\Gamma$ ).

**Claim 1.** The transformed Cauchy data for the equation (2) are analytic.

The hypersurface  $\tilde{\Gamma}$  given by  $y_n = 0$  as well as the coefficients of the equation are analytic. Compute  $\frac{\partial^\ell v}{\partial y_n^\ell}$  on  $\tilde{\Gamma}$ .

$$\begin{aligned} v &= c_0 \circ \Phi \\ \frac{\partial v}{\partial y_n} &= \nabla u \cdot \frac{\partial \Phi}{\partial y_n} = \mu \nabla u \cdot \nu = \mu \frac{\partial u}{\partial \nu} = \mu c_1 \\ \frac{\partial^2 v}{\partial y_n^2} &= \frac{\partial \mu}{\partial y_n} \frac{\partial u}{\partial \nu} + \mu^2 \frac{\partial^2 u}{\partial \nu^2} = \frac{\partial \mu}{\partial y_n} c_1 + \mu^2 c_2 \\ \frac{\partial^3 v}{\partial y_n^3} &= \frac{\partial^2 \mu}{\partial y_n^2} \frac{\partial u}{\partial \nu} + 3\mu \frac{\partial \mu}{\partial y_n} \frac{\partial^2 u}{\partial \nu^2} + \mu^3 \frac{\partial^3 u}{\partial \nu^3} \\ &= \frac{\partial^2 \mu}{\partial y_n^2} c_1 + 3\mu \frac{\partial \mu}{\partial y_n} c_2 + \mu^3 c_3. \end{aligned}$$

Inductively, we see that the transformed functions  $\tilde{c}_j$  are obtained in an analytic way from the functions  $c_i$ ,  $i = 0, \dots, j$ .

**Claim 2.** The Cauchy data for the equation (1) are non-characteristic if and only if the transformed Cauchy data for (2) are non-characteristic, i.e.  $\tilde{a}_{(0, \dots, 0, k)} \neq 0$ .

Compute using the chain rule (remind  $\nabla \Psi_n$  is a vector, the gradient of the last coordinate function of  $\Psi$ , and it is equal to  $\nu$ , up to the non-zero multiple  $\mu^{-1}$ )

$$\begin{aligned} \partial_\alpha u &= \frac{\partial^k v}{\partial y_n^k} (\nabla \Psi_n)^\alpha + \text{lot of terms of lower order in } \frac{\partial}{\partial y_n} \\ &= \mu^{-k} \frac{\partial^k v}{\partial y_n^k} \nu^\alpha + \dots \end{aligned}$$

Substitute into (1)

$$\sum_{|\alpha|=k} a_\alpha \partial_\alpha u = \mu^{-k} \sum_{|\alpha|} a_\alpha \nu^\alpha \frac{\partial^k v}{\partial y_n^k} + \dots$$

We have computed

$$\tilde{a}_{(0,\dots,0,k)} = \mu^{-k} \sum_{|\alpha|=k} a_\alpha \nu^\alpha$$

which is non-zero if and only if the original Cauchy data were non-characteristic.

Since we already verified that all the partial derivatives of  $v$  along  $\tilde{\Gamma}$  can be computed for the non-characteristic Cauchy data with the flat hypersurface  $\tilde{\Gamma}$ , we have actually proved the following claim.

**Proposition.** *The Cauchy data for (1) allow to compute all partial derivatives of its solution  $u$  along the hypersurface  $\Gamma$  if and only if the data are non-characteristic.*

**9.2.16. Reduction to a first-order system.** Without loss of generality, we may consider only the Cauchy data of the form discussed in 9.2.13, i.e. the quasi-linear equation on a domain in  $\mathbb{R}^n$  is

$$(1) \quad \frac{\partial^k}{\partial x_n^k} u = \sum_{|\alpha|=k, \alpha_n \neq k} a_\alpha \partial_\alpha u + b$$

and  $\Gamma$  is given by  $x_n = 0$  with prescribed normal derivatives  $c_0, \dots, c_{k-1}$ . Moreover, we can subtract suitable fixed functions from  $u$  in order to transform the equation into a new one of the same shape and with all the Cauchy data  $c_j$  vanishing on  $\Gamma$ . Indeed, start with  $v = u - c_0$ . This transforms the equation and Cauchy data so that the new  $\tilde{c}_0 = 0$ . If we killed the functions  $\tilde{c}_0, \dots, \tilde{c}_{\ell-1}$ , then we may subtract  $g(x_1, \dots, x_n) = \frac{1}{\ell!} x_n^\ell \tilde{c}_\ell(x_1, \dots, x_{n-1})$  which kills the next one.

The final reduction step is to introduce new functions for all components in the vector  $(u, \nabla u, \dots, \nabla^{k-1} u)$ . Write  $v_1, \dots, v_N$  for all these functions, and add one more function  $v_0(x) = x_n$ . Then we can rewrite our equation (1) as a system of quasi-linear equations of first order on the vector function  $v = (v_0, \dots, v_N)$ .

$$(2) \quad \frac{\partial}{\partial x_n} v_s = \sum_{0 \leq r \leq N} \sum_{i=1}^{n-1} a_{sri} \frac{\partial}{\partial x_i} v_r + b_s, \quad s = 0, \dots, N,$$

where all the coefficients  $a_{sri}$ ,  $b$ , are functions in  $x_1, \dots, x_{n-1}, v_0, \dots, v_N$  and the boundary condition on  $\Gamma = \{x_n = 0\}$  is  $v|_\Gamma = 0$ .

Notice two important facts, the coefficients do not depend on  $x_n$  and all derivatives on the left hand side are  $\frac{\partial}{\partial x_n}$ . This is a technicality which makes the problem similar to the autonomous systems of ODEs.

The principle is obvious from a simple example. Consider 2nd order equation with coefficients  $a_{xx}, a_{xt}, b$

$$u_{tt} = a_{xt} u_{xt} + a_{xx} u_{xx} + b$$

and view  $t, u, u_t, u_x$  as unknown function. Then our equation rewrites as the system of four equations

$$\begin{aligned}\frac{\partial}{\partial t}t &= 1, & \frac{\partial}{\partial t}u &= u_t, & \frac{\partial}{\partial t}u_x &= \frac{\partial}{\partial x}u_t, \\ \frac{\partial}{\partial t}u_t &= a_{xt}\frac{\partial}{\partial x}u_t + a_{xx}\frac{\partial}{\partial x}u_x + b\end{aligned}$$

with boundary condition  $t = u = u_t = u_x = 0$  on the line  $t = 0$ .

**9.2.17. The majorant.** The rest of the proof is very technical, but it is based on the straightforward idea of a majorant for the Cauchy problem 9.2.16(2). Remind we used this method in 8.3.13 when proving the ODE version of the Cauchy-Kovalevskaya theorem.

We shall not go into much detail and only indicate how to generalize the method from 8.3.13. The first step is easy – we have seen already that all derivatives of the solution vector  $v$  at a fixed point  $x$  in  $I$  are computed by chain rule from the Cauchy data. This proves the uniqueness of the analytic solution, if such a solution exists.

Again, it turns out the derivatives are given via universal polynomials in the derivatives of the coefficients  $a_{sri}, b_s$  of the system 9.2.16(2), and the polynomials have got non-negative real coefficients. The reader may easily fill the details as an exercise.

Now, a very similar majorant of the coefficients as in the ODE case can be chosen. First, the analyticity of the coefficients ensures the existence of some suitably small  $r > 0$  and (perhaps big) constant  $C$  such that  $\frac{1}{\alpha!}|\partial_\alpha a_{sri}|r^{|\alpha|} \leq C$ ,  $\frac{1}{\alpha!}|\partial_\alpha b_s|r^{|\alpha|} \leq C$ , and thus

$$|\partial_\alpha a_{sri}| \leq C|\alpha!|r^{-|\alpha|}, \quad |\partial_\alpha b_s| \leq C|\alpha!|r^{-|\alpha|},$$

for all coefficients and multiindices  $\alpha$ .

In particular, all the coefficients can be majorized by the function

$$h(x_1, \dots, x_{n-1}, v_0, \dots, v_N) = \frac{Cr}{r - \sum_{j=1}^{n-1} x_j - \sum_{s=0}^N v_s}.$$

Now, the majorizing system for the vector  $(V_0, \dots, V_N)$  is

$$\frac{\partial V_s}{\partial x_n} = \sum_{0 \leq r \leq N} \sum_{i=1}^{n-1} h \frac{\partial}{\partial x_i} V_r + h, \quad s = 0, \dots, N.$$

Since the coefficients are completely symmetric in the variables, let us expect the solution in the form

$$V_0 = \dots = V_N = W(x_1 + \dots + x_{n-1}, x_n),$$

i.e.  $W$  is a real function of two variables, say  $W(t, y)$ . Substituting into the system we arrive at the linear first order PDE

$$\frac{\partial W}{\partial y} = \frac{Cr}{r - t - NW(t, y)} \left( N(n-1) \frac{\partial W}{\partial t} + 1 \right),$$

with boundary condition  $W(t, 0) = 0$ . The reader may find the solution (e.g. by the method of characteristics)

$$W(t, y) = \frac{1}{Nn} \left( r - t - \sqrt{(r-t)^2 - 2nNCry} \right),$$

a real analytic function on a neighborhood of the origin.

This concludes the proof.<sup>6</sup>

**9.2.18. Back to second order equations.** Let us continue our brief excursion to the PDE world by more detailed comments on the second order semilinear equations. We shall deal with scalar PDEs on a domain  $\Omega \subset \mathbb{R}^n$  with one of the usual boundary conditions.

Thus consider a general linear operator

$$(1) \quad L = \sum_{1 \leq i, j \leq n} a_{ij} \frac{\partial^2}{\partial x_i \partial x_j} + \sum_{1 \leq i \leq n} a_i \frac{\partial}{\partial x_i} + a$$

written in coordinates  $(x_1, \dots, x_n)$ . If we consider any other coordinate system  $y = \Phi(x)$ , then the chain rule determines how to transform the equation  $Lu = f$  in coordinates  $x$  into  $\tilde{L}\tilde{v} = \tilde{f}$ , where  $u(x) = v(\Phi(x))$ . Write  $\nabla = (\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n})$  for the gradient operator, dot for the standard scalar product of vectors,  $D^1\Phi$  for the Jacobi matrix of  $\Phi$  in the coordinates  $y$  and  $x$ ,  $\frac{\partial\Phi}{\partial x_i}$  for the  $i$ th column of  $D^1\Phi$ .

$$\begin{aligned} \frac{\partial}{\partial x_i} &= \nabla \cdot \frac{\partial\Phi}{\partial x_i} = \sum_k \frac{\partial\Phi_k}{\partial x_i} \frac{\partial}{\partial y_k} \\ \frac{\partial}{\partial x_i \partial x_\ell} &= \sum_{k, \ell} \frac{\partial\Phi_k}{\partial x_i} \frac{\partial\Phi_\ell}{\partial x_j} \frac{\partial^2}{\partial y_k \partial y_\ell} + \sum_k \frac{\Phi_k}{\partial x_i \partial x_j} \frac{\partial}{\partial y_k}. \end{aligned}$$

Thus, the operator (1) transforms into

$$\tilde{L} = \sum_{1 \leq i, j, k, \ell \leq n} a_{ij} \frac{\partial\Phi_k}{\partial x_i} \frac{\partial\Phi_\ell}{\partial x_j} \frac{\partial^2}{\partial y_k \partial y_\ell} + \sum_{1 \leq i, k \leq n} a_i \frac{\partial\Phi_k}{\partial x_i} \frac{\partial}{\partial y_k} + a.$$

In particular, the principal symbol transforms pointwise as a quadratic form under the linearized transformation  $D^1\Phi$ .

As we know from the linear algebra, the global behavior of real quadratic forms is classified by their signature, i.e. the number of positive and negative entries in the diagonalized matrix, cf. 4.3.2. This is transferred to the following

CLASSIFICATION OF 2ND ORDER QUASI-LINEAR PDES

Consider a second order quasi-linear operator (1) with the principal symbol  $Q$ . The equations  $Lu = f$  and the operator  $L$  are called

- *elliptic* if  $Q$  is either positive or negative definite
- *hyperbolic* if  $Q$  has got the signature  $(n - 1, 1)$  (or equivalently  $(1, n - 1)$ )
- *parabolic* if  $Q$  is positive semidefinite with rank  $n - 1$  and the equation can be rewritten as  $\frac{\partial}{\partial t} u = \tilde{L}(u)$ , where the principal symbol of  $\tilde{L}$  depends on the remaining variables only.

Notice that we actually did not include all possibilities into the above list. We omitted the *ultra-hyperbolic* case, where the rank of  $Q$  is maximal, with the remaining possibilities of signatures. Further, the parabolic equations could appear with the minus sign at  $\frac{\partial}{\partial t}$  (the so called “backwards

<sup>6</sup>The reader may find detailed exposition in many basic books, for instance see the Chapter 1 of the book "Introduction to partial differential equations" by Gerald B. Folland, Princeton, 1995.

parabolic equations”), and the rank of  $Q$  could also drop by more than one. Most of these cases cannot be seen in low dimensions.

If the coefficients  $a_{ij}$ ,  $a_i$  and  $a$  are constant, then the principal symbol  $Q$  is a constant quadratic form, too, and we may choose just linear transformations  $T = D^1\Phi$  instead of general  $\Phi$ . This will always allow us to transform the quadratic form to its canonical form over the entire domain  $\Omega$ .

Many particular examples are discussed explicitly in the other column, see ??, in particular in low dimensions.

Let us also stress that while in dimension  $n = 2$  we may even locally integrate the necessary linearized transformations into a genuine mapping  $\Phi$  and get the canonical forms of the equations even in more general context, see ??, this is mostly not possible in higher dimensions.

Before coming to a few most important examples, let us look at the characteristic directions in the individual cases. If  $L$  is elliptic, then of course there cannot be any characteristic direction. So the (local) Cauchy problem prescribing the analytic value and first normal derivative along any analytic hypersurface  $\Gamma$  will have a locally converging analytic solution around any fixed point. Unfortunately, we have already encountered that this is not a well posed problem even for the two dimensional Laplace equation, cf. 9.2.11.

On the contrary, there will be a  $(n-1)$ -dimensional cone of characteristic direction at each point of a hyperbolic equation, while the parabolic equations will come equipped with a line of characteristic directions.

**9.2.19. The wave equation.** The wave operator in dimension  $n$  is

$$(1) \quad L = \frac{\partial^2}{\partial t^2} - c^2 \Delta,$$

where  $\Delta$  is the Laplace operator  $\Delta = \frac{\partial^2}{\partial x_1^2} + \dots + \frac{\partial^2}{\partial x_n^2}$ ,  $c^2 > 0$  a real constant. The operator  $L$  lives on domains in  $\mathbb{R}^{n+1}$ .

Let us first return to the 2D wave equation  $u_{tt} = c^2 u_{xx}$ . We know the general solution

$$u(x, t) = f(x - ct) + g(y + ct),$$

cf. 9.2.6, which is the superposition of the forward and backward waves  $u_1(x, 0) = f(x)$  and  $u_2(x, 0) = g(x)$ .

This perfectly matches our general expectation from the Cauchy-Kovalevskaya theorem that general solutions to quasilinear second order equations in two variables should depend on two real single variable functions. Moreover, the characteristic directions are  $x \pm ct = 0$  and thus the line  $\Gamma = \{t = 0\}$  is non-characteristic.

Setting the Cauchy boundary data  $u(x, 0) = \varphi(x)$ ,  $\frac{\partial}{\partial t} u(x, 0) = \psi(x)$  and substituting the general solution, we arrive at

$$\varphi(x) = f(x) + g(x), \quad \psi(x) = -cf'(x) + cg'(x),$$

where dash stays for the derivative of the single variable function, as usual. Thus, for any  $s_0$  and  $s$

$$\frac{1}{c} \int_{s_0}^s \psi(x) dx = -f(s) + g(s) + f(s_0) - g(s_0).$$

Add and subtract the equations

$$2g(s) = \varphi(s) + \frac{1}{c} \int_{s_0}^s \psi(x) dx - f(s_0) + g(s_0)$$

$$2f(s) = \varphi(s) - \frac{1}{c} \int_{s_0}^s \psi(x) dx + f(s_0) - g(s_0).$$

Finally, substitute  $s = x - ct$  into  $f(s)$ , and  $s = x + ct$  into  $g(s)$  in order to get the value of  $u(x, t)$  (notice the integrals add nicely, while the constants depending on the choice of  $s_0$  cancel).

$$(2) \quad u(x, y) = \frac{1}{2}(\varphi(x-ct) + \varphi(x+ct)) + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(y) dy.$$

This solution is often called the *D'Alembert's solution*.

The formula also reveals the continuous dependence of the solution on the boundary conditions. We may conclude that the Cauchy problem seems to be the right boundary value problem for the wave equation (although we have fully proved that it is well-posed only in the dimension two and the analytic category).

In higher dimensions, the situation is much more complicated. One of useful options is to employ the method of separation of variables, but splitting only the time and space variables. Consider the  $n$ -dimensional wave equation and expect the solution in the form  $u(x, t) = F(x)T(t)$  (now  $x \in \mathbb{R}^n$ ,  $t \in \mathbb{R}$ ). Plugging this into (1) and playing the separation method game, we arrive at two equations

$$\Delta F + \alpha F = 0, \quad T'' + \alpha \frac{1}{c^2} T = 0,$$

where  $\alpha$  is the separation constant (usually we consider either  $\alpha^2$  or  $-\alpha^2$  to fix the types of the equations). The first equation is called the *Helmholtz equation* and we shall come back to it below.

**9.2.20. The diffusion equation.** In general dimension  $n$  the *diffusion operator* is

$$(1) \quad L = \frac{\partial}{\partial t} - \kappa \Delta,$$

$\kappa > 0$ , the diffusion equation is considered on domains in  $\mathbb{R}^n \times \mathbb{R}$ .

Again, let us have a look at the simplest 1D diffusion equation  $u_t = \kappa u_{xx}$ . It describes the diffusion process in a one-dimensional object with diffusivity  $\kappa$  (assumed to be constant here) in time. First of all, let us notice that the usual boundary value prescription of the state at time  $t = 0$  is not matching the assumption of the Cauchy-Kovalevskaya theorem. Indeed, taking  $\Gamma = \{t = 0\}$ , the normal direction vector  $\frac{\partial}{\partial t}$  is characteristic.

The intuition related to the expectation on diffusion problems suggests that Dirichlet boundary data should suffice (we just need the initial state and the diffusion then does the rest), or we can combine them with some Neumann data (if we supply heat at some parts of the boundary). Moreover, the process should not be reversible in time, so we should not expect that the solution would extend across the line  $t = 0$ .

Let us look at a classical example considered already by Kovalevskaya. Posit

$$u(0, x) = g(x) = \frac{1}{1 + x^2}$$

on a neighborhood of the origin (perfect analytic boundary data and equation), and expect  $u$  is a solution of  $u_t = u_{xx}$  in the form  $u(t, x) = \sum_{k, \ell \geq 0} c_{k, \ell} \frac{t^k}{k!} \frac{x^\ell}{\ell!}$ .

The equation obviously implies the relations  $c_{k+1, \ell} = c_{k, \ell+2}$  for all  $k, \ell$ . Further, the power series of  $(1 + x^2)^{-1} = \sum_{\ell} (-1)^\ell x^{2\ell}$  is obtained from the geometric power series with argument  $-x$ , and with  $x^2$  substituted for  $x$  in the end.

Thus, for all  $\ell$ ,  $c_{0, 2\ell+1} = 0$ ,  $c_{0, 2\ell} = (-1)^\ell (2\ell)!$ . By the recurrence,  $c_{k, 2\ell} = (-1)^{k+\ell} (2(k + \ell))!$ .

This is a too quick growth for a converging power series. For example, looking at the terms

$$\frac{1}{k!k!} c_{k, k} = \frac{(4k)!}{k!(2k)!},$$

they grow as fast towards the infinity as the expression  $e^{-k} k^k 8^{2k}$ , by the Stirling formula for the factorial (cf. 6.2.17).

We have learned that there cannot be any analytic solution to our Dirichlet boundary problem at all. This example also shows the relevance of all assumptions in the Cauchy-Kovalevskaya theorem.

**9.2.21. Diffusion via Fourier transform.** Fortunately, another straightforward method helps us to solve

the simplest diffusion equation with Dirichlet data. Let us assume  $u(x, t)$  is a solution of  $u_t = \kappa u_{xx}$ ,  $u(x, 0) = \varphi(x)$ . Remind, the Fourier transform (with respect to  $x$ ) transfers the differentiation  $\frac{\partial}{\partial x}$  to algebraic multiplication by  $ix$ , while the other variable  $t$  remains as parameter.

Thus, the Fourier image  $\tilde{u}(\xi, t)$  must obey

$$\tilde{u}_t = -\kappa \xi^2 \tilde{u}, \quad \tilde{u}(\xi, 0) = \tilde{\varphi}.$$

This is a quite simple ODE problem with the general solution

$$\tilde{u}(\xi, t) = C(\xi) e^{-\kappa t \xi^2},$$

while the initial condition implies that the integration constant is just  $C(\xi) = \tilde{\varphi}$ .

Now remember the relation between the Fourier transform and convolution, 7.2.7 at page 660. The image of the convolution is the product of the images, up to the factor  $\sqrt{2\pi}$ . Thus we shall immediately write down the solution  $u$  with

$t > 0$ , once we find the inverse Fourier image of the Gaussian  $f(\xi) = e^{-\kappa t \xi^2}$ . But Fourier images  $\mathcal{F}(f)$  of Gaussians  $f$  are again Gaussians, up to constant, see ??,

$$\mathcal{F}(e^{-ax^2})(\xi) = \frac{1}{\sqrt{2a}} e^{-\frac{\xi^2}{4a}},$$

with any real constant  $a > 0$ . Thus, we can write for  $t > 0$

$$\tilde{u}(\xi, t) = \mathcal{F}(\varphi)\mathcal{F}\left(\frac{1}{\sqrt{2\kappa t}} e^{-\frac{\xi^2}{4\kappa t}}\right).$$

Finally, we obtain  $u$  as the convolution of the initial condition with the so called *heat kernel* function

$$u(x, t) = \frac{1}{2\sqrt{\pi\kappa t}} \int_{-\infty}^{\infty} e^{-\frac{(x-y)^2}{4\kappa t}} \varphi(y) dy.$$

Obviously, the solution depends continuously on the boundary condition. We may imagine it models the dynamics of temperature in an infinite homogeneous bar, with some initial distribution of temperature and no losses or gains of energy in time.

Let us also observe the behavior of the solution for  $t$  close to zero. As mentioned in 7.2.9, the Gaussians with variance converging to zero are a good approximation for the so called Dirac delta functions, and indeed the limit of the convolution for  $t \rightarrow 0_+$  is exactly the function  $\varphi$ , as expected.

We shall come back to such convolution based principles a few pages later, after investigating simpler methods.

**9.2.22. Superposition of the solutions.** A general idea to solve boundary value problems is to take a good supply of general solutions and try to take linear combination of even infinite many of them. This means we consider the solution in a form of a series. The type of the series is governed by the available solutions.

Let us illustrate the method on the diffusion equation discussed above. Imagine we want to model the temperature of a homogeneous bar of length  $d$ . Initially, at time  $t = 0$ , the temperature at all points  $x$  is zero. At one of its ends we keep the temperature zero, while the other end will be heated with some constant intensity. Set the bar as the interval  $x \in [0, d] \subset \mathbb{R}$ , and the domain  $\Omega = [0, d] \times [0, \infty)$ . Our boundary problem is

$$(1) \quad u_t = \kappa u_{xx}, \quad u(x, 0) = 0, \quad u(0, t) = 0, \quad \frac{\partial}{\partial x} u(d, t) = \rho,$$

where  $\rho$  is a constant representing the effect of the heating.

The idea is to exploit the general solutions

$$u(x, t) = (A \cos \alpha x + B \sin \alpha x) e^{-\alpha^2 \kappa t}$$

from 9.2.6 with free parameters  $\alpha$ ,  $A$ , and  $B$ . We want to consider a superposition of such solutions with properly chosen parameters and get the solution to our boundary problem in the form combining Fourier series terms with the exponentials. This approach is often called the *Fourier method*.

The condition  $u(0, t) = 0$  suggests to restrict ourselves to  $A = 0$ . Then,  $u_x(x, t) = B\alpha \cos(\alpha x) e^{-\alpha^2 \kappa t}$ . It seems to be difficult now to guess how to combine such solutions, to get something constant in time, as the Neumann part boundary condition requests. But we can help with a small trick.

There are some further obvious solutions to the equation – those with  $u$  depending on the space coordinate only. We may consider

$$v(x, t) = \rho x$$

and seek further our solution in the form  $u(x, t) + v(x)$ . Then  $u$  must again be a solution of the same diffusion equation (1), but the boundary conditions change to  $u(x, 0) = -\rho x$ ,  $u(0, t) = 0$ ,  $\frac{\partial}{\partial x} u(d, t) = 0$ .

Now, we want

$$u_x(x, t) = B\alpha \cos(\alpha x) e^{-\alpha^2 \kappa t} = 0,$$

i.e. we should restrict to frequencies  $\alpha = \frac{1}{2d} n\pi$ , with odd non-negative integers  $n$ . This has settled the second of the boundary condition. The remaining one is  $u(x, 0) = -\rho x$  which sets the condition on the coefficients  $B$  in the superposition

$$\sum_{k \geq 0} B_{2k+1} \sin\left(\frac{(2k+1)\pi x}{2d}\right) = -\rho x$$

on the interval  $x \in [0, d]$ . This is a simple task of finding the Fourier series of the function  $x$ , which we handled in 7.1.10. Combining all this, we get the requested solution  $u(x, t)$  to our problem:

$$\rho x - 8\rho d \frac{1}{\pi^2} \sum_{k \geq 0} \frac{(-1)^k}{(2k+1)^2} \sin\left(\frac{(2k+1)\pi x}{2d}\right) e^{-\kappa \frac{(2k+1)^2 \pi^2 t}{4d^2}}.$$

Even though our supply of general solutions was not big, superposing countably many of them helped us to solve our problem. Notice the behavior at the heated end. If  $t \rightarrow \infty$ , then the all exponential terms in the sum vanish faster than the very first one, the sine terms are bounded, and thus the entire component with the sum vanishes quite fast. Thus, for big  $t$ , the heated end will increase its temperature nearly linearly with the speed  $\rho$ .

**9.2.23. Separation in transformed coordinates.** As we

have seen several times, it is very useful to view a given equation rather as an independent object expressed in some particular coordinates.

The practical problems mostly include some symmetries and then we should like to find some suitable coordinates in order to see the equation in some simple form.

As an example, let us look at the Laplace operator  $\Delta$  in the polar coordinates in the plane, and cylindrical or spherical coordinates in the space. Writing as usual  $x = r \cos \varphi$ ,  $y = r \sin \varphi$  for the polar transformation, the Laplace operator gets the neat form

$$(1) \quad \Delta = \frac{\partial^2}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{r} \frac{\partial}{\partial r} = \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2}{\partial \varphi^2}.$$

The reader should perform the tedious but straightforward computation. Similarly,

$$(2) \quad \Delta = \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2}{\partial \varphi^2} + \frac{\partial^2}{\partial z^2},$$

$$(3) \quad \Delta = \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2 \sin^2 \psi} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{r^2 \sin \psi} \frac{\partial}{\partial \psi} \left( \sin \psi \frac{\partial}{\partial \psi} \right)$$

in the cylindrical and spherical coordinates, respectively.

Let us illustrate the use on the following problem. Imagine a twisted circular drum, whose rim suffers a small vertical displacement. We should model the stabilized position of the drumskin.

Intuitively, we should describe the drumskin position by the  $2D$  wave equation, but since we are interested in the state with  $\frac{\partial}{\partial t}$  vanishing, we actually take  $u$  as the vertical displacement in the interior of the unit circle,  $\Omega = \{x^2 + y^2 \leq 1\} \subset \mathbb{R}^2$  and request  $\Delta u = 0$ , subject to the Dirichlet boundary problem prescribing the vertical displacement  $u(x, y) = f(x, y)$  of the rim.

Obviously, we want to consider the problem in the polar coordinates, where the boundary condition gets the neat form  $u(1, \varphi) = g(\varphi)$ . Say  $g(\varphi) = \varepsilon \sin \varphi + \varepsilon^2 \sin 5\varphi$  with some small constant  $\varepsilon \geq 0$ .

We shall apply the separation of variables method to these data. Expecting the solution in the form  $u(r, \varphi) = R(r)\Phi(\varphi)$ , the equation implies (after dividing by  $R\Phi$ )

$$\frac{R''}{R} + \frac{1}{r} \frac{R'}{R} + \frac{1}{r^2} \frac{\Phi''}{\Phi} = 0.$$

Thus, multiplying by  $r^2$  and considering the separation constant  $\alpha^2$ , we arrive at two ODEs

$$\Phi'' + \alpha^2 \Phi = 0, \quad r^2 R'' + rR' - \alpha^2 R = 0.$$

Fortunately, they are both easy to solve. From the first equation (with  $\alpha > 0$ )

$$\Phi(\varphi) = A \cos \alpha\varphi + B \sin \alpha\varphi,$$

while the other equation transform by  $S(t) = R(\exp t)$  into an equation with constant coefficients and its solution yields

$$R(r) = Cr^\alpha + Dr^{-\alpha}$$

with  $\alpha \neq 0$ . If  $\alpha = 0$ , then the solution for  $R$  is  $R(r) = C \ln r + D$  and the previous equation implies  $\Phi(\varphi) = A\varphi + B$ .

In fact, we insist the solution  $u = R\Phi$  be a single valued function in the plane and so we can allow only integer values of  $\alpha$ , including  $\alpha = 0$  when  $\Phi$  becomes a constant (again, any non-zero multiple would lead to multi-valued solutions  $u$ ). Thus the general solution of the Laplace equation coming from the separation of variables method and superposition is

$$(4) \quad u(r, \varphi) = C_0 \ln r + D_0 + \sum_{n=1}^{\infty} (A_n \cos n\varphi + B_n \sin n\varphi)(C_n r^n + D_n r^{-n}).$$

In our problem, we clearly insist in having  $u$  finite at the origin and thus all  $D_n$  and the  $C_0$  have to vanish. Now we can employ the boundary condition

$$D_0 + \sum_{n=1}^{\infty} c_n (A_n \cos n\varphi + B_n \sin n\varphi) = \varepsilon \sin \varphi + \varepsilon \sin 5\varphi.$$

This is a very simple case of Fourier series and we see immediately that all the coefficients have to vanish except of the  $B_1$  and  $B_5$  and the requested solution is

$$u(r, \varphi) = \varepsilon r \sin \varphi + \varepsilon r^5 \sin 5\varphi.$$

The higher the frequency of the twist of the rim, the slower the distortion develops in the center of the drumskin. The method works for every boundary condition  $u(1, \varphi) = g(\varphi)$ , if we are able to find its Fourier series.

**9.2.24. The Helmholtz equation.** In 9.2.19, we looked for solutions of the nD wave equation  $u_{tt} - c^2 \Delta u = 0$  in the form  $u(x, t) = F(x)T(t)$ , where  $x \in \mathbb{R}^n$ ,  $t \in \mathbb{R}$ . This (partial) separation of variables with negative separation constant  $-\alpha^2$  leads to the *Helmholtz equation*

$$\Delta F + \alpha F = 0,$$

together with the easily solved  $T'' + \alpha^2 T = 0$ .

Let us treat the 2D case in the polar coordinates, again using separation of variables. Thus, the Helmholtz equation gets the form

$$\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2}{\partial \varphi^2} + \alpha^2 F = 0$$

and we seek for  $F(r, \varphi) = R(r)\Phi(\varphi)$ . Writing  $\beta^2$  for the separation constant now, we arrive at the two equations (the second one is multiplied by  $r^2$ , for convenience)

$$\Phi'' + \beta^2 \Phi = 0, \quad r^2 R'' + rR' + (\alpha^2 r^2 - \beta^2)R = 0.$$

The angular component equation has got the obvious solutions  $A \cos \beta\varphi + B \sin \beta\varphi$ , and again we have to restrict  $\beta$  to integers in order to get single-valued solutions. With  $\beta = m$ , the radial equation is the well known Bessel's ODE of order  $m$  (notice our equation gets the form we had in ?? once we substitute  $z = \alpha r$ ), with the general solution

$$R(r) = CJ_m(\alpha r) + DY_m(\alpha r),$$

where  $J_m$  and  $Y_m$  are the special Bessel functions of the first and second kinds.

We have obtained a general solution which is very useful in practical problems, cf. ??.

**9.2.25. Non-homogeneous equations.** Finally, we add a

few comments on the non-homogeneous linear PDEs. Although we provide arguments for the claims, we shall not go into technical details of proofs because of the lack of space. Still, we hope this limited insight will motivate the reader to seek for further sources to learn more.

As always, facing a problem  $Lu = f$ , we have to find a single particular solution to this problem, and we may then add all solutions to the homogeneous problem  $Lu = 0$ . Thus, if we have to match say Dirichlet conditions  $u = g$  on the boundary  $\partial\Omega$  of a domain  $\Omega$ , and we know some solution  $w$ , i.e.  $Lw = f$  (not taking care of the boundary conditions), then we should find a solution  $v$  to the homogenous Dirichlet problem with the boundary condition  $g - w|_{\partial\Omega}$ . Clearly the sum  $u = v + w$  will solve our problem.

In principle, we may always consider superpositions of known solutions as in the Fourier method above. We shall indicate a more conceptual and general approach now briefly.

Let us come back to the 1D diffusion equation and our solution of a homogeneous problem by means of the Fourier transform in 9.2.21. The solution of  $u_t = \kappa u_{xx}$  with  $u(x, 0) = \varphi$  is a convolution of the boundary values  $u(x, 0)$  with the *heat kernel*

$$(1) \quad Q(x, t) = \frac{1}{\sqrt{4\pi\kappa t}} e^{-\frac{x^2}{4\kappa t}}.$$

Now, the crucial observation is that  $u(x, t) = Q(x, t)$  is a solution to  $L(u) = u_t - \kappa u_{xx} = 0$  for all  $x$  and  $t > 0$ , while on neighborhood of the origin it behaves as the Dirac delta function in the variable  $x$ . (The first part is a matter of direct computation, the second one was revealed in 9.2.21 already.)

The latter observation suggests, how to find the particular solutions to a non-homogeneous problem. Consider the integral of the convolution

$$(2) \quad u(x, t) = \int_0^t \left( \int_{-\infty}^{\infty} Q(x-y, t-s) f(y, s) dy \right) ds.$$

The derivative  $u_t$  will have two terms. In the first one we differentiate with respect to the upper limit of the outer integral, while the other one is the derivative inside the integrals. The derivatives with respect to  $x$  are evaluated inside the integrals. Thus, in the evaluation of  $L = \frac{\partial}{\partial t} - \kappa \frac{\partial^2}{\partial x^2}$  the terms inside of the integral cancel each other (remember  $Q$  is a solution for all  $x$ , and  $t > 0$ ) and only the first term of  $u_t$  survives.

It seems obvious that this term is the evaluation of the integrand with  $s = t$ . Although, these values are not properly defined, we may verify this claim in terms of taking limit  $(t-s) \rightarrow 0_+$ . This leads to

$$\lim_{s \rightarrow t_-} \int_{-\infty}^{\infty} Q(x-y, t-s) f(y, s) dy = f(x, s).$$

Thus, (2) is a particular solution and clearly  $u(x, 0) = 0$ .

The solution of the general Dirichlet problem  $L(u) = f$ ,  $u(x, 0) = \varphi$  on  $\Omega = \mathbb{R} \times [0, \infty)$  is

$$(3) \quad u(x, t) = \int_{-\infty}^{\infty} Q(x-y, t) \varphi(y) dy + \int_0^t \left( \int_{-\infty}^{\infty} Q(x-y, t-s) f(y, s) dy \right) ds.$$

Let us summarize the achievements and try to get generalization to general dimensions.

First, we can generalize the heat kernel function  $Q$  writing its nD variant depending on the distance  $r$  from the origin only. Consider the formula with  $x \in \mathbb{R}^n$  as the product of the 1D heat kernels for each of the variables in  $x$ .

$$(4) \quad Q(x, t) = \frac{1}{\sqrt{(4\pi\kappa t)^n}} e^{-\frac{\|x\|^2}{4\kappa t}}.$$

Then taking the  $n$ -dimensional (iterated) convolution of  $Q$  with the boundary condition  $\varphi$  on the hyperplane  $t = 0$  provides the solution candidate

$$(5) \quad u(x, t) = \int_{\mathbb{R}^n} Q(x-y, t) \varphi(y) dy_1 \dots dy_n.$$

Indeed, a straightforward (but tedious) computation reveals that  $Q$  is a solution to  $L(u) = 0$  in all points  $(x, t)$  with  $t > 0$ , and  $Q$  behaves again as the Dirac delta at the origin. In particular (5) is a solution to the Dirichlet problem  $L(u) = 0$ ,  $u(x, 0) = \varphi$  and we can also obtain the non-homogeneous solutions similarly to the 1D case.

**9.2.26. The Green's functions.** The solutions to the (non-homogeneous) diffusion equation constructed in the last paragraph are built on a very simple idea – we find a solution  $G$  to our equation which is defined everywhere except in the origin and blows up in the origin at the speed making it into a Dirac delta function at the origin. A convolution with such kernel  $G$  is then a good candidate for solutions for . Let us try to mimic this approach for the Laplace and Poisson equations now.

Actually, we shall modify the strategy by requesting

ABOUT 1 PAGE TO BE FINISHED – THE SPHERICAL SYMMETRIC SOLUTION TO LAPLACE  $\Rightarrow$  GREEN'S FUNCTION  $\Rightarrow$  SOLUTION TO POISSON SIMILARLY TO THE DIFFUSION.

### 3. Remarks on Variational Calculus

Many practical problems look for minima or maxima of real functions  $\mathcal{J} : \mathcal{S} \rightarrow \mathbb{R}$  defined on some spaces of functions. In particular, many laws of nature can be expressed as certain “minimum principle” concerning some space of mappings.

The basic idea is exactly the same as in the elementary differential calculus: we aim at finding the best linear approximations of  $\mathcal{J}$  at fixed arguments  $u \in \mathcal{S}$ , we recognize the critical points (those with vanishing linearization), and then we perhaps look at the quadratic approximations at the critical points. However, all these steps are far more intricate, need a lot of care, and may provide nasty surprises.

#### 9.3.1. Simple examples first.

If we know the sizes of tangent vectors to curves, we may ask what is the shortest distance between two points. In the plane  $\mathbb{R}^2$ , this means we have got a quadratic form  $g(x) = (g_{ij}(x))$ ,  $1 \leq i, j \leq 2$ , at each  $x \in \mathbb{R}^2$  and we want to integrate (the dots mean derivatives in time  $t$ ,  $u(t) = (u_1(t), u_2(t))$  are differentiable paths)

$$(1) \quad \mathcal{J}(u) = \int_{t_1}^{t_2} \sqrt{g(u(t))(\dot{u}(t))} dt$$

to get the distance between the two given points  $u(t_1) = (u_1(t_1), u_2(t_1)) = A$  and  $u(t_2) = (u_1(t_2), u_2(t_2)) = B$ . If the size of the vectors is just the Euclidean one, and we consider curves  $u(t) = (t, v(t))$ , i.e., graphs of functions of one variable, the length (1) becomes the well known formula

$$(2) \quad \mathcal{J}(u) = \int_{t_1}^{t_2} \sqrt{1 + \dot{v}(t)^2} dt.$$

Quite certainly we all believe that the minimum for fixed boundary values  $v(t_1)$  and  $v(t_2)$  must be a straight line. But so far, we have not formulated the problem itself. What is the space of curves we deal with? If we allowed non-continuous ones, then shorter paths are available! So we should aim at proving that the lines are the minimal curves among the continuous ones. Do we need them to be differentiable? In some sense we do, since the derivative appears in our formula for  $\mathcal{J}$ , but we need to have the integrand defined only almost everywhere. For example, this will be true for all Lipschitz curves.

In general,  $g(u)(\dot{u}) = g_{11}(u)\dot{u}_1^2 + 2g_{12}(u)\dot{u}_1\dot{u}_2 + g_{22}(u)\dot{u}_2^2$ . Such lengths of vectors are automatically inherited from the ambient Euclidean  $\mathbb{R}^3$  on every hypersurface in the space. Thus, finding the minimum of  $\mathcal{J}$  means finding the shortest track in a real terrain (with hills and valleys).

If we choose a positive function  $\alpha$  on  $\mathbb{R}^2$  and consider  $g(x) = \alpha(x)^2 \text{id}_{\mathbb{R}^2}$ , i.e., the Euclidean size of vectors scaled by  $\alpha(x) > 0$  at each point  $x \in \mathbb{R}^2$ , we obtain

$$(3) \quad \mathcal{J}(u) = \int_{t_1}^{t_2} \alpha(t, v(t)) \sqrt{1 + \dot{v}(t)^2} dt.$$

We can imagine the speed  $1/\alpha$  of a moving particle (or light) in the plane depends of the values of  $\alpha$  (the smaller is  $\alpha$ , the

bigger is the speed) and our problem will be to find the shortest path in terms of the time necessary to pass from  $A$  to  $B$ .

As a warm up, consider  $\alpha = 1$  in the entire plane, except the vertical strip  $V = \{(t, y); t \in [a, a + b]\}$  where  $\alpha = N$  and take  $A = (0, 0)$ ,  $B = (a + b, c)$ ,  $a, b, c > 0$ . We can imagine  $V$  is a lake, you have to get from  $A$  to  $B$  by running and swimming, and you are swimming  $N$  times slower than running. If we believe that the straight lines are the minimizers for constant  $\alpha$ , then it is clear that we have to find the optimal point  $P = (a, p)$  on the bank of the lake where we start swimming. The total time  $T(p)$  will then be ( $s$  is our actual speed when running straight)

$$\frac{|AP|}{s} + \frac{|PB|}{s/N} = \frac{1}{s} \left( \sqrt{p^2 + a^2} + N \sqrt{(c - p)^2 + b^2} \right)$$

and we want to find the minimum of  $T(p)$ . The critical point is given by

$$\frac{p}{\sqrt{p^2 + a^2}} = N \frac{c - p}{\sqrt{(c - p)^2 + b^2}} \implies \sin \varphi = N \sin \psi,$$

where  $\varphi$  is the angle between our running track and the normal to the boundary of  $V$ , while  $\psi$  is the angle between our swimming track and the normal to the boundary (draw a picture yourself!). Thus we have recovered the famous Snell law of light diffraction saying that the proportion of the sine values of the angles is equal to the proportion of the speeds. (Of course, to finish the solution of the problem, the reader should find the solution  $p$  of the quartic equation and check that it is a minimum.)

**9.3.2. Variational problems.** We shall restrict our attention to the following class of problems.

GENERAL FIRST ORDER VARIATIONAL PROBLEMS

Consider an open Riemann measurable set  $\Omega \subset \mathbb{R}^n$ , the space  $C^1(\Omega)$  of all differentiable mappings  $u : \Omega \rightarrow \mathbb{R}^m$ , a  $C^2$  function  $F = F(x, y, p) : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{nm}$  and set the functional

$$(1) \quad \mathcal{J}(u) = \int_{\Omega} F(x, u(x), D^1 u(x)) \omega_{\mathbb{R}^n},$$

i.e.,  $\mathcal{J}(u)$  is computed as the ordinary integral of a Riemann integrable function  $f(x) = F(x, u(x), D^1 u(x))$  where  $D^1 u$  is the Jacobi matrix (the differential) of  $u$ . The function  $F$  is called the *Lagrangian* of the *variational problem* and our task is to find the minimum of  $\mathcal{J}$  and the corresponding *minimizer*  $u$  with prescribed boundary values  $u$  on the boundary  $\partial\Omega$  (and perhaps some further conditions restricting  $u$ ).

Mostly we shall restrict ourselves to the case  $n = m = 1$ , like in the previous paragraph, where  $u$  is a real differentiable function defined on an interval  $(t_1, t_2)$  and the function  $F = F(t, y, p) : \mathbb{R}^3 \rightarrow \mathbb{R}$ ,

$$(2) \quad \mathcal{J}(u) = \int_{\Omega} F(t, u(t), \dot{u}(t)) dt.$$

We saw  $F = \sqrt{1 + p^2}$ ,  $F = \alpha(t)\sqrt{1 + p^2}$  in the previous paragraph. If we take  $F = y\sqrt{1 + p^2}$ , the functional  $\mathcal{J}$  computes the area of the rotational surface given by the graph of the function  $u$  (up to a constant multiple). In all cases we may set the boundary values  $u(t_1)$  and  $u(t_2)$ .

Actually, our differentiability assumptions are too strict as we saw already in our last example above, where  $F$  was differentiable except of the boundary of the lake  $V$ . We can easily extend our space of functions to piecewise differentiable  $u$  and request  $F(t, u(t), \dot{u}(t))$  to be piecewise differentiable for all such  $u$ 's (as always, piecewise differentiable means the one-side derivatives exist at all points).

A maybe shocking example is the following functional:

$$(3) \quad \mathcal{J}(u) = \int_0^1 (\dot{u}(t)^2 - 1)^2 dt$$

on piece-wise differentiable functions on  $[0, 1]$  (i.e.  $F$  is the neat polynomial  $(p^2 - 1)^2$ ). Clearly,  $\mathcal{J}(u) \geq 0$  for all  $u$  and if we set  $u(0) = u(1) = 0$ , then any zig-zag piecewise linear function  $u$  with derivatives  $\pm 1$  satisfying the boundary conditions achieves the zero minimum. At the same time, there is no minimum among the differentiable functions  $u$  (find a quick proof of that!), but we can approximate any of the zig-zag minima by smooth ones at any precision.

**9.3.3. More examples.** Let us develop a general method how to find the analogy to the critical points form the elementary calculus here. We shall find the necessary steps dealing with a specific set of problems in this paragraph. Let us work with the Lagrangian generalizing the previous examples:

$$(1) \quad F(t, y, p) = y^r \sqrt{1 + p^2}$$

$r > 0$ , and write  $F_t, F_y, F_p$ , etc., for the corresponding partial derivatives. Consider the variational problem on an interval  $I = (t_1, t_2)$  with fixed boundary conditions  $u(t_1)$  and  $u(t_2)$  and assume  $u \in C^2(I)$ ,  $u(t) > 0$ . Let us consider any differentiable  $v$  on  $I$  with  $v(t_1) = v(t_2) = 0$  (or even better  $v$  with compact support inside of  $I$ ). Then  $u + \delta v$  fulfills the boundary conditions for all small real  $\delta$ 's and consider

$$\mathcal{J}(u + \delta v) = \int_{t_1}^{t_2} F(t, u(t) + \delta v(t), \dot{u}(t) + \delta \dot{v}(t)) dt.$$

Of course, the necessary condition for  $u$  being a critical point must be  $\frac{d}{d\delta}|_0 \mathcal{J}(u + \delta v) = 0$ , i.e., (remind the derivative with respect to a parameter can be swapped with the integration)

$$(2) \quad 0 = \int_{t_1}^{t_2} F_y(t, u(t), \dot{u}(t))v(t) + F_p(t, u(t), \dot{u}(t))\dot{v}(t) dt.$$

Integrating the second term in (2) per partes immediately yields (remember  $v(t_1) = v(t_2) = 0$ )

$$0 = \int_{t_1}^{t_2} (F_y(t, u(t), \dot{u}(t))v(t) - \frac{d}{dt} F_p(t, u(t), \dot{u}(t)))v(t) dt.$$

This condition will be certainly satisfied if the so called *Euler equation* holds true for  $u$  (we prove this is a necessary condition in lemma 9.3.6)

$$(3) \quad \frac{d}{dt} F_p(t, u(t), \dot{u}(t)) = F_y(t, u(t), \dot{u}(t)).$$

An equivalent form of this equation for  $\dot{u}(t) \neq 0$  is (we omit the arguments  $t$  of  $u$  and  $\dot{u}$ )

$$(4) \quad F_t(t, u, \dot{u}) = \frac{d}{dt} (F(t, u, \dot{u}) - \dot{u} F_p(t, u, \dot{u})).$$

In our case of  $F(t, y, p) = y^r (1 + p^2)^{1/2}$ ,  $F_t$  vanishes identically,  $F_p = y^r p (1 + p^2)^{-1/2}$  and thus, if we further assume  $r \neq 0$ ,  $u > 0$ , the term in the bracket has to be a positive constant  $C^r$ :

$$C^r = u^r (1 + \dot{u}^2)^{1/2} - \dot{u} u^r \dot{u} (1 + \dot{u}^2)^{-1/2} = u^r (1 + \dot{u}^2)^{-1/2}.$$

We have arrived at the differential equation

$$(5) \quad u = C(1 + \dot{u}^2)^{1/2r}$$

which we are going to solve.

Consider the transformation  $\dot{u} = \tan \tau$ , i.e.,

$$u = C(1 + (\tan \tau)^2)^{1/2r} = C(\cos \tau)^{-1/r},$$

and so  $du = \frac{C}{r} (\cos \tau)^{-1/r} \tan \tau d\tau$ . Consequently,  $dt = \frac{1}{\dot{u}} du = \frac{C}{r} (\cos \tau)^{-1/r} d\tau$  and by integration we arrive at the very useful parametrization of the solutions by the parameter  $\tau$  (which is actually the slope of the tangent to the solution graph):

$$(6) \quad t = t_0 + \frac{C}{r} \int_0^\tau (\cos s)^{-1/r} ds \quad u = C(\cos \tau)^{-1/r}.$$

Now, we can summarize the result for several interesting values of  $r$ . First, if  $r = 0$  (which we excluded on the way), then the Euler equation (3) reads

$$\ddot{u}(1 + \dot{u}^2)^{-3/2} = 0,$$

which implies  $\ddot{u} = 0$  and thus the potential minimizers should be straight lines as expected. (Notice that we have not proved yet that the Euler equation is indeed a necessary condition, we shall come to that in the next paragraphs.)

For general  $r \neq 0$ , the Euler equation (3) tells (a straightforward computation!)

$$\ddot{u} = r \frac{1 + \dot{u}^2}{u}$$

and thus the sign of the second derivative coincides with the sign of  $r$ . In particular, the potential minimizers are always concave functions (if  $r < 0$ ) or convex (if  $r > 0$ ).

If  $r = -1$ , the parametrization (6) leads to (an easy integration!)

$$(7) \quad t = t_0 - C \sin \tau, \quad u = C \cos \tau,$$

thus for  $\tau \in [-\pi/2, \pi/2]$  our solutions are half-circles with radius  $C$  in the upper halfplane, centred at  $(t_0, 0)$ .

For  $r = -1/2$ , the solution is

$$(8) \quad t = t_0 - \frac{C}{2} (2\tau + \sin 2\tau), \quad \frac{C}{2} (1 + \cos 2\tau)$$

which is a parametric description of a fixed point on a circle with diameter  $C$  rolling along the  $t$  axis, the so called *cycloid* curve. Now,  $\tau \in [-\pi/2, \pi/2]$  provides  $t$  running from  $t_0 + \frac{1}{2}C\pi$  to  $t_0 - \frac{1}{2}C\pi$ , while  $u$  is zero in the point  $t_0 \pm \frac{1}{2}C\pi$  and reaches the highest point at  $t = t_0$ . (Draw pictures!)

Next, look at  $r = 1/2$ . Another quick integration reveals  $t = t_0 + 2C \tan \tau = t_0 + 2C\dot{u}$ , and we can compute  $\dot{u}$  and substitute into (5) to obtain

$$u = C + \frac{1}{4C}(t - t_0)^2.$$

Thus the potential minimizers are parabolas with the axis of symmetry  $t = t_0$ . If we fix  $A = (0, 1)$  and a  $t_0$ , there are two relevant choices  $C = \frac{1}{2}(1 \pm \sqrt{1 - t_0^2})$  whenever  $|t_0| < 1$  (and no options for  $|t_0| > 1$ ). The two parabolas will have two points of intersection,  $A$  and another point  $B$ . Clearly only one of them should be the actual minimizer. Moreover, the reader could try to prove that the parabola  $u = \frac{1}{4}t^2$  touches all of them and has them all on the left (this is the so called envelope of all the family of parabolas). Thus, there will be no potential minimizer joining the point  $A = (1, 0)$  to an arbitrary point on the right of the parabola  $u = \frac{1}{4}t^2$ .

The last case we come to is  $r = 1$ , i.e., the case of the area of the surface of the rotational body drawn by the graph. Here we better use another parametrization of the slope of the tangent, we set  $\dot{u} = \sinh \tau$ . A very similar computation as above then immediately leads to  $t = t_0 + \frac{C}{r} \int_0^\tau \cosh s \, ds$  and we arrive at the result<sup>7</sup>

$$(9) \quad u(t) = C \cosh \frac{t-t_0}{C}.$$

**9.3.4. Critical points of functionals.** Now we shall develop a bit of theory verifying that the steps done in the previous examples really provided necessary conditions for solutions of the variational problems. In order to underline the essential features, we shall first introduce the basic tools in the realm of general normed vector spaces, see 7.3.1. The spaces of piecewise differentiable functions on an interval with the  $L_p$  norms can serve as typical examples. We shall deal with mappings  $\mathcal{F} : \mathcal{S} \rightarrow \mathbb{R}$  called (real) *functionals*.

#### THE FIRST DIFFERENTIAL

Let  $\mathcal{S}$  be a vector space equipped with a norm  $\| \cdot \|$ . A continuous linear mapping  $L : \mathcal{S} \rightarrow \mathbb{R}$  is called a *continuous linear functional*.

A functional  $\mathcal{F} : \mathcal{S} \rightarrow \mathbb{R}$  is said to have the *differential*  $D_u \mathcal{F}$  at a point  $u \in \mathcal{S}$  if there is a continuous linear functional  $L$  such that

$$(1) \quad \lim_{v \rightarrow 0} \frac{\mathcal{F}(u+v) - \mathcal{F}(u) - L(v)}{\|v\|} = 0.$$

<sup>7</sup>Some more details on the set of examples of this paragraph can be found in the article "Elementary Introduction to the Calculus of Variations" by Magnus R. Hestenes, *Mathematics Magazine*, Vol. 23, No. 5 (May - Jun., 1950), pp. 249-267.

In the very special case of the Euclidean  $\mathcal{S} = \mathbb{R}^n$ , we have recovered the standard definition of the differential, cf. 8.1.7 (just notice that all linear functionals are continuous on a finite dimensional vector space). Again, the differential is computed via the directional derivatives.<sup>8</sup> Indeed, if (1) holds true, then for each fixed  $v \in \mathcal{S}$

$$(2) \quad \delta\mathcal{F}(u)(v) = \lim_{t \rightarrow 0} \frac{\mathcal{F}(u + tv) - \mathcal{F}(u)}{t} = \frac{d}{dt}\bigg|_0 \mathcal{F}(u + tv)$$

exists and  $L(v) = \delta\mathcal{F}(u)(v)$ . We call  $\delta\mathcal{F}(u)$  the *variation of the functional  $\mathcal{F}$  at  $u$* .

A point  $u \in \mathcal{S}$  is called a *critical point* if  $\delta\mathcal{F}(u) = 0$ . We say that  $\mathcal{F}$  has got a *local minimum* at  $u$  if there is an open neighborhood  $U$  of  $u$  such that  $\mathcal{F}(w) \geq \mathcal{F}(u)$  for all  $w \in U$ . Similarly, we define local maxima and talk about local extrema.

If  $u$  is an extreme of  $\mathcal{F}$ , then in particular  $t = 0$  must be an extreme of the function  $\mathcal{F}(u + tv)$  of one real variable  $t$ , where  $v$  is arbitrary. Thus the extremes have to be at critical points, if the variations exist.

Next, let us assume the variations exist at all points in a neighborhood of a critical point  $u \in \mathcal{S}$ . Then, again exactly as in the elementary calculus, considering two increments  $v, w \in \mathcal{S}$  we consider the limit

$$(3) \quad \delta^2\mathcal{F}(u)(v, w) = \lim_{t \rightarrow 0} \frac{\delta\mathcal{F}(u + tv)(w) - \delta\mathcal{F}(u)(w)}{t}.$$

If the limits exist for all  $u, v$ , then clearly  $\delta^2\mathcal{F}(u)$  is a bilinear mapping. Then,  $\delta^2\mathcal{F}(u)(w, w)$  is a quadratic form which we can consider as a second order approximation of  $\mathcal{F}$  at  $u$ . We call it the *second variation of  $\mathcal{F}$* . Moreover, again as in the elementary calculus,  $\delta^2\mathcal{F}(u)(w, w) = \frac{d^2}{dt^2}\bigg|_0 \mathcal{F}(u + tw)$ , if the second variation exists. We may summarize:

**Theorem.** *Let  $\mathcal{F} : \mathcal{S} \rightarrow \mathbb{R}$  be a functional with a local extreme in  $u \in \mathcal{S}$ . If the variation  $\delta\mathcal{F}(u)$  exists, then it has to vanish. If the second variation  $\delta^2\mathcal{F}(u)$  exists (thus in particular,  $\delta\mathcal{F}$  exists on a neighborhood of  $u$ ), then  $\delta^2\mathcal{F}(u)(w, w) \geq 0$  for a minimum, while  $\delta^2\mathcal{F}(u)(w, w) \leq 0$  for a maximum.*

**PROOF.** Assume  $\mathcal{F}$  has got a local minimum at  $u$ . We have already seen,  $f(t) = \mathcal{F}(u + tv)$  has to achieve a local minimum for each  $v$  at  $t = 0$ . Thus  $f'(0) = 0$  if  $f(t)$  is differentiable, and so  $\delta\mathcal{F}(u)$  vanishes.

Now assume  $\delta^2\mathcal{F}(u)(w, w) = f''(0) = \tau < 0$  for some  $w$ . Then the mean value theorem implies

$$f(t) - f(0) = f'(c)t = \frac{1}{c}(f'(c) - f'(0))ct$$

for some  $t \geq c > 0$ . Thus, for  $t$  small enough  $f(t) - f(0) < 0$  which contradicts  $f(0)$  being a local minimum.

The claim for maximum follows analogously (or we may apply the already proved result to the functional  $-\mathcal{F}$ ).  $\square$

<sup>8</sup>In functional analysis, this directional derivative is usually called the *Gâteaux differential*, while the continuous functional  $L$  satisfying (1) is usually called the *Fréchet differential*, going back to two of the founders of functional analysis from the beginning of the 20th century.

**Corollary.** *On top of all assumptions of the above theorem suppose  $\mathcal{F}(v + tw)$  is 2 times differentiable at  $t = 0$  and  $\delta^2 \mathcal{F}(v)(w, w) \geq 0$  for all  $v$  in a neighborhood of the critical point  $u$  and  $w \in \mathcal{S}$ . Then  $\mathcal{F}$  has got a minimum at  $u$ .*

**PROOF.** As before we consider  $f(t) = \mathcal{F}(u + tw)$ ,  $w = z - u$ . Thus, for some  $0 < c \leq 1$

$$\begin{aligned} \mathcal{F}(z) - \mathcal{F}(u) &= f(1) - f(0) = f'(0) + \frac{1}{2}f''(c) \\ &= \frac{1}{2}\delta^2 \mathcal{F}(u + cw)(w, w) \geq 0. \end{aligned}$$

□

**Remark.** Actually, the condition from the collorary is far too strong in infinite dimensional spaces. It is possible to replace it by the condition  $\delta^2 \mathcal{F}$  continuous at  $u$  and  $\delta^2 \mathcal{F}(u)(w, w) \geq C\|w\|^2$  for some real constant  $C > 0$  just in the critical point  $u$ . In the finite dimensional case, this is equivalent to the requirement  $\delta^2 \mathcal{F}$  continuous and positive definite.

**9.3.5. Back to variational problems.** As we already noticed, the answer to a variational problem minimizing a functional (we omit the arguments  $t$  of the unknown function  $u$ )

$$(1) \quad \mathcal{J}(u) = \int_{t_1}^{t_2} F(t, u, \dot{u}) dt$$

depends very much on the boundary conditions and the space of functions we deal with. If we posit  $u(t_1) = A$ ,  $u(t_2) = B$  with arbitrary  $A, B \in \mathbb{R}$  we may deal with spaces of differentiable or piecewise differentiable functions satisfying these boundary conditions. But these subspaces will not be vector spaces any more. Thus, strictly speaking, we cannot apply the concepts from the previous paragraph here.

However, we may fix any differentiable function  $v$  on  $[t_1, t_2]$  satisfying  $v(t_1) = A$ ,  $v(t_2) = B$ , e.g.  $v(t) = A + (B - A)\frac{t-t_1}{t_2-t_1}$ , and replace the functional  $\mathcal{J}$  by

$$\tilde{\mathcal{J}}(u) = \mathcal{J}(u + v) = \int_{t_1}^{t_2} F(t, u + v, \dot{u} + \dot{v}) dt.$$

Now, the intitial problem transforms to one with boundary conditions  $u(t_1) = u(t_2) = 0$  and computing the variations  $\frac{d}{d\delta} \tilde{\mathcal{J}}(u + \delta w) = \frac{d}{d\delta} \mathcal{J}(u + v + \delta w)$  does not change, i.e. we have to request  $w(t_1) = w(t_2) = 0$  and we differentiate in a vector space.

Essentially, we just exploit the natural affine structures on the subspaces of functions defined by the general boundary conditions and thus the derivatives have to live in their modeling vector subspaces.

THE FIRST AND SECOND VARIATIONS

**Corollary.** Let  $F(t, y, p)$  be a twice differentiable Lagrangian and consider the variational problem of finding a minimum of the functional (1) on the space of differentiable functions  $u \in C^1[t_1, t_2]$  with boundary conditions  $u(t_1) = A$ ,  $u(t_2) = B$ . Then the first and second variations exist and can be computed for all  $v \in \mathcal{S} = \{v \in C^1[t_1, t_2]; v(t_1) = v(t_2) = 0\}$ , as follows:

$$(2) \quad \delta\mathcal{J}(u)(v) = \int_{t_1}^{t_2} (F_y(t, u, \dot{u})v + F_p(t, u, \dot{u})\dot{v}) dt$$

$$(3) \quad \delta^2\mathcal{J}(u)(v, v) = \int_{t_1}^{t_2} (F_{yy}(t, u, \dot{u})v^2 + 2F_{yp}(t, u, \dot{u})v\dot{v} + F_{pp}(t, u, \dot{u})\dot{v}^2) dt.$$

If  $u$  is a local minimum of the variational problem, then  $\delta\mathcal{J}(u)(v) = 0$  for all  $v \in \mathcal{S}$ , while  $\delta^2\mathcal{J}(u)(v, v) \geq 0$  for all  $v$  in a neighborhood of the origin in  $\mathcal{S}$ .

**PROOF.** Thanks to our strong assumptions on the differentiability of  $F$ ,  $u$ , and  $v$ , we may differentiate the real function  $f(t) = \mathcal{J}(u + tv)$  at  $t = 0$  swapping the integral and the derivative. This immediately provides both formulae.

The remaining two claims are straightforward consequences of the theorem and corollary in the previous paragraph 9.3.4.  $\square$

**9.3.6. Euler-Lagrange equations.** We are following the path which we already tried when discussing our first bunch of examples in 9.3.3. Our next step was to guess the consequences of vanishing of the first variation in terms of a differential equation. Now we complete the arguments. We start with a simple result called the *fundamental lemma of the calculus of variation*.

**Lemma.** Assume  $u$  is a continuous function on the interval  $[t_1, t_2]$  and for all compactly supported smooth  $\varphi \in C_c^\infty[t_1, t_2]$ ,

$$\int_{t_1}^{t_2} u(t)\varphi(t) dt = 0.$$

Then  $u$  vanishes identically on  $[t_1, t_2]$ .

**PROOF.** Assume there is a  $c \in (t_1, t_2)$  such that  $u(c) > 0$ . Due to the continuity,  $u(t) > u(c)/2 > 0$  on a neighborhood  $(c - s, c + s) \subset (t_1, t_2)$ ,  $s > 0$ . Next, remind the smooth variants of indicator functions constructed in 6.1.10. For every pair of positive numbers  $0 < \varepsilon < r$ , we constructed a function  $\varphi_{\varepsilon, r}(t)$  of one real variable  $t$  such that  $\varphi_{\varepsilon, r}(t) = 1$  for  $|t| < r - \varepsilon$ , while  $\varphi_{\varepsilon, r}(t) = 0$  for  $|t| > r + \varepsilon$ , and  $0 \leq \varphi_{\varepsilon, r}(t) \leq 1$  everywhere. Thus, choosing such a function for  $\varphi$ , with  $r + \varepsilon < s$  and the origin shifted to  $t = c$ , we certainly obtain

$$\int_{t_1}^{t_2} u(t)\varphi(t) dt > \frac{1}{2}u(c)2(r - \varepsilon) > 0.$$

If we find some negative value  $u(c)$ , the same argumentation finishes the proof (notice there is no need to consider the boundary points due to the continuity of  $u$ ).  $\square$

## EULER-LAGRANGE EQUATIONS

**Theorem.** Consider a twice differentiable Lagrangian  $F(t, y, p)$  on  $[t_1, t_2] \times \mathbb{R}^2$  and a differentiable critical point  $u$  of the functional  $\mathcal{J}(u) = \int_{t_1}^{t_2} F(t, u, \dot{u}) dt$  with fixed boundary values  $u(t_1), u(t_2)$ . Then  $u$  is a solution of the differential equation

$$(1) \quad F_y(t, u, \dot{u}) - \frac{d}{dt} F_p(t, u, \dot{u}) = 0.$$

Notice that the derivative in the second term of the Euler-Lagrange equation means the so called *total derivative*, i.e. we should differentiate the composed mapping via the chain rule. This can be a problem, if we do not assume  $u$  to be twice differentiable.

**PROOF.** We already know that vanishing of the first variation  $\delta\mathcal{J}(u)$  is a necessary condition for  $u$  being a critical point. Thus we can start with the equality (2) in the previous paragraph 9.3.5 and compute by integrating per partes:

$$(2) \quad \begin{aligned} 0 &= \int_{t_1}^{t_2} (F_y(t, u, \dot{u})v + F_p(t, u, \dot{u})\dot{v}) dt \\ &= \int_{t_1}^{t_2} (F_y(t, u, \dot{u}) - \frac{d}{dt} F_p(t, u, \dot{u}))v dt \\ &\quad + F_p(t, u, \dot{u})v|_{t=t_2} - F_p(t, u, \dot{u})v|_{t=t_1}. \end{aligned}$$

Finally we exploit the above fundamental lemma of the calculus of variation with arbitrary smooth test functions  $v$  with compact supports inside  $(t_1, t_2)$ . Thus the last term with boundary values vanishes and by the lemma, the Euler-Lagrange equation has to hold true for  $u$ .  $\square$

**9.3.7. Remarks.** We made our life comfortable by taking very strong differentiability assumptions in the theorem above. In the last century, there was a lot effort to get much more general results with weaker assumptions. This is really important in practice where we need to deal with piece-wise differentiable extremals. On the other hand, we need even twice differentiable critical points in order to write down the Euler-Lagrange equation explicitly.

Another difficult point is to recognize which of the critical points are the minima or maxima of the functional. We saw that the second variation is a very specific quadratic functional, see 9.3.5(3), and there is a rich theory dealing with its properties. We do not have time to go into details here, but we mention just one simple necessary condition for the extreme (with a bit tricky proof), to get feeling about the topic).

**Lemma** (Lagrange necessary condition). Consider a twice differentiable Lagrangian  $F(t, y, p)$  on  $[t_1, t_2] \times \mathbb{R}^2$  and a differentiable critical point  $u$  of the functional  $\mathcal{J}(u) = \int_{t_1}^{t_2} F(t, u, \dot{u}) dt$  with fixed boundary values  $u(t_1), u(t_2)$ . If

$u$  is a local minimum of  $\mathcal{J}$ , then  $F_{pp}(t, u(t), \dot{u}(t)) \geq 0$  on the entire interval  $[t_1, t_2]$ .

**PROOF.** Assume there is  $t_0 \in (t_1, t_2)$  such that  $F_{pp}(t_0, u(t_0), \dot{u}(t_0)) = -\mu < 0$ . Similarly as in the proof of the fundamental lemma in the previous paragraph, we choose  $s > 0$  so that  $F_{pp}(t, u, \dot{u}) < -\frac{1}{2}\mu$  on  $(t_0 - s, t_0 + s)$ , and a smooth analog of an indicator function  $\varphi = \varphi_{\varepsilon, r}$ , centered at  $t_0$  and satisfying  $r + \varepsilon < s$ . Then the second variation evaluated on  $v(t) = \alpha\varphi(t_0 + \frac{t}{\alpha})$  with some  $\alpha > 0$  can be estimated as follows (we use a constant  $C > |F_{yy}(t, u, \dot{u})|$ ,  $C > |F_{yp}(t, u, \dot{u})|$  on the entire interval, the fact that  $\dot{v} = \dot{\varphi}$  and the derivative  $|\dot{\varphi}_{\varepsilon, r}|$  integrates over its support to two, and the substitution  $\tau = t_0 + \frac{t}{\alpha}$ )

$$\begin{aligned} \delta^2 \mathcal{J}(u)(\varphi, \varphi) &= \int_{t_1}^{t_2} (F_{yy}(t, u, \dot{u})v^2 + 2F_{yp}(t, u, \dot{u})v\dot{v} \\ &\quad + F_{pp}(t, u, \dot{u})\dot{v}^2) dt \\ &\leq \int_{t_0-\alpha s}^{t_0+\alpha s} (C\alpha^2 + 2C\alpha|\dot{v}|) dt - \frac{1}{2}\mu \int_{t_0-\alpha s}^{t_0+\alpha s} \dot{v}^2 dt \\ &= 2Cs\alpha^3 + 2C\alpha^2 \int_{t_0-s}^{t_0+s} |\dot{\varphi}| d\tau - \frac{1}{2}\mu\alpha \int_{t_0-s}^{t_0+s} \dot{\varphi}^2 d\tau \\ &= 2Cs\alpha^3 + 4Cs\alpha^2 - \frac{1}{2}\mu \left( \int_{t_0-s}^{t_0+s} \dot{\varphi}^2 d\tau \right) \alpha. \end{aligned}$$

The integral on the right-hand side is strictly positive and, thus, the entire expression is negative if  $\alpha$  is small enough. This is a contradiction and the proof is complete.  $\square$

**9.3.8. Special cases.** Very often the Lagrangians do not depend on all variables and then the variations and the Euler-Lagrange equations get special forms. The following summary is a straightforward consequence of the general equation 9.3.6(1), whose equivalent form we saw already in 9.3.3(4)

## SPECIAL FORMS OF LAGRANGIANS

**Case 1.** If the Lagrangian is  $F(t, y)$ , i.e., does not depend on the derivatives, then the Euler-Lagrange equation says

$$(1) \quad F_y(t, u) = 0$$

which is an implicit equation for  $u(t)$ . Moreover, the second variation is  $\delta^2 \mathcal{J}(u)(v, v) = \int_{t_1}^{t_2} F_{yy}(t, u)v^2 dt$ .

**Case 2.** If the Lagrangian is  $F(t, p)$ , then the Euler-Lagrange equation is

$$(2) \quad \frac{d}{dt} F_p(t, \dot{u}) = 0$$

and its solutions are given by the first order differential equation  $F_p(t, \dot{u}) = C$  with a constant parameter  $C$ . Moreover, the second variation is  $\delta^2 \mathcal{J}(u)(v, v) = \int_{t_1}^{t_2} F_{pp}(t, \dot{u})v\dot{v}^2 dt$ .

**Case 3.** If the Lagrangian is  $F(u, \dot{u})$ , then there is a consequence of the Euler-Lagrange equation (for  $\dot{u} \neq 0$ )

$$(3) \quad \frac{d}{dt} (F(u, \dot{u}) - \dot{u}F_p(u, \dot{u})) = 0$$

which again reduces the equation to the first order including a free constant parameter.

#### 4. Complex Analytic Functions

In the rest of the chapter, we shall look at the (single complex variable) functions defined on the complex plane  $\mathbb{C} = \mathbb{R}^2$ . On many occasions we saw how helpful it was to extend objects from the real line into the complex plane. We provide a few glimpses into the rich classical theory, and we hope the readers will enjoy the use of it in the practical column.

**9.4.1. Complex derivative.** An open and connected subset  $\Omega \subset \mathbb{C}$  is called a *region*, or a *domain*. A mapping  $f : \Omega \rightarrow \mathbb{C}$  is called a *complex function of a single complex variable*. Working with complex numbers, we may repeat the definition of derivative:

##### COMPLEX DERIVATIVE

We say that a complex function  $f : \Omega \rightarrow \mathbb{C}$  has the *complex derivative*  $f'(a)$  at a point  $a \in \Omega$ , if the complex limit

$$f'(a) = \lim_{z \rightarrow a} \frac{f(z) - f(a)}{z - a} \in \mathbb{C}$$

exists. We say that  $f$  is *differentiable* in the complex sense, or *holomorphic*, on  $\Omega$ , if its complex derivative  $f'(z)$  exists at each  $z \in \Omega$ .

Clearly, this definition restricts itself to the definition of the derivative of functions of one real variable along  $\mathbb{R} \subset \mathbb{C}$ , when restricting the defining limit to real  $z$  and  $a$ . We shall see that the existence of a complex derivative is much more restrictive than in the real case.

The simplest example of a differentiable complex function is  $z \mapsto z^n$ ,  $n \in \mathbb{N}$ .

Indeed, exactly as with the real polynomials, we compute  $(z+h)^n - z^n = h(nz^{n-1} + \frac{1}{2}n(n-1)z^{n-2}h + \dots + h^{n-1})$  and thus for all  $z \in \mathbb{C}$  we obtain the limit

$$(z^n)' = \lim_{h \rightarrow 0} \frac{(z+h)^n - z^n}{h} = nz^{n-1}.$$

By the very definition, the mapping  $f \mapsto f'$  is linear over the complex scalars and thus all polynomials  $f(z)$  are differentiable this way:

$$f(z) = \sum_{k=0}^n a_k z^k \mapsto f'(z) = \sum_{k=0}^{n-1} (k+1)a_{k+1} z^k.$$

**9.4.2. Analytic functions.** A complex function  $f : \Omega \rightarrow \mathbb{C}$  is called *analytic* in the region  $\Omega$  if for each  $a \in \Omega$ , there is an open disc  $D = \{|z-a| < r\} \subset \Omega$  on which  $f$  is represented by a convergent power series

$$(1) \quad f(z) = \sum_{n=0}^{\infty} c_n (z-a)^n.$$

The restrictions of such power series to real arguments  $z$  are the analytic functions dealt with already in Chapter 5 and the direct proof of the following theorem (not relying on any real multivariate calculus) was promised already in 5.4.10.

The theorem reveals that the analytic functions behave as polynomials. The basic principle in its proof is to try to bound a series which we know very little about, by a geometric series, which we fully understand. This is a frequent technique in analysis. An important property of every power series is that it is (complex) differentiable within its radius of convergence.<sup>9</sup>

CONVERGENCE AND DERIVATIVE OF POWER SERIES

**Theorem.** Consider an analytic function (1). There exists  $R$ , which is either a non-negative real number or infinity, such that

- $f(z)$  converges absolutely if  $|z - a| < R$ ;
- $f(z)$  diverges if  $|z - a| > R$ ;
- $\frac{1}{R} = \limsup_{n \rightarrow \infty} |c_n|^{\frac{1}{n}}$ .

Further, if the radius of convergence is  $R > 0$ , then  $f$  is differentiable (in complex sense) for  $|z - a| < R$ , and its derivative equals the power series

$$f'(z) = \sum_{n=1}^{\infty} n c_n (z - a)^{n-1},$$

obtained by differentiating  $f(z)$  term by term. Moreover, the power series representing  $f'(z)$  has the same radius of convergence as  $f(z)$ .

The open disc  $|z - a| < R$  is called the *disc of convergence* of  $f(z) = \sum_{n=0}^{\infty} c_n (z - a)^n$ .

**PROOF.** Let  $L = \frac{1}{R}$ . Suppose  $|z - a| < R$ . We show that  $\sum_{n=0}^{\infty} c_n (z - a)^n$  converges. Notice, we mean that  $L = 0$  if  $R = \infty$ , and so the statement is trivially true in this case. For our fixed  $z$ , there is  $\varepsilon > 0$  such that  $(L + \varepsilon)|z - a| < 1$ .

Since  $L = \limsup_{n \rightarrow \infty} |c_n|^{\frac{1}{n}}$ , this means that  $|c_n|^{\frac{1}{n}} < L + \varepsilon$ , i.e.  $|c_n| < (L + \varepsilon)^n$  for sufficiently large  $n$ . Therefore,  $|c_n||z - a|^n \leq (L + \varepsilon)^n |z - a|^n$  and  $\sum_{n=0}^{\infty} |c_n||z - a|^n$  is majorized by the convergent geometric series  $\sum_{n=0}^{\infty} \rho^n$  with  $\rho = (L + \varepsilon)|z - a|$ . Therefore  $f(z) = \sum_{n=0}^{\infty} c_n (z - a)^n$  converges.

Now suppose  $|z - a| > R$ . By the definition of  $\limsup$ , for any  $\varepsilon > 0$ , there exists infinitely many  $c_n$  satisfying  $|c_n| > (L - \varepsilon)^n$ .

Choose  $\varepsilon > 0$  small enough such that  $(L - \varepsilon)|z - a| > 1$ . Then  $|c_n||z - a|^n > (L - \varepsilon)^n |z - a|^n$  for infinitely many  $n$ , and because  $(L - \varepsilon)|z - a| > 1$ , this implies that  $c_n (z - a)^n$  does not converge to 0 as  $n \rightarrow \infty$ . Therefore  $\sum_{n=0}^{\infty} c_n (z - a)^n$  diverges.

Next, we move to the derivative. First, notice that  $f(z) = \sum_{n=0}^{\infty} c_n (z - a)^n$  and  $g(z) = \sum_{n=1}^{\infty} n c_n (z - a)^{n-1}$  have the same radius of convergence because  $\lim n^{\frac{1}{n}} = 1$ .

<sup>9</sup>Actually the opposite implication is true as well: A holomorphic function on a domain  $\Omega$  is analytic on  $\Omega$ . We shall not provide a full proof of this result, but we come close to it below. The reader may find the full argument at nearly all basic textbooks on complex analysis.

Fix  $z_0$  in the disc of convergence, so that  $|z_0 - a| < r < R$  for some value of  $r$ . Let  $S_N(z)$ ,  $E_N(z)$  be defined by

$$S_N(z) = \sum_{n=0}^N c_n(z-a)^n, \quad E_N(z) = \sum_{n=N+1}^{\infty} c_n(z-a)^n.$$

We may think of  $S_N$ , which consists of the lower order terms of the power series, as the *main term*, and  $E_N$  as the *error term*. Notice that  $g(z) = \sum_{n=1}^{\infty} n c_n(z-a)^{n-1}$  is the term-by-term derivative of  $f(z)$ . We prove that  $f'(z_0) = g(z_0)$ , which means

$$\lim_{h \rightarrow 0} \frac{f(z_0+h) - f(z_0)}{h} - g(z_0) = 0.$$

Thus, given any  $\varepsilon > 0$ , we must show that there exists a  $\delta > 0$  such that if  $0 < |h| < \delta$ , then the expression above has absolute value less than  $\varepsilon$ . To do so, we break the expression into three parts and estimate each of those separately. More precisely, since  $f(z) = S_N(z) + E_N(z)$ , and we know the derivative  $S'_N$  of the polynomial  $S_N$ , we write

$$\begin{aligned} \frac{f(z_0+h) - f(z_0)}{h} - g(z_0) &= \\ &= \left( \frac{S_N(z_0+h) - S_N(z_0)}{h} - S'_N(z_0) \right) + \\ &+ (S'_N(z_0) - g(z_0)) + \frac{E_N(z_0+h) - E_N(z_0)}{h}. \end{aligned}$$

We analyze the individual terms. The first term contains the main term and its derivative, which exists because  $S_N$  is a polynomial. Thus, this term approaches 0 as  $h \rightarrow 0$ . In other words, given  $\frac{\varepsilon}{3} > 0$ , we can find  $\delta > 0$  such that  $0 < |h| < \delta$  implies

$$\left| \frac{S_N(z_0+h) - S_N(z_0)}{h} - S'_N(z_0) \right| < \frac{\varepsilon}{3}.$$

The second term is  $S'_N(z_0) - g(z_0)$ . Since  $S'_N(z_0) \rightarrow g(z_0)$  as  $N \rightarrow \infty$  (because we know that  $g(z)$  is a power series which converges absolutely for  $z$  in its convergence disc centered at  $a$ , and  $S'_N(z)$  is the  $N$ -th partial sum of this power series), this means that for  $\frac{\varepsilon}{3} > 0$ , we can find some  $N_1$  such that if  $N > N_1$ , then  $|S'_N(z_0) - g(z_0)| < \frac{\varepsilon}{3}$ .

The third term is the most tricky one to estimate effectively. We can write

$$E_N(z_0+h) - E_N(z_0) = \sum_{n=N+1}^{\infty} (c_n(z_0+h-a)^n - c_n(z_0-a)^n)$$

Expanding  $(z_0+h-a)^n - (z_0-a)^n = h((z_0+h-a)^{n-1} + (z_0+h-a)^{n-2}(z_0-a) + \cdots + (z_0-a)^{n-1})$ , we obtain

$$\begin{aligned} \frac{E_N(z_0+h) - E_N(z_0)}{h} &= \sum_{n=N+1}^{\infty} (c_n((z_0+h-a)^{n-1} + \\ &+ (z_0+h-a)^{n-2}(z_0-a) + \cdots + (z_0-a)^{n-1})). \end{aligned}$$

Observe, that for  $h$  sufficiently small,  $|z_0+h-a| < r$  as well as  $|z_0-a| < r$ . Therefore, if we replace all terms by their

absolute values and apply the triangle inequality, we obtain:

$$\left| \frac{E_N(z_0 + h) - E_N(z_0)}{h} \right| \leq \sum_{n=N+1}^{\infty} |c_n|nr^{n-1}.$$

The series on the right converges, and furthermore, its value approaches 0 as  $N \rightarrow \infty$ . Indeed,  $\sum_{n=N+1}^{\infty} |c_n|nr^{n-1}$  is just the tail of the series  $g(r)$  with absolute values on all of its individual terms, and we know that  $g(z)$  converges absolutely for  $|z - a| < R$ . So the series in question does converge, and since it is the end of a convergent series, its terms must approach 0 as  $N \rightarrow \infty$ . Therefore, given  $\frac{\varepsilon}{3} > 0$ , we can find  $N_2$  such that for all sufficiently small  $h$  and  $N > N_2$ ,

$$\left| \frac{E_N(z_0 + h) - E_N(z_0)}{h} \right| < \frac{\varepsilon}{3}.$$

Select now  $N > \max\{N_1, N_2\}$ . Then an application of the triangle inequality yields:

$$\begin{aligned} & \left| \frac{S_N(z_0 + h) - S_N(z_0)}{h} - S'_N(z_0) \right| + \\ & \left| S'_N(z_0) - g(z_0) \right| + \left| \frac{E_N(z_0 + h) - E_N(z_0)}{h} \right| \leq \varepsilon \quad \square \end{aligned}$$

**9.4.3. Corollaries.** We can apply the above theorem any number of times to obtain the following consequences. In particular, notice the straightforward existence of the antiderivative which we shall link with integrals in the next subsections.

COROLLARIES ON THE DERIVATIVES OF POWER SERIES

**Corollary.** Consider any power series

$$f(z) = \sum_{n=0}^{\infty} c_n(z - a)^n$$

with convergence radius  $R > 0$  and write  $D$  for its convergence disk.

(1)  $f(z)$  is infinitely (complex) differentiable in  $D$  and each of its  $k$ -th derivatives  $f^{(k)}(z)$  can be obtained by differentiating term-by-term  $k$  times. The resulting power series has radius of convergence again equal to  $R$ .

(2) There exists the (complex) antiderivative

$$F(z) = \sum_{n=0}^{\infty} \frac{1}{n+1} c_n(z - a)^{n+1},$$

such that  $F'(z) = f(z)$  in the disc of convergence  $D$ , which is the same for both series.

(3) The coefficients  $c_k$  of the power series  $f(z)$  are

$$c_k = \frac{f^{(k)}(a)}{k!}.$$

**PROOF.** All the claims are more or less obvious. Differentiating consecutively we see that  $f$  is infinitely differentiable at all  $z \in D$ , as claimed in (1). Furthermore, we see that  $f^{(k)}(z) = \sum_{n=k}^{\infty} n(n-1)\dots(n-k+1)c_n(z-a)^{n-k}$ , which

in particular yields (2) with  $k = 1$ . Finally, substituting  $z = a$  gives  $f^{(k)}(a) = k!c_k$ , since all terms containing  $(z - a)^{n-k}$  where  $n > k$  vanish at  $z = a$ . Therefore  $c_k = \frac{f^{(k)}(a)}{k!}$ .  $\square$

**9.4.4. Links to the real calculus.** Each complex valued function  $f$  on  $\Omega$  can be viewed as a mapping  $f : \Omega \subset \mathbb{R}^2 \rightarrow \mathbb{R}^2$ . If this mapping is differentiable in the real sense (i.e. all partial derivatives are continuous) we may write

$$f(z) = f(a) + D^1 f(a)(z - a) + (z - a)\alpha(z)$$

for  $a \in \Omega$  and  $z$  in a small neighborhood of  $a$  in  $\Omega$ , with  $D^1 f$  being the Jacobi matrix of first partial derivatives in the two real coordinates and  $\lim_{z \rightarrow a} \alpha(z) = 0$ .

Thus it is legitimate to question whether the real linear approximation  $D^1 f(a)$  is complex linear. Obviously this happens if and only if the complex derivative  $f'(z)$  exists.

If  $f(z) = u(x + iy) + iv(x + iy)$  is the coordinate expression of a complex differentiable function  $f$  viewed as a differentiable mapping  $\mathbb{R}^2 \rightarrow \mathbb{R}^2$ ,  $z = x + iy$ , then clearly

$$\frac{\partial f}{\partial x}(z) = f'(z) \cdot 1, \quad \frac{\partial f}{\partial y}(z) = f'(z) \cdot i.$$

Thus,  $\frac{\partial u}{\partial y} + i \frac{\partial v}{\partial y} = i(\frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x})$  and we have arrived at the sufficient and necessary conditions for  $D^1 f(z)$  being complex linear

$$(1) \quad u_x = v_y, \quad u_y = -v_x.$$

Yet another argument goes as follows: the rank two matrix describing multiplication by a complex number  $a + ib$  has  $a$  in the diagonal entries.  $-b$  and  $b$  are the other two entries.

In particular, this implies  $u_{xx} + u_{yy} = 0$ . The same Laplace equation holds true for the other component function  $v$  of any holomorphic function  $f = u + iv$ .

At the level of differentials, it is useful to consider two (complex valued) linear forms

$$dz = dx + i dy, \quad d\bar{z} = dx - i dy,$$

together with the dual basis at the complexified tangent space

$$\frac{\partial}{\partial z} = \frac{1}{2} \left( \frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right), \quad \frac{\partial}{\partial \bar{z}} = \frac{1}{2} \left( \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right).$$

A straightforward check reveals that a differentiable function  $f : \Omega \subset \mathbb{C} = \mathbb{R}^2 \rightarrow \mathbb{C}$  is complex differentiable if and only if

$$\frac{\partial}{\partial \bar{z}} f = 0.$$

**9.4.5. Integrals along paths.** Another important link concerns integration along paths. A *continuous path*  $\gamma$  in the complex plane is a continuous mapping  $\gamma : J \subset \mathbb{R} \rightarrow \mathbb{C}$  defined on a bounded closed interval  $J = [a, b]$ . A path is called a *simple closed path*, or a *Jordan curve* in the complex plane<sup>10</sup>, if it does not intersect itself and  $\gamma(a) = \gamma(b)$ .

<sup>10</sup>We shall be interested in piecewise differentiable Jordan curves only, and it is quite easy to see that these curves always divide the complex planes into exactly two connected components (it is obvious for piecewise linear and the rest comes via approximation). For general Jordan curves, this is a

The composition of a path  $\gamma$  with any continuous mapping  $f$  defined on the target of  $\gamma$  is again continuous, and thus the (complex valued) Riemann integral  $\int_a^b f \circ \gamma(t) dt$  exists, but it is dependent on the parametrization of the path.

An easy way out is to restrict ourselves to differentiable paths with the derivative  $\dot{\gamma}(t) \neq 0$  for all  $t$ , and define the integral  $I_\gamma$  along a path  $\gamma$  as the Riemann integral

$$I_\gamma = \int_a^b f(\gamma(t))\dot{\gamma}(t) dt.$$

This coincides perfectly with the Riemann integrals of real functions of one variable restricted to a reparametrization  $\gamma$  of an interval in  $\mathbb{R} \subset \mathbb{C}$ .

Writing  $f = u + iv$  and  $\gamma(t) = x(t) + iy(t)$ ,

$$f(\gamma)\dot{\gamma} = (u + iv)(\dot{x} + i\dot{y}) = (u\dot{x} - v\dot{y}) + i(v\dot{x} + u\dot{y}).$$

Now we may check that the complex value  $I_\gamma$  is independent of the choice of parametrization directly by the substitution formula for real integrals. We should also notice that actually the (complex valued) linear form  $f(z) dz$  on  $\mathbb{R}^2 = \mathbb{C}$  equals

$$(u + iv)(dx + i dy) = (u dx - v dy) + i(v dx + u dy).$$

Thus,  $I_\gamma$  equals the integral of the linear form  $f(z) dz$  over the (unparametrized) submanifold  $\gamma \subset \mathbb{C}$  in the sense introduced in the first part of this chapter:

$$I_\gamma = \int_a^b (u\dot{x} - v\dot{y}) dt + i \int_a^b (v\dot{x} + u\dot{y}) dt = \int_\gamma f(z) dz.$$

In fact, any choice of parametrization ( $\dot{\gamma} \neq 0$  on  $J$ ) determines the orientation of  $\gamma$ . Thus the integral is independent of the parametrization, up to sign.

If  $\gamma$  is a composition  $\gamma_2 \circ \gamma_1$  of two paths (we simply concatenate the curves  $\gamma_1 : [a, b] \rightarrow \mathbb{C}$  and  $\gamma_2 : [b, c] \rightarrow \mathbb{C}$ ,  $\gamma_2(b) = \gamma_1(b)$ ), then clearly

$$\int_\gamma f(z) dz = \int_{\gamma_1} f(z) dz + \int_{\gamma_2} f(z) dz.$$

In particular if  $\gamma_2 = \gamma_1^{-1}$ , i.e. the same curve with opposite parametrizations, then  $\int_\gamma f(z) dz = 0$ .

Clearly, our definition of integration extends to piecewise differentiable paths. By uniform continuity over compact domains, the value  $I_\gamma$  depends continuously on the choice of the path  $\gamma$  in the  $C^0$  metric on the functions on the interval  $J$ . Thus we may approximate any integral  $I_\gamma$  by integrating the same function over a piecewise linear path  $\tilde{\gamma}$ .

**9.4.6. Antiderivatives.** If  $F(z)$  is an antiderivative of  $f(z)$ , then clearly

$$\frac{d}{dt} F(\gamma(t)) = F'(\gamma(t)) \cdot \dot{\gamma}(t) = f(\gamma(t)) \cdot \dot{\gamma}(t)$$

and therefore we have verified the straightforward generalization of the Newton integral formula in one real variable calculus:

---

difficult topological result attributed to the French mathematician Camille Jordan (1838-1922). This is the same Jordan related to the Jordan canonical form of matrices discussed in Chapter 4.

NEWTON INTEGRAL FORMULA

For each piecewise differentiable path  $\gamma : [a, b] \rightarrow \mathbb{C}$  and antiderivative  $F(z)$  of the function  $f(z)$  defined on a neighborhood of  $\gamma$ ,

$$(1) \quad I_\gamma = \int_\gamma f(z) dz = F(\gamma(b)) - F(\gamma(a)).$$

In particular, the value of the integral depends only on the values of  $F$  in the endpoints of  $\gamma$  and not on the path itself.

**Corollary.** *Antiderivatives to complex functions on connected domains are uniquely defined, up to complex constants.*

PROOF. Assume  $F'(z) = G'(z)$ , i.e.  $(F - G)'(z) = 0$ . Then for each path  $\gamma$ ,  $\gamma(0) = z$ ,  $\gamma(1) = w$ ,

$$(F - G)(w) - (F - G)(z) = \int_\gamma 0 dz = 0,$$

and thus  $F - G$  is a constant function. □

As an example, consider the paths  $\gamma_r : [0, 2\pi] \rightarrow \mathbb{C}$ ,  $\gamma_r(t) = r e^{it}$ , i.e. the positively oriented boundary of the ball  $B(0, r)$  centered at the origin, with radius  $r > 0$ . It is easy to compute the integral of  $f(z) = z^n$  along these paths, for all  $n \in \mathbb{Z}$ .

$$(2) \quad \int_{\gamma_r} z^n dz = \int_0^{2\pi} r^n e^{nit} ir e^{it} dt = \begin{cases} \frac{r^{n+1}}{n+1} [e^{(n+1)it}]_0^{2\pi} = 0 & n \neq -1 \\ ir^0 \int_0^{2\pi} e^0 dt = 2\pi i & n = -1. \end{cases}$$

In particular, we see that the integral of any polynomial along any circle vanishes (cf. more details in ??).

**9.4.7. Cauchy integral theorem.** The formula 9.4.6(1) can be applied to closed paths and we arrive immediately at the important *Cauchy integral theorem* on the convergence discs of analytic functions. This result is actually available for all holomorphic functions on much more general domains.

Recall that a domain  $\Omega$  is called *simply connected* if every simple closed continuous path in  $\Omega$  can be shrunk continuously into a point without leaving  $\Omega$ .

CAUCHY INTEGRAL THEOREM

**Theorem.** *Let  $f : \Omega \rightarrow \mathbb{C}$  be analytic on a simply connected domain  $\Omega$  and  $\gamma$  be a closed piecewise differentiable path in  $\Omega$ . Then*

$$\int_\gamma f(z) dz = 0.$$

SKETCHY PROOF. The analytic function  $f$  has an antiderivative  $F$  on each of its convergence discs. Assume first that the entire domain  $\Omega$  is contained in one such disc. Then we break the closed path  $\gamma : [0, 1] \rightarrow \Omega$  into the intervals

$0 < t_1 < t_2 < \dots < t_m = 1$  on which  $\gamma$  is differentiable, and

$$\begin{aligned} \int_{\gamma} f(z) dz &= \sum_{j=0}^{m-1} (F(\gamma(t_{j+1})) - F(\gamma(t_j))) \\ &= F(\gamma(1)) - F(\gamma(0)) = 0 \end{aligned}$$

since  $\gamma(0) = \gamma(1)$ .

In particular, if  $T$  is a triangle lying entirely in a convergence disc of the analytic function  $f(z)$  inside of  $\Omega$ , then  $\int_{\partial T} f(z) dz = 0$ , where  $\partial T$  is the oriented boundary of  $T$ .

Next, without loss of generality, the path  $\gamma$  can be viewed as a polygon, since any piecewise differentiable path  $\gamma(t)$  can be uniformly approximated by piecewise linear functions  $\gamma_n(t)$ , that form closed polygons. The integrals of  $f$  over  $\gamma_n$  approximate the integral under question. Thus, if we show  $\int_{\gamma_n} f(z) dz = 0$ , this would imply that  $\int_{\gamma} f(z) dz = 0$ , too.

It seems to be clear, that the interior of any closed polygon  $\gamma_n$  can be triangulated into closed triangles  $T_j$  so that all  $T_j$  lie in  $\Omega$  with their interiors. Actually, here we need the assumption that  $\Omega$  is simply connected if we want to fill in all the details. The integral along the path  $\gamma_n$  is then equal to the sum of the integrals over all the individual triangles (notice we integrate twice in the opposite directions over each edge which does not belong to  $\gamma_n$ ). Finally, possibly refining the polygon  $\gamma_n$  and the triangulation, we may assume that the size of each triangle  $T_j$  is so small, that  $T_j$  lies entirely in some convergence disc of  $f(z)$ . Therefore,

$$\int_{\gamma_n} f(z) dz = \sum_j \int_{\partial T_j} f(z) dz = 0,$$

and hence  $\int_{\gamma} f(z) dz = 0$  as requested.  $\square$

**9.4.8. Cauchy integral theorem again.** We were quite sloppy about the topological issues in the above sketch of the proof. Actually, there is a more general theorem deducing the conclusion of the Cauchy integral theorem under the assumption that the function  $f$  is complex differentiable (holomorphic). We shall prove this theorem under the additional assumption that  $f$  is (continuously) differentiable as a mapping of two real variables. Both conditions are obviously satisfied for analytic functions.

We remark that the general claim of the theorem is proved by a procedure similar to the above argumentation, dealing first with the claim for triangles etc. The reader may find the full proof in any basic textbook on complex analysis.

**Theorem** (Cauchy integral theorem). *If  $f(z)$  is holomorphic in a simply connected domain  $\Omega \subset \mathbb{C}$ , then for every piecewise differentiable simple closed path  $\gamma \subset \Omega$*

$$\int_{\gamma} f(z) dz = 0.$$

**PROOF OF A SPECIAL CASE.** Without loss of generality, assume that  $\gamma$  is a piecewise differentiable path bounding some simple connected region  $G$ . Write as usual  $f(z) = u(x, y) + i v(x, y)$  and so

$$\int_{\partial G} f(z) dz = \int_{\partial G} u dx - v dy + i \int_{\partial G} v dx + u dy.$$

Now, assuming  $f$  is differentiable as a functions of two real variables, the Green's version 9.1.13 of the general Stokes' theorem 9.1.12 implies

$$\begin{aligned} \int_{\partial G} f(z) dz &= \int_G \left( -\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} + i \left( \frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) \right) dx dy \\ &= 2i \int_G \frac{\partial f}{\partial \bar{z}} dx dy = 0, \end{aligned}$$

since  $\frac{\partial f}{\partial \bar{z}} = 0$  is equivalent to being holomorphic.  $\square$

The Cauchy integral theorem has an immediate consequence, ensuring the existence of antiderivatives:

**9.4.9. Theorem.** *For every analytic function  $f(z)$  in a simply connected region  $\Omega$ , its antiderivative  $F(z)$  exists in that region.*

**PROOF.** If  $\Omega$  is the convergence disc of a power series expression for  $f$ , then the claim is obvious, cf. 9.4.3.

In general, fix a point  $z_0 \in \Omega$ , and consider an arbitrary  $\zeta \in \Omega$  and any path  $\gamma \subset \Omega$  with the initial point  $z_0$  and end point  $\zeta$ . Define

$$F(\zeta) = \int_{\gamma} f(z) dz.$$

Choose any other  $\tilde{\gamma}$  with the same beginning and end, and prolong the path  $\gamma$  by  $\tilde{\gamma}^{-1}$ . This provides a closed path  $\mu = \tilde{\gamma}^{-1} \circ \gamma$ , and therefore, by the Cauchy integral theorem,  $\int_{\mu} f(z) dz = 0$ . Thus  $F(\zeta)$  is well defined, independent of the choice of  $\gamma$ .

Next, consider a small  $h$  such that the entire oriented segment  $\nu$  joining  $\zeta$  and  $\zeta + h$  is in  $\Omega$ . Then

$$F(\zeta+h) - F(\zeta) = \int_{\nu \circ \gamma} f(z) dz - \int_{\gamma} f(z) dz = \int_0^1 f(\zeta+ht) h dt.$$

In particular

$$\lim_{h \rightarrow 0} \frac{F(\zeta+h) - F(\zeta)}{h} = \lim_{h \rightarrow 0} \int_0^1 f(\zeta+ht) dt = f(\zeta)$$

and thus,  $F(\zeta)$  is the requested antiderivative.  $\square$

Clearly, the antiderivative of an analytic function on a simply connected domain is again analytic. This follows immediately from corollary 9.4.6 and the local formula for antiderivative,  $F(z) = \sum_{n=0}^{\infty} \frac{1}{n+1} c_n (z-a)^{n+1}$  of the analytic functions  $f(z) = \sum_{n=0}^{\infty} c_n (z-a)^n$  on the individual convergence discs. It is related to the much more general concept of analytic extension which we shall discuss now.

**9.4.10. Uniqueness.** At first glance, the power series representing locally an analytic function in a domain  $\Omega$  should glue together. We shall deal first with the uniqueness issues.

UNIQUENESS THEOREM

**Lemma.** Consider an analytic function  $f(z)$  in  $\Omega$  and a sequence of its zeroes  $a_n \in \Omega$  which has a limit point  $a \in \Omega$ . Then  $f(z) = 0$  everywhere in  $\Omega$ .

**PROOF.** We start with a simple observation on the non-vanishing of analytic functions:

**Claim.** Let  $f(z) \neq 0$  be analytic in  $\Omega$ , with  $f(a) = 0$  for some  $a \in \Omega$ . Then, there exists  $\varepsilon > 0$  such that  $f(z) \neq 0$  for  $0 < |z - a| < \varepsilon$ .

Indeed, in some neighbourhood of  $a$ , the analytic function  $f(z)$  is represented by a power series  $f(z) = \sum_{n=0}^{\infty} c_n(z - a)^n$ . Since  $f(a) = 0$ , we have  $c_0 = 0$ . Let  $c_k$  be the first non-zero coefficient in the series. Then  $f(z) = (z - a)^k g(z)$ , where  $g(z) = \sum_{n=k}^{\infty} c_n(z - a)^{n-k}$  and  $g(a) \neq 0$ . Therefore, by continuity of  $g(z)$ , there exists a disc centered at  $a$  of the radius  $\varepsilon > 0$  where  $g(z)$  does not have zeroes and, consequently,  $f(z) \neq 0$  for  $0 < |z - a| < \varepsilon$ .

The lemma is now a simple corollary of the above claim. Under the assumptions,  $f(z)$  must vanish identically on a non-trivial disc centered at  $a$ . Assume  $f(w) \neq 0$ ,  $w \in \Omega$ , and choose a path  $\gamma$  with  $\gamma(0) = a$ ,  $\gamma(1) = w$ . Define  $t_0$  to be the infimum of the nonempty set  $\{t \in [0, 1]; f(\gamma(t)) \neq 0\}$ . Then  $t_0 > 0$  and  $f(\gamma(t))$  is identically zero for  $t \in [0, t_0)$ . Thus the above claim applies for  $a = \gamma(t_0)$ , which leads to a contradiction with  $f(t_0) \neq 0$  and we are done.  $\square$

As a corollary, we see that any function  $f(z)$ , analytic in two concentric discs is represented in those discs by the same power series  $f(z) = \sum_{n=0}^{\infty} c_n(z - a)^n$ , where  $a$  is the centre of those discs, and  $c_k$  are Taylor coefficients  $c_k = \frac{1}{k!} f^{(k)}(a)$ ,  $k = 0, 1, \dots$

**9.4.11. Analytic extension.** The basic idea for gluing non-zero powerseries together is very simple. Consider a power series  $f(z) = \sum_{n=0}^{\infty} c_n(z - a)^n$ , converging in  $D = \{|z - a| < r\}$  and some point  $b \in D$ . If  $|z - b| + |b - a| < r$ , then  $\sum_{n=0}^{\infty} |c_n|(|z - b| + |b - a|)^n$  converges and, thus, on the smaller disc  $D_b = \{|z - b| < s = r - |b - a|\}$  we may rewrite the power series  $f(z)$  by expanding  $(z - a)^n = (z - b + b - a)^n$ :

$$\sum_{n=0}^{\infty} c_n(z - a)^n = \sum_{n=0}^{\infty} \sum_{k=0}^n \binom{n}{k} c_n (b - a)^{n-k} (z - b)^k$$

$$= \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \binom{n}{k} c_n (b - a)^{n-k} (z - b)^k,$$

where all the series converge absolutely, and so the order of summation is irrelevant.

Thus, writing  $d_k = \sum_{n=k}^{\infty} \binom{n}{k} c_n (b-a)^{n-k}$ , the new power series  $f(z) = \sum_{k=0}^{\infty} d_k (z-b)^k$  converges at least on the disc  $D_b$  and we shall call it the *re-expansion* of  $\sum_{n=0}^{\infty} c_n (z-a)^n$  at the centre  $b$ .

The re-expansion is guaranteed to converge for  $|z-b| < r - |b-a|$ . However, the radius of convergence of  $\sum_{n=0}^{\infty} d_n (z-b)^n$  can be larger. The concept of analytic extension is based on this.

#### ANALYTIC ELEMENTS AND EXTENSIONS

An *analytic element*  $\Phi$  with centre at  $a \in \mathbb{C}$  is a pair  $\Phi = (D, f)$ , where  $D$  is some disc  $D = \{|z-a| \leq R\}$  and  $f$  is a convergent power series in  $D$ . The element  $\Phi$  is called *canonical*, if  $R$  is the radius of convergence of  $f$  at  $a$ .

Elements  $\Phi_1 = (D_1, f_1)$  and  $\Phi_2 = (D_2, f_2)$  are called *immediate extensions* of each other if  $D_1 \cap D_2 \neq \emptyset$  and  $f_1(z) = f_2(z)$  on  $D_1 \cap D_2$ . An element  $\Psi$  is called an *analytic extension* of  $\Phi$  along the chain  $\Phi_0 = \Phi, \Phi_1, \dots, \Phi_n = \Psi$  if  $\Phi_{j+1}$  is an immediate analytic extension of  $\Phi_j$ ,  $j = 0, 1, \dots, n-1$ .

A parametric family  $\Phi_t = (D_t, f_t)$  of canonical elements is called an *analytic extension of  $\Phi_0$  along a path*  $\gamma : [0, 1] \rightarrow \mathbb{C}$ , if (i) for all  $t \in [0, 1]$  the radii of convergence of the discs  $D_t$  are  $R_t > 0$  and the centres of  $\Phi_t$  are  $a_t = \gamma(t)$ ; and (ii) for all  $\tau \in [0, 1]$  there exist open intervals  $U_\tau \subset [0, 1]$  containing  $\tau$  such that for all  $t \in U_\tau$ ,  $\gamma(t) \in D_\tau$  and  $\Phi_t$  is an immediate extension of  $\Phi_\tau$ .

For example, the pair

$$(1) \quad \log z = \left( |z-1| < 1, \sum_{n=0}^{\infty} \frac{(-1)^n}{n} (z-1)^n \right)$$

is the canonical element restricted to the standard real logarithm function, centered at 1.

Obviously, if  $\Psi = (D_2, f_2)$  is an immediate extension of  $\Phi = (D_1, f_1)$  and the centre  $a_2$  of  $\Psi$  lies in  $D_1$  then the series  $f_2$  is just a re-expansion of  $f_1$  around  $a_2$ . This follows from the uniqueness theorem and the possibility of re-expansion.

**Lemma.** *Assume that the element  $\Phi_1 = (D_1, f_1)$  is an immediate extension of  $\Phi_0 = (D_0, f_0)$ , and that  $\Phi_2 = (D_2, f_2)$  is an immediate extension of  $\Phi_1$ . Then,  $\Phi_2$  is also an immediate extension of  $\Phi_0$  if  $D_0 \cap D_1 \cap D_2 \neq \emptyset$ .*

*If  $\Phi_t$  and  $\Psi_t$  are two analytic extensions of canonical element  $\Phi_0 = \Psi_0$  along the same path  $\gamma : [0, 1] \rightarrow \mathbb{C}$ , then  $\Psi_t = \Phi_t$ , for all  $t \in [0, 1]$ .*

**PROOF.** Clearly,  $f_0 = f_1 = f_2$  on the non-empty open subset  $D_0 \cap D_1 \cap D_2$  of  $D_0 \cap D_2$ . By the uniqueness theorem  $f_2 = f_0$  everywhere in  $D_0 \cap D_2$ , which proves the first claim.

Next, consider  $E = \{t \in [0, 1] : \Psi_t = \Phi_t\}$ . Since  $0 \in E$ , the set  $E$  is not empty. It is open, because  $U_\tau^\Phi \cap U_\tau^\Psi \subset E$  for all  $\tau \in [0, 1]$ . Further, if  $t_0 \in [0, 1]$  is a limit point of  $E$  then the elements  $\Phi_{t_0}$  and  $\Psi_{t_0}$  are immediate extensions of  $\Phi_{t_1} = \Psi_{t_1}$  for all  $t_1 \in U_{t_0}^\Phi \cap U_{t_0}^\Psi$ ,  $t_1 < t_0$ . Since  $\Phi_{t_0}$  and  $\Psi_{t_0}$  have the common centre  $\gamma(t_0)$ , they must be equal. So  $E$  is closed and thus,  $E = [0, 1]$ , i.e.  $\Phi_t = \Psi_t$  for all  $t$ .  $\square$

**9.4.12. Technical observations.** In a sequence of simple observations, we show that analytic extension along a path can be always be obtained by analytic extensions along some chain of elements and vice versa.

First, consider the family  $\Phi_t$  of elements that extend  $\Phi_0$  along some  $\gamma(t) : [0, 1] \rightarrow \mathbb{C}$  and write  $R(t)$  for the corresponding radii of convergence.

**Proposition.** *If  $R(\tau) = \infty$  for some  $\tau \in [0, 1]$ , then it is infinite for all  $t$ . If finite, then  $R(t)$  is continuous on  $[0, 1]$ .*

**PROOF.** If  $R(\tau) = \infty$ , then each element  $\Phi_t$  is a re-expansion of  $\Phi_\tau$ , and therefore  $R(t) = \infty$  for all  $t$ .

On the other hand, if  $R(\tau) < \infty$  for some  $\tau$ , then for all  $t \in U_\tau$ , the circles  $\{|z - \gamma(t)| = R(t)\}$  and  $\{|z - \gamma(\tau)| = R(\tau)\}$  intersect at a pair of points because neither of these circles lies inside the other one. Let  $w$  be one such point of intersection. Then for the triangle with vertices  $w, \gamma(\tau), \gamma(t)$  we arrive at  $|R(t) - R(\tau)| < |\gamma(t) - \gamma(\tau)|$ . Since  $\gamma$  is uniformly continuous on  $[0, 1]$ ,  $R(t)$  is continuous on  $U_\tau$ , and thus also on  $[0, 1]$ .  $\square$

**Lemma.** *Consider an analytic extension  $\{\Phi_t, t \in [0, 1]\}$  of  $\Phi_0$  along a path  $\gamma$ . There exist a finite number of intermediate points  $0 = t_0 < t_1 < \dots < t_n = 1$  such that  $\Phi_1$  is obtained by analytic extension along the chain of elements  $\Phi_0 = \Phi_{t_0}, \Phi_{t_1}, \dots, \Phi_{t_n} = \Phi_1$ .*

*Conversely, if a canonical element  $\Psi$  extends  $\Phi$  along the chain  $\Phi = \Phi_0, \Phi_1, \dots, \Phi_n = \Psi$  and  $\gamma : [0, 1] \rightarrow \mathbb{C}$  is the piece-wise linear path through the centres of  $\Phi_0, \Phi_1, \dots, \Phi_n$ , then there is a family  $\{\Psi_t\}$  of canonical elements extending  $\Psi_0 = \Phi_0$  along  $\gamma$ , such that  $\Psi_1 = \Phi_n = \Psi$ .*

**PROOF.** Since  $R(t) > 0$  for all  $t$  and is continuous, due to the compactness of  $[0, 1]$  it is separated from zero and, therefore  $R(t) > c$  for some constant  $c > 0$ . Uniform continuity of  $\gamma(t)$  implies that  $\exists \delta > 0$  such that  $|t_2 - t_1| < \delta$  yields  $|\gamma(t_2) - \gamma(t_1)| < c$ .

Since the intervals  $J_t = U_t \cap (t - \frac{\delta}{2}, t + \frac{\delta}{2})$  cover  $[0, 1]$  one can choose a finite subcover  $J_{t_1}, \dots, J_{t_{n-1}}$  for some  $t_1 < \dots < t_{n-1}$ , to which we append  $t_0 = 0$  and  $t_n = 1$  if these terminal points are missing from the sequence. Then,  $|\gamma(t_{j+1}) - \gamma(t_j)| < c$  and the centres of  $\Phi_{t_{j+1}}$  and  $\Phi_{t_j}$  lie in the disc of convergence of each other, respectively. So, these elements are re-expansions, and hence, immediate extensions of each other.

As there are a finite number of straight segments in  $\gamma(t)$ , it is sufficient to consider the case  $n = 1$ . The rest follows by induction. Thus  $\gamma(t)$  will be a segment connecting  $\gamma(0)$  and  $\gamma(1)$ , that lies in  $D_0 \cup D_1$  with  $D_0 \cap D_1 \neq \emptyset$ . Define  $\Phi_t = (D_t, f_t)$  as re-expansion of either  $\Phi_0$  or  $\Phi_1$ , depending on where  $\gamma(t)$  appears, in  $D_0$  or  $D_1$ . If  $\gamma(t) \in D_0 \cap D_1$  then re-expansion of both  $\Phi_0$  or  $\Phi_1$  at the centre  $\gamma(t)$  determine same canonical element as noticed above. The interval  $U_\tau$  can be chosen so that  $\gamma(t), t \in U_\tau$  entirely lies in either  $D_0$  or  $D_1$ . Then  $\Phi_t$  for  $t \in U_\tau$  will be an immediate extension of  $\Phi_\tau$ .  $\square$

**9.4.13. Monodromy theorem.** In general, it is very difficult to say whether there is an analytic extension of a given analytic element along a given path. But we may quite easily find out conditions under which existing extensions along paths  $\gamma_0$  and  $\gamma_1$  with a common beginning and end must coincide.

HOMOTOPIC PATHS

We say that two paths  $\gamma_0(t)$  and  $\gamma_1(t)$  with common terminal points  $\gamma_0(0) = \gamma_1(0) = a$  and  $\gamma_0(1) = \gamma_1(1) = b$  are homotopic if there exists a continuous function  $\gamma : [0, 1] \times [0, 1] \rightarrow \mathbb{C}$  such that

$\gamma(0, t) = \gamma_0(t)$ ,  $\gamma(1, t) = \gamma_1(t)$ ,  $\gamma(s, 0) = a$ ,  $\gamma(s, 1) = b$  for all  $s \in [0, 1]$ . We say that the paths  $\gamma_s(t) = \gamma(s, t)$  provide a *homotopic deformation* of  $\gamma_0$  to  $\gamma_1$ .

The following theorem says that homotopic paths lead to the same analytic extensions.

MONODROMY THEOREM

**Theorem.** *Suppose that a canonical element  $\Phi_0 = (D_0, f_0)$  centred at  $a$  can be analytically extended along every path  $\gamma_s$  in a homotopic deformation. Then the extensions along each of those paths terminate with the same canonical element  $\Phi_1$ .*

**PROOF.** Write  $\Phi_{st}$ ,  $s \in [0, 1]$ ,  $t \in [0, 1]$  the canonical elements of the extension of  $\Phi_0 = \Phi_0$  along  $\gamma_s(t)$ . Let  $R_s(t)$  be the radius of convergence of  $\Phi_{st}$ . Since  $R_s(t) > 0$  for all  $(s, t) \in [0, 1] \times [0, 1]$ , there exists  $\rho > 0$  such that  $R_s(t) > \rho$  for all  $s$  and  $t$ . Notice that  $\gamma(s, t)$  is uniformly continuous and thus, fixing  $s_0 \in [0, 1]$  we may choose an interval  $V_{s_0}$  around  $s_0$  on the  $s$ -axis such that

$$\max_{t \in [0, 1]} |\gamma(s, t) - \gamma(s_0, t)| < \frac{\rho}{4}.$$

Then, for all  $s \in V_{s_0}$ , the result of analytic extension remains the same as every element  $\Phi_{st}$  centred at  $\gamma(s, t)$  is a re-expansion of  $\Phi_{s_0t}$  because the centre  $\gamma(s, t)$  lies in the disc of convergence of  $\Phi_{s_0t}$ . Thus, extensions along  $\gamma_s(t)$  and  $\gamma_{s_0}(t)$  produce the same terminal element  $\Phi_{s_0t}$ .

Consider the set  $E = \{s \in [0, 1] : \Phi_{s1} = \Phi_{01}\}$ . Clearly,  $E$  is not empty as it contains  $s = 0$ . By the previous argument,  $E$  is open. We shall see that  $E$  is also closed. Let  $s_0$  be a limit point of  $E$ . Consider the interval  $V_{s_0}$  as constructed above. Then there is  $s' \in V_{s_0} \cap E$ , and extensions along  $\gamma_{s'}(t)$  and  $\gamma_{s_0}(t)$  coincide, and so  $s_0 \in E$ . Hence  $E = [0, 1]$ , which proves the theorem.  $\square$

**Corollary (Monodromy theorem).** *Consider a simply connected region  $\Omega \subset \mathbb{C}$  and a canonical element  $\Phi = (D, f)$  centred at  $a \in \Omega$ . Suppose that  $\Phi$  extends along any path  $\gamma \subset \Omega$  through  $a$ . Then for any  $b \in \Omega$ , the extension of  $\Phi$  along any path terminating at  $b$  is independent on the path*

and as a result, produces the same analytic element for any such path.

Thus, an analytic extension of  $\Phi$  to every point in  $\Omega$  generates an analytic function that is represented as a convergent power series in any disc inscribed in  $\Omega$ .

**9.4.14. Remarks.** We look at some simple examples where the analytic extension is crucial. Consider the function  $f(z) = \sqrt{z}$ . Clearly we may choose the two different options  $f(1) = \pm 1$  and each of the choices will lead to a canonical element. The analytic extensions of them are called the *branches* of a multivalued complex function  $f$ . Notice that  $\sqrt{z}$  is not analytic at the origin since the derivatives blow up to infinity there.

Intuitively, it seems that two closed paths in  $\mathbb{C} \setminus \{0\}$  are homotopic if and only if they run around the origin the same number of times (the *winding number*). We may imagine what happens to the values if we move  $z$  along a circle  $z = r e^{i\theta}$ . The two initial options lead to

$$f_1(z) = \sqrt{r} e^{i\theta/2} \quad f_2(z) = \sqrt{r} e^{i(\pi+\theta/2)}.$$

Once we run  $\theta$  from 0 to  $2\pi$ , the value of the branches swap. See ?? for more observations on root functions.

more in the other column

Another very important example is  $f(z) = z^{-1}$ . Since  $f(z)$  integrates to  $2\pi i$  over each circle centered in origin, there cannot exist an antiderivative to  $f$  along any of such circles. But locally, the antiderivative is the logarithmic function  $\log z$ . The canonical element 9.4.11(1) extends to one of infinite branches and running along a circle must change its value by the constant  $2\pi i$ .

We return to general analytic functions. As promised a few pages back, the monodromy theorem implies that for any analytic function  $f(z)$  in a simply connected region  $\Omega$ , there exists an analytic function representing the antiderivative. Moreover, for each analytic element of  $f$ , this is just the antiderivative of the power series representing the function on the disc. Now we may also deduce the Cauchy integral theorem for simple connected regions  $\Omega$  in another way: The integral along the closed path  $\partial\Omega$  is given by the difference of the values of the antiderivative at the terminal points. Since the boundary  $\partial\Omega$  is homotopic to a point, the integral vanishes.

**9.4.15. Cauchy theorem the third time.** The Cauchy integral theorem holds also for analytic functions on domains  $\Omega$  which are not simply connected. A bounded open domain  $\Omega \subset \mathbb{C}$  is said to have a *regular boundary*  $\partial\Omega$  if the set of boundary points  $\partial\Omega$  consists of finitely many piece-wise smooth and mutually disjoint Jordan curves  $\gamma_0, \gamma_1, \dots, \gamma_n$ .

Notice, the Jordan curves in the boundary divide the complex plane into  $n+2$  connected components. Just one of them is unbounded, one of them coincides with  $\Omega$  and all the others are bounded “holes” inside of  $\Omega$ . We write  $\gamma_0$  for the oriented exterior boundary, i.e. the boundary of the connected unbounded component of  $\mathbb{C} \setminus \Omega$  oriented counter-clockwise,

while  $\gamma_1, \dots, \gamma_n$  form the oriented interior boundary, i.e. the curves are oriented clockwise.

CAUCHY INTEGRAL THEOREM

**Theorem.** Let  $\Omega \subset \mathbb{C}$  be a bounded region with regular boundary and  $f(z)$  analytic on the closure  $\overline{\Omega}$  (i.e. analytic on some domain containing  $\overline{\Omega}$ ). Then

$$\int_{\partial\Omega} f(z) dz = 0.$$

**PROOF.** With our choice of orientation of the boundary, we must prove

$$\int_{\partial\Omega} f(z) dz = \int_{\gamma_0} f(z) dz + \sum_{j=1}^n \int_{\gamma_j} f(z) dz = 0.$$

We proceed by induction on  $n$ . If  $n = 0$ , then clearly  $\Omega$  is simply connected and the theorem is proved already, see Theorem 9.4.8.

If  $n = 1$ , then there is exactly one interior part of the boundary  $\gamma_1$  and we may choose any two smooth paths  $\mu_1$  and  $\mu_2$  joining the left most points and the right most points in  $\gamma_0$  and  $\gamma_1$ , respectively. This way, we split  $\Omega$  into two simply connected regions  $\Omega^+$  (say the upper one) and  $\Omega^-$  (the lower one), with boundaries  $\partial\Omega^+ = \gamma_0^+ \circ \mu_1 \circ \gamma_1^+ \circ \mu_2^{-1}$  and  $\partial\Omega^- = \gamma_0^- \circ \mu_2 \circ \gamma_1^- \circ \mu_1^{-1}$ . At the same time,

$$\int_{\partial\Omega} f(z) dz = \int_{\partial\Omega^+} f(z) dz + \int_{\partial\Omega^-} f(z) dz$$

since the integration over  $\mu_i$  and  $\mu_i^{-1}$ ,  $i = 1, 2$ , cancel each other on the right hand side. Moreover, the boundaries  $\partial\Omega^\pm$  are again piecewise differentiable Jordan curves and therefore both integrals on the right hand side vanish.

The general induction step is completely analogous. If  $n > 1$ , we find one of the interior boundaries  $\gamma_i$  closest to  $\gamma_0$ . Choose two cuts  $\mu_1, \mu_2$  so that one of the two newly created components of  $\Omega$  is simply connected. Then the other component has one less interior boundary and thus the theorem follows by induction. □

it needs a diagram with the cuts, see the illustration on the diagram

**9.4.16. Cauchy integral formula.** Consider an open ball without its center,  $\Omega = B(z_0, r) \setminus \{z_0\}$ , an analytic function  $f(z)$  in  $\Omega$ , and positively oriented Jordan curves  $\gamma \subset \Omega$  including  $z_0$  in its interior. Due to the Cauchy integral theorem, the integral  $\int_\gamma f(z) dz$  does depend on the choice of such  $\gamma$ . Indeed, the region enclosed between the two choices  $\gamma_1, \gamma_2$  is bounded by them, but with opposite orientations. Thus the vanishing of the integral over the boundary means that actually the integrals over  $\gamma_1$  and  $\gamma_2$  are equal.

Next, recall that the integral of  $z^{-1}$  over any circle centered at the origin is  $2\pi i$ , see 9.4.6(2). These observations suggest the following essential formula (we may expect that  $f(\zeta)$  will behave similarly as the constant  $f(z)$  for  $\gamma$  very small):

## CAUCHY INTEGRAL FORMULA

**Theorem.** Let  $f(z)$  be analytic function in the closure of the region  $\Omega \subset \mathbb{C}$  with regular boundary. Then for all  $z$  in  $\Omega$ ,

$$f(z) = \frac{1}{2\pi i} \int_{\partial\Omega} \frac{f(\zeta)}{\zeta - z} d\zeta.$$

**PROOF.** Fix  $z \in \Omega$  and consider an open disc  $D_\rho = \{\zeta \in \mathbb{C}; |\zeta - z| < \rho\}$  lying inside of  $\Omega$ .

The function  $g(\zeta) = \frac{f(\zeta)}{\zeta - z}$  is analytic in the closure of  $\Omega \setminus \overline{D_\rho}$ . Adopting the counterclockwise orientation of the boundary of  $D_\rho$ , the Cauchy integral theorem implies

$$\int_{\partial\Omega} \frac{f(\zeta)}{\zeta - z} d\zeta = \int_{\partial D_\rho} \frac{f(\zeta)}{\zeta - z} d\zeta.$$

We aim at showing that  $\int_{\partial D_\rho} \frac{f(\zeta)}{\zeta - z} d\zeta = 2\pi i f(z)$ . We know  $2\pi i f(z) = \int_{\partial D_\rho} \frac{f(z)}{\zeta - z} d\zeta$ . Thus, we consider

$$\int_{\partial D_\rho} \frac{f(\zeta)}{\zeta - z} d\zeta - 2\pi i f(z) = \int_{\partial D_\rho} \frac{f(\zeta) - f(z)}{\zeta - z} d\zeta$$

and estimate

$$\begin{aligned} \left| \int_{\partial D_\rho} \frac{f(\zeta) - f(z)}{\zeta - z} d\zeta \right| &\leq \max_{|\zeta - z| = \rho} \frac{2\pi\rho |f(\zeta) - f(z)|}{\rho} \\ &= 2\pi \max_{|\zeta - z| = \rho} |f(\zeta) - f(z)|. \end{aligned}$$

Clearly, the right hand side approaches zero as  $\rho \rightarrow 0$ . Hence,

$$\int_{\partial D_\rho} \frac{f(\zeta) - f(z)}{\zeta - z} d\zeta = 0$$

and the formula in the theorem has been verified.  $\square$

Notice that if we consider  $z \in \mathbb{C} \setminus \Omega$  in the above theorem, then the function  $\frac{f(\zeta)}{\zeta - z}$  is analytic in  $\Omega$  and thus the integral vanishes by the Cauchy integral theorem.

**9.4.17. Corollaries.** Taking consecutive derivatives with respect to  $z$  in the above formula, we obtain expressions for all derivatives of  $f(z)$ :

## CAUCHY INTEGRAL FORMULA FOR DERIVATIVES

**Corollary.** Let  $f(z)$  be an analytic function in the closure of the region  $\Omega \subset \mathbb{C}$  with regular boundary. Then for all  $z$  in  $\Omega$ ,

$$f^{(n)}(z) = \frac{n!}{2\pi i} \int_{\partial\Omega} \frac{f(\zeta)}{(\zeta - z)^{n+1}} d\zeta.$$

**PROOF.** Indeed,  $z$  is an independent argument in the smooth integrand, thus we may differentiate the integral, which yields the formula.  $\square$

Apply the Cauchy integral formula to the disc  $D_r = \{z - a < r\}$  to obtain

MEAN VALUE THEOREM

**Theorem.** For  $f(z)$  analytic in  $\overline{D_r}$  the value at the centre of the disc can be evaluated as

$$f(a) = \frac{1}{2\pi} \int_0^{2\pi} f(a + r e^{i\theta}) d\theta.$$

PROOF. By the Cauchy integral formula

$$f(a) = \frac{1}{2\pi i} \int_{|\zeta - a| = r} \frac{f(\zeta)}{\zeta - a} d\zeta.$$

Substitute  $\zeta = a + r e^{i\theta}$  and  $d\zeta = i r e^{i\theta} d\theta$  to obtain

$$f(a) = \frac{1}{2\pi} \int_0^{2\pi} f(a + r e^{i\theta}) d\theta.$$

□

**9.4.18. Laurent series.** Already in 6.3.10, we noticed that quotients  $\frac{f(z)}{g(z)}$  of two polynomials enjoy a quite nice expansion similar to power series. We called series of the form  $\sum_{n=-\infty}^{\infty} c_n (z - a)^n$  a *Laurent series*. Now we do the same with complex arguments and coefficients.

The part of the Laurent series with positive powers,  $\sum_{n=0}^{\infty} c_n (z - a)^n$ , is called the *regular part*, while the remaining part  $\sum_{n=-1}^{-\infty} c_n (z - a)^n$ , consisting of negative powers of  $(z - a)$ , is called its *principal part*. A Laurent series is called convergent if both the regular and principal parts converge.

LAURENT SERIES

**Theorem.** Every function  $f(z)$  analytic in the annulus  $A = \{r < |z - a| < R\}$ , with  $0 \leq r < R \leq \infty$  admits a representation by a Laurent series

$$(1) \quad f(z) = \sum_{n=-\infty}^{\infty} c_n (z - a)^n,$$

where the coefficients  $c_n$  can be calculated by

$$(2) \quad c_n = \int_{|\zeta - a| = \rho} \frac{f(\zeta)}{(\zeta - a)^{n+1}} d\zeta, \quad n \in \mathbb{Z}, \quad r < \rho < R.$$

The coefficients  $c_n$ , called the *Laurent coefficients* of  $f(z)$  in  $A$ , are uniquely determined. In particular they do not depend on  $\rho$ .

PROOF. Choose  $z \in A$  and  $r', R'$  such that  $r < r' < R' < R$ . The function  $f(z)$  is now analytic in the closure of the annulus  $A' = \{r' < |z - a| < R'\}$ . Therefore, by the

Cauchy integral formula, adopting the anticlockwise orientation,  $f(z)$  is a difference of two integrals,  $f(z) = J_1 - J_2$ ,

$$f(z) = \frac{1}{2\pi i} \int_{|\zeta-a|=R'} \frac{f(\zeta)}{\zeta-z} d\zeta - \frac{1}{2\pi i} \int_{|\zeta-a|=r'} \frac{f(\zeta)}{\zeta-z} d\zeta.$$

If  $|\zeta-a| = R'$ , then  $|z-a| < |\zeta-a|$  and we may expand

$$\frac{f(\zeta)}{\zeta-z} = \frac{f(\zeta)}{(\zeta-a)} \frac{1}{1 - \frac{z-a}{\zeta-a}} = \sum_{n=0}^{\infty} \frac{f(\zeta)}{(\zeta-a)^{n+1}} (z-a)^n.$$

Next, we can estimate

$$\left| \frac{f(\zeta)}{(\zeta-a)^{n+1}} (z-a)^n \right| < \frac{\max_{|\zeta-a|=R'} |f(\zeta)|}{R'} \left( \frac{|z-a|}{R'} \right)^n$$

and thus the series is uniformly convergent and admits term by term integration. Therefore

$$J_1 = \frac{1}{2\pi i} \sum_{n=0}^{\infty} c_n (z-a)^n, \quad c_n = \int_{|\zeta-a|=R'} \frac{f(\zeta)}{(\zeta-a)^{n+1}} d\zeta.$$

If  $|\zeta-a| = r'$ , then  $|\zeta-a| < |z-a|$  and similarly to the above, the expansion

$$\frac{f(\zeta)}{\zeta-z} = \frac{f(\zeta)}{(z-a)} \frac{1}{\frac{\zeta-a}{z-a} - 1} = - \sum_{n=0}^{\infty} \frac{f(\zeta)}{(z-a)^{n+1}} (\zeta-a)^n$$

leads to the equality (via term by term integration)

$$-J_2 = \frac{1}{2\pi i} \sum_{n=-1}^{-\infty} c_n (z-a)^n, \quad c_n = \int_{|\zeta-a|=r'} \frac{f(\zeta)}{(\zeta-a)^{n+1}} d\zeta.$$

Thus, we have obtained the Laurent series representation

$$f(z) = \sum_{n=-\infty}^{\infty} c_n (z-a)^n$$

as requested.

On the other hand, if we are given a Laurent series (1), then fixing arbitrary  $n \in \mathbb{Z}$  and multiplying this formula by  $(z-a)^{-(n+1)}$  we can integrate over  $|z-a| = \rho$  in order to obtain

$$\int_{|z-a|=\rho} \frac{f(z)}{(z-a)^{n+1}} dz = 2\pi i c_n.$$

The circle  $\{|z-a| = \rho\}$  with  $r < \rho < R$  was chosen arbitrarily, and in particular we see that the integrals  $\int_{|z-a|=\rho} \frac{f(z)}{(z-a)^{n+1}} dz$  cannot depend on  $\rho$ .  $\square$

**9.4.19. Remarks on convergence.** Given a Laurent series, its regular part  $\sum_{n=0}^{\infty} c_n (z-a)^n$  represents a power series that converges absolutely and uniformly on compact sets in its disc of convergence  $\{|z-a| < R\}$  with  $\frac{1}{R} = \limsup_{n \rightarrow \infty} |c_n|^{\frac{1}{n}}$ , see the *Cauchy-Hadamard formula* in Theorem 9.4.2.

The principal part  $\sum_{n=-1}^{-\infty} c_n (z-a)^n$  becomes a power series  $\sum_{n=1}^{\infty} c_{-n} w^n$  after a coordinate change  $w = \frac{1}{z-a}$  and this series converges for  $|w| < \frac{1}{r}$  with  $r = \limsup_{n \rightarrow \infty} |c_{-n}|^{\frac{1}{n}}$ . Thus we have verified:

**Proposition.** For any set of coefficients  $\{c_n, n \in \mathbb{Z}\}$  set

$$\frac{1}{R} = \limsup_{n \rightarrow \infty} |c_n|^{\frac{1}{n}}, \quad r = \limsup_{n \rightarrow \infty} |c_{-n}|^{\frac{1}{n}}.$$

Then the Laurent series

$$f(z) = \sum_{n=-\infty}^{\infty} c_n(z-a)^n$$

converges absolutely and uniformly on any compact set in the annulus  $A = \{r < |z-a| < R\}$ . It is analytic in  $A$  and if  $|z-a| < r$ , then the principal part  $\sum_{n=-1}^{-\infty} c_n(z-a)^n$  diverges, while the regular part  $\sum_{n=0}^{\infty} c_n(z-a)^n$  diverges for  $|z-a| > R$ .

**9.4.20. Link to Fourier series.** There is a very interesting link between Laurent and Fourier series. If  $f$  is analytic in  $A = \{1-\rho < |z| < 1+\rho\}$  for some  $\rho > 0$  then its  $n$ -th Laurent series coefficient

$$c_n = \frac{1}{2\pi i} \int_{|z|=\rho} \frac{f(z)}{z^{n+1}} dz = \frac{1}{2\pi} \int_0^{2\pi} f(e^{it}) e^{-int} dt.$$

Therefore,  $c_n$  represents the  $n$ -th Fourier coefficient of  $\varphi(t) = f(e^{it})$  on  $t \in [0, 2\pi]$ , and the Fourier series of  $f(e^{it})$  converges uniformly to  $f(e^{it})$  on  $t \in [0, 2\pi]$ .

**9.4.21. Liouville theorem.** The formula 9.4.18(2) for Laurent series coefficients yields the following *Cauchy inequalities*:

$$(1) \quad |c_n| = \left| \frac{1}{2\pi i} \int_{|z-a|=\rho} \frac{f(z)}{(z-a)^{n+1}} dz \right| \leq \frac{\max_{|z-a|=\rho} |f(z)|}{\rho^n}$$

for all  $n \in \mathbb{Z}$ . As a straightforward consequence we obtain the following

LIOUVILLE THEOREM

**Theorem.** If  $f(z)$  is analytic in  $\mathbb{C}$  and bounded, i.e.  $|f(z)| \leq M$  for some constant  $M$  and all  $z \in \mathbb{C}$ , then  $f(z)$  is constant.

**PROOF.** The Cauchy inequalities applied to  $f(z) = \sum_{n=0}^{\infty} c_n(z-a)^n$  yield that  $|c_n| \leq \frac{M}{R^n}$ ,  $n > 0$  for any  $R > 0$ . Thus,  $c_n = 0$  for any  $n \geq 1$  and consequently  $f(z) = c_0$ . □

**9.4.22. Isolated singularities.** We look at typical examples of analytic functions around "suspicious" points. Consider the fraction  $f(z) = \frac{\sin z}{z}$ . The origin is the zero point of both  $\sin z$  and  $z$ , and since they behave very similarly for small  $z$ , we see  $\lim_{z \rightarrow 0} f(z) = 1$ .

On the other hand  $f(z) = \frac{1}{z}$  grows towards infinity,  $\lim_{z \rightarrow 0} \frac{1}{z} = \infty$ , in the sense of the *extended complex plane*  $\overline{\mathbb{C}} = \mathbb{C} \cup \infty$  (also called the *Riemann sphere*). We can imagine  $\overline{\mathbb{C}}$  as the sphere with the stereographic projection onto the plane  $\mathbb{C}$ , see the picture. Then clearly  $\lim_{z \rightarrow a} f(z) = \infty$  if and only if  $\lim_{z \rightarrow 0} |f(z)| = \infty$  in the sense of standard analysis in real variables.

picture of the Riemann sphere  $\overline{\mathbb{C}}$  missing

It might easily happen that the limit does not exist at all, see the theorem below. For example, take  $f(z) = e^{\frac{1}{z}}$  around the point  $z = 0$ . It is given by the infinite principle part of a Laurent series,  $f(z) = \sum_{n=-1}^{-\infty} \frac{1}{n!} z^n$ . In general we talk about isolated singular points:

ISOLATED SINGULARITIES

If  $f(z)$  is analytic in a punctured neighbourhood  $V = \{0 < |z - a| < \rho\}$  then  $a$  is called an *isolated singular point* for  $f(z)$ . We say that the singular point is

- *removable*, if there is a finite limit  $\lim_{z \rightarrow a} f(z) = b \in \mathbb{C}$ ;
- a *pole*, if  $\lim_{z \rightarrow a} f(z) = \infty$ ;
- an *essential singularity*, if  $\lim_{z \rightarrow a} f(z)$  does not exist in  $\overline{\mathbb{C}}$ .

A function  $f(z)$  with only isolated singularities in a domain  $\Omega \subset \mathbb{C}$  and without any essential singularities is called a *meromorphic function* in  $\Omega$ .

The function  $f(z) = \tan \frac{1}{z}$  provides an example of a non-isolated singularity at  $a = 0$ , as 0 is the limit of poles  $(\frac{\pi}{2} + n\pi)^{-1}$ ,  $n \in \mathbb{Z}$ , of  $f(z)$ .

On the other hand, all rational functions  $f(z)/g(z)$  are meromorphic in  $\mathbb{C}$ .

The following theorem classifies isolated singularities and poles in terms of Laurent series.

**Theorem.** *The following properties are equivalent:*

- *the point  $z = a$  is a removable singularity for  $f(z)$ ;*
- *$|f(z)|$  is bounded in some punctured neighbourhood  $V = \{0 < |z - a| < \rho\}$ ;*
- *the Laurent series of  $f(z)$  in  $V = \{0 < |z - a| < \rho\}$  is the Taylor series  $f(z) = \sum_{n=0}^{\infty} c_n(z - a)^n$ , i.e. the principal part vanishes;*
- *$f(a)$  can be defined so that  $f(z)$  becomes analytic in  $\{|z - a| < \rho\}$ .*

Further, the point  $z = a$  is a pole for  $f(z)$  if and only if the principal part of the Laurent series of  $f(z)$  in  $\{0 < |z - a| < \rho\}$  contains only finitely many terms, i.e.  $f(z) = \sum_{n=-N}^{\infty} c_n(z - a)^n$ ,  $n \in \mathbb{N}$ , for some integer  $N$  (the smallest  $N$  with this property is called the *order* or the *pole* at  $z = a$ ).

Finally, the Laurent series  $f(z) = \sum_{n=-\infty}^{\infty} c_n(z - a)^n$  in the punctured neighbourhood of  $a$  contains infinitely many terms with non-zero coefficients  $c_n$ ,  $n < 0$ , if and only if  $z = a$  is an *essential singularity* for  $f(z)$ .

**PROOF.** If  $|f(z)| \leq M$  for  $0 < |z - a| < \rho$ , then by the Cauchy inequalities 9.4.21(1),  $|c_{-n}| \leq M\varepsilon^n$ ,  $n > 0$ , for all  $0 < \varepsilon < \rho$ . Therefore, all coefficients with negative indices

vanish, and

$$f(z) = \sum_{n=0}^{\infty} c_n(z-a)^n.$$

Define  $f(a) = c_0$  to obtain a power series that converges in the entire disc  $\{|z-a| < \rho\}$ .

This implies the equivalence of the four conditions in the first part of the theorem.

By the definition of a pole,  $f(z) \neq 0$  in some punctured disc  $D = \{0 < |z-a| < \rho' < \rho\}$  around  $a$  as  $\lim_{z \rightarrow a} f(z) = \infty$ . Therefore  $g(z) = \frac{1}{f(z)}$  is also analytic in  $D$  and  $\lim_{z \rightarrow a} g(z) = 0$ . Hence,  $g(z)$  is analytic in  $\overline{D}$  assuming  $g(a) = 0$  and, therefore,  $g(z) = (z-a)^N h(z)$  for some integer  $n$  and analytic function  $h(z)$  with  $h(a) \neq 0$ . Thus,  $\frac{1}{h(z)}$  is also analytic on a neighborhood of  $a$  and, therefore,

$$f(z) = \frac{1}{(z-a)^N} \sum_{n=0}^{\infty} c_n(z-a)^n.$$

Conversely, if  $f(z) = \frac{1}{(z-a)^N} h(z)$ , where  $h(a) \neq 0$ , then  $\lim_{z \rightarrow a} f(z) = \infty$  and  $a$  is a pole for  $f$ .

Finally, an isolated singularity of  $f(z)$  is neither removable nor a pole if and only if the principle part of its Laurent series is infinite and this observation finishes the proof.  $\square$

**9.4.23. Some consequences.** There are several straightforward corollaries of our classification of isolated singularities. In particular, if  $\lim_{z \rightarrow a} f(z)$  does not exist, then  $f(z)$  has really chaotic behaviour:

**Theorem.** *If  $a \in \mathbb{C}$  is an essential singularity of  $f(z)$ , then for any  $w \in \overline{\mathbb{C}}$  there is a sequence  $z_n \rightarrow a$  such that  $\lim_{n \rightarrow \infty} f(z_n) = w$ .*

**PROOF.** Let  $w = \infty$ . Since the singularity  $z = a$  is not removable,  $f(z)$  cannot be bounded in any punctured neighbourhood of  $a$ . So there exists a sequence  $z_n \rightarrow a$  such that  $\lim_{n \rightarrow \infty} f(z_n) = \infty$ .

For  $w \in \mathbb{C}$ , if in any punctured neighbourhood of  $a$  there is a point  $z$  such that  $f(z) = w$ , then by making a sequence with those points we obtain a sequence  $z_n$  such that  $f(z_n) = w$ , as required. If there is a punctured neighbourhood of  $a$  where  $f(z) \neq w$ , then  $g(z) = \frac{1}{f(z)-w}$  also has an isolated singularity at  $z = a$ , which cannot be a pole or a removable one, as otherwise  $f(z) = w + \frac{1}{g(z)}$  would have a limit as  $z \rightarrow a$ . Therefore  $z = a$  is an essential singularity for  $g(z)$  and, thus, there is a sequence  $z_n \rightarrow a$  such that  $g(z_n) = \infty$ , which implies that  $\lim_{n \rightarrow \infty} f(z_n) = w$ .  $\square$

We say that  $\infty \in \overline{\mathbb{C}}$  is an *isolated singularity* of  $f(z)$  if  $f(z)$  is analytic in  $\{|z-a| > R\}$  for some  $R > 0$ . These are straightforward consequences of the Liouville theorem if  $\infty$  is the only singularity of  $f(z)$ :

**Corollary.** *If  $f(z)$  is analytic in  $\mathbb{C}$  and  $z = \infty$  is a removable singularity for  $f(z)$  then  $f(z)$  is a constant.*

*If  $f(z)$  is analytic in  $\mathbb{C}$  and  $z = \infty$  is a pole then  $f(z)$  is a polynomial  $f(z) = \sum_{j=0}^n c_j(z-a)^j$ .*

**PROOF.** The first claim is a simple reformulation of the Liouville theorem, cf. 9.4.21.

To deal with the other claim, consider  $g(w) = f(\frac{1}{w})$ . Then  $w = 0$  is a pole for  $g(w)$ . Let  $P(w) = \sum_{j=1}^N c_j w^{-j}$  be the principal part of Laurent series for  $g(w)$ . Thus,  $h(w) = g(w) - P(w)$  is analytic in  $\mathbb{C}$  with a removable singularity at  $w = 0$ . Moreover,  $\lim_{w \rightarrow \infty} h(w) = \lim_{w \rightarrow \infty} g(w) = f(0)$ . Thus,  $|h(w)|$  is bounded, and by the Liouville theorem  $h(w) = \text{const} = f(0) = c_0$ . Hence  $f(z) = g(z^{-1}) = \sum_{j=0}^N c_j z^j$ , which is a polynomial in  $z$ .  $\square$

**9.4.24. Residues.** Next we return to the Cauchy integral theorem, with our knowledge of isolated singularities.

A *residue* of an analytic function  $f(z)$  at its isolated singular point  $a \in C$  is defined as

$$\text{res}_a f = \frac{1}{2\pi i} \int_{|z|=r} f(z) dz,$$

where  $0 < r < \rho$ . Obviously, the definition does not depend on the choice of  $r$ .

#### RESIDUE THEOREM

**Theorem.** If  $f(z)$  is represented by the Laurent series  $\sum_{n=-\infty}^{\infty} c_n (z-a)^n$ , then  $\text{res}_a f = c_{-1}$ .

Further, consider a domain  $D \subset \mathbb{C}$  and a function  $f(z)$  analytic in  $\bar{D} \setminus \{a_1, \dots, a_n\}$ , where  $a_j \in D$ ,  $j = 1, \dots, n$ . Then

$$\int_{\partial D} f(z) dz = 2\pi i \sum_{j=1}^n \text{res}_{a_j} f.$$

**PROOF.** Integrating the Laurent series  $\sum_{n=-\infty}^{\infty} c_n (z-a)^n$  and using the fact that  $\int_{|z-a|=\rho} (z-a)^n dz = 0$  unless  $n = -1$ , while  $\int_{|z-a|=\rho} (z-a)^{-1} dz = 2\pi i$ , we obtain that  $\text{res}_a f = c_{-1}$ .

Next, choose such  $\rho > 0$  that open discs  $D_j = \{|z - a_j| < \rho\}$ ,  $j = 1, \dots, n$ , have pairwise empty intersections and their closures  $\bar{D}_j$  belong to  $D$ . Then the Cauchy Integral theorem 9.4.15, applied to  $D_\rho = D \setminus \bigcup_{j=1}^n D_j$  yields

$$\begin{aligned} 0 &= \int_{\partial D_\rho} f(z) dz = \int_{\partial D} f(z) dz - \sum_{j=1}^n \int_{\partial D_j} f(z) dz \\ &= \int_{\partial D} f(z) dz - \sum_{j=1}^n \text{res}_{a_j} f. \end{aligned} \quad \square$$

**9.4.25. Residues at infinity.** Recall that when integrating along the circle  $|z - a| = R$ , we always assume counterclockwise orientation on the circle. Thus we use the minus sign in the definition:

If  $f(z)$  is analytic in the closure of an exterior of a disc  $\{|z| \geq R\}$ , then

$$\text{res}_\infty f = -\frac{1}{2\pi i} \int_{|z|=R} f(z) dz.$$

In terms of the Laurent series  $f(z) = \sum_{n=-\infty}^{\infty} c_n(z-a)^n$ , valid in  $\{|z| \geq R\}$ , we have  $\operatorname{res}_{\infty} f = -c_{-1}$ .

Note that if  $f(z)$  is analytic in  $\mathbb{C} \setminus \{a_1, \dots, a_n\}$ , then

$$\operatorname{res}_{\infty} f + \sum_{j=1}^n \operatorname{res}_{a_j} f = 0.$$

Indeed, by taking a disc  $\{|z| < R\}$  of sufficiently large radius that does not contain singularities on its boundary, we conclude that

$$\frac{1}{2\pi i} \int_{|z|=R} f(z) dz = \sum_{j=1}^n \operatorname{res}_{a_j} f.$$

**9.4.26. Example of applications.** Residues of analytic functions are used for the evaluation of improper integrals in real analysis. The following lemma turns out to be very useful for such purposes. We shall write  $M(R)$  for the maximum of  $|f(z)|$  over the upper half of the circle with radius  $R$ , i.e.  $M(R) = \max_{|z|=R, \operatorname{Im} z \geq 0} |f(z)|$ .

#### JORDAN'S LEMMA

**Lemma.** Consider the function  $f(z)$  continuous on  $\{\operatorname{Im} z \geq 0, |z| = R\}$ . Then, for each positive real parameter  $t$ ,

$$\int_{|z|=R, \operatorname{Im} z \geq 0} f(z) e^{itz} dz \leq \frac{\pi}{t} M(R).$$

Consequently, if  $f(z)$  is continuous on  $\{\operatorname{Im} z \geq 0, |z| \geq R_0\}$  and  $\lim_{R \rightarrow \infty} M(R) = 0$ , then

$$\lim_{R \rightarrow \infty} \int_{|z|=R, \operatorname{Im} z \geq 0} f(z) e^{itz} dz = 0.$$

**PROOF.** We estimate the integral from the lemma:

$$\begin{aligned} \left| \int_0^{\pi} f(R e^{i\theta}) e^{-tR \sin \theta + itR \cos \theta} iR e^{i\theta} d\theta \right| \\ \leq R M(R) \int_0^{\pi} e^{-tR \sin \theta} d\theta. \end{aligned}$$

To evaluate the latter integral, we observe that  $\sin \theta \geq \frac{2}{\pi} \theta$  for  $0 \leq \theta \leq \frac{\pi}{2}$ . Thus, using  $t > 0$  and the substitution  $\tau = \frac{2Rt\theta}{\pi}$ , we arrive at

$$\begin{aligned} R M(R) \int_0^{\pi} e^{-tR \sin \theta} d\theta &= 2R M(R) \int_0^{\frac{\pi}{2}} e^{-tR \sin \theta} d\theta \\ &\leq 2R M(R) \int_0^{\frac{\pi}{2}} e^{-\frac{2tR\theta}{\pi}} d\theta = \frac{\pi}{t} M(R) \int_0^{Rt} e^{-\tau} d\tau \\ &= \frac{\pi}{t} M(R) (1 - e^{-Rt}) \leq \frac{\pi}{t} M(R). \end{aligned}$$

The consequence for  $R \rightarrow \infty$  is obvious.  $\square$

Typically, the Jordan lemma is used to compute improper integrals of real analytic (complex valued) functions  $g(x) =$

$f(x) e^{itx}$  along the entire real line (or rather the real or imaginary parts of such integrals). If the corresponding complex analytic function  $f(z)$  has only a finite number of poles  $a_k$  in the upper half plane and  $\lim_{R \rightarrow \infty} M(R) = 0$ , then we may compute the real integral

$$\int_{-\infty}^{\infty} g(x) dx = \lim_{R \rightarrow \infty} \int_{\gamma_R} g(z) dz = 2\pi i \sum_k \text{res}_{a_k} g(z),$$

where  $\gamma_R$  is the path composed by the interval  $[-R, R]$  and the half upper circle of radius  $R$ . See the diagram and the examples in the other column.

picture for the half circle area

**9.4.27. Concluding remarks.** Of course we have not touched on many important issues in this short introduction. These include the *conformal properties* of all analytic functions, i.e. they preserve all angles of curves, the richness of analytic functions which allow the mapping of any simply connected region  $\Omega$  bijectively to the unit open disc (i.e. both the map and its inverse are analytic, the *Riemann mapping theorem*). The proper setup for analytic extensions are the *Riemann surfaces* with their fascinating topological properties. Also, we only commented on the possibility of proving the Cauchy integral theorem for triangles just assuming the existence of complex derivative. The analyticity of all holomorphic functions then follows from the Cauchy integral formula. Moreover, we have not mentioned the functions of several complex variables at all!

We hope that all of these interesting issues will challenge the readers to go for further more detailed study in the relevant literature.

**G. Additional exercises to the whole chapter**

**9.G.1. Solution.**

**9.G.2. Solution.**

**9.G.3. Solution.**

**9.G.4. Solution.**

**9.G.5. Solution.**

Solutions of the exercises

**9.B.6.** The answer is  $4\pi$ .

**9.B.7.** The answer is  $36\pi$ .

**9.B.8.** The answer is  $\frac{65\pi}{24}$ .

**9.D.2.** The general solution has the form  $u = \Phi(x^2 - y^2)$ . Moreover,  $u_{(i)} = \sqrt{x^2 - y^2}$ ,  $x > y$ ,  $u_{(ii)} = y^2 - x^2$ , and the condition (iii) makes no sense.

**9.D.3.** The general solution has the form  $u = \Phi(x^2 + y^2)$ . Moreover, we see that  $u_{(i)} = x^2 + y^2$ ,  $u_{(ii)} = \frac{1}{1+x^2+y^2}$ ,  $u_{(iii)} = (x^2 + y^2 - 1)^2$  (unique for  $x^2 + y^2 > 1$ ).

**9.D.4.** The answer has the form  $u(x, y) = 2 \cos(y) \sin(x) - 1$ .

**9.D.8.** The general solution has the form  $u = K(y^2 - 2x) \cdot e^y$ .

**9.D.9.** The general solution has the form  $u(x, y) = K(y - x) \cdot e^y$ . Moreover,  $u_{(i)} = (y - x) \cdot e^{x(y-x)}$ ,  $u_{(ii)} = \frac{2}{x-y} \cdot e^{\frac{y^2-x^2}{2}}$ ,  $u_{(iii)} = (y - x)^2 \cdot e^{y(y-x)}$ .

**9.D.10.** The solution is given by  $u = \frac{y}{yC(\frac{1}{y}-x)-1}$ ,  $u_p = \frac{y}{2xy+3y-3}$ .

**9.D.11.** The solution has the form  $u = x^2 + y^2 + C(\frac{y}{x})$ ,  $u_p = x^2 + y^2 + \frac{y^2}{x^2}$ .

**9.D.12.** The solution is given by  $u = \frac{1}{4}x^2 - \frac{1}{2}y^2 + C(y\sqrt{x})$ ,  $u_p = \frac{1}{4}(x^2 - 2y^2 - xy^2)$ .

**9.D.13.** The solution is given by  $u = y^2 C\left(ye^{\frac{1}{x}}\right)$ ,  $u_p = y^3 e^{\frac{1}{x}-1}$ .

**9.D.15.** The solution is given by  $u(x, y) = \sqrt{x^2 + y^2}$ ,  $u(x, y) = 2 - \sqrt{x^2 + y^2}$ .

**9.D.16.** The solution is given by  $u(x, y) = \frac{x^2+y^2}{2}$ ,  $u(x, y) = -\frac{1}{2}\left(1 - \sqrt{x^2 + y^2}\right)^2$ .

**9.D.17.** The solution is the function  $u(x, y) = e^{\sqrt{x^2+y^2}-1}$ .

**9.D.18.** The solution is the function  $u(x, y) = \frac{1}{4}\left(x^2 + y^2 + 2\sqrt{x^2 + y^2} + 1\right)$ .

**9.D.19.** The solution is the function  $u(x, y) = -e^{1-\sqrt{x^2+y^2}}$ .

**9.D.20.** The answer is given by  $u(x, y) = x(1 - y)$ .

**9.D.21.** The answer is the function  $u(x, y) = x + y$ .

**9.D.22.** The answer is given as follows:  $u(x, y) = (2 - \sqrt{x})^2$ ,  $u = x$ .

**9.D.23.** The answer is  $u(x, y) = x^2 - y^2$ .

**9.D.24.** The answer is  $u(x, y) = y$ .

**9.D.26.**  $u(x, y) = De^{x^2 y^2}$ .

**9.D.27.**  $u(x, y) = x + y + Dxy$ .

**9.D.30.** We get  $\alpha_0 = 1$ ,  $\beta_0 = 0$ ,  $\alpha_1 = x$ ,  $\beta_1 = y$ ,  $\alpha_2 = x^2 - y^2$ ,  $\beta_2 = 2xy$ ,  $\alpha_3 = x^3 - 3xy^2$ ,  $\beta_3 = 3x^2y - y^3$ .

**9.D.34.** Parabolic equation,  $\xi = y + \ln x$ ,  $\eta = y$ ,  $u_{\eta\eta} = 0$ , solution  $u = yC(y + \ln x) + D(y + \ln x)$ .

**9.D.35.** Hyperbolic equation,  $\xi = xy$ ,  $\eta = y$ ,  $u_{\xi\eta} = 0$ ,  $u = F(y) + G(xy)$ .

**9.D.36.** Elliptic equation,  $\xi = x + 2y$ ,  $\eta = \sqrt{7}x$ ,  $\Delta u = 0$ ,  $u(x, y) = C(x + 2y + i\sqrt{7}x) + D(x + 2y - i\sqrt{7}x)$ .

**9.D.37.** Elliptic equation,  $\xi = y^2$ ,  $\eta = x^2$ ,

$$\Delta u = -\frac{1}{2}\left(\frac{u_\eta}{\eta} + \frac{u_\xi}{\xi}\right).$$

**9.D.38.** Substitute formula into equation and initial condition.

**9.D.40.**

$$u_a = \frac{1}{2} [\sin(x-t) + \sin(x+t) + (x+t)\sin(x+t) + \cos(x+t) - (x-t)\sin(x-t) - \cos(x-t)],$$

$$u_b = 2x + \frac{1}{2} [(x+t)\ln(1+(x+t)^2) - 2(x+t) + 2\arctan(x+t) - (x-t)\ln(1+(x-t)^2) + 2(x-t) - 2\arctan(x-t)],$$

$$u_c = x + \ln \sqrt{\frac{x+t}{x-t}} + \sin x - \sin x \cos t.$$

**9.D.41.**

$$u(t, x) = x^2 + 2x + t^2 + 2\sin x - 2\sin x \cos t + \frac{1}{2} [(x+t)\sin(x+t) - (x-t)\sin(x-t) + \cos(x+t) - \cos(x-t)].$$

**9.D.42.**

$$u(t, x) = 2x^2 - x + 2t^2 + 2\cos x - 2\cos x \cos t + \frac{1}{2} [-(x+t)\cos(x+t) + (x-t)\cos(x-t) + \sin(x+t) - \sin(x-t)].$$

**9.D.43.**

$$u(t, x) = x^3 + 12xt^2 + \frac{1}{4} \ln \frac{x+2t + \sqrt{1+(x+2t)^2}}{x-2t + \sqrt{1+(x-2t)^2}} + \frac{1}{4}t^2 + \frac{1}{8} \cos 2x - \frac{1}{8} \cos 2x \cos 4t.$$

**9.D.44.**

$$u(t, x) = x^2 + 9t^2 + \frac{1}{6} [(x+3t)e^{x+3t} - (x-3t)e^{x-3t} + e^{x-3t} - e^{x+3t}] + \frac{4}{9} [\cos x \cos 3t - \cos x].$$

**9.D.48.**

$$u(x, y) = \sin y \cdot \left( \frac{1}{1 - e^{2\pi}} e^x + \frac{1}{1 - e^{-2\pi}} e^{-x} \right).$$

**9.D.49.**

$$u(t, x) = -\cos \frac{\pi x}{l} \cos \frac{\pi t}{l} + \frac{l}{2\pi} \cos \frac{2\pi x}{l} \sin \frac{2\pi t}{l}.$$

**9.D.50.**

$$u(t, x) = -e^{-4t} \sin(2x) + e^{-16t} \sin(4x).$$

**9.D.51.**

$$u(t, x) = -3\sin(4x)\cos(4t) - \sin x \sin t + \sin(2x)\sin(2t)$$

**9.D.52.**

$$u(t, x) = \sum_{n=1}^{\infty} c_n e^{-\left[\frac{(2n-1)\pi}{2a}\right]^2 t} \sin\left(\frac{2n-1}{2a}\pi x\right), \quad c_n = \frac{2}{a} \int_0^a x(2a-x) \sin\left(\frac{2n-1}{2a}\pi x\right) dx = \frac{32a^2}{\pi^3(2n-1)^3}$$

**9.D.53.**

$$u(t, x) = \frac{8A^2}{\pi^3} \sum_{n=1,3,5,\dots}^{\infty} \frac{1}{n^3} \sin \frac{n\pi x}{A} \cos \frac{n\pi t}{A}.$$

**9.D.54.**

$$u(x, y) = \sum_{n=1}^{\infty} \sin \frac{n\pi x}{a} (a_n e^{\frac{n\pi}{a}y} + b_n e^{-\frac{n\pi}{a}y}), \quad a_n = \frac{1}{1 - e^{2n\pi}} \cdot \frac{2}{a} \int_0^a x(a-x) \sin \frac{n\pi x}{a} dx, \quad b_n = \frac{1}{1 - e^{-2n\pi}} \cdot \frac{2}{a} \int_0^a x(a-x) \sin \frac{n\pi x}{a} dx$$

$$u(x, y) = \sum_{n=0}^{\infty} \sin \frac{(2n+1)\pi x}{a} \left( \frac{8a^2}{(2n+1)^3\pi^3 (1 - e^{2(2n+1)\pi})} e^{\frac{(2n+1)\pi}{a}y} + \frac{8a^2}{(2n+1)^3\pi^3 (1 - e^{-2(2n+1)\pi})} e^{-\frac{(2n+1)\pi}{a}y} \right).$$

**9.D.55.**

$$u(t, x) = - \sum_{n=0}^{\infty} \frac{8}{(2n+1)^2 \pi^2} \cos\left(\frac{2n+1}{2} \pi x\right) \cdot e^{-(2n+1)^2 \pi^2 t}.$$

**9.D.58.**

$$u(x, y) = \frac{xy}{A^2}.$$

**9.D.59.**

$$u(x, y) = \frac{5}{2} + \frac{A^2}{2} \cdot \frac{x^2 - y^2}{(x^2 + y^2)^2}.$$

**9.D.60.**

$$u(x, y) = \frac{1}{2} + \frac{x^2 - y^2}{2} + y.$$

**9.D.62.**

$$u(t, x) = \operatorname{erf}\left(\frac{x}{2\sqrt{t}}\right) - \operatorname{erf}\left(\frac{x-1}{2\sqrt{t}}\right).$$

## Statistics and probability methods

*Is statistics a part of mathematics?  
– whenever it is so, we need much of mathematics there...!*

### A. Dots, lines, rectangles

The obtained data from reality can be displayed in many ways. Let us illustrate some of them.

**10.A.1. Presenting the collected data.** 20 mathematicians were asked about the number of members of their household. The following table displays the frequency of each number of members.

Number of members	1	2	3	4	5	6
Number of households	5	5	1	6	2	1

Create the frequency distribution table. Find the mean, median and mode of the number of members. Build a column diagram of the data.

**Solution.** Let us begin with the frequency distribution table. There, we write not only the frequencies, but also the cumulative frequencies and relative frequencies (i. e., the probability that there is a given number of members in a randomly picked household). Let us denote the number of members by  $x_i$ , the corresponding frequency by  $n_i$ , the relative frequency by  $p_i$  ( $= n_i / \sum_{j=1}^6 n_j = n_i / 20$ ), the cumulative frequency by  $N_i$  ( $= \sum_{j=1}^i x_j$ ), and the relative cumulative frequency by  $F_i$

Roughly speaking, statistics is any processing of numerical or other type of data about a population of objects and their presentation. In this context, we talk about *descriptive statistics*. Its objective is thus to process and comprehensibly represent data about objects of a given “population” — for instance, the annual income of all citizens obtained from the complete data of revenue authorities, or the quality of hotel accommodation in some region. In order to achieve this, we focus on simple numerical characterization and visualization of the data.

in general, many pictures missing!!

Mathematical statistics uses mathematical methods to derive conclusions valid for the whole (potentially infinite) population of objects, based on a “small” sample. For instance, we might want to find out how much a certain disease is spread in the population by collecting data about a few randomly chosen people, but we interpret the results with regard to the entire population. In other words, mathematical statistics makes conclusions about a large population of objects based on the study of a small (usually randomly selected) sample collection. It also estimates the reliability of the resulting conclusions.

Mathematical statistics is based on the tools of probability theory, which is very useful (and amazing) in itself. Therefore, probability theory is discussed first.

This chapter provides an elementary introduction to the methods of probability theory, which should be sufficient for correct comprehension of ordinary statistical information all around us. However, for a serious understanding of a mathematical statistician’s work, one must look for other resources.

### 1. Descriptive statistics

Descriptive statistics alone is not a mathematical discipline although it uses many manipulations with numbers and sometimes even very sophisticated methods. However, it is a good opportunity for illustrating the mathematical approach to building generally useful tools.

At the same time, it should serve as a motivation for studying probability theory because of later applications in statistics.

$$(\text{= } N_i/20 = \sum_{j=1}^i p_j):$$

$x_i$	$n_i$	$p_i$	$N_i$	$F_i$
1	5	1/2	5	1/4
2	5	1/4	10	1/2
3	1	1/20	11	11/20
4	6	3/10	17	17/20
5	2	1/10	19	19/20
6	1	1/20	20	1

Now, we can easily construct the wanted (column) graphs of (relative, cumulative) frequencies:

The mean number of members of a household is:

$$\bar{x} = \frac{5 \cdot 1 + 5 \cdot 2 + 1 \cdot 3 + 6 \cdot 4 + 2 \cdot 5 + 1 \cdot 6}{20} = 2.9.$$

The median is the arithmetic mean of the tenth and eleventh values (having been sorted), which are respectively 2 and 3, i. e.,  $\tilde{x} = 2.5$ .

The mode is the most frequent value, i. e.,  $\hat{x} = 4$ .

The collected data can also be presented using a *box plot*:

The upper and lower sides of the “box” correspond respectively to the first (lower) and the third (upper) quartile, so its height is equal to the interquartile range. The thick horizontal line is drawn at the median level; the lower and upper horizontal lines correspond respectively to the minimum and maximum elements of the data set, or to the value that is 1.5 times the interquartile range less than the lower side of the box (and greater than the upper side, respectively). The data outside this range would be shown as circles.

We can also build the histogram of the data:

In our brief introduction, we first introduce the concepts allowing to measure the positions of data values and the variability of the data values (means, percentiles etc.). We touch the problem how to visualize or otherwise present the data sets (diagrams). Then we deal with the potential relations between more data sets (covariance and principal components) and, finally, we deal with data without numerical values relying just on their frequencies of appearance (entropy).

### 10.1.1. Probability, or statistics?

It is not by accident that we return to a part of the motivating hints from the first chapter, as soon as we have managed to gather enough mathematical tools both discrete and continuous.

Nowadays, many communications are of a statistical nature, be it in media, politics, or science. Nevertheless, in order to properly understand the meaning of such a communication and using particular statistical methods and concepts, one must have a broad knowledge of miscellaneous parts of mathematics. In this subsection, we move away from the mathematical theory; and think about the following steps and our objectives.

As an example of a population of objects, consider the students of a given basic course. Then, the examined numerical data can be:

- the “mean number of points” obtained during the course in the previous semester and the “variance” of these values,
- the “mean marks” for the examination of this and other courses and the “correlation” (i.e. mutual dependence) of these results,
- the “correlation” of data about the past results of given students,
- the “correlation” of the number of failed exams of a given student and the number of hours spent in a temporary job,
- ...

With regard to the first item, the arithmetic mean itself does not carry enough information about the quality of the lecture or of the lecturer, nor about the results of particular students. Maybe the value which is “in the middle” of the population, or the number of points achieved by the student who was just better than half of the students is of more concern. Similarly, the first quarter, the last quarter, the first tenth, etc. maybe of interest. Such data are called *statistics* of the population. Such statistics are interesting for the students in question as well, and it is quite easy to define, compute, and communicate them.

From general experience or as a theoretical result outside mathematics, a reasonable assessment should be “normally” distributed. This is a concept of probability theory, and it requires quite advanced mathematics to be properly defined. Comparing the collected data about even a small random population of students to theoretical results can serve in two ways: We can estimate the parameters of the distribution as well as draw a conclusion whether the assessment is reasonable.

Note that the frequencies of one- and two-member households were merged into a single rectangle. This is used in order to make the data “easier to read” – there exist (various and ambiguous) rules for the merging.

We simply mention this fact without presenting an exact procedure (it is just as anyone likes). □

**10.A.2.** Given a data set  $x = (x_1, x_2, \dots, x_n)$ , find the mean and variance of the centered values  $x_i - \bar{x}$  and the standardized values  $\frac{x_i - \bar{x}}{s_x}$ .

**Solution.** The mean of the centered values can be found directly using the definition of arithmetic mean:

$$\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x}) = \frac{1}{n} \sum_{i=1}^n x_i - \frac{\bar{x}}{n} \sum_{i=1}^n 1 = \bar{x} - \bar{x} = 0.$$

The variance of the centered values is clearly the same as for the original ones ( $s_x$ ). For the standardized values, the mean is equal to zero again, and the variance is

$$\frac{1}{n} \sum_{i=1}^n \left( \frac{x_i - \bar{x}}{s_x} \right)^2 = \frac{1}{s_x^2} \cdot \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 = 1. \quad \square$$

**10.A.3.** Prove that the variance satisfies  $s_x^2 = \frac{1}{n} \sum_{i=1}^n x_i^2 - \bar{x}^2$ .

**Solution.** Using the definitions of variance and arithmetic mean, we get:

$$\begin{aligned} s_x^2 &= \frac{1}{n} \sum_{i=1}^n (x_i^2 - 2x_i\bar{x} + \bar{x}^2) = \frac{1}{n} \sum_{i=1}^n x_i^2 - \frac{2\bar{x}}{n} \sum_{i=1}^n x_i + \bar{x}^2 \\ &= \frac{1}{n} \sum_{i=1}^n x_i^2 - \bar{x}^2. \end{aligned}$$

At the same time, the numerical values of statistics for a given population can yield qualitative description of the likelihood of our conclusions. We can compute statistics which reflect the variability of the examined values, rather than where these values are positioned within a given population. For instance, if the assessment does not show enough variability, it may be concluded that it is badly designed, because the students’ skills are of course different. The same applies if the collected data seem completely random.

In the above paragraph, it is assumed that the examined data is reliable. This is not always the case in practice. On the contrary, the data is often perturbed with errors due to construction of the experiment and the data collection itself.

In many cases, not much is known about the type of the data distribution. Then, methods of non-parametric statistics are often used (to be mentioned at the end of this chapter). Very interesting conclusions can be found if we compare the statistics for different quantities and then derive information about their relations. For example, if there is no evident relation between the history of previous studies and the results in a given course, then it may be that the course is managed wrongly.

These ideas can be summarized as follows:

- In descriptive statistics, there are tools which allow the understanding of the structure and nature of even a huge collection of data;
- in mathematics, one works with an abstract mathematical description of probability, which can be used for analysis of given data. Especially, this is when there is a theoretical model to which the data should correspond;
- conclusions of statistical investigation of samples of particular data sets can be given by mathematical statistics;
- mathematical statistics can also estimate how adequate such a description is for a given data set.

**10.1.2. Terminology.** Statisticians have introduced a great many concepts which need mastering. The fundamental concept is that of a *statistical population*, which is an exactly defined set of basic *statistical units*. These can be given by enumeration or by some rules, in case of a larger population.

On every statistical unit, *statistical data* is measured, with the “measurement” perceived very broadly.

For instance, the population can consist of all students of a given university. Then, each of the students is a *statistical unit* and much data can be gathered about these units – the numerical values obtainable from the information system, what is their favorite colour, what they had for dinner before their fast test, etc.

The basic object for examining particular pieces of data is a *data set*. It usually consists of ordered values. The ordering can be either natural (when the data values are real numbers, for example) or we can define it (for instance, when we observe colours, we can express them in the RGB format

**10.A.4.** The following values have been collected:

10; 7; 7; 8; 8; 9; 10; 9; 4; 9; 10; 9; 11; 9; 7; 8; 3; 9; 8; 7.

Find the arithmetic mean, median, quartiles, variance, and the corresponding box diagram.

**Solution.** Denoting the individual values by  $a_i$  and their frequencies by  $n_i$ , we can arrange the given data set into the following table.

$a_i$	3	4	7	8	9	10	11
$n_i$	1	1	4	4	6	3	1

From the definition of arithmetic mean, we have

$$\bar{x} = \frac{3 + 4 + 4 \cdot 7 + 4 \cdot 8 + 6 \cdot 9 + 3 \cdot 10 + 11}{1 + 1 + 4 + 4 + 6 + 3 + 1} = \frac{162}{20} = 8.1.$$

Since the tenth least collected value is  $x_{(10)} = 8$  and the eleventh one is  $x_{(11)} = 9$ , the median is equal to  $\tilde{x} = \frac{8+9}{2} = 8.5$ . The first quartile is  $x_{0.25} = \frac{x_{(5)}+x_{(6)}}{2} = 7$ , and the third quartile is  $x_{0.75} = \frac{x_{(15)}+x_{(16)}}{2} = 9$ . From the definition of variance, we get  $s_x^2$ :

$$\frac{5 \cdot 1^2 + 4 \cdot 1^2 + 4 \cdot 1.1^2 + 4 \cdot 0.1^2 + 6 \cdot 0.9^2 + 3 \cdot 1.9^2 + 2 \cdot 9^2}{1 + 1 + 4 + 4 + 6 + 3 + 1} = 3.59.$$

The histogram and box diagram are shown in the following pictures.

where we have used "statistics" method to make the histogram "nice" and "clear". You can find a lot of these conventions in the books on statistics, but if you do not know them, you are lost. This is the default setting of the R program. For example if you replace just value 3 by 2 you get quite different looking histogram:

and order them with respect to this sign). We can also work with unordered values.

Since statistical description aims at telling comprehensible information about the entire population, we should be able to compare and take ratios of the data values. Therefore, we need to have a *measurement scale* at our disposal. In most cases, the data values are expressed as numbers. However, the meaning of the data can be quantified variously, and thus we distinguish between the following *types of data measurement scales*.

TYPES OF DATA MEASUREMENT SCALES

The data values are called:

- *nominal* if there is no relation between particular values; they are just qualitative names, i.e. possible values (for instance, political parties or lecturers at a university when surveying how popular they are);
- *ordinal* the same as above, but with an ordering (for example, number of stars for hotels in guidebooks);
- *interval* if the values are numbers which serve for comparisons but do not correspond to any absolute value (for example, when expressing temperature in Celsius or Fahrenheit degrees, the position of zero is only conventional);
- *ratio* if the scale and the position of zero are fixed (most physical and economical quantities).

With nominal types, we can interpret only equalities  $x_1 = x_2$ ; with ordinal types, we can also interpret inequalities  $x_1 < x_2$  (or  $x_1 > x_2$ ); with interval types, we can also interpret differences  $x_1 - x_2$ . Finally, with rational types, we have also ratios  $x_1/x_2$  available.

**10.1.3. Data sorting.** In this subsection, we work with a *data set*  $x_1, x_2, \dots, x_n$ , which can be ordered (thus, their type is not nominal) and which have been obtained through measurement on  $n$  statistical units. These values are sorted in a *sorted data set*

$$(1) \quad x_{(1)}, x_{(2)}, \dots, x_{(n)}.$$

The integer  $n$  is called the *size of the data set*.

When working with large data sets where only a few values occur, the simplest way to represent the data set is to enumerate the values' frequencies.

For instance, when surveying the political party preference or when presenting the quality of a hotel, write only the number of occurrences of each value.

If there are many possible values (or there can even be continuously distributed real values), divide them into a suitable number of intervals and then observe the frequencies in the given intervals. The intervals are also called *classes* and the frequencies are called *class frequencies*. We also use *cumulative frequencies* and *cumulative class frequencies* which correspond to the sum of frequencies of values not exceeding a given one.

Most often, the mean  $a_i$  of a given class is considered to be its representative, and the value  $a_i n_i$  (where  $n_i$  is the frequency of the class) is the total contribution of the class. *Relative frequencies*  $a_i/n$ , and *relative cumulative frequencies*, can also be considered.

A graph which has the intervals of particular classes on one axis and rectangles above them with height corresponding to the frequency is called a *histogram*. Cumulative frequency is represented similarly.

The following diagram shows histograms of data sets of size  $n = 500$  which were randomly generated with various standard distributions (called normal,  $\chi^2$ , respectively).

**10.A.5.** 425 carps were fished, and each one was taken weighed. Then, mass intervals were set, resulting in the following frequency distribution table:

Weight (kg)	0–1	1–2	2–3	3–4	4–5	5–6	6–7
Class midpoint	0.5	1.5	2.5	3.5	4.5	5.5	6.5
Frequency	75	90	97	63	48	42	10

Draw a histogram, find the arithmetic, geometric, and harmonic means of the carps' weights. Furthermore, find the median, quartiles, mode, variance, standard deviation, coefficient of variation, and draw a box plot.

**Solution.** The histogram looks as follows:

From the definitions of the corresponding concepts in subsection 10.1.4, we can directly compute that the arithmetic mean is  $\bar{x} = 2.7$  kg, the geometric mean is  $\bar{x}^G = 2.1$  kg, and the harmonic mean is  $\bar{x}^H = 1.5$  kg. By the definitions of subsection 10.1.5, the median is equal to  $\tilde{x} = x_{0.5} = 2.5$

**10.1.4. Measures of the position of statistical values.** If

the magnitude of values around which the collected data values gather are to be expressed, then the concepts of the definition below can be used. There, we work with ratios or interval types of scales.

Consider an (unsorted) data set  $(x_1, \dots, x_n)$  of the values for all examined statistical units and let  $n_1, \dots, n_m$  be the class frequencies of  $m$  distinct values  $a_1, \dots, a_m$  that occur in this set.

MEANS

**Definition.** The *arithmetic mean* (often only *mean*) is given as

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i = \frac{1}{n} \sum_{j=1}^m n_j a_j.$$

The *geometric mean* is given as

$$\bar{x}^G = \sqrt[n]{x_1 x_2 \cdots x_n}$$

and makes sense for positive values  $x_i$  only. The *harmonic mean* is given as

$$\bar{x}^H = \left( \frac{1}{n} \sum_{i=1}^n \frac{1}{x_i} \right)^{-1}$$

and is also used for positive values  $x_i$  only.

The arithmetic mean is the only one of the three above which is invariant with respect to affine transformations. For all scalars  $a, b$ ,

$$\overline{(a + b \cdot x)} = \frac{1}{n} \sum_{i=1}^n (a + b x_i) = a + b \sum_{i=1}^n x_i = a + b \cdot \bar{x}.$$

kg, the lower quartile to  $x_{0.25} = 1.5$  kg, the upper quartile to  $x_{0.75} = 3.5$  kg, and the mode is  $\hat{x} = 2.5$  kg. From the definitions of subsection 10.1.6, we compute the variance of the weights, which is  $s_x^2 = 2.7 \text{ kg}^2$ , whence it follows that the standard deviation is  $s_x = 1.7$  kg, and the coefficient of variation is  $V_x = 0,6$ .  $\square$

**10.A.6.** Prove that the entropy is maximal if the nominal values are distributed uniformly, i. e., the frequency of each class is  $n_i = 1$ .

**Solution.** By the definition of entropy (see 10.1.11), we are looking for the maximum of the function  $H_X = -\sum_{i=1}^n p_i \ln p_i$  with respect to unknown relative frequencies  $p_i = \frac{n_i}{n}$ , which satisfy  $\sum_{i=1}^n p_i = 1$ . Therefore, this is a typical example of finding constrained extrema, which can be solved using Lagrange multipliers. The corresponding Lagrange function is

$$L(p_1, \dots, p_n, \lambda) = -\sum_{i=1}^n p_i \ln p_i + \lambda \left( \sum_{i=1}^n p_i - 1 \right).$$

The partial derivatives are  $\frac{\partial L}{\partial p_i} = -\ln p_i - 1 + \lambda$ , hence its stationary points is determined by the equations  $p_i = e^{\lambda-1}$  for all  $i = 1, \dots, n$ . Moreover, we know that the sum of the relative frequencies  $p_i$  is equal to one. This means that  $ne^{\lambda-1} = 1$ , whence we get  $\lambda = 1 - \ln n$ . Substitution then yields  $p_i = \frac{1}{n}$ .  $\square$

**10.A.7.** The following graphs depict the frequencies of particular amounts of points obtained by students of the MB104 lecture at the Faculty of Informatics of Masaryk University in 2012. The axes of the cumulative graph are “swapped”, as opposed to the previous example.

The frequencies of particular amounts of points are enumerated in the following table:

Therefore, the arithmetic mean is especially suitable for interval types.

The logarithm of the geometric mean is the arithmetic mean of the logarithms of the values. It is especially suitable for those quantities which cumulate multiplicatively, e. g. interests. If the interest rate for each time period is  $x_i\%$ , then the final result is the same as if the interest rate had constant value of  $\bar{x}^G\%$ . See 10.A.9 for an example where the harmonic mean is appropriate.

In subsection 8.1.30 (page 746), we use the methods invented there to prove that the geometric mean never exceeds the arithmetic mean. The harmonic mean never exceeds the geometric mean, and so

$$\bar{x}^H \leq \bar{x}^G \leq \bar{x}.$$

**10.1.5. Median, quartile, decile, percentile, ...** Another way of expressing the position or distribution of the values is to find, for a number  $\alpha$  between zero and one, such a value  $x_\alpha$  that  $100\alpha\%$  of values from the set are at most  $x_\alpha$  and the remaining ones are greater than  $x_\alpha$ . If such a value is not unique, one can choose the mean of the two nearest possibilities.

The number  $x_\alpha$  is called the  $\alpha$ -quantile. Thus, if the result of a contestant puts him into  $x_{1.00}$ , it does not mean that he is better than anyone else yet. However, there is surely no one better than him.

The most common values of  $x_\alpha$  are the following:

- The *median* (also sample median) is defined by

$$\tilde{x} = x_{0.50} = \begin{cases} x_{((n+1)/2)} & \text{for odd } n \\ \frac{1}{2}(x_{(n/2)} + x_{(n/2+1)}) & \text{for even } n \end{cases},$$

where  $x_{(k)}$  corresponds to the value in the sorted data set 10.1.3(1).

- The *first and third quartile* are  $Q_1 = x_{0.25}$  and  $Q_3 = x_{0.75}$ , respectively.
- The *p-th quantile* (also *sample quantile* or *percentile*)  $x_p$ , where  $0 < p < 1$  (usually rounded to two decimal places).

One can also meet the *mode*, which is the value  $\hat{x}$  that is most frequent in the data set  $x$ .

The arithmetic mean, median (with ratio types), and mode (with ordinal or nominal types) correspond to the “anticipated” values.

Note that all  $\alpha$ -quantiles with interval scales are invariant with respect to affine transformations of the values (check this yourselves!).

**10.1.6. Measures of the variability.** Surely any measure of the variability of a data set  $x \in \mathbb{R}^n$  should be invariant with respect to constant translations. In the Euclidean space  $\mathbb{R}^n$ , both the standard distance and the sample mean have this property.

Therefore, choose the following:

# of points	# of students
20.5	1
20	1
19	2
18.5	1
18	2
17.5	3
17	2
16.5	4
16	3
15.5	5
15	7
14.5	6
14	14
13.5	21
13	21
12.5	19
12	17
11.5	18
11	31
10.5	22
10	53

# of points	# of students
9.5	9
9	9
8.5	13
8	8
7.5	13
7	4
6.5	7

The corresponding histogram looks as follows:

The histogram was obtained from the Information System of Masaryk University. We can see that the data are shown in a somewhat unusual way: individual amounts of points correspond to “double rectangles”. It is a matter of taste how to represent the data (it is possible to merge some values, thereby decreasing the number of rectangles, or to use thinner rectangles).

VARIANCE AND STANDARD DEVIATION

**Definition.** The *variance* of a data set  $x$  is defined by

$$s_x^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2.$$

The *standard deviation*  $s_x$  is defined to be the square root of the variance.

As requested, the variability of statistical values is independent of constant translation of all values. Indeed, the unsorted data set

$$y = (x_1 + c, x_2 + c, \dots, x_n + c)$$

has the same variance  $s_y = s_x$ .

Sometimes, the *sample variance* is used, where there is  $(n - 1)$  in the denominator instead of  $n$ . The reason will be clear later, cf. 10.3.2.

In case of class frequencies  $n_j$  of values  $a_j$  for  $m$  classes, this expression leads to the value

$$s_x^2 = \frac{1}{n} \sum_{j=1}^m n_j (a_j - \bar{x})^2$$

of the variance. In practice, it is recommended to use the Sheppard’s correction, which decreases  $s_x^2$  by  $h^2/12$ , where  $h$  is the width of the intervals that define the classes.

Further, one can encounter the *data-set range*

$$R = x_{(n)} - x_{(1)}$$

and the *interquartile range*

$$Q = Q_3 - Q_1.$$

The *mean deviation*, which is defined as the mean distance of the values from the median:

$$D_x = \frac{1}{n} \sum_{i=1}^n |x_i - \tilde{x}|.$$

The following theorem clarifies why these measures of variability are chosen:

**Theorem.** The function  $S(t) = (1/n) \sum_{i=1}^n (x_i - t)^2$  has the minimum value at  $t = \bar{x}$ , i.e., at the sample mean.

The function  $D(t) = (1/n) \sum_{i=1}^n |x_i - t|$  has the minimum value at  $t = \tilde{x}$ , i.e., the median.

**PROOF.** The minimum of the quadratic polynomial  $f(t) = \sum_{i=1}^n (x_i - t)^2$  is at the only root of its derivative:

$$f'(t) = -2 \sum_{i=1}^n (x_i - t).$$

Since the sum of the distances of all values from the sample mean is zero  $t = \bar{x}$  is the requested root and the first proposition is proved.

As for the second proposition, return to the definition of the median. For this purpose, rearrange the sum so that the first and the last summand is added, then the second and the last-but-one summand, etc. In the first case, this leads to the

We can notice that the mode of the values is 10, which, accidentally, was also the number of points necessary to pass the course. The mean of the obtained points is 9.48.

**10.A.8.** Here, we present column diagrams of the amounts of points of MB101 students in autumn 2010 (the very first semester of their studies). The first one corresponds to all students of the course; the second one does to those who (3 years later) successfully finished their studies and got the bachelor's degree.

Again, the results can be depicted in an alternative way:

expression  $|x_{(1)} - t| + |x_{(n)} - t|$ , and this is equal to the distance  $x_{(n)} - x_{(1)}$  provided  $t$  lies inside the range, and it is even greater otherwise. Similarly, the other pair in the sum gives  $x_{(n-1)} - x_{(2)}$  if  $x_{(2)} \leq t \leq x_{(n-1)}$ , and it is greater otherwise. Therefore, the minimality assumption leads to  $t = \tilde{x}$ .  $\square$

In practice, it is required to compare the variability of data sets of different statistical populations. For this purpose, it is convenient to relativize the scale, and so use the *coefficient of variation* of a data set  $x$ :

$$V_x = \frac{\sqrt{s_x^2}}{|\bar{x}|}.$$

This relative measure of variability can be perceived in percentage of the deviation with respect to the sample mean  $\bar{x}$ .

**10.1.7. Skewness of a data set.** If the values of a data set are distributed symmetrically around the mean value, then

$$\bar{x} = \tilde{x}$$

However, there are distributions where

$$\bar{x} > \tilde{x}.$$

This is common, for instance, with the distribution of salaries in a population where the mean is driven up by a few very large incomes, while much of the population is below the average.

A useful characteristic concerning this is the *Pearson coefficient*, given by

$$\beta = 3 \frac{\bar{x} - \tilde{x}}{s_x}.$$

It estimates the relative measure (the absolute value of  $\beta$ ) and the direction of the skewness (the sign). In particular, note that the standard deviation is always positive, so it is already the sign of  $\bar{x} - \tilde{x}$  which shows the direction of the skewness.

#### QUANTILE COEFFICIENTS OF SKEWNESS

More detailed information can be obtained from the *quantile coefficients of skewness*

$$\beta_p = \frac{x_{1-p} + x_p - 2\tilde{x}}{x_{1-p} - x_p},$$

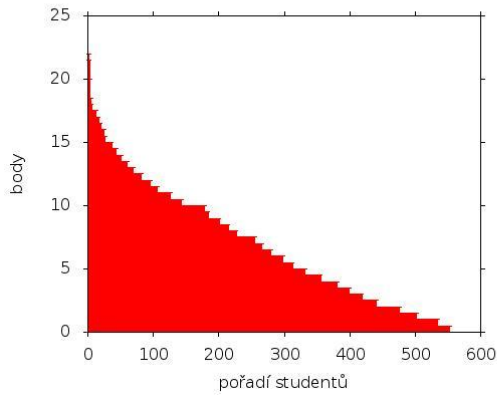

for each  $0 < p < 1/2$ . Their meaning is clear when the numerator is expressed as  $(x_{1-p} - \tilde{x}) - (\tilde{x} - x_p)$ .

In particular, the *quartile coefficient of skewness* is obtained when selecting  $p = 0.25$ .

**10.1.8. Diagrams.** People's eyes are well suited for perceiving information with a complicated structure. That is why there exist many standardized tools for displaying statistical data or their correlations. One of

them is the *box diagram*.

And these are the graphs of amounts of points obtained by those students who continued their studies:

We can see that in the former case, the mode is equal to 0, while in the latter case, it is 10 again. The frequency distribution is close to the one of the MB104 course, which is recommended for the fourth semester.

BOX DIAGRAM

The diagram illustrates a histogram and a box diagram of the same data set (normal distribution with mean equal to 10 and variance equal to 3,  $n = 500$ ).

The middle line is the median; the edges of the box are the quartiles; the “paws” show 1.5 of the interquartile range, but not more than the edges of the sample range. Potential outliers are indicated too.

Common displaying tools allow us to view potential dependencies of two data sets. For instance, in the left-hand diagram below, the coordinates are chosen as the values of two independent normal distributions with mean equal to 10 and variance equal to 3. In the right-hand illustration, the first coordinate is from the same data set, and the second coordinate is given by the formula  $y = 3x + 4$ . It is also perturbed with a small error.

**10.1.9. Covariance matrix.** Actually, the dependencies between several data sets associated to the same statistical units are at the core of our interest in many real world problems. When defining the variance in 10.1.6 above, we employed the euclidean distance, i.e. we evaluated the scalar product of the values of the square of distances from the mean with itself. Thus, having two vectors of data sets, we may define

**10.A.9.** A car was traveling from Brno to Prague at 160 km/h, and then back from Prague to Brno at 120 km/h. What was its average speed?

**Solution.** This is an example where one might think of using the arithmetic mean, which is incorrect. The arithmetic mean would be the correct result if the car spent the same period of time going at each speed. However, in this case, it traveled the same distance, not time, at each speed. Denoting by  $d$  the distance of Brno and Prague and by  $v_p$  the average speed, we obtain

$$\frac{d}{160} + \frac{d}{120} = \frac{2d}{v_p},$$

whence

$$v_p = \frac{2}{\frac{1}{160} + \frac{1}{120}} \doteq 137.14.$$

Therefore, the average speed is the harmonic mean (see 10.1.3) of the two speeds.

□

### B. Visualization of multidimensional data

The above examples were devoted to displaying one numerical characteristic measured for more objects (number of points obtained by individual students, for example). Graphical visualization of data helps us understand them better. However, how to depict the data if we measure  $p$  different characteristics,  $p \geq 3$ , of  $n$  objects. Such measurements cannot be displayed using graphs we have met.

**10.B.1.** One of the possible methods is the so-called *principal component analysis*. In this method, we use eigenvectors and eigenvalues (see 2.4.2) of the sample covariance matrix (see 10.2.35). We will use the following notation:

- random vectors of the measurement  
 $\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{ip})^T, i = 1, \dots, n,$
- the mean of the  $j$ -th component  
 $m_j = \frac{1}{n} \sum_{i=1}^n x_{ij}, j = 1, \dots, p,$
- the sample variance of the  $j$ -th component  
 $s_j = \frac{1}{n-1} \sum_{i=1}^n (x_{ij} - m_j)^2, j = 1, \dots, p,$
- the vector of means  $\mathbf{m} = (m_1, \dots, m_p),$
- the sample covariance matrix  
 $\frac{1}{n-1} \sum_{i=1}^n (\mathbf{x}_i - \mathbf{m})(\mathbf{x}_i - \mathbf{m})^T$   
 (note that each summand is a  $p$ -by- $p$  matrix).

The covariance matrix is symmetric, hence all its eigenvalues are real and its eigenvectors are pairwise orthogonal. Moreover, considering the eigenvectors of unit length, we can see that the eigenvalue corresponding to an eigenvector of the covariance matrix yields the variance of (the size of) the projection of the data onto this direction (the projection takes place in the  $p$ -dimensional space). The goal of this method is to find the direction (in the  $p$ -dimensional space of the measured characteristics) for which the variance of the projections is as great as possible. Thus, this direction corresponds to the eigenvector of the covariance matrix whose eigenvalue is the greatest one. The linear combination given

### COVARIANCE AND COVARIANCE MATRIX

Consider two data sets  $x = (x_1, \dots, x_n), y = (y_1, \dots, y_n),$  and their means  $\bar{x}, \bar{y}.$  We define their *covariance* by the formula

$$\text{cov}(x, y) = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}).$$

If there are  $k$  sample sets  $x^{(1)} = (x_1^{(1)}, \dots, x_n^{(1)}), \dots, x^{(k)} = (x_1^{(k)}, \dots, x_n^{(k)}),$  then their *covariance matrix* is the symmetric matrix  $C = (c_{ij})$  with  $c_{ij} = \text{cov}(x^{(i)}, x^{(j)}).$

Again, the *sample covariance* and *sample covariance matrix* are defined by the same formulae with  $n$  replaced by  $(n - 1).$

Clearly the covariance matrix has got the variances of the individual data sets on its diagonal.

In order to imagine what the covariance should say, consider the two possible behaviours of two data sets: (a) they will deviate from their means in a very similar way (comparing individually  $x_i$  and  $y_i$ ), (b) they behave very independently. In first case, we should assume that the signs of the deviations will mostly coincide and thus the sum in the definition will lead to a quite big positive number. In the other case the signs should be rather independent and thus the positive and negative contributions should effectively cancel each other in the covariance sum.

Thus we expect the data sets expressing independent features to be close to zero while the covariance of dependent sets should be far from zero. The sign of the covariance shows the character of the dependence. For example, the two sets of data depicted in the left hand diagram above had covariance about -0.11, while the covariance of the data from the right hand picture was about 25.9.

Similarly to the variance, we are often interested in normalized values. The *correlation coefficient* takes the covariance and divides it by the standard deviation of each of the data sets. In our two latter cases, the correlation coefficients are about -0.01 and 0.99. As expected, they very clearly indicate which of the data are correlated.

**10.1.10. Principal components analysis.** If we deal with statistics involving many parameters and we need to decide quickly about their similarity (correlation) with some given patterns, we might use a simple idea from linear algebra.

Assume we have got  $k$  data sets  $x^{(i)}.$  Since their covariance matrix  $C$  is symmetric, there is an orthonormal basis  $\underline{e}$  in  $\mathbb{R}^k$  such that in this basis the corresponding quadratic form given by  $C$  will enjoy a diagonal matrix. The relevant basis  $\underline{e}$  consists of the real eigenvectors  $e_i \in \mathbb{R}^k$  for the eigenvalues  $\lambda_i.$  The bigger is the absolute value  $|\lambda_i|,$  the bigger is the variation of the orthogonal projection  $\hat{x}$  of all the  $k$  data sets into this one-dimensional subspace spanned by  $e_i.$

Thus we may restrict ourselves to just this one data set  $\hat{x}$  and consider the statistics concerning this one set as representing the multi-parametric data sets  $x^{(i)}.$  Similarly we may

by the components of this vector is called the first principal component. The size of the projection onto this direction estimates the data quite well (the principal component can be viewed as a characteristic which substitutes for the  $p$  characteristics, i. e., it is a random vector with  $n$  components). If we subtract this projection from the data and consider the direction of the greatest variance again, we get the second principal component. Repeating this procedure further, we obtain the other principal components. The directions of the principal components correspond to the eigenvectors of the covariance matrix in decreasing order with respect to the size of the corresponding eigenvalues.

**10.B.2.** Find the first principal component of the following simple data and the vector which substitutes them: Five people were taken their height, little finger length, and index finger length. The measured data are shown in the following table (in centimeters).

**Solution.**

	Martin	Michael	Matthew	John	Peggy
index f.	9	11	8	8	8
little f.	7.5	8	6.3	6	6.5
height	186	187	173	174	167

The vectors of the collected data are:  $\mathbf{x}_1 = (9; 7.5; 186)$ ,  $\mathbf{x}_2 = (11; 8; 187)$ ,  $\mathbf{x}_3 = (8; 6; 173)$ ,  $\mathbf{x}_4 = (8; 6; 174)$ ,  $\mathbf{x}_5 = (8; 6.5; 167)$ . The covariance matrices of these vectors are:

$$\begin{pmatrix} 0.04 & 0.14 & 1.72 \\ 0.14 & 0.49 & 6.02 \\ 1.72 & 6.02 & 73.96 \end{pmatrix}, \quad \begin{pmatrix} 4.840 & 2.64 & 21.12 \\ 2.64 & 1.44 & 11.52 \\ 21.12 & 11.52 & 92.16 \end{pmatrix},$$

$$\begin{pmatrix} 0.641 & 0.640 & 3.521 \\ 0.640 & 0.640 & 3.52 \\ 3.521 & 3.52 & 19.36 \end{pmatrix}, \quad \begin{pmatrix} 0.641 & 0.640 & 2.721 \\ 0.640 & 0.640 & 2.72 \\ 2.721 & 2.72 & 11.56 \end{pmatrix},$$

$$\begin{pmatrix} 0.641 & 0.240 & 8.321 \\ 0.240 & 0.09 & 3.12 \\ 8.32 & 3.12 & 108.16 \end{pmatrix}.$$

The sample covariance matrix is then a quarter of their sum, i. e.,

$$S = \begin{pmatrix} 1.70 & 1.075 & 9.35 \\ 1.075 & 0.825 & 6.725 \\ 9.35 & 6.725 & 76.30 \end{pmatrix}$$

The eigenvalues of  $S$  are approximately 2.7, 312.2, and 0.38. The unit eigenvector corresponding to the greatest one is approximately  $(0.122; 0.09; 0.989)$ . Thus, the first principal component is  $(185.5; 186.8; 172.4; 173.4; 166.5)$ , which is not far from the people's heights.  $\square$

**10.B.3.** The students of a class had the following marks in various subjects:

also use several biggest eigen-values instead of one and reduce the dimension of our parameter space in this way. Finally, considering the unit length eigenvector  $(\alpha_1, \dots, \alpha_k)$  corresponding to the chosen eigenvalue  $\lambda$ , then the values  $\alpha_j$  provide the right coefficients in the orthogonal projection  $(x^{(1)}, \dots, x^{(k)}) \mapsto \hat{x} = \alpha_1 x^{(1)} + \dots + \alpha_k x^{(k)}$ .

See the exercise 10.B.2 for an illustration, together with another description how to proceed with the data in 10.B.1.

The latter approach is called the *principal component analysis*.

**10.1.11. Entropy.** We also need to describe the variability of data sets even with nominal types, for instance in statistical physics or information theory. The only thing at disposal is the class frequencies, so the principle of classical probability can be used (see the fourth part of chapter one). There, the relative frequency of the  $i$ -th class,  $p_i = \frac{n_i}{n}$ , is understood to be the probability that a random object belongs to this class.

The variance of ratio-type values with class frequencies  $n_j$  was given by the formula (see 10.1.6)

$$s_x^2 = \sum_{j=1}^m \frac{n_j}{n} (a_j - \bar{x})^2 = \sum_{j=1}^m p_j (a_j - \bar{x})^2,$$

where  $p_j$  denotes the (classical) probability that the value is in the  $j$ -th class. Therefore, it is a weighted mean of the adjusted values where the weight of the term  $(a_j - \bar{x})^2$  is  $p_j$ .

The variability of nominal values are expressed similarly (denote it by  $H_X$ ). Even though there are no numerical values  $a_j$  for the indices  $j$ , we can be interested in functions  $F$  that depend on the relative frequencies  $p_j$ . For a data set  $x$  we can define

$$H_X = \sum_{i=1}^n p_i F(p_i),$$

where  $F$  is an unknown function with some reasonable properties.

If the data set has only one value, i.e.  $p_k = 1$  for some  $k$  and otherwise  $p_j = 0$ , then we agree that the variability is zero, and so  $F(1) = 0$ .

Moreover,  $H_X$  is required to have the following property: If a data set  $Z$  consists of pairs of values from data sets  $X$  and  $Y$  (for example, one can observe eye colour and hair colour of people – statistical units), it is reasonable that the variability of  $Z$  be the sum of the variabilities, that is,  $H_Z = H_X + H_Y$ .

The relative class frequencies  $p_i$  for the values of the data set  $X$  and  $q_j$  for those of  $Y$  are known. The relative class frequencies for  $Z$  are then

$$r_{ij} = \frac{n_i m_j}{nm} = p_i q_j,$$

so we demand the equality (the ranges of the sums are clear from the context)

$$\sum_{i,j} p_i q_j F(p_i q_j) = \sum_i p_i F(p_i) + \sum_j q_j F(q_j).$$

Student id	Maths	Physics	History	English	PE
1	1	1	2	2	1
2	1	3	1	1	1
3	2	1	1	1	1
4	2	2	2	2	1
5	1	1	3	2	1

8	3	2	1	1	1
9	4	3	2	3	1
10	2	3	1	2	1

Find the first principal component of the following simple data and the vector which substitutes them.

**Solution.** The vectors of observation are  $\mathbf{x}_1 = (1, 1, 2, 2, 1), \dots, \mathbf{x}_{10} = (2, 3, 1, 2, 1)$ . The corresponding covariance matrices are:

$$\begin{pmatrix} 1.21 & 1.10 & -0.330 & -0.330 & 0.110 \\ 1.10 & 1. & -0.300 & -0.300 & 0.100 \\ -0.330 & -0.300 & 0.0900 & 0.0900 & -0.0300 \\ -0.330 & -0.300 & 0.0900 & 0.0900 & -0.0300 \\ 0.110 & 0.100 & -0.0300 & -0.0300 & 0.0100 \end{pmatrix}, \dots, \begin{pmatrix} 0.0100 & -0.100 & 0.0701 & -0.0300 & 0.0100 \\ -0.100 & 1. & -0.700 & 0.300 & -0.100 \\ 0.0701 & -0.700 & 0.490 & -0.210 & 0.0701 \\ -0.0300 & 0.300 & -0.210 & 0.0900 & -0.0300 \\ 0.0100 & -0.100 & 0.0701 & -0.0300 & 0.0100 \end{pmatrix}$$

The sample covariance matrix is

$$\begin{pmatrix} 0.99 & 0.44 & -0.078 & 0.26 & -0.01 \\ 0.44 & 0.89 & -0.22 & 0.22 & -0.11 \\ -0.078 & -0.22 & 0.45 & 0.23 & 0.03 \\ 0.26 & 0.22 & 0.23 & 0.45 & -0.078 \\ -0.01 & -0.11 & 0.033 & -0.0778 & 0.100 \end{pmatrix}.$$

Its dominant eigenvalue is about 13.68, and the corresponding unit eigenvector is approximately (0.70; 0.65; -0.13; 0.28; -0.07). Therefore, the principal component is (1.58; 2.73; 2.13; 2.93; 1.45; 1.93; 4.28; 3.48; 5.26; 3.71)  $\square$

Another possible method of visualization of multidimensional data is the so-called cluster analysis, but we will not go into further details here.

### C. Classical and conditional probability

In the first chapter, we met the so-called classical probability, see 1.4.1. Just to recall it, let us try to solve the following (a bit more complicated) problem:

**10.C.1.** Aleš wants to buy a new bike, which costs 5100 crowns. He has 2500 crowns left from organizing a camp. Aleš is no dope: he took 50 more crowns from his pocket money and went to the casino to play the roulette. Aleš always bets on red. This means that the probability of winning is 18/37 and the amount he wins is equal to the amount he has

Since  $p_i$  and  $q_j$  are relative frequencies, they sum to 1. So the right-hand side of the equality can be written as

$$\left(\sum_j q_j\right)\left(\sum_i p_i F(p_i)\right) + \left(\sum_i p_i\right)\left(\sum_j q_j F(q_j)\right),$$

leading to

$$\sum_{i,j} p_i q_j F(p_i q_j) = \sum_{i,j} p_i q_j (F(p_i) + F(q_j)).$$

This is satisfied by any constant multiple of a logarithm of any fixed base  $a > 1$ . It can be shown that no other continuous solution  $F$  exists.

Since  $p_i \leq 1$ ,  $\ln p_i \leq 0$ . The variability must be non-negative, so  $F$  is chosen to be a logarithmic function multiplied by  $-1$ . Such a choice also satisfies  $F(1) = 0$ , as desired.

### ENTROPY

The measure of variability of nominal values is expressed in terms of *entropy*. It is given by

$$H_X = -\sum_{i=1}^k \frac{n_i}{n} \ln\left(\frac{n_i}{n}\right),$$

where  $k$  is the number of sample classes. Sometimes (especially in information theory), the binary logarithm is used instead of the natural logarithm.

One often works with the quantity

$$e^{H_X} = \prod_i p_i^{-p_i},$$

(or with another logarithm base).

In this form, for a data set  $X$  with  $k$  equal class frequencies, compute

$$e^{H_X} = \left(\left(\frac{1}{k}\right)^{-\frac{1}{k}}\right)^k = k,$$

which is independent of the sample size. The next illustration shows 2-based entropy  $y$  for the number of occurrences of letters  $a, b$  in 10-letter words consisting of these characters, and  $x$  is the number of occurrences of  $b$ .

Note that the maximum entropy 1 occurs for the same number of  $a$ 's and  $b$ 's, and indeed  $2^1 = 2$  as computed above.

The following illustration displays the entropy of 11 randomly chosen strings of length 10 made of 8 characters. The values are all much less than the theoretical maximal value of 3. This reflects the fact that the number of occurrences of the individual 8 characters cannot be equal (or it could happen with a very small probability if the length of the string was 8

bet. His betting strategy is as follows: The first time, he bets 10 crowns. Each time he has lost, he bets twice the previous bet (if he does not have enough money to make this bet, he leaves the casino, deeply depressed). Each time he has won, he bets 10 crowns again. What is the probability that, using this strategy, he wins the desired 2550 more crowns? (As soon as this happens, he immediately runs to buy the bike.)

**Solution.** First of all, we calculate how many times Aleš can lose in a row. If he bets 10 crowns the first time, then in order to bet  $n$  times, he needs

$$10+20+\dots+10\cdot 2^{n-1} = 10\cdot\left(\sum_{i=0}^{n-1} 2^i\right) = 10\cdot\left(\frac{2^n-1}{2-1}\right) = 10\cdot(2^n-1).$$

As we can see, the number 2550 is of the form  $10(2^n - 1)$ , for  $n = 8$ . This means that Aleš can bet eight times in a row regardless of the odds. He can never bet nine times in a row, because for that he would have to have  $10(2^9 - 1) = 5110$  crowns, which he will never reach (he stops betting as soon as he has 5100 crowns). Therefore, Aleš loses the whole game if and only if he loses eight consecutive bets. The probability of losing one bet is  $19/37$ ; hence, the probability of losing eight consecutive (independent) bets is  $(19/37)^8$ . Thus, the probability that he wins 10 crowns (using his strategy) is  $1 - (19/37)^8$ . In order to win 2550 crowns, he must win 255 times, and the probability of this is

$$\left(1 - \left(\frac{19}{37}\right)^8\right)^{255} \doteq 0.29.$$

Therefore, the probability of winning using his strategy is much lower than if he bet everything on red straightaway.  $\square$

**10.C.2.** You could try to solve a slight modification of the above problem: Joe stops playing only if he loses all his money; if he still has some money, but not enough to bet twice the previous bet, he bets 10 dollars again.

We also met the conditional probability in the first chapter, see 1.4.8.

**10.C.3.** Let  $A, B$  be two events such that  $B$  is a disjoint union of events  $B_1, B_2, \dots, B_n$ . Using the definition of conditional probability (see 10.2.6), prove that

$$(1) \quad P(A|B) = \sum_{i=1}^n P(A|B_i)P(B_i|B)$$

or 16). If the same is done with, say, strings of length 10000, we would get very close to 3 (typically the difference would be in the order of  $10^{-3}$ , if the random string generator was good enough).

## 2. Probability

Before further reading, the reader is advised to go through the fourth part of chapter one (the subsection beginning on page 18). Back then, we worked mainly with classical finite probability. We defined the basics of a formalism which we extend now. The main extension is that the sample space  $\Omega$  can be infinite, even uncountable. Recall that when we talked about geometric probability at the end of the fourth part of chapter one, the sample space for description of an event was a part of the Euclidean space, and events were suitable subsets of it. All of those sets were uncountable.

Begin with a simple (infinite, yet still discrete) example, to which we return from time to time throughout this section.

**10.2.1. Why infinite sets of events?** Imagine an experiment where a coin is repeatedly tossed until it comes up heads. There are many questions to be asked about this experiment: What is the probability of tossing the coin at least 3 times? (or exactly 35 times, or at most 10 times, etc.)

The outcomes of this experiment can be considered in the form  $\omega_k \in \mathbb{N}_{\geq 1} \cup \{\infty\}$ , which could be read as “the coin comes up heads for the first time in the  $k$ -th toss”. Note that  $k = \infty$  is inserted, since the possibility that the coin always comes up tails must be allowed, too.

This problem is solved if the classical probability  $1/2$  of the coin coming up heads in one toss is used (and the same for tails). In the abstract model, the total number of tosses by any natural number  $N$  cannot be bounded. On the other hand, the probability that the coin always comes up tails in the first  $(k - 1)$  tosses out of the total number of  $n \geq k$  tosses is given by the fraction

$$\frac{2^{n-k}}{2^n} = 2^{-k},$$

where in the numerator, there is the number of favorable possibilities out of  $n$  independent tosses (i.e. the number of possibilities how to distribute two values into the  $n - k$  remaining positions), while in the denominator, there is the number of

**Solution.** First, note that the events  $A \cap B_1, A \cap B_2, \dots, A \cap B_n$  are also disjoint. Therefore, we can write

$$\begin{aligned} P(A|B_1 \cup \dots \cup B_n) &= \frac{P(A \cap (B_1 \cup \dots \cup B_n))}{P(B_1 \cup \dots \cup B_n)} = \\ &= \frac{P((A \cap B_1) \cup (A \cap B_2) \cup \dots \cup (A \cap B_n))}{P(B)} = \\ &= \frac{\sum_{i=1}^n P(A \cap B_i)}{P(B)} \cdot \frac{P(B_i)}{P(B)} = \\ &= \sum_{i=1}^n P(A|B_i)P(B_i|B). \end{aligned}$$

□

**10.C.4.** We have four bags with balls: In the first bag, there are four white balls. In the second bag, there are three white balls and one black ball. In the third bag, there are two white and two black balls. Finally, in the fourth bag, there are four black balls. We randomly pick a bag and take two balls out of it (without putting the first one back). Find the probability that

- the balls are of different colors;
- the second ball is white provided the first ball was white.

**Solution.** Since there is the same number of balls in each of the bags, any ball has the same probability of being taken (similarly for any pair of balls lying in the same bag). Therefore, we can solve this problem using classical probability

- Altogether, there are 24 pairs of balls that can be taken. Out of them, 7 consist of balls of different colors. Therefore, the wanted probability is  $7/24$ .
- Let  $A$  denote the event that the first ball is white and  $B$  denote the event that the second ball is white. Then,  $P(B \cap A)$  is the probability that both balls are white, and this is equal to  $10/24 = 5/12$  since there are 10 such pairs. Again, we can use classical probability to calculate  $P(A)$ : there are 16 balls in total, and 9 of them are white. Altogether, we have

$$P(B|A) = \frac{P(B \cap A)}{P(A)} = \frac{\frac{5}{12}}{\frac{9}{16}} = \frac{20}{27}.$$

**Another solution.** The event  $A$  can be viewed as the union of three mutually exclusive events  $A_1, A_2, A_3$  that we took a white ball from the first, second, and third bag, respectively. Since there is the same number of balls in each of the bags, the probability of taking any (white) ball is also the same (independent of which ball it is), so we get  $P(A) = \frac{9}{16}$  and  $P(A_1|A) = \frac{\frac{4}{16}}{\frac{9}{16}} = \frac{4}{9}$ ,  $P(A_2|A) = \frac{3}{9} = \frac{1}{3}$ ,  $P(A_3|A) = \frac{2}{9}$ . Applying (5), we obtain

$$\begin{aligned} P(B|A) &= P(B|A_1)P(A_1|A) + P(B|A_2)P(A_2|A) + P(B|A_3)P(A_3|A) = \\ &= P(B|A_1) \cdot \frac{P(A_1)}{P(A)} + P(B|A_2) \cdot \frac{P(A_2)}{P(A)} + P(B|A_3) \cdot \frac{P(A_3)}{P(A)} = \frac{\Omega \setminus \cup_{i \in I} A_i^c = \cap_{i \in I} A_i}{P(A)} = \\ &= 1 \cdot \frac{4}{9} + \frac{2}{3} \cdot \frac{3}{9} + \frac{1}{3} \cdot \frac{2}{9} = \frac{20}{27}. \end{aligned}$$

□

all possible outcomes. As expected, this probability is independent of the chosen  $n$ , and there is the  $\sum_{k=1}^{\infty} 2^{-k} = 1$ . Therefore, the probability of tossing only tails is zero.

Thus we can define probability on the sample space  $\Omega$  with sample points (outcomes)  $\omega_k$ , whose probability is  $2^{-k}$ . This leads to a probability according to the definitions below.

We return to this example throughout this section.

**10.2.2.  $\sigma$ -fields.** Work with a fixed non-empty set  $\Omega$ , which contains the possible outcomes of the experiment and which is called the *sample space*. The possible outcomes  $\omega \in \Omega$  are also called *sample points*. In probability models, not all subsets of outcomes need be admitted. In particular, the singletons  $\{\omega\}$  need not be considered. Those subsets whose probability we want to measure are required to satisfy the axioms of the so called  *$\sigma$ -algebras*.

The axioms listed below are chosen from a larger collection of natural requirements in a minimal form. The first one is based on the assumption that the universal event should be a measurable set. The second one is forced by the assumption that events can be negated. The third one reflects the necessity to examine the event of the occurrence of at least one event from a countably infinite collection. (For instance, in the example from the previous subsection, the coin is tossed only finitely many times, but there is no upper bound on the number of tosses.)

$\sigma$ -ALGEBRAS OF SUBSETS

A collection  $\mathcal{A}$  of subsets of the sample space is called a  *$\sigma$ -algebra* or  *$\sigma$ -field* and its elements are called *events* or *measurable sets* if and only if

- $\Omega \in \mathcal{A}$ , i.e., the sample space is an event;
- if  $A, B \in \mathcal{A}$ , then  $A \setminus B \in \mathcal{A}$ , i.e., the set difference of two events is also an event;
- if  $A_i \in \mathcal{A}$ ,  $i \in I$ , is a countable collection of events, then their union is also an event, i.e.,  $\cup_{i \in I} A_i \in \mathcal{A}$ .

As usual, the basic axioms imply simple corollaries which describe further (intuitively required) properties in the form of mathematical theorems. The reader should check carefully that both following properties hold.

- The complement  $A^c = \Omega \setminus A$  of an event  $A$  is again an event.
- The intersection of two events is again an event since for any two subsets  $A, B \subset \Omega$ ,

$$A \setminus (\Omega \setminus B) = A \cap B.$$

Actually, for any countable system of events  $A_i$ ,  $i \in I$ , the event  $\Omega \setminus \cup_{i \in I} A_i^c = \cap_{i \in I} A_i$  is also in the  $\sigma$ -algebra  $\mathcal{A}$ .

Altogether, a  $\sigma$ -algebra is a collection of subsets of the sample space which is closed with respect to set differences, countable unions, and countable intersections.

**10.C.5.** We have four bags with balls: In the first bag, there are four white balls. In the second bag, there are three white balls and one black ball. In the third bag, there are two white and two black balls. Finally, in the fourth bag, there are one white and three black balls. We randomly pick a bag and take a ball out of it, finding out that it is black. Then we throw away this bag, pick another one and take a ball out of it. What is the probability that it is white?

**Solution.** Similarly as in the above exercise, let  $A$  denote the event that the very first ball is black. This event can be viewed as the union of mutually exclusive events  $A_i$ ,  $i = 2, 3, 4$ , where  $A_i$  is the event of picking the  $i$ -th bag and taking a black ball from there. Again, the probability of picking any (black) ball is the same. Hence,  $P(A_2|A) = \frac{1}{6}$ ,  $P(A_3|A) = \frac{2}{6} = \frac{1}{3}$ , and  $P(A_4|A) = \frac{3}{6} = \frac{1}{2}$ . Let  $B$  denote the event that the second ball is white. If the thrown bag is the second one, then there are a total of 7 white balls remaining, so the probability of taking one of them is  $P(B|A_2) = \frac{7}{12}$  (we can use classical probability again because each of the bags contains the same number of balls, so any ball has the same probability of being taken). Similarly,  $P(B|A_3) = \frac{8}{12}$  and  $P(B|A_4) = \frac{9}{12}$ . Applying (5), we get that the wanted probability is

$$\begin{aligned} P(B|A) &= P(B|A_2)P(A_2|A) + P(B|A_3)P(A_3|A) + P(B|A_4)P(A_4|A) \\ &= \frac{7}{12} \cdot \frac{1}{6} + \frac{8}{12} \cdot \frac{1}{3} + \frac{9}{12} \cdot \frac{1}{2} = \frac{25}{36}. \quad \square \end{aligned}$$

**10.C.6.** We have four bags with balls: In the first bag, there are a white ball and a black ball. In the second bag, there are three white balls and one black ball. In the third bag, there are one white and two black balls. Finally, in the fourth bag, there are one white and three black balls. We randomly pick a bag and take a ball out of it, finding out that it is white. Then we throw away this bag, pick another one and take a ball out of it. What is the probability that it is white?

**Solution.** Similarly as in the above exercise, we view the event  $A$  of the first ball being white as the union of four mutually exclusive events  $A_1, A_2, A_3$ , and  $A_4$  that we take a white ball from the first, second, third, and fourth bag, respectively. The probability of taking a white ball out of the first bag is  $P(A_1) = \frac{1}{4} \cdot \frac{1}{2}$  (the probability of  $A_1$  is the product of the probability that we pick the first bag and the probability that we take a white ball from there); similarly,  $P(A_2) = \frac{1}{4} \cdot \frac{3}{4}$ ,  $P(A_3) = \frac{1}{4} \cdot \frac{1}{3}$ ,  $P(A_4) = \frac{1}{4} \cdot \frac{1}{4}$ .  $P(A) = P(A_1) + P(A_2) + P(A_3) + P(A_4) = \frac{11}{24}$ . Note that the probability  $P(A)$  cannot be calculated classically, i. e., by simply dividing the number of white balls by the total number of the balls, because, for instance, the probability of taking a white ball from the first bag is twice greater than from the fourth bag. As for the conditional probabilities, we have  $P(A_1|A) = P(A_1)/P(A) = \frac{3}{11}$ ,  $P(A_2|A) = \frac{9}{22}$ ,  $P(A_3|A) = \frac{2}{11}$ ,  $P(A_4|A) = \frac{3}{22}$ . Now, let  $B$  denote the event that we take another white ball after we have thrown away the first bag. We want to apply (5) again. It remains to compute  $P(B|A_i)$ ,  $i = 1, \dots, 4$ . The probability  $P(B|A_1)$  can be

**10.2.3. Probability space.** Now introduce probability in the mathematical model, recalling the concepts used already in the first chapter.

ELEMENTARY CONCEPTS

Use the following terminology in connection with events:

- the entire sample space  $\Omega$  is called the *universal event*; the empty set  $\emptyset \in \mathcal{A}$  is called the *null event*;
- the singletons  $\omega \in \Omega$  are called *elementary events* (note that  $\{\omega\}$  may not even be an event in  $\mathcal{A}$ );
- the intersection of events  $\cap_{i \in I} A_i$  corresponds to the *simultaneous occurrence* of all the events  $A_i, i \in I$ ;
- the union of events  $\cup_{i \in I} A_i$  corresponds to the *occurrence of at least one* of the events  $A_i, i \in I$ ;
- if  $A \cap B = \emptyset$ , then  $A, B \in \mathcal{A}$  are called *exclusive events* or *disjoint events*,
- if  $A \subset B$ , then the event  $A$  *implies* the event  $B$ ;
- if  $A \in \mathcal{A}$ , then the event  $B = \Omega \setminus A$  is called the *complementary event to  $A$*  and denoted  $B = A^c$ .

We have seen an example of probability defined on an infinite sample space in 10.2.1 above. In general, probability is comprehended as follows:

PROBABILITY

**Definition.** A *probability space* is the  $\sigma$ -algebra  $\mathcal{A}$  of subsets of the sample space  $\Omega$  on which there is a scalar function  $P : \mathcal{A} \rightarrow \mathbb{R}$  with the following properties:

- $P$  is non-negative, i.e.,  $P(A) \geq 0$  for all events  $A$ ;
- $P$  is countably additive, i.e.,

$$P(\cup_{i \in I} A_i) = \sum_{i \in I} P(A_i),$$

for every countable collection of mutually exclusive events;

- the probability of the universal event is 1.

The function  $P$  is called the *probability function* on  $(\Omega, \mathcal{A})$ .

Immediately from the definition, the complementary event satisfies

$$P(A^c) = 1 - P(A).$$

In chapter one, theorems on addition of probabilities were derived. Although dealing with finite sample spaces, the arguments remain the same now. In particular, the *inclusion and exclusion principle* says for any finite collection of  $k$  events  $A_i$  that

$$\begin{aligned} P(\cup_{i=1}^k A_i) &= \sum_{i=1}^k P(A_i) - \sum_{i=1}^{k-1} \sum_{j=i+1}^k P(A_i \cap A_j) \\ &+ \sum_{i=1}^{k-2} \sum_{j=i+1}^{k-1} \sum_{\ell=j+1}^k P(A_i \cap A_j \cap A_\ell) \\ &- \dots + \\ &+ (-1)^{k-1} P(A_1 \cap A_2 \cap \dots \cap A_k). \end{aligned}$$

computed as the sum of the probabilities of the mutually exclusive events  $B_2, B_3, B_4$  (given  $A_1$ ) that the second white ball comes from the second, third, fourth bag, respectively. Altogether, we have

$$P(B|A_1) = P(B_2|A_1) + P(B_3|A_1) + P(B_4|A_1) = \frac{1}{3} \cdot \frac{3}{4} + \frac{1}{3} \cdot \frac{1}{3} + \frac{1}{3} \cdot \frac{1}{4}$$

Similarly,

$$P(B|A_2) = \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{3} \cdot \frac{1}{3} + \frac{1}{3} \cdot \frac{1}{4} = \frac{13}{36}$$

$$P(B|A_3) = \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{3} \cdot \frac{3}{4} + \frac{1}{3} \cdot \frac{1}{4} = \frac{1}{2}$$

$$P(B|A_4) = \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{3} \cdot \frac{3}{4} + \frac{1}{3} \cdot \frac{1}{3} = \frac{19}{36}$$

Altogether, we get

$$P(B|A) = P(B|A_1)P(A_1|A) + P(B|A_2)P(A_2|A) + P(B|A_3)P(A_3|A) + P(B|A_4)P(A_4|A) = \frac{4}{9} \cdot \frac{3}{11} + \frac{13}{36} \cdot \frac{9}{22} + \frac{1}{2} \cdot \frac{2}{11} + \frac{19}{36} \cdot \frac{3}{22} = \frac{19}{44}$$

□

**10.C.7.** Two shooters shoot at a target, each makes two shots. Their respective accuracies are 80 % and 60 %. We have found two hits in the target. What is the probability that they belong to the first shooter?

**Solution.** The probability of hitting the target is  $4/5$  for the first shooter, and  $3/5$  for the second one. Consider the events:

$A \dots$  there are two hits in the target, both of the first shooter,

$B \dots$  there are two hits in the target.

Our task is to find  $P(B|A)$ . We can divide the event  $B$  into six disjoint events according to which shot(s) of each shooter was/were successful. We enumerate the events in a table and, for each of them, we compute its probability. This is easy as each of the events is the intersection of four independent events (results of the four shots). A hits is denoted by 1, a miss by 0.

	Shooter 1	Shooter 2	probability		
$B_1$	0	1	0	1	$\frac{1}{5} \cdot \frac{4}{5} \cdot \frac{2}{5} \cdot \frac{3}{5}$
$B_2$	0	1	1	0	$\frac{24}{25^2}$
$B_3$	1	0	1	0	$\frac{24}{25^2}$
$B_4$	1	0	0	1	$\frac{24}{25^2}$
$B_5$	1	1	0	0	$\frac{64}{25^2}$
$B_6$	0	0	1	1	$\frac{9}{25^2}$

Adding up the probabilities of these disjoint events, we get:

$$P(B) = \sum_{i=1}^6 P(B_i) = 169/625.$$

The reader should look back at 1.4.5 and think about the details.

**10.2.4. Independent events.** The definition of *stochastically independent events* also remains unchanged. It reflects the intuition that the probability of the simultaneous occurrence of independent events is equal to the product of the particular probabilities.

STOCHASTIC INDEPENDENCE

Events  $A, B$  are said to be stochastically independent if and only if

$$P(A \cap B) = P(A)P(B).$$

Of course, the universal event and the null event are stochastically independent of any event.

Recall that replacing an event  $A_i$  with the complementary event  $A_i^c$  in a collection of stochastically independent events  $A_1, A_2, \dots$ , again results in a collection of stochastically independent events, and (see 1.4.7, page 23)

$$P(A_1 \cup \dots \cup A_k) = 1 - P(A_1^c \cap \dots \cap A_k^c) = 1 - (1 - P(A_1)) \dots (1 - P(A_k)).$$

Classical finite probability remains the fundamental example of probability, used as the inspiration during creation of the mathematical model. Recall that in this case,  $\Omega$  is a finite set, the  $\sigma$ -algebra  $\mathcal{A}$  is the collection of all subsets of  $\Omega$ , and the *classical probability* is the probability space  $(\Omega, \mathcal{A}, P)$  with probability function  $P : \mathcal{A} \rightarrow \mathbb{R}$ ,

$$P(A) = \frac{|A|}{|\Omega|}.$$

This corresponds precisely to the intuition about the relative frequency  $p_A$  of an event  $A$  when drawing a random element from the sample set  $\Omega$ .

This definition of probability guarantees reasonable behaviour of monotone sequences of events:

**10.2.5. Theorem.** Consider a probability space  $(\Omega, \mathcal{A}, P)$  and a non-decreasing sequence of events  $A_1 \subset A_2 \subset \dots$ . Then,

$$P\left(\bigcup_{i=1}^{\infty} A_i\right) = \lim_{i \rightarrow \infty} P(A_i).$$

Similarly, if  $A_1 \supset A_2 \supset A_3 \supset \dots$ , then

$$P\left(\bigcap_{i=1}^{\infty} A_i\right) = \lim_{i \rightarrow \infty} P(A_i).$$

**PROOF.** The considered union  $A = \bigcup_{i=1}^{\infty} A_i$  can be rewritten in terms of mutually exclusive events

$$\tilde{A}_i = A_i \setminus A_{i-1},$$

defined for all  $i = 2, 3, \dots$ . Set  $\tilde{A}_1 = A_1$ . Then,

$$P(A) = P\left(\bigcup_{i=1}^{\infty} \tilde{A}_i\right) = \sum_{i=1}^{\infty} P(\tilde{A}_i) = \lim_{k \rightarrow \infty} \sum_{i=1}^k P(\tilde{A}_i).$$

Now, we can compute the conditional probability, using the formula of subsection 10.2.6:

$$P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{P(B_5)}{P(B)} = \frac{\frac{64}{625}}{\frac{169}{625}} = \frac{64}{164} \cdot 0.38.$$

□

**10.C.8.** We toss a coin. If it comes up heads, we put a white ball into an (initially empty) bag; otherwise we put a black ball there. This is repeated  $n$  times. Then, we take a ball randomly from the bag (without replacement). Suppose it is white. What is the probability that another ball we take randomly from the bag is black?

**Solution.** We will solve the problem for a general (possibly biased) coin. In particular, we assume that the individual tosses are independent and that there exists a fixed probability of the coin coming up heads, which we denote  $p$ . The event “a ball in the bag is white” corresponds to the event “the coin came up heads in the corresponding toss”. Since the first ball was white, we deduce that  $p > 0$ . We can also see that the probability space “taking a random ball from the bag” is isomorphic to the probability space “tossing a coin”. Since we assume that the individual tosses are independent, we also get the independence of the colors of the selected balls. This leads to the conclusion that the probability in question is  $1-p$ .

Is this reasoning correct? Do we not expect the probability of taking a black ball to be greater than  $1-p$ ? See, there were approximately  $np$  white and  $n(1-p)$  black balls in the bag, so if we had removed one white ball, the probability of selecting a black one should increase, shouldn't it? Before reading further, try to figure out which (if any) of these two presented reasonings is correct, and whether the probability is also dependent on  $n$  (the number of balls in the bag before any were removed).

Now, we select a more sophisticated approach to the problem. Let  $B_i$  denote the event “there were  $i$  white balls in the bag” (before any were removed),  $i \in \{0, 1, 2, \dots, n\}$ . Further, let  $A$  denote the event “the first ball is white” and  $C$  denote the event “the second ball is black”. Actually, the event  $B_i$  says that the coin came up heads  $i$  times out of  $n$ ; hence, its probability is

$$P(B_i) = \binom{n}{i} p^i (1-p)^{n-i}.$$

The conditional probability of taking a white ball provided there are exactly  $i$  white balls in the bag is equal to

$$P(A|B_i) = \frac{i}{n}.$$

We are interested in the probability of  $C$ , knowing that  $A$  has occurred, i. e., we want to know  $P(C|A)$ . Since the events  $B_i$  are pairwise disjoint, this is also true for the events  $C \cap B_i$ . Since  $C$  can be decomposed as the disjoint union  $\bigcup_{i=0}^n (C \cap$

For the finite sums,

$$\sum_{i=1}^k P(\tilde{A}_i) = P(A_1) + \sum_{i=2}^k (P(A_i) - P(A_{i-1})) = P(A_n)$$

by the assumptions  $A_{i-1} \subset A_i$ . This proves the first part of the theorem.

In the second part, consider the complements  $B_i = A_i^c$  instead of the events  $A_i$ . They satisfy the assumptions of the first part of this theorem. Then, the complement of the considered intersection is

$$B = A^c = \left( \bigcap_{i=1}^{\infty} A_i \right)^c = \bigcup_{i=1}^{\infty} B_i.$$

The desired statement follows from the fact that

$$P(A) = 1 - P(B) = 1 - \lim_{i \rightarrow \infty} P(B_i) = \lim_{i \rightarrow \infty} (1 - P(B_i))$$

which completes the proof. □

**10.2.6. Conditional probability.** Consider the following problem: On average, 40% of students succeed in course  $X$  and 80% of students succeed in course  $Y$ . If a random student is enrolled in both these courses saying that he has passed one of them (but we overhear which one), what is the probability that he has meant course  $X$ ?

As mentioned in subsection 1.4.8 (page 24), such problems can be formalized in the way described below. (We shall come back to the solution of the latter problem in 10.3.12.)

CONDITIONAL PROBABILITY

**Definition.** Let  $H$  be an event with non-zero probability in the  $\sigma$ -algebra  $\mathcal{A}$  of a probability space  $(\Omega, \mathcal{A}, P)$ . The *conditional probability*  $P(A|H)$  of an event  $A \in \mathcal{A}$  with respect to the hypothesis  $H$  is defined as

$$P(A|H) = \frac{P(A \cap H)}{P(H)}.$$

The definition corresponds to the intuition from the classical probability that the probability of events  $A$  and  $H$  occurring simultaneously, provided the event  $H$  has occurred, is  $P(A \cap H)/P(H)$ .

Directly from the definition, the hypothesis  $H$  and the event  $A$  are independent if and only if  $P(A) = P(A|H)$ .

At first sight, it may seem that introducing conditional probability does not add anything new. Actually, it is a very important type of approach which is needed in statistics as well. The hypothesis can be the a priori probability (i.e. the prior belief assumed beforehand), and the resulting probability is said to be posterior (i.e., it is considered to be a consequence of the assumption). This is the core of the Bayesian approach to statistics as is seen later.

The definition also implies the following result.

$B_i$ ), we can write

$$\begin{aligned} P(C|A) &= P\left(\bigcup_{i=0}^n (C \cap B_i) | A\right) = \sum_{i=0}^n \frac{P((C \cap B_i) \cap A)}{P(A)} = \\ &= \frac{1}{P(A)} \sum_{i=0}^n P(C \cap (A \cap B_i)) = \\ &= \frac{1}{P(A)} \sum_{i=0}^n P(A \cap B_i) P(C|A \cap B_i) = \\ &= \frac{1}{P(A)} \sum_{i=0}^n P(B_i) P(A|B_i) P(C|A \cap B_i). \end{aligned}$$

We use the law of total probability and substitute for  $P(A)$ , which leads to

$$\begin{aligned} P(C|A) &= \frac{\sum_{i=0}^n P(B_i) P(A|B_i) P(C|A \cap B_i)}{P(A)} = \\ (1) \quad &= \frac{\sum_{i=0}^n P(B_i) P(A|B_i) P(C|A \cap B_i)}{\sum_{i=0}^n P(B_i) P(A|B_i)}. \end{aligned}$$

This formula is sometimes called the *second Bayes' formula*; it holds in general provided the space  $\Omega$  is a disjoint union of the events  $B_i$ .

Since we tossed the coin at least once, we have  $n \geq 1$ . Now, we can calculate:

$$\begin{aligned} \sum_{i=0}^n P(B_i) P(A|B_i) &= \sum_{i=0}^n \binom{n}{i} p^i (1-p)^{n-i} \cdot \frac{i}{n} = \\ &= \sum_{i=1}^n \frac{(n-1)!}{(i-1)!(n-i)!} p^i (1-p)^{n-i} = \\ &= \sum_{i=0}^{n-1} \frac{(n-1)!}{i!(n-i-1)!} p^{i+1} (1-p)^{n-i-1} = \\ &= p \sum_{i=0}^{n-1} \binom{n-1}{i} p^i (1-p)^{n-1-i} = \\ &= p(p + (1-p))^{n-1} = p, \\ \sum_{i=0}^n P(B_i) P(A|B_i) P(C|A \cap B_i) &= \\ &= \sum_{i=0}^n \binom{n}{i} p^i (1-p)^{n-i} \cdot \frac{i}{n} \cdot \frac{n-i}{n-1} = \\ &= \sum_{i=1}^{n-1} \frac{(n-2)!}{(i-1)!(n-i-1)!} p^i (1-p)^{n-i} = \\ &= \sum_{i=0}^{n-2} \frac{(n-2)!}{i!(n-2-i)!} p^{i+1} (1-p)^{n-i-1} = \\ &= p(1-p) \sum_{i=0}^{n-2} \binom{n-2}{i} p^i (1-p)^{n-2-i} = \end{aligned}$$

**Lemma.** Let an event  $B$  be the union of mutually exclusive events  $B_1, B_2, \dots, B_n$ . Then,

$$(1) \quad P(A|B) = \sum_{i=1}^n P(A|B_i) P(B_i|B)$$

**PROOF.** The events  $A \cap B_1, A \cap B_2, \dots, A \cap B_n$  are also mutually exclusive. Therefore,

$$\begin{aligned} P(A|B_1 \cup \dots \cup B_n) &= \frac{P(A \cap (B_1 \cup \dots \cup B_n))}{P(B_1 \cup \dots \cup B_n)} = \\ &= \frac{P((A \cap B_1) \cup (A \cap B_2) \cup \dots \cup (A \cap B_n))}{P(B)} = \\ &= \sum_{i=1}^n \frac{P(A \cap B_i) P(B_i)}{P(B_i) P(B)} = \\ &= \sum_{i=1}^n P(A|B_i) P(B_i|B). \quad \square \end{aligned}$$

Consider the special case  $B = \Omega$ . Then, the events  $B_i$  can be considered the “possible states of the universe”,  $P(A|B_i)$  expresses the probability of  $A$  provided the universe is in its  $i$ -th state, and  $P(B_i|\Omega) = P(B_i)$  is the probability of the universe being in its  $i$ -th state. By the above lemma,

$$P(A) = P(A|\Omega) = \sum_{i=1}^n P(A|B_i) P(B_i).$$

This formula is called the *law of total probability*.

**10.2.7. Bayes' theorem.** Simple rearrangement of the conditional probability formula leads to

$$P(A \cap B) = P(B \cap A) = P(A)P(B|A) = P(B)P(A|B).$$

There are two important corollaries:

BAYES' RULES

**Theorem.** The probabilities of events  $A$  and  $B$  satisfy

$$\begin{aligned} (1) \quad P(A|B) &= \frac{P(A)P(B|A)}{P(B)} \\ (2) \quad P(A|B) &= \frac{P(A)P(B|A)}{P(A)P(B|A) + P(A^c)P(B|A^c)}. \end{aligned}$$

The first proposition is called the *inverse probability formula*. The second proposition is called the first *Bayes' formula*.

**PROOF.** The first statement is a mere rearrangement of the formula above the theorem. To obtain the second statement, note that

$$P(B) = P(B \cap A) + P(B \cap A^c).$$

Applying the law of total probability,  $P(B) = P(A)P(B|A) + P(A^c)P(B|A^c)$  can be substituted into the inverse probability formula, thereby obtaining the second statement of the theorem.  $\square$

these two subsections are now moved to Chapter one, modify/extend here ...

$$= \begin{cases} p(1-p), & n > 1 \\ 0, & n = 1. \end{cases}$$

Substituting this into the second Bayes' formula, we obtain the wanted probability

$$P(C|A) = \begin{cases} 0, & n = 1, \\ 1-p, & n > 1. \end{cases}$$

Thus, the simple reasoning about the probability spaces being isomorphic led to the correct result. The second reasoning was wrong because it omitted the fact that since the first ball was white, the expected number of white balls in the bag (before removing the first one) was greater than  $np$ . The calculation highlights the singular case  $n = 1$ .  $\square$

**10.C.9.** Once upon a time, there was a quiz where the first prize was Ferrari 599 GTB Fiorano. The contestant who won the final round was taken into a room where there were three identical doors. Behind two of them, there were goats, while the third one contained the car. In order to win the car, the contestant had to guess the correct door. First, the contestant pointed at one of the three doors. Then, an assistant opened one of the other two doors behind which there was a goat. Now, the contestant is given the option to change his guess. Should he do so?

**Solution.** Of course, we assume that the contestant wants to win the car. First of all, try to examine your intuition for random events. For example, you can reason as follows: "One of the two remaining doors contains the car, each with the same probability. Therefore, it does not matter which door we choose." Or: "The probability of choosing the correct door at the beginning is  $\frac{1}{3}$ . The shown goat changes nothing, so the probability that the guess is wrong is  $\frac{2}{3}$ . Therefore, we should change the door, thereby winning by  $\frac{2}{3}$ ."

Apparently, it is wise to change the door only if the probability of the car being behind that door is greater than behind the initially chosen one. We consider the following events:  $H$  stands for "the initial guess is correct",  $A$  stands for "we have changed the door", and  $C$  for "we have won". We are thus interested in the probabilities  $P(C|A)$  and  $P(C|A^c)$ .

First, we choose one of three doors, and the Ferrari is behind one of them, so

$$P(H) = \frac{1}{3}, \quad P(H^c) = 1 - \frac{1}{3} = \frac{2}{3}.$$

We assume that the event of changing the door is independent of the original guess, hence

$$P(A|H) = P(A|H^c) = P(A), \quad P(A^c|H) = P(A^c|H^c) = P(A^c).$$

If the original guess is correct and it is changed, then we surely lose; while if it is originally wrong and then it is changed, then we surely win. Therefore, we have

$$\begin{aligned} P(C|A \cap H) &= 0 = P(C|A^c \cap H^c), \\ P(C|A^c \cap H) &= 1 = P(C|A \cap H^c). \end{aligned}$$

Bayes' rule is sometimes formulated in a somewhat more general form, proved similarly as in (??):

Let the sample space  $\Omega$  be the union of mutually exclusive events  $A_1, \dots, A_n$ . Then, for any  $i \in \{1, \dots, n\}$ ,

$$(3) \quad P(A_i|B) = \frac{P(B|A_i)P(A_i)}{\sum_{k=1}^n P(B|A_k)P(A_k)}.$$

**10.2.8. Example and remarks.** Now, the introductory question from 10.2.6 can be dealt with easily. Consider the event  $A$  which corresponds to "the student having passed an exam" and the event

$B$  which corresponds to "the exam in question concerning course  $X$ ". Assume that the probabilities of the exam concerning either course are the same, i.e.,  $P(B) = P(B^c) = 0.5$ . While the wanted probability  $P(B|A)$  is unclear, the probability  $P(A|B) = 0.4$  is given, as well as  $P(A|B^c) = 0.8$ .

This is a typical application of Bayes' formula ??(??). There is no need to calculate  $P(A)$  at all:

$$\begin{aligned} P(B|A) &= \frac{P(B)P(A|B)}{P(B)P(A|B) + P(B^c)P(A|B^c)} = \\ &= \frac{0.5 \cdot 0.4}{0.5 \cdot 0.4 + 0.5 \cdot 0.8} = \frac{1}{3}. \end{aligned}$$

In order to better understand the role of the prior probability hypothesis, here is another example.

Consider a university using entrance exams with the following reliability: 99% of intelligent people pass them, while concerning non-intelligent people, only 0.5% are able to pass. It is desired to find the probability that a random student (accepted applicant) of the university is intelligent.

Thus, let  $A$  be the event "a random person is intelligent" and  $B$  be the event "the person passed the exams successfully". Using Bayes' formula, the probability that  $A$  occurs provided  $B$  has occurred can be computed. It is only necessary to supply the general probability  $p = P(A)$  that a random applicant is intelligent.

$$P(A|B) = \frac{p \cdot 0.99}{p \cdot 0.99 + (1-p) \cdot 0.005}.$$

The following table presents the result for various values of  $p$ . The first column corresponds to the case that every other applicant is intelligent, etc.

$p$	0.5	0.1	0.05	0.01	0.001	0.0001
$P(A B)$	0.99	0.96	0.91	0.67	0.17	0.02

Therefore, if every other applicant is intelligent, then 99% of the students are intelligent. If only 1% of the population meets an expectation of "intelligence" and the applicants form a good random sample, then only about two thirds of the students are intelligent, etc.

Consider similar tests for the occurrence of a disease, say HIV. There may be a test with the same reliability as the one above and use it to test all students that are present at the university. In this case, assume that the parameter  $p$  is close to the one for the entire population (say 1 out of 10000 people is infected, on average), which corresponds to the last column

It follows from the second Bayes' formula (1) that

$$\begin{aligned}
 P(C|A) &= \\
 &= \frac{P(H)P(A|H)P(C|A \cap H) + P(H^c)P(A|H^c)P(C|A \cap H^c)}{P(A)} \\
 &= P(H^c) = \frac{2}{3}
 \end{aligned}$$

and, analogously,

$$\begin{aligned}
 P(C|A^c) &= \\
 &= \frac{P(H)P(A^c|H)P(C|A^c \cap H) + P(H^c)P(A^c|H^c)P(C|A^c \cap H^c)}{P(A^c)} \\
 &= P(H) = \frac{1}{3}.
 \end{aligned}$$

We have thus obtained  $P(C|A) > P(C|A^c)$ , which means that it is wise to change the door.

Note that the solution is based upon the assumption that the assistant *deliberately* opens a door behind which there is a goat. If the contestant believes it was an accident or if instead, say, he happens to see (or hear) a goat behind one of the two not chosen doors, then the first reasoning is correct and the probability remains to be  $\frac{1}{2}$ .  $\square$

**10.C.10.** We have two bags. The first one contains two white and two black balls, while the second one contains one white and two black balls. We randomly select one of the bags and take two balls out of it (without replacement). What is the probability that the second ball is black provided the first one is white?  $\circ$

### D. What is probability?

First of all, recall the geometric probability, which was introduced in ??.

**10.D.1. Buffon's needle.** A plane is covered with parallel lines, creating bands of width  $l$ . Then, a needle of length  $l$  is thrown onto the plane. What is the probability that the needle crosses one of the lines?

**Solution.** The position of the needle is given by two independent parameters: the distance  $d$  of the needle's center from the closest line ( $d \in [0, l/2]$ ) and the angle  $\alpha$  ( $\alpha \in [0, \pi/2]$ ) between the lines and the needle's direction. The needle crosses one of the lines if and only if  $l/2 \sin \alpha > d$ . The space of all events  $(\alpha, d)$  is a rectangle  $\pi/2 \times l/2$ . The favorable events  $(\alpha, d)$  (i. e. those for which  $l/2 \sin \alpha > d$ ) correspond to those points in the rectangle which lie under the curve  $l/2 \sin \alpha$  ( $\alpha$  being the variable of the  $x$ -axis). By 6.2.20, the area of the figure is

$$\int_0^{\pi/2} \frac{l}{2} \sin \alpha \, d\alpha = \frac{l}{2}.$$

Thus, the wanted probability is (see ??)

$$\frac{\frac{l}{2}}{\frac{\pi}{2} \cdot \frac{l}{2}} = \frac{2}{\pi}.$$

of the table above. Clearly the result of the test is catastrophically unreliable. Only about 2% of the students who are tested positive are really infected!

Note that the problem with both tests is the same one. It is clear that real entrance exams require good selectivity and reliability. So the university marketing must ensure that the actual applicants do not provide a good random sample of population. Perhaps the university should try to discourage "non-intelligent" people from applying and thus secure a sufficiently low number of such applicants. With diseases, even the very rare occurrence of healthy people tested positively can be devastating. If the test is improved so that it is 100% reliable for positive people, it would have almost no impact on the resulting probabilities in the table.

Thus, if a person is tested positive when diagnosing a rare disease, it is necessary to make further tests. Then, the result  $P(A|B)$  of the first test plays the role of the prior probability  $P(A)$  during the second test, etc. This approach allows one to "cumulate the experience".

**10.2.9. Borel sets.** In practice, the probability of events which are expressed by questioning whether some numerical quantity falls into a given interval is of interested. We illustrate this on the example dealing with the results of students in a given course, measured for instance by the number of points in a written exam (cf. 10.1.1).

On one hand, there is only a finite number of students, and there are only a finite number of possible results (say, the numbers of points in the written exam can be the integers 0 through 20). On the other hand, imagining the results of the students as an analogy to independent rolls of a regular die is inappropriate. Even if a regular 21-hedron would exist (it cannot, see chapter 13); that would be somewhat weird.

Thus it is better to focus on the assessing function  $X : \Omega \rightarrow \mathbb{R}$  in the sample space  $\Omega$  of all students and model the probability that its value falls into a fixed interval when a random student is picked. For instance, if the table transferring points into marks A through F is fixed, the probability that the student obtained an A or a B can be modeled.

In the case of a reasonable course, we should expect that the most probable results are somewhere in the middle of the "interval of success", while the ideal result of the full number of points is not very probable. Similarly, if many values of  $X$  lie in the interval of failure, this may be at most universities perceived as a significant failure of the lecturer. This is a typical example of the random variables or random vectors, as defined below (it depends whether the result of just one or several students is chosen randomly).

One way to proceed is to model the behaviour of  $X$  as probability defined for all intervals. This requires the following  $\sigma$ -algebra.<sup>1</sup>

<sup>1</sup>In this connection, we also talk about the  $\sigma$ -algebra of *Borel-measurable sets* on  $\mathbb{R}^k$ , and then the following definition says that random variables are *Borel-measurable functions*.  $\square$

The following (known) problem, which also deals with geometric probability, illustrates that we must be cautious about what is assumed to be “clear”.

**10.D.2. Bertrand’s paradox.** What is the probability that a random chord of a given circle is longer than the side of an equilateral triangle inscribed into the circle?

**Solution.** We will show three ways how to find “this” probability.

1) Every chord is determined by its center. Thus, a random choice of the chord is given by a random choice of the center. The chord is greater than the side of the inscribed equilateral triangle if and only if its center lies inside the concentric circle with half radius. The center is chosen “randomly” from the whole inside of the circle. Therefore, the probability that it will lie in the inner disc is given by the ratio of the areas of these discs, which is  $\frac{1}{4}$ .

2) Unlike above, we claim that the wanted probability does not change if the direction of the chord is fixed. Then, the centers of such chords lie on a fixed diameter of the circle. The favorable centers are those which lie inside the inner circle (see 1)), i. e., inside a fixed diameter of the inner circle. The ratio of the diameters is 1 : 2, hence the wanted probability is  $\frac{1}{2}$ .

3) Now, we observe that a chord is determined by its endpoints (which must lie on the circle). Let us fix one of the endpoints (call it  $A$ )—thanks to the apparent symmetry, this should not affect the resulting probability. Then, the chord satisfies the given condition if and only if the other endpoint lies on the shorter arc  $BC$ , where  $ABC$  is the inscribed equilateral triangle. However, the length of this arc is one third of the length of the entire circle, which means that the wanted probability is equal to  $\frac{1}{3}$ .

How is it possible that we came to three different probabilities? It is caused by a hidden ambiguity in the statement of the problem. It is necessary to specify what exactly it means to choose a chord “randomly”. Each of the three results is correct provided the chord is chosen in the corresponding way. However, these ways are not equivalent; this is apparent not only from the different results, but also from the distribution of the chords’ centers. In the first case, they are distributed uniformly throughout the inside of the circle. In the second and third cases, the centers are concentrated more towards the center of the circle.

□

**10.D.3. Two envelopes.** There are two envelopes, each contains a certain amount of money. We know that the amount in one of them is twice as great as in the other one. We can choose either of the envelopes (and take its contents). As soon as we choose one, we are allowed to change our mind and take the other envelope instead. Is it advantageous to do so?

**Solution.** At the first sight, it must not matter which envelope we choose. The probability of choosing the one which contains more is 1/2, so it is no good to change our choice.

BOREL SETS

The *Borel sets* in  $\mathbb{R}$  are all those subsets that can be obtained from intervals using complements, countable unions, and countable intersections.

More generally, on the sample space  $\Omega = \mathbb{R}^k$ , one considers the smallest  $\sigma$ -algebra  $\mathcal{B}$  which contains all  $k$ -dimensional intervals.

The sets in  $\mathcal{B}$  are called the *Borel sets* on  $\mathbb{R}^k$ .

**10.2.10. Random variables.** The probabilities of the individual intervals in the Borel algebra are usually given as follows. Consider a numerical quantity  $X$  on any sample space, that is, a function  $X : \Omega \rightarrow \mathbb{R}$ . Since it is desired to work with the probability of  $X$  taking on values from any fixed interval, the probability space and the properties of the function  $X$  have to allow this.

Notice that working with finite probability spaces where all subsets are events, every function  $X : \Omega \rightarrow \mathbb{R}$  is a random variable in the following sense.

RANDOM VARIABLES AND VECTORS

**Definition.** A *random variable*  $X$  on a probability space  $(\Omega, \mathcal{A}, P)$  is a function  $X : \Omega \rightarrow \mathbb{R}$  such that the inverse image  $X^{-1}(B)$  lies in  $\mathcal{A}$  for every Borel set  $B \in \mathcal{B}$  on  $\mathbb{R}$ . The real-valued function  $P_X(B) = P(X^{-1}(B))$  defined on all intervals  $B \subset \mathbb{R}$  is called the (*probability*) *distribution of a random variable*  $X$ .

A *random vector*  $X = (X_1, \dots, X_k)$  on  $(\Omega, \mathcal{A}, P)$  is a  $k$ -tuple of random variables  $X_i : \Omega \rightarrow \mathbb{R}$  defined on the same probability space  $(\Omega, \mathcal{A}, P)$ .

If intervals  $I_1, \dots, I_k$  in  $\mathbb{R}$  are chosen, then the probability of simultaneous occurrence of all of the  $k$  events  $X_i \in I_i$  must exist. Thus, as in the scalar case, there is a real-valued function defined on the  $k$ -dimensional intervals  $B = I_1 \times \dots \times I_k$ ,  $P_X(B) = P(X^{-1}(B))$  (and thus also for all Borel sets  $B \subset \mathbb{R}^k$ ). It is called the *probability distribution of the random vector*  $X$ .

**10.2.11. Distribution function.** The distribution of random variables is usually given by a rule which shows how the probability grows as the interval  $B$  is extended.

In particular, consider the intervals  $I$  with endpoints  $a, b$ ,  $-\infty \leq a \leq b \leq \infty$ . Denote  $P(a < X < b)$  the probability of  $X$  lying in  $I = (a, b)$ , or  $P(X < b)$  if  $a = -\infty$ ; and analogously for other types of intervals. In the special case of a singleton, write  $P(X = a)$ .

In the case of a random vector  $X = (X_1, \dots, X_k)$ , write  $P(a_1 < X_1 < b_1, \dots, a_k < X_k < b_k)$  for the probability of simultaneous occurrence of the events where the values of  $X_i$  fall into the corresponding intervals (which may also be closed, unbounded, etc.).

However, consider the following reasoning: the envelope we have chosen contains  $a$ . Therefore, the other one contains  $a/2$  or  $2a$ , each with probability  $1/2$ . This means that if we change the envelope, then we get  $a/2$  with probability  $1/2$  and  $2a$  with probability  $1/2$ , i. e., the expected outcome is

$$\frac{1}{2} \frac{a}{2} + \frac{1}{2} 2a = \frac{5}{4} a.$$

Therefore, it is wise to change the envelope. What is wrong with this reasoning?

There are several issues. Mainly, it is not generally true that if there is amount  $a$  in one of the envelopes, then the second one contains  $a/2$  with probability  $1/2$ . This depends on the initial distribution of the amounts that have been put into the envelopes, which is not precisely stated in the problem.

However, the paradox is rooted not only in the concealed a priori distribution. There are (even discrete) distributions for which the choice of changing the envelope always produces greater expected outcome than that of not changing it. Nevertheless, any distribution with this property must have infinite expected value (if the expectation is finite, then there is always a value which, when seen in the envelope, it is more advantageous to keep), so it is dubious to say that it is better to get “greater” infinity on average.  $\square$

### E. Random variables, density, distribution function

**10.E.1.** Consider rolling a die. The set of sample points is  $\Omega = \{\omega_1, \dots, \omega_6\}$ , where  $\omega_i$  means that we have rolled number  $i$ . Further, consider the  $\sigma$ -field

$$\mathcal{A} = \{\emptyset, \{\omega_1, \omega_2\}, \{\omega_3, \omega_4, \omega_5, \omega_6\}, \Omega\}.$$

Find whether the mapping  $X : \Omega \rightarrow \mathbb{R}$  defined by

- i)  $X(\omega_i) = i$  for each  $i \in \{1, 2, 3, 4, 5, 6\}$ ,
- ii)  $X(\omega_1) = X(\omega_2) = -2, X(\omega_3) = X(\omega_4) = X(\omega_5) = X(\omega_6) = 3$

is a random variable with respect to  $\mathcal{A}$ .

**Solution.** First of all, we should make sure that the set  $\mathcal{A}$  really satisfies all axioms of 10.2.2, i. e., that it is a well-defined  $\sigma$ -field. Then, by definition 10.2.10, a random variable is any function  $X : \Omega \rightarrow \mathbb{R}$  such that the preimage of every Borel-measurable set  $B \subset \mathbb{R}$  lies in  $\mathcal{A}$ . As for the first case, consider the interval  $[2, 3]$ . Since  $X^{-1}([2, 3]) = \{\omega_2, \omega_3\} \notin \mathcal{A}$ , we can see that the function  $X$  is not a random variable.

In the second case, we can easily see that  $X$  is a random variable: Consider any interval in  $\mathbb{R}$ . Then, exactly one of the four following occurs: 1) If the interval contains neither  $-2$  nor  $3$ , then the preimage in  $X$  is the empty set. 2) If it contains  $-2$  but not  $3$ , then the preimage is  $\{\omega_1, \omega_2\}$ . 3) On the other hand, if it contains  $3$  but not  $-2$ , then the preimage is  $\{\omega_3, \omega_4, \omega_5, \omega_6\}$ . 4) Finally, if it contains both these numbers, then the preimage is the whole sample space  $\Omega$ . In each case, the preimage lies in the  $\sigma$ -field  $\mathcal{A}$ .  $\square$

### DISTRIBUTION FUNCTION

**Definition.** The *distribution function* or *cumulative distribution function* of a random variable  $X$  is the function  $F_X : \mathbb{R} \rightarrow [0, 1]$  defined for all  $x \in \mathbb{R}$  by

$$F_X(x) = P(X < x).$$

The *distribution function* of a random vector  $(X_1, \dots, X_k)$  is the function  $F_X : \mathbb{R}^k \rightarrow \mathbb{R}$  defined for all vectors  $x = (x_1, \dots, x_k) \in \mathbb{R}^k$  by

$$F_X(x) = P(X_1 < x_1, \dots, X_k < x_k).$$

If it is clear from the context which distribution function is discussed, omit the random variable name and write simply  $F(x)$ .

The following theorem guarantees that, for every random variable, the probability that the value of  $X$  falls into any (fixed) interval (and thus into any Borel set  $B$ ) can be calculated purely from the knowledge of its distribution function.<sup>2</sup>

**10.2.12. Theorem.** For every random variable  $X$ , its distribution function  $F : \mathbb{R} \rightarrow [0, 1]$  has the following properties:

- (1)  $F$  is a non-decreasing function;
- (2)  $F$  has both side-limits at every point  $x \in \mathbb{R}$ , yet these limits may differ;
- (3)  $F$  is left-continuous;
- (4) at the infinite points, the limits of  $F$  are

$$\lim_{x \rightarrow -\infty} F(x) = 0, \quad \lim_{x \rightarrow \infty} F(x) = 1;$$

- (5) the probability of  $X$  taking on the value  $x$  is given by

$$P(X = x) = \lim_{y \rightarrow x+} F(y) - F(x).$$

- (6) The distribution function of a random variable always has only countably many points of discontinuity.

**PROOF.** The proof consists of quite simple and straightforward calculations. In particular, note that the events  $a \leq X < b$  and  $X < a$  are exclusive, so

$$P(a \leq X < b) = P(X < b) - P(X < a) = F(b) - F(a).$$

Hence the first property follows immediately from the definition of probability.

The next two statements follow from the probability of monotone sequences of events, discussed in 10.2.5. Fix a non-increasing sequence of numbers  $r_n > 0$  which converges to 0, and consider the events  $A_n$  given by  $X < x - r_n$ . The union of these events is exactly the event  $A$  given by  $X < x$ . Of course, the event  $A$  does not depend on the choice of the sequence  $r_n$ . By the first proposition of 10.2.5,

$$P(A) = \lim_{n \rightarrow \infty} P(A_n).$$

<sup>2</sup>In literature, the definition with the non-strict inequality  $F(x) = P(X \leq x)$  is often met. In this case, the probability  $P(X = x)$  is also included in  $F_X(x)$ . Then, the distribution function has similar properties as those in 10.2.12, only it is right-continuous instead of left-continuous, etc.

**10.E.2.** Consider a  $\sigma$ -field  $(\Omega, \mathcal{A})$ , where  $\Omega = \{\omega_1, \omega_2, \omega_3, \omega_4, \omega_5\}$  and

$$\mathcal{A} = \{\emptyset, \{\omega_1, \omega_2\}, \{\omega_3\}, \{\omega_4, \omega_5\}, \{\omega_1, \omega_2, \omega_3\}, \{\omega_1, \omega_2, \omega_4, \omega_5\}, \{\omega_3, \omega_4, \omega_5\}, \Omega\}.$$

Find a mapping  $X : \Omega \rightarrow \mathbb{R}$ , as general as possible, which is a random variable with respect to  $\mathcal{A}$ .

**Solution.** Since the events  $\omega_1, \omega_2$  do not occur individually in  $\mathcal{A}$ , the random variable  $X$  must map them to the same number, i. e.  $X(\omega_1) = X(\omega_2) = a$  for an  $a \in \mathbb{R}$ . For the same reason, we must have  $X(\omega_4) = X(\omega_5) = b$  for a  $b \in \mathbb{R}$ . If an interval contains both  $a$  and  $b$ , then its preimage is  $\{\omega_1, \omega_2, \omega_4, \omega_5\} \in \mathcal{A}$ , which is okay. Clearly, the event  $\omega_3$  may be mapped to an arbitrary  $c \in \mathbb{R}$ . Then, we can easily verify that the  $X$ -preimage of every interval is contained in  $\mathcal{A}$ , i. e.,  $X$  is a random variable with respect to  $\mathcal{A}$ .  $\square$

**10.E.3.** Consider a random variable  $X$  which takes on value  $i$  with probability  $P(X = i) = \frac{1}{6}$ , for each  $i = 1, \dots, 6$ . Find the distribution function  $F_X(x)$  and draw its graph.

**Solution.** By definition 10.2.11, the distribution function is  $F_X(x) = P(X < x)$ . This means that  $F_X(x) = 0$  for  $x < 1$ ,  $F_X(x) = \frac{\lfloor x \rfloor}{6}$  for  $1 \leq x < 6$  (where  $\lfloor x \rfloor$  stands for the floor of  $x$ ), and  $F_X(x) = 1$  for  $x \geq 6$ . The graph looks as follows:

**10.E.4.** An archer keeps shooting at a target until he hits. He has 4 arrows at his disposal. In each attempt, the probability that he hits the target is 0.6. Let  $X$  be the random variable which gives the number of unused arrows. Find the probability mass function and the distribution function of  $X$  and draw their graphs.

**Solution.** Clearly, the probability of  $k$  consecutive misses followed by a hit is equal to  $0.4^k \cdot 0.6$ . Therefore,  $f_X(x) = P(X = x) = 0.4^{3-x} \cdot 0.6$  for  $x \in \{1, 2, 3\}$ . If the archer misses three times, then there will be no arrow left at the

The distribution function is non-decreasing, and thus the left-sided limit equals the supremum. Thus, the left-sided limit  $F_X$  at  $x$  exists and equals  $P(A)$ . This proves one half of proposition (2) as well as all of proposition (3).

Similarly, the above sequence  $r_n$  can be used to define the events  $A_n$  by  $X_n < x + r_n$ . This time, it is a non-increasing sequence  $A_1 \supset A_2 \supset \dots$ , and its intersection is the event  $X \leq x$ . By the second property of 10.2.5,

$$P(A) = \lim_{n \rightarrow \infty} P(A_n) = P(X \leq x),$$

which verifies that the right-sided limit of  $F$  at  $x$  exists. At the same time, property (5) is proved.

The limit values of property (4) can be derived similarly by applying theorem 10.2.5, as shown for the one-sided limits above. In the first case, use the events  $A_n$  given by  $X < r_n$ , for an arbitrary increasing sequence  $r_n \rightarrow \infty$ . Their union is the universal event  $\Omega$ . In the second case, use the events  $A_n$  given by  $X < r_n$ , for any decreasing sequence  $r_n \rightarrow -\infty$ , and their intersection is the null event.

It remains to prove the last statement. As already shown, the discontinuity points of the distribution function are exactly those values  $x$  which the random variable has with non-zero probability, i.e.,  $P(X = x) \neq 0$ . Now, let  $M_n$  denote the set of points  $x$  for which  $P(X = x) > \frac{1}{n}$ . Clearly, the set  $M$  of all discontinuity points equals the union of the sets  $M_n: M = \cup_{n=2}^{\infty} M_n$ . Since the sum of probabilities of mutually exclusive events cannot exceed 1,  $M_n$  can contain no more than  $n - 1$  elements. Thus,  $M$  is a countable union of finite sets, thus it is countable.  $\square$

**10.2.13. Probability measure.** The probability that a random variable has a value lying in an arbitrarily chosen interval can be computed purely from the knowledge of its distribution function. The distribution function  $F_X$  thus defines the entire probability distribution of the random variable  $X$ .

How a particular random variable  $X$  is defined can be ignored.  $X$  can be viewed directly as a probability definition on the  $\sigma$ -algebra of all the Borel sets in  $\mathbb{R}$ .

In this sense, every function  $F : \mathbb{R} \rightarrow \mathbb{R}$  satisfying the first four properties of the latter theorem is a distribution function of a unique random variable. Check the properties of the probability function defined on all intervals this way!

The probability obtained in this way is also called a *probability measure* on  $\mathbb{R}$ . Similarly one deals with probability measures on the algebra of Borel sets in  $\mathbb{R}^k$  in terms of the distribution functions of the random vectors.

In this sense, a random variable or random vector can be considered without any explicit link to a probability space  $(\Omega, \mathcal{A}, P)$ .

**10.2.14. Discrete random variables.** Random variables behave substantially differently according to whether the non-zero probability is “concentrated in isolated points” or it is “continuously distributed” along (a part of) the real axis.

end, no matter whether he hits the last time or not. Thus,  $f_X(0) = P(X = 0) = 0.4^3$ .

By the definition of the distribution function (see 10.2.11), we have

$$F_X(x) = P(X < x) = \begin{cases} 0 & \text{for } x \leq 0, \\ 0.4^3 = 0.064 & \text{for } x \in (0, 1], \\ 0.4^3 + 0.4^2 \cdot 0.6 = 0.16 & \text{for } x \in (1, 2], \\ 0.4^3 + 0.4^2 \cdot 0.6 + 0.4 \cdot 0.6 = 0.4 & \text{for } x \in (2, 3], \\ 1 & \text{for } x > 3. \end{cases}$$

The graphs of the probability mass function and the distribution function are as follows:

□

**10.E.5.** The distribution function of a random variable  $X$  is

$$F_X(x) = \begin{cases} 0 & \text{for } x \leq 3 \\ \frac{1}{3}x - 1 & \text{for } 3 < x \leq 6 \\ 1 & \text{for } 6 < x. \end{cases}$$

i) Justify that  $F_X$  is indeed a distribution function.

DISCRETE RANDOM VARIABLES

If a random variable  $X$  assumes only finitely many values  $x_1, x_2, \dots, x_n \in \mathbb{R}$  or countably infinitely many values  $x_1, x_2, \dots$ , it is called a *discrete random variable*.

One can define its *probability mass function*  $f(x)$  by

$$f(x) = \begin{cases} P(X = x_i) & x = x_i \\ 0 & \text{otherwise.} \end{cases}$$

Since the probability is countably additive and the singleton events  $X = x_i$  are mutually exclusive, the sum of all values  $f(x_i)$  is given by either a finite sum or an absolutely convergent series

$$\sum_i f(x_i) = 1.$$

The probability distribution of a random variable  $X$  satisfies

$$P(X \in B) = \sum_{x_i \in B} f(x_i).$$

In particular, the distribution function is of the form

$$F_X(t) = \sum_{x_i < t} f(x_i).$$

Note the the distribution function  $F(x)$  of a discrete random variable is piecewise constant.  $F(x) = 1$  for those  $x$  which are greater than all the  $x_i$ 's.

Every random variable defined on a classical finite probability space is discrete.

**10.2.15. Continuous random variables.** Even if the values of a random variable  $X$  are not discrete, one can proceed similarly. Intuitively, increasing the value of  $x$  infinitesimally by  $dx$ , the density function  $f(x)$  of the random variable  $X$  can be perceived as

$$P(x \leq X < x + dx) = f(x)dx.$$

This means that whenever  $-\infty \leq a \leq b \leq \infty$ , it is required that

$$P(a \leq X < b) = \int_a^b f(x)dx.$$

CONTINUOUS RANDOM VARIABLES

A random variable  $X$  for which there exists a function  $f$  satisfying

$$F_X(b) = \int_{-\infty}^b f(x)dx,$$

is said to be a *continuous random variable*, and the function  $f$  is called its *density function*.

It is convenient to view the random variables as probability measures, cf. 10.2.13. Generally, this means not referring to any other sample space  $\Omega$  on which  $X$  would be defined as a function.  $X$  is represented just by its density or distribution function.

- ii) Find the density of the random variable  $X$ .
- iii) Compute  $P(2 < X < 4)$ .

**Solution.** a) Clearly,  $F_X$  is continuous and non-decreasing. Moreover, we have  $\lim_{x \rightarrow -\infty} F(x) = 0$  and  $\lim_{x \rightarrow \infty} F(x) = 1$ , as needed.

b) By 10.2.14, the density of a continuous random variable is the derivative of its distribution function. We can see that on the interval  $(3, 6)$ , the density is equal to  $f(x) = \frac{1}{3}$ , while on the intervals  $(-\infty, 3)$  and  $(6, \infty)$ , it is equal to zero. Therefore, the variable  $X$  has uniform distribution, see 10.2.20.

c) We have from the definition of the distribution function that  $P(2 < X < 4) = F_X(4) - F_X(2) = \frac{4}{3} - 1 = \frac{1}{3}$ .  $\square$

**10.E.6.** Consider a random variable  $X$  and a function  $f : \mathbb{R} \rightarrow \mathbb{R}$  given by  $f(x) = \frac{a}{1+x^2}$  for  $x \in \mathbb{R}$ , where  $a$  is a parameter. Suppose that  $f$  is the density of  $X$ . Find

- i) the value of  $a$ ,
- ii) the distribution function of  $X$ ,
- iii)  $P(-1 < X < 1)$ .

**Solution.** a) If the function  $f$  is to be a probability density, then its integral over  $\mathbb{R}$  must be equal to one. This yields the condition

$$1 = \int_{-\infty}^{\infty} \frac{a}{1+x^2} dx = a[\arctg x]_{-\infty}^{\infty} = a\pi.$$

Hence  $a = \frac{1}{\pi}$ .

b) By 10.2.14, the distribution function is given by the following integral:

$$F_X(x) = \int_{-\infty}^x f(t) dt = \frac{1}{\pi} \int_{-\infty}^x \frac{dt}{1+t^2} = \frac{1}{\pi} \arctg x + \frac{1}{2}.$$

c) By b) and the definition of the distribution function, we have

$$P(-1 < X < 1) = F_X(1) - F_X(-1) = \frac{1}{\pi} \cdot \frac{\pi}{4} - \frac{1}{\pi} \cdot \left(-\frac{\pi}{4}\right) = \frac{1}{2}.$$

$\square$

**10.E.7.** The joint probability mass function of a discrete random vector is given by the following table:

Y \ X	2	5	6
1	$\frac{1}{5}$	$\frac{1}{10}$	$\frac{1}{20}$
2	$\frac{1}{10}$	$\frac{1}{20}$	0
3	$\frac{3}{10}$	$\frac{1}{20}$	$\frac{3}{20}$

Find

- i) the marginal distribution and probability mass functions;
- ii) the joint distribution function and draw it in a suitable way;
- iii)  $P(Y > 3X)$ .

**Solution.** a) By 10.2.22, the marginal distribution of the random variable  $X$  is obtained by summing up the joint probability mass function over all possible values of  $Y$  in each row. Similarly, the marginal distribution of  $Y$  is obtained by

Note that the distribution function  $F(x)$  of a continuous random variable  $X$  is always differentiable. Its derivative is the density function of  $X$ , i.e.,  $F'(x) = f(x)$ .

**10.2.16. The general case.** Of course, there are also random variables with mixed behaviour, where some part of the probability is distributed continuously, while there are values that are taken on with non-zero probability. This means, the probability measure of some singletons  $x \in \mathbb{R}$  is non-zero and still  $X$  is not a discrete random variable.

For instance, consider a chaotic lecturer who remains to stand at his laptop with probability  $p$  throughout the entire lecture, but once he decides to move, he happens to be at any position in front of the lecture room with equal probability.

Then, the random variable which corresponds to his position (assume that the desk with the laptop is at position 0 and the lecture room is bounded by the values  $\pm 1$ ) has the following distribution function:

$$F(t) = \begin{cases} 0 & \text{if } t \leq -1 \\ \frac{1-p}{2}(t+1) & \text{if } t \in (-1, 0) \\ p + \frac{1-p}{2}(t+1) & \text{if } t \in [0, 1) \\ 1 & \text{if } t \geq 1. \end{cases}$$

The distribution function of all such variables can be expressed directly using the Riemann-Stieltjes integral

$$F(t) = \int_{-\infty}^t f(x) d(g(x)),$$

developed in subsection 6.3.14 (page 570). In the example above, choose  $f(x) = 1$  and

$$g(x) = \begin{cases} -1 & \text{for } x \leq -1 \\ \frac{1-p}{2}x & \text{for } -1 < x < 0 \\ \frac{1-p}{2}x + p & \text{for } 0 \leq x < 1 \\ \frac{1+p}{2} & \text{for } x \geq 1. \end{cases}$$

This corresponds again to the idea, that the distribution function is equivalent to a probability measure. Thus the measure of any interval is given by integrating its indicator function with respect to this measure. This is what the Riemann-Stieltjes integral achieves.

The Riemann integral corresponds to the choice  $g(x) = x$ . One could add only the jump  $p$  at  $x = 0$  (i.e.  $g(x) = x$  for  $x < 0$ , while  $g(x) = x + p$  otherwise) and leave the constant density  $\frac{1-p}{2}$  to  $f(x)$ , which would be nonzero only on  $[-1, 1]$ . This corresponds to splitting the probability measure into its discrete part (hidden in  $g$ ) and continuous part (expressed by the probability density).

Notice that any distribution function can have only countably many points of discontinuity.

**10.2.17. Basic discrete distributions.** The requirements on the properties of probability distributions of random variables are based on the modeled situations. Here is a list of the simplest discrete distributions.

summing up the entries in each column. Thus, we get the following:

X	1	2	3
$f_X$	$\frac{7}{20}$	$\frac{3}{20}$	$\frac{1}{2}$

and

Y	2	5	6
$f_Y$	$\frac{3}{5}$	$\frac{1}{5}$	$\frac{1}{5}$

b) The joint distribution function is at point  $(a, b)$  equal to the sum of all values of the joint probability mass function  $f_{(X,Y)}$  such that  $X \leq a$  and  $Y \leq b$ . This corresponds to values of the subtable whose lower-right corner is  $(a, b)$ . Precisely, the joint distribution function  $F_{(X,Y)}$  looks as follows **is missing ...** and on intervals  $(-\infty, 1) \times \mathbb{R}$  and  $\mathbb{R} \times (-\infty, 2)$ ,  $F_{(X,Y)}$  is clearly zero.

c) Apparently,  $P(Y > 3X) = P(X = 1, Y = 5) + P(X = 1, Y = 6) = \frac{1}{10} + \frac{1}{20} = \frac{3}{20}$  □

**10.E.8.** Find the probability  $P(2X > Y)$  provided the density of the random vector  $(X, Y)$  is given by:

$$f_{(X,Y)}(x, y) = \begin{cases} \frac{1}{6}(4x - y) & \text{for } 1 \leq x \leq 2, 2 \leq y \leq 4, \\ 0 & \text{otherwise.} \end{cases}$$

**Solution.** By definition, we have

$$\begin{aligned} P(2X > Y) &= \int_{-\infty}^{\infty} \int_{-\infty}^{2x} f_{(X,Y)}(x, y) dy dx = \\ &= \int_1^2 \int_2^{2x} \frac{1}{6}(4x - y) dy dx = \\ &= \int_1^2 \left[ \frac{2}{3}xy - \frac{1}{12}y^2 \right]_2^{2x} dx = \\ &= \int_2^4 \left( x^2 - \frac{4}{3}x + \frac{1}{3} \right) dx = \\ &= \left[ \frac{1}{3}x^3 - \frac{2}{3}x^2 + \frac{1}{3}x \right]_1^2 = \frac{2}{3}. \end{aligned}$$

□

**10.E.9.** Find the marginal distribution function and the joint and marginal density of the random vector  $(X, Y)$  provided

$$F_{(X,Y)}(x, y) = \begin{cases} 0 & \text{for } x < 0, y < 0 \\ \frac{1}{4}x^2y^2 & \text{for } 0 \leq x \leq 1, 0 \leq y \leq 2 \\ 1 & \text{for } x > 1, y > 2 \end{cases}$$

**Solution.** The density of the random vector  $(X, Y)$  is obtained by differentiation with respect to  $x$  and  $y$ . Thus, for  $0 \leq x \leq 1, 0 \leq y \leq 2$ , we have  $f_{(X,Y)}(x, y) = xy$ , and elsewhere the density is zero. The marginal density of the random variable  $X$  is then

$$f_X(x) = \int_{-\infty}^{\infty} f_{(X,Y)}(x, y) dy = \int_0^2 xy dy = \left[ \frac{1}{2}xy^2 \right]_0^2 = 2x.$$

Similarly, for  $Y$ , we get  $f_Y(y) = \frac{1}{2}y$ . The marginal distribution functions are

$$F_X(x) = \int_{-\infty}^x f_X(t) dt = \int_0^x 2t dt = x^2$$

DEGENERATE DISTRIBUTION

The distribution which corresponds to a constant random variable  $X = \mu$  is called the *degenerate distribution*  $Dg(\mu)$ .

Its distribution function  $F_X$  and probability mass function  $f_X$  are given by

$$F_X(t) = \begin{cases} 0 & t \leq \mu \\ 1 & t > \mu \end{cases} \quad f_X(t) = \begin{cases} 1 & t = \mu \\ 0 & \text{otherwise.} \end{cases}$$

Here follows a description of an experiment with two possible outcomes called success and failure. If the probability of success is  $p$ , then the probability of failure must be  $1 - p$ .

It is convenient to take the values 0 and 1 for the two possible results.

BERNOULLI DISTRIBUTION

The distribution of a random variable  $X$  which is 0 (failure) with probability  $q = 1 - p$  and 1 (success) with probability  $p$  is called the *Bernoulli distribution*  $A(p)$ .

Its distribution function  $F_X$  and probability mass function  $f_X$  are given by

$$F_X(t) = \begin{cases} 0 & t \leq 0 \\ q & 0 < t \leq 1 \\ 1 & t > 1 \end{cases} \quad f_X(t) = \begin{cases} p & t = 1 \\ q & t = 0 \\ 0 & t \notin \{0, 1\}. \end{cases}$$

Further, consider a random variable  $X$  which corresponds to  $n$  independent experiments described by the Bernoulli distribution, where  $X$  measures the number of successes. Clearly the probability mass function is non-zero exactly at the integers  $t = 0, \dots, n$ , which correspond to the total number of successes in the experiments (the order does not matter).

The probability that  $t$  successes are encountered in  $t$  chosen experiments out of  $n$  is  $p^t(1 - p)^{n-t}$ . It is necessary to sum all the  $\binom{n}{t}$  possibilities. This leads to the binomial distribution of  $X$ :

BINOMIAL DISTRIBUTION

The *binomial distribution*  $Bi(n, p)$  has probability mass function

$$f_X(t) = \begin{cases} \binom{n}{t} p^t (1 - p)^{n-t} & t \in \{0, 1, \dots, n\} \\ 0 & \text{otherwise.} \end{cases}$$

The illustration shows the probability mass functions for  $Bi(50, 0.2)$ , and  $Bi(50, 0.9)$ . The distribution of the probability corresponds to the intuition that most outcomes occur near the value  $np$ :

and

$$F_Y(y) = \int_{-\infty}^y f_Y(t) dt = \int_0^y \frac{1}{2} t dt = \frac{1}{4} y^2. \quad \square$$

**10.E.10.** In a bag, there are 14 balls—4 red, 5 white, and 5 blue ones. We randomly take 6 balls out of the bag (without replacement). Find the distribution of the random vector  $(X, Y)$  where  $X$  stands for the number of red balls taken and  $Y$  for the number of white balls. In addition, find the marginal distributions of  $X$  and  $Y$ . Then, compute  $P(X \leq 3)$ ,  $P(1 \leq Y \leq 4)$ .

**Solution.** The value of the probability mass function at point  $(x, y)$  is defined as the probability  $P(X = x, Y = y)$ , i. e. the probability of taking  $x$  red balls and  $y$  white balls. The number of ways how to take  $x$  red balls is  $\binom{4}{x}$ ; for  $y$  white balls, it is  $\binom{5}{y}$ ; and the remaining  $6 - x - y$  blue balls can be selected in  $\binom{5}{6-x-y}$  ways. Altogether, there are  $\binom{4}{x} \binom{5}{y} \binom{5}{6-x-y}$  possibilities. The values of this expression for all  $x, y$  are in the following table.

$x \backslash y$	0	1	2	3	4	5	$\sum_X$
0	0	5	50	100	50	5	210
1	4	100	400	400	100	4	1008
2	30	300	600	300	30	0	1260
3	40	200	200	40	0	0	480
4	10	25	10	0	0	0	45
$\sum_Y$	84	630	1260	840	180	9	3003

The values in the last column and row are the sums over all values of  $y$  and  $x$ , respectively. Then, the values of the probability mass function are obtained after dividing by the number of all possibilities how to take the 6 balls, i. e.  $\binom{14}{6} = 3003$ . The marginal distributions of  $X$  and  $Y$  correspond to the last column and row, respectively.

The probability  $P(X \leq 3)$  can be calculated easily from the marginal distribution of  $X$ :

$$P(X \leq 3) = F_X(3) = \frac{1}{3003} (210 + 1008 + 1260 + 480) = 0.985.$$

Similarly, for the probability  $P(1 \leq Y \leq 4)$ , we have

$$\begin{aligned} P(1 \leq Y \leq 4) &= F_Y(4) - F_Y(1) = \\ &= \frac{1}{3003} (630 + 1260 + 840 + 180) = 0.969. \end{aligned} \quad \square$$

**10.E.11.** The density of a random vector  $(X, Y, Z)$  is

$$f(x, y, z) = \begin{cases} c(x + y + z) & \text{for } 0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1 \\ 0 & \text{otherwise.} \end{cases}$$

Find the value of the parameter  $c$  as well as the distribution function of the vector, and compute  $P(0 \leq X \leq \frac{1}{2}, 0 \leq Y \leq \frac{1}{2}, 0 \leq Z \leq \frac{1}{2})$ .

**Solution.** The integral of the density over the entire space must be equal to one. This gives us

$$\begin{aligned} 1 &= \int_0^1 \int_0^1 \int_0^1 c(x + y + z) dz dy dx = c \int_0^1 \int_0^1 (x + y + \frac{1}{2}) dy dx \\ &= c \int_0^1 (x + 1) dx = \frac{3}{2} c. \end{aligned}$$

Next, consider distributions similar to the Bernoulli process referred to in 10.2.1. Consider independent experiments with the Bernoulli distribution  $A(p)$ , as in the case of the binomial distribution, and fix a positive integer  $r$ . Repeat the experiment until  $r$  successes occur.

The random variable  $X$  is defined as the number of failures before the  $r$ -th success. In the case of  $r = 1$ , it is exactly the example from 10.2.1. The event  $X = k$  occurs if and only if there are exactly  $r - 1$  successes in the first  $k + r - 1$  experiments and the  $(k + r)$ -th experiment also ends with a success. Thus the following probability mass function is arrived at:

#### GEOMETRIC DISTRIBUTION

The random variable  $X$  which corresponds to the number of failures before reaching the  $r$ -th success has probability distribution

$$P(X = k) = \binom{k + r - 1}{r - 1} p^r (1 - p)^k, \quad k = 0, 1, 2, \dots$$

This is called the *negative binomial distribution*. In the case of  $r = 1$ , it is the *geometric distribution*.

Often the same definition is used with the successes and failures interchanged. This results in the same formula for the probability mass function with  $p$  and  $1 - p$  interchanged.

The geometric distribution appears in physics in connection with Einstein–Bose statistics.

**10.2.18. Poisson distribution.** In practice, the binomial distribution often leads to further model problems.

Consider the situation that  $r$  (mutually indistinguishable) objects are to be divided into  $n$  (distinguishable) boxes, and each object is equally probable (i.e., has probability  $1/n$ ) to fall into any of the boxes.

The random variable which describes the number  $X$  of objects in one fixed box can be described as follows: The admissible values are  $X = k$ , where  $k = 0, \dots, r$ , and the individual probabilities are

$$P(X = k) = \binom{r}{k} \left(\frac{1}{n}\right)^k \left(1 - \frac{1}{n}\right)^{r-k} = \binom{r}{k} \frac{(n-1)^{r-k}}{n^r}.$$

Thus, the distribution of  $X$  is of the type  $Bi(r, 1/n)$ .

Such a variable can be encountered, for example, when describing a physical system with a huge number of gas molecules. The boxes represent small volumes of the space.

Hence,  $c = \frac{2}{3}$ . By definition, the distribution function is equal to

$$\begin{aligned} F_X(x, y, z) &= \frac{2}{3} \int_0^x \int_0^y \int_0^z (r + s + t) dt ds dr = \\ &= \frac{2}{3} \int_0^x \int_0^y (rz + sz + \frac{1}{2}z^2) ds dr = \frac{2}{3} \int_0^x (ryz + \frac{1}{2}y^2z + \frac{1}{2}z^2y) dy = \\ &= \frac{2}{3} (\frac{1}{2}x^2zy + \frac{1}{2}y^2zx + \frac{1}{2}z^2yx) = \frac{2}{3} (x^2zy + y^2zx + z^2yx), \end{aligned}$$

so the wanted probability is

$$P(0 \leq X \leq \frac{1}{2}, 0 \leq Y \leq \frac{1}{2}, 0 \leq Z \leq \frac{1}{2}) = F(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}) = \frac{1}{16}. \quad \square$$

**10.E.12.** Find the value of the parameter  $a$  so that the function

$$f(x) = \begin{cases} 0 & \text{for } x \leq 1 \\ a \ln(x) & \text{for } 1 < x < 2 \\ 0 & \text{for } 2 \leq x \end{cases}$$

would be the probability density of a random variable.

**Solution.** We know that the condition for the function to be a density is

$$\int_{-\infty}^{\infty} f(x) dx = 1$$

Thus, we have to calculate  $\int \ln(x) dx$ :

$$\int \ln(x) dx = x \ln(x) - \int 1 dx = x \ln(x) - x = x(\ln(x) - 1).$$

Altogether,

$$\int_{-\infty}^{\infty} f(x) dx = \int_1^2 a \ln(x) dx = a[x(\ln(x) - 1)]_1^2 = a(2 \ln(2) - 1),$$

so  $a = \frac{1}{2 \ln(2) - 1}$ . □

**10.E.13.** A child has become lost in a forest whose shape is that of a regular hexagon. Suppose that the probability that the child happens to be in a given part of the forest is directly proportional to the size of that part, but independent of its position in the forest.

- What is the probability distribution of the distance of the child from a given side (extended to a straight line) of the forest?
- What is the probability distribution of the distance of the child from the closest side of the forest?

**Solution.**

- Let  $a$  be the length of the sides of the hexagon (forest). Then, the probability distribution satisfies

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \frac{4}{9a^2}x + \frac{2}{3\sqrt{3}a} & \text{for } 0 < x \leq \frac{1}{2}\sqrt{3}a \\ -\frac{4}{9a^2}x + \frac{2}{\sqrt{3}a} & \text{for } \frac{1}{2}\sqrt{3}a \leq x \leq \sqrt{3}a \\ 0 & \text{for } x > \sqrt{3}a \end{cases},$$

as for the first question.

- First, let us compute the distribution function  $F$  of the wanted random variable  $X$  that corresponds to the distance of the child from the closest side. The distance can

Observe the distribution of the molecules. Then, the behaviour of  $X_n$  as the number  $n$  of boxes as well as the number  $r_n$  of objects increases so that their ratio  $r_n/n = \lambda$  remains constant is of interest. In other words, every box is to contain (approximately) the same number  $\lambda$  of elements, on average.

We are interested in the asymptotic behaviour of the variables  $X_n$  as  $n \rightarrow \infty$ . Letting  $\lim_{n \rightarrow \infty} r_n/n = \lambda$ , the standard procedure (with details to be added – take it as a challenge to recall the methods from the analysis of univariate functions!) leads to:

$$\begin{aligned} \lim_{n \rightarrow \infty} P(X_n = k) &= \lim_{n \rightarrow \infty} \binom{r_n}{k} \frac{(n-1)^{r_n-k}}{n^{r_n}} \\ &= \lim_{n \rightarrow \infty} \frac{r_n(r_n-1) \dots (r_n-k+1)}{(n-1)^k} \frac{1}{k!} \left(1 - \frac{1}{n}\right)^{r_n} \\ &= \frac{\lambda^k}{k!} \lim_{n \rightarrow \infty} \left(1 + \frac{-r_n}{r_n}\right)^{r_n} = \frac{\lambda^k}{k!} \lim_{m \rightarrow \infty} \left(1 + \frac{-\lambda}{m}\right)^m \\ &= \frac{\lambda^k}{k!} e^{-\lambda}, \end{aligned}$$

since the functions  $(1+x/n)^n$  converge uniformly to the function  $e^x$  on every bounded interval in  $\mathbb{R}$ .

POISSON DISTRIBUTION

The *Poisson distribution*  $Po(\lambda)$  describes the random variables with probability mass function

$$f_X(k) = \begin{cases} \frac{\lambda^k}{k!} e^{-\lambda} & k \in \mathbb{N} \\ 0 & \text{otherwise.} \end{cases}$$

Of course,

$$\sum_{k=0}^{\infty} f_X(k) = \sum_{k=0}^{\infty} \frac{\lambda^k}{k!} e^{-\lambda} = e^{-\lambda} \sum_{k=0}^{\infty} \frac{\lambda^k}{k!} = e^{-\lambda + \lambda} = 1.$$

As seen above, this discrete distribution  $Po(\lambda)$  with an arbitrary  $\lambda > 0$  (distributed into infinitely many points) is a good approximation of the binomial distributions  $Bi(n, \lambda/n)$ , for large values of  $n$ .

**10.2.19. Two examples.** Besides the physical model mentioned above, such a behaviour can be encountered when observing occurrences of events in a space with constant expected density in a unit volume. Observing bacteria under a microscope, when the bacteria are expected to occur in any part of the image with the same probability, provides an example. If the “mean density of occurrence” in a unit area is  $\lambda$  and the whole region is divided into  $n$  identical parts, then the occurrence of  $k$  events in a fixed part is modeled by a random variable  $X$  with the Poisson distribution. When diagnosing in practice, such an observation allows us to compute the total number of bacteria with a relatively good accuracy from the actual numbers in only several randomly chosen samples.

be anywhere in the interval  $I = \langle 0, \frac{\sqrt{3}}{2}a \rangle$ . Then, for  $y \in I$ , we have

$$F(y) = P[X < y] = \frac{\frac{\sqrt{3}}{4}a^2 - \frac{(\frac{\sqrt{3}}{2}a - y)^2}{\frac{3}{4}a^2} \frac{\sqrt{3}}{4}a^2}{\frac{\sqrt{3}}{4}a^2} = 1 - \frac{4(\frac{\sqrt{3}}{2}a - y)^2}{3a^2}$$

Altogether,

$$F(y) = \begin{cases} 0 & \text{for } y \leq 0 \\ 1 - \frac{4(\frac{\sqrt{3}}{2}a - y)^2}{3a^2} & \text{for } y \in \langle 0, \frac{\sqrt{3}}{2}a \rangle \\ 1 & \text{for } y \geq \frac{\sqrt{3}}{2}a \end{cases}$$

Thus, the density, being the derivative of the distribution function, satisfies:

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \frac{8(\frac{\sqrt{3}}{2}a - y)}{3a^2} & \text{for } y \in \langle 0, \frac{\sqrt{3}}{2}a \rangle \\ 0 & \text{for } y \geq \frac{\sqrt{3}}{2}a \end{cases}$$

□

**10.E.14.** Let a random variable  $X$  have uniform distribution on an interval  $\langle 0, r \rangle$ . Find the distribution function and probability density of the volume of the ball whose radius is equal to  $X$ .

**Solution.** First, we find the distribution function  $F$  (for  $0 < d < \frac{4}{3}\pi r^3$ )

$$F(d) = P\left[\frac{4}{3}\pi X^3 \leq d\right] = P\left[X \leq \sqrt[3]{\frac{3d}{4\pi}}\right] = \frac{\sqrt[3]{\frac{3d}{4\pi}}}{r}$$

Altogether,

$$F(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \sqrt[3]{\frac{3}{4\pi r^3}} x^{\frac{1}{3}} & \text{for } 0 < x < \frac{4}{3}\pi r^3 \\ 1 & \text{for } x \geq \frac{4}{3}\pi r^3 \end{cases}$$

Differentiating this, we obtain the density:

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \sqrt[3]{\frac{1}{36\pi r^3}} x^{-\frac{2}{3}} & \text{for } 0 < x < \frac{4}{3}\pi r^3 \\ 0 & \text{for } x \geq \frac{4}{3}\pi r^3 \end{cases}$$

□

**10.E.15.** Find the value(s) of the parameter  $a \in \mathbb{R}$  so that the function

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ ax^2 & \text{for } 0 < x < 3 \\ 0 & \text{for } x \geq 3 \end{cases}$$

defines the probability density of a random variable  $X$ . Then, find its distribution function, probability density, and the expected value of the volume of the cube whose edge-length has probability density determined by  $f$ .

**Solution.** Simply,  $a = \frac{1}{9}$ . Thus, the distribution function of the random variable  $X$  is  $F_X(t) = \frac{1}{27}t^3$  for  $t \in (0, 3)$ , zero for smaller values of  $t$ , and one for greater. Let  $Z = X^3$  denote the random variable corresponding to the volume of the considered cube. It lies in the interval  $(0, 27)$ . Thus, for

The second example is more challenging. We describe events which occur randomly at time  $t \geq 0$ . Here, the probability of an occurrence in the following small time period of length  $h$  does not depend on what had happened before and equals the same value  $h\lambda$  for a fixed  $\lambda > 0$ . At the same time, the probability that the event occurs more than once in a given time period is small.

Let  $X_t$  denote the random variable which corresponds to the number of occurrences of the examined event in the interval  $[0, t)$ . The requirements are expressed infinitesimally. We want:

- the probability of exactly one event in each time period of length  $h$  equals  $h\lambda + \alpha(h)$ , where the function  $\alpha(h)$  satisfies  $\lim_{h \rightarrow 0_+} \frac{\alpha(h)}{h} = 0$ ;
- the probability  $\beta(h)$  of more than one event occurring in a time period of length  $h$  to satisfy  $\lim_{h \rightarrow 0_+} \frac{\beta(h)}{h} = 0$ ;
- the events  $X_t = j$  and  $X_{t+h} - X_t = k$  to be independent for all  $j, k \in \mathbb{N}$  and  $t, h > 0$ .

Use the notation  $p_k(t) = P(X_t = k)$ ,  $k \in \mathbb{N}$ , and set the initial conditions  $p_0(0) = 1$  and  $p_k(0) = 0$  for  $k > 0$ . Compute directly

$$p_0(t+h) = p_0(t)P(X_{t+h} - X_t = 0) = p_0(t)(1 - h\lambda - \alpha(h) - \beta(h))$$

and similarly,

$$\begin{aligned} p_k(t+h) &= P(X_t = k, X_{t+h} - X_t = 0) \\ &\quad + P(X_t = k-1, X_{t+h} - X_t = 1) \\ &\quad + P(X_t \leq k-2, X_{t+h} = k) \\ &= p_k(t)P(X_{t+h} - X_t = 0) + p_{k-1}P(X_{t+h} - X_t = 1) \\ &\quad + \sum_{i=0}^{k-2} P(X_t = i, X_{t+h} - X_t = k-i) \\ &= p_k(t)(1 - h\lambda - \alpha(h) - \beta(h)) + p_{k-1}(t)(h\lambda + \alpha(h)) \\ &\quad + \sum_{i=0}^{k-2} p_i(t)P(X_{t+h} - X_t = k-i). \end{aligned}$$

Hence (similar to in 6.1.12, page 520, the symbol  $o(h)$  is written for expressions which, when divided by  $h$ , approach zero as  $h \rightarrow 0_+$ )

$$\begin{aligned} \frac{p_0(t+h) - p_0(t)}{h} &= -\lambda p_0(t) + \frac{1}{h} o(h) \\ \frac{p_k(t+h) - p_k(t)}{h} &= -\lambda p_k(t) + \lambda p_{k-1}(t) + \frac{1}{h} o(h). \end{aligned}$$

Letting  $h \rightarrow 0_+$ , an (infinite!) system of ordinary differential equations is obtained:

$$\begin{aligned} p'_0(t) &= -\lambda p_0(t), & p_0(0) &= 1 \\ p'_k(t) &= -\lambda p_k(t) + \lambda p_{k-1}(t), & p_k(0) &= 0 \end{aligned}$$

for all  $t > 0$  and  $k \in \mathbb{N}$ , with an initial condition.

The first equation has a unique solution

$$p_0(t) = e^{-\lambda t},$$

$t \in (0, 27)$  and the distribution function  $F_Z$  of the random variable  $Z$ , we can write  $F_Z(t) = P[Z < t] = P[X^3 < t] = P[X < \sqrt[3]{t}] = F_X(\sqrt[3]{t}) = \frac{1}{27}t$ . Then, the density is  $f_Z(t) = \frac{1}{27}$  on the interval  $(0, 27)$  and zero elsewhere. Since this is the uniform distribution on the given interval, the expected value is equal to 13.5.  $\square$

**10.E.16.** Find the value(s) of the parameter  $a \in \mathbb{R}$  so that the function

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ ax & \text{for } 0 < x < 3 \\ 0 & \text{for } x \geq 3 \end{cases}$$

defines the probability density of a random variable  $X$ . Then, find its distribution function, probability density, and the expected value of the area of the square whose side-length has probability density determined by  $f$ .

**Solution.** We proceed similarly as in the previous example. Again, we can easily find that  $a = \frac{2}{9}$ . Thus, the distribution function of the random variable  $X$  is  $F_X(t) = \frac{1}{9}t^2$  for  $t \in (0, 3)$ , zero for smaller values of  $t$ , and one for greater. Let  $Z = X^3$  denote the random variable corresponding to the area of the considered square. It lies in the interval  $(0, 9)$ . Thus, for  $t \in (0, 9)$  and the distribution function  $F_Z$  of the random variable  $Z$ , we can write  $F_Z(t) = P[Z < t] = P[X^2 < t] = P[X < \sqrt{t}] = F_X(\sqrt{t}) = \frac{1}{9}t$ . Then, the density is  $f_Z(t) = \frac{1}{9}$  on the interval  $(0, 9)$  and zero elsewhere. Since this is the uniform distribution on the given interval, the expected value is equal to 4.5.  $\square$

**10.E.17.** Find the value(s) of the parameter  $a \in \mathbb{R}$  so that the function

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ ax^2 & \text{for } 0 < x < 2 \\ 0 & \text{for } x \geq 2 \end{cases}$$

defines the probability density of a random variable  $X$ . Then, find its distribution function, probability density, and the expected value of the volume of the cube whose edge-length has probability density determined by  $f$ .  $\circ$

**10.E.18.** We randomly cut a line segment of length  $l$  into two pieces. Find the distribution function and the density of the area of the rectangle whose side-lengths are equal to the obtained pieces.

**Solution.** Let us compute the distribution function: Let  $X$  denote the random variable with uniform distribution on the interval  $\langle 0, l \rangle$ , which corresponds to the length of one of the pieces (then, the length of the other piece is  $l - X$ ). The area  $S = x(l - x)$  of the rectangle, for  $x \in \langle 0, l \rangle$ , can lie anywhere in the interval  $\langle 0, l^2/4 \rangle$ . Setting  $d \in \langle 0, l^2/4 \rangle$ , we can write

$$F(d) = P[S \leq d] = P[X(l - X) \leq d]$$

Thus, we are looking for those values of  $x$  for which  $x(l - x) \leq d$ , which is a quadratic inequality. The roots of the corresponding quadratic equation are  $\frac{l - \sqrt{l^2 - 4d}}{2}$  and  $\frac{l + \sqrt{l^2 - 4d}}{2}$ .

which can be immediately substituted into the second equation. This leads to

$$p_1(t) = \lambda t e^{-\lambda t}.$$

A trivial induction argument shows that the system has a unique solution

$$p_k(t) = \frac{(\lambda t)^k}{k!} e^{-\lambda t}, \quad t > 0, \quad k \in \mathbb{N}.$$

It is thus verified that for every process which satisfies the three properties above, the random variable  $X_t$  which corresponds to the number of occurrences in the time period  $[0, t)$  has distribution  $\text{Po}(\lambda t)$ .

In practice, these processes are connected with the failure rate of machines.

**10.2.20. Continuous distributions.** The simplest example of a continuous distribution is the uniform distribution of the probability throughout a fixed interval. This is also a good illustration of the fact that a simply formulated requirement does not leave many free choices in the definition. Now, the probability of  $X$  taking on a value inside an interval which is included in the sample interval  $(a, b) \subset \mathbb{R}$  is required to be dependent only on the length of the interval, but not on its actual position. This means that the density  $f_X$  of the random variable  $X$  should be constant and the value of this constant is given by the requirement  $P(a \leq X < b) = 1$ .

UNIFORM DISTRIBUTION

For any real numbers  $a, b, -\infty < a < b < \infty$ , define the density and distribution function as follows:

$$f_X(t) = \begin{cases} 0 & t \leq a \\ \frac{1}{b-a} & t \in (a, b) \\ 0 & t \geq b, \end{cases} \quad F_X(t) = \begin{cases} 0 & t \leq a \\ \frac{t-a}{b-a} & t \in (a, b) \\ 1 & t \geq b. \end{cases}$$

Here, the random variable  $X$  has *uniform distribution*.

The next distribution is similar to the discrete Poisson distribution. Suppose the occurrence of a random event is observed such that its occurrences in non-overlapping intervals are independent. Thus, if  $p(t)$  is the probability of the event not occurring during an interval of length  $t$ , then of necessity  $p(t + s) = p(t)p(s)$  for all  $t, s > 0$ . Moreover, assume that  $p$  is differentiable and  $p(0) = 1$ .

Then,  $\ln p(t + s) = \ln p(t) + \ln p(s)$ . Letting  $s \rightarrow 0_+$  (and applying l'Hospital's rule),

$$\begin{aligned} (\ln(p))'(t) &= \lim_{s \rightarrow 0_+} \frac{\ln p(t + s) - \ln p(t)}{s} \\ &= \lim_{s \rightarrow 0_+} \frac{(\ln p(s))'}{1} = \frac{p'(0)}{p(0)} = p'(0). \end{aligned}$$

Thus,  $p'(0) = -\lambda \in \mathbb{R}$  (Note:  $\lambda > 0$ , and  $p'(0)$  cannot be positive as  $p(0) = 1$ ).

Then,  $p(t)$  satisfies  $\ln p(t) = -\lambda t + C$ . The initial condition leads to the only solution

$$p(t) = e^{-\lambda t}.$$

The inequality is satisfied by exactly those values of  $x$  which lie outside this interval. Therefore,

$$P[X(l - X) \leq d] = P[X \in \langle 0, l \rangle \setminus \left( \frac{l - \sqrt{l^2 - 4d}}{2}, \frac{l + \sqrt{l^2 - 4d}}{2} \right)] \\ = \frac{l - \sqrt{l^2 - 4d}}{l} = 1 - \frac{\sqrt{l^2 - 4d}}{l}$$

Altogether,

$$F(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ 1 - \frac{\sqrt{l^2 - 4x}}{l} & \text{for } 0 \leq x \leq \frac{l^2}{4} \\ 1 & \text{for } x > \frac{l^2}{4} \end{cases}$$

The density is obtained by differentiation:

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \frac{2}{l\sqrt{l^2 - 4x}} & \text{for } 0 \leq x \leq \frac{l^2}{4} \\ 0 & \text{for } x > \frac{l^2}{4} \end{cases}$$

□

**10.E.19.** Nezávislé náhodné veličiny  $X$  a  $Y$  mají následující hustoty pravděpodobnosti:

$$f_X(t) = \begin{cases} 0 & \text{for } t \leq 0, \\ 1 & \text{for } 0 < t < 1, \\ 0 & \text{for } 1 \leq t, \end{cases} \quad f_Y(t) = \begin{cases} 0 & \text{for } t \leq 0, \\ 2t & \text{for } 0 < t < 1, \\ 0 & \text{for } 1 \leq t. \end{cases}$$

Určete distribuční funkci náhodné veličiny udávající obsah obdélníka o stranách  $X$  a  $Y$ .

**Solution.**

$$F_Y(t) = \begin{cases} 0 & \text{for } t \leq 0 \\ 2t - t^2 & \text{for } 0 < t < 1 \\ 1 & \text{for } 1 \leq t \end{cases}$$

□

**10.E.20.** Let  $X, Y$  be independent random variables, where  $X$  has uniform distribution on the interval  $(0, 2)$  and  $Y$  is given by its density function:

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ 2x & \text{for } 0 < x < 1 \\ 0 & \text{for } x \geq 1. \end{cases}$$

Find the probability that  $Y$  is less than  $X^2$ .

**Solution.** Since  $X$  and  $Y$  are independent random variables, the joint density  $f_{(X,Y)} : \mathbb{R}^2 \rightarrow \mathbb{R}^2$  of the variable  $(X, Y)$  is given by the densities  $f_X$  and  $f_Y$  of the individual random variables. Thus, we have

$$f_{(X,Y)}(u, v) = \begin{cases} f_X(u) \cdot f_Y(v) = \frac{1}{2} \cdot 2v = v & \text{for } (u, v) \in (0, 2) \times (0, 1), \\ 0 & \text{otherwise.} \end{cases}$$

Now, consider the random variable  $X$  which corresponds to a (random) moment when the event occurs for the first time. Apparently, the distribution function of  $X$  is given by

$$F_X(t) = 1 - p(t) = \begin{cases} 1 - e^{-\lambda t} & t > 0 \\ 0 & t \leq 0. \end{cases}$$

This function has the desired properties: It has values between zero and one, it is increasing and it has the required behaviour at  $\pm\infty$ . The density of this random variable can be obtained by differentiation of the distribution function.

#### EXPONENTIAL DISTRIBUTION

The distribution corresponding to the continuous random variable  $X$  with density

$$f_X(t) = \begin{cases} \lambda e^{-\lambda t} & t > 0 \\ 0 & t \leq 0. \end{cases}$$

is called the *exponential distribution*  $\text{ex}(\lambda)$ .

The exponential distribution belongs to the more general family of important distributions with the densities of the form

$$cx^{a-1} e^{-bx}$$

for  $x > 0$ , with given constants  $a > 0, b > 0$ , while the constant  $c$  is to be computed. The following expression is required to equal one:

$$\int_0^\infty cx^{a-1} e^{-bx} dx = \int_0^\infty c \left(\frac{t}{b}\right)^{a-1} e^{-t} \frac{1}{b} dt = \frac{c}{b^a} \Gamma(a).$$

$\Gamma$  is the famous transcendental function providing the analytic extension of the factorial function, discussed in 6.2.17 on the page 546.

#### GAMMA DISTRIBUTION

The distribution whose density is zero for  $x \leq 0$ , while for  $x > 0$ . It is given by

$$f(x) = \frac{b^a}{\Gamma(a)} x^{a-1} e^{-bx},$$

called the *gamma distribution*  $\Gamma(a, b)$  with parameters  $a > 0, b > 0$ .

Thus, the exponential distribution is the special case of this one for the value  $a = 1$ .

**10.2.21. Normal distribution.** Recall the binomial distribution. If the success rate  $p$  is left constant, but the number  $n$  of experiments is increased, the probability mass function keeps its shape (although the scale changes). As  $n$  increases, the values of the probability mass function merges into a curve that should correspond to the density of a continuous distribution which is a good approximation for  $\text{Bi}(n, p)$  for large values of  $n$ .

Recall the smooth function  $y = e^{-x^2/2}$ , mentioned in subsection 6.1.9 (page 516) as an appropriate tool for the construction of functions which are smooth but not analytic. The

Then, the wanted probability  $P$  is the integral of the density  $f_{(X,Y)}$  over the part  $O$  of the plane where  $Y < X^2$ :

$$P = \iint_O f_{(X,Y)} dx dy = 1 - \iint_{\mathbb{R}^2 \setminus O} f_{(X,Y)} dx dy = 1 - \int_0^1 \int_{x^2}^1 y dy dx = \frac{3}{5}.$$

□

**10.E.21.** Let  $X, Y$  be independent random variables, where  $X$  has density function

$$f_1(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ 2x & \text{for } 0 < x < 1 \\ 0 & \text{for } x \geq 1, \end{cases}$$

and  $Y$  has density function

$$f_2(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \frac{x}{2} & \text{for } 0 < x < 2 \\ 0 & \text{for } x \geq 2. \end{cases}$$

Find the probability that  $Y$  is greater than  $X^2$ . ○

**10.E.22.** Let  $X, Y$  be independent random variables, where  $X$  has density function

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \frac{2x}{9} & \text{for } 0 < x < 3 \\ 0 & \text{for } x \geq 3, \end{cases}$$

and  $Y$  has density function

$$f(x) = \begin{cases} 0 & \text{for } x \leq 0 \\ \frac{x}{2} & \text{for } 0 < x < 2 \\ 0 & \text{for } x \geq 2. \end{cases}$$

Find the probability that  $Y$  is greater than  $X^3$ . ○

### F. Expected value, correlation

Compute the expected value and variance of the binomial distribution.

**Solution.** The direct calculation from the definitions is a nice exercise on combinatorics. We prove this statement using the properties of the expected value and variance. Using the definition of the binomial distribution (see 10.2.17), we can view the random variable  $X \sim \text{Bi}(n, p)$  as the sum  $X = \sum_{k=1}^n Y_k$ , where  $Y_1, \dots, Y_n \sim A(p)$  are independent random variables saying whether the  $k$ -th experiment was successful. Clearly, the Bernoulli distribution has expected value  $E Y_i = p$ , hence by theorem 10.2.29, we have  $E X = \sum_{k=1}^n E Y_k = np$ . Similarly, we compute  $E(Y_k^2) = 1^2 \cdot p + 0^2 \cdot (1 - p) = p$ , so  $\text{var } Y_k = E(Y_k^2) - (E Y_k)^2 = p - p^2$ . By theorem 10.2.33, we have  $\text{var } X = \sum_{k=1}^n \text{var } Y_k = np(1 - p)$ . □

illustration compares this curve (in the right hand part) to the values of  $\text{Bi}(40, 0.5)$ .

This suggests looking for a convenient continuous distribution whose density would be given by a suitably adjusted variation of this function.

The function  $e^{-x^2/2}$  is everywhere positive, so it suffices to compute  $\int_{-\infty}^{\infty} e^{-x^2/2} dx$ . If this results in a finite value, just multiply the function by its reciprocal value. Unfortunately, this integral cannot be computed in terms of elementary functions. Luckily, multidimensional integration and Fubini's theorem can be used. Transform to polar coordinates, to obtain

$$\begin{aligned} & \left( \int_{-\infty}^{\infty} e^{-x^2/2} dx \right) \left( \int_{-\infty}^{\infty} e^{-y^2/2} dy \right) \\ &= \int_{\mathbb{R}^2} e^{-(x^2+y^2)/2} dx dy \\ &= \int_0^{\infty} \int_0^{2\pi} e^{-(r^2)/2} r dr d\theta \\ &= 2\pi \end{aligned}$$
